In honor of 10 May 2011, the 10th anniversary of my last Cerro Grande posting:
A day that should have seen some of the most significant struggles passed.

Blake C. Stacey, Editor

VERY ROUGH, VERY VERY INCOMPLETE DRAFT

Build of: 16 July 2013

What does determinism profess? It professes that those parts of the universe already laid down absolutely appoint and decree what the other parts shall be. The future has no ambiguous possibilities hidden in its womb; the part we call the present is compatible with only one totality. Any other future complement than the one fixed from eternity is impossible. The whole is in each and every part, and welds it with the rest into an absolute unity, an iron block, in which there can be no equivocation or shadow of turning.

Indeterminism, on the contrary, says that the parts have a certain amount of loose play on one another, so that the laying down of one of them does not necessarily determine what the others shall be. It admits that possibilities may be in excess of actualities, and that things not yet revealed to our knowledge may really in themselves be ambiguous. Of two alternative futures which we conceive, both may now be really possible; and the one become impossible only at the very moment when the other excludes it by becoming real itself. Indeterminism thus denies the world to be one unbending unit of fact. It says there is a certain ultimate pluralism in it.

— *William James*

Chance is a purely negative and relative term, giving us no information about that of which it is predicated, except that it happens to be disconnected with something else—not controlled, secured, or necessitated by other things in advance of its own actual presence. What I say is that it tells us nothing about what a thing may be in itself to call it "chance." All you mean by calling it "chance" is that this is not guaranteed, that it may also fall out otherwise. For the system of other things has no positive hold on the chance-thing. Its origin is in a certain fashion negative: it escapes, and says, Hands off! coming, when it comes, as a free gift, or not at all.

This negativeness, however, and this opacity of the chance-thing when thus considered *ab extra*, or from the point of view of previous things or distant things, do not preclude its having any amount of positiveness and luminosity from within, and at its own place and moment. All that its chance-character asserts about it is that there is something in it really of its own, something that is not the unconditional property of the whole. If the whole wants this property, the whole must wait till it can get it, if it be a matter of chance. That the universe may actually be a sort of joint-stock society of this sort, in which the sharers have both limited liabilities and limited powers, is of course a simple and conceivable notion.

— *William James*

Introduction

This document is the second installment of three in the *Cerro Grande Fire Series*. It is a collection of emails compiled in the same spirit as my previous `quant-ph/0105039`, *Notes on a Paulian Idea: Foundational, Historical, Anecdotal and Forward-Looking Thoughts on the Quantum*. One could joke that it represents the loquacious side of my quantum-foundations research program, but even that would be an understatement. Nearly every one of my emails from the period January 2001 – May 2011 having anything at all to do with the conceptual side of quantum theory—from my growing understanding of it, to fights over its meaning, advocacy[1], dreams, "business" opportunities, jokes, even simple reverence and awe—anything and everything on the subject—has some representation in this volume. To zeroth-order approximation, the compilation represents a grand exercise in "intellectual waste not, want not." But, I bring it forward with a more serious goal in mind.

One of the correspondents in my earlier collection wrote me just before its release, "I would not object to [your selection of our correspondence] in your volume ... but I wonder if our amicable banter would really be of value/interest to a wider readership!?" The question of interest, of course, can only be answered by the reader. But on the question of value for those who are interested in issues of quantum interpretation, my answer is a resounding yes. I am convinced that the email compositions collected here provide an essential ingredient, unavailable anywhere else, for turning the point of view of quantum theory put forth in technical detail here

`arXiv:1003.5209v1 [quant-ph]`

and

`arXiv:1301.3274v1 [quant-ph]`.

into a "live option" within the vast spectrum of quantum foundational thought.

The papers cited above comprise the most developed statements of the "Quantum Bayesian" research program, or QBism, to date, but they are no substitute for the kind of understanding—the living feeling—that can only be gotten by the actual process of fighting one's way day after day, sleepless night after sleepless night, through an inchoate and only slowly forming worldview.

No textbook on any subject can leave a student knowing the subject from a mere reading of its pages. The student must actively work at understanding. He must live through the struggles the book's exercises mean to provide, always testing his understanding, always practicing how to respond if confronted on this or that issue. Yet, all this is only the start of a process; it is just the glimmer of knowing. Ultimately, the student must set the book's subject matter to work in his wider stream of activities. But if this is so for "knowing" a textbook's subject, so much more so it must be for a worldview—a vision of the thrust and character of the world itself.

To get oneself into seeing or comprehending a worldview at all, one must gain a feel for its proponents' temperaments. William James—the veritable mascot of this volume—makes the point most forcefully in his 1907 monograph *Pragmatism*:

[1] And, my gosh, will one find advocacy in this volume. Be prepared for repetition. If the despicable years of George W. Bush's presidency had anything positive which I incorporated into my own palette, it was, "Stay on message."

> The history of philosophy is to a great extent that of a certain clash of human temperaments. Undignified as such a treatment may seem to some of my colleagues, I shall have to take account of this clash and explain a good many of the divergencies of philosophies by it. Of whatever temperament a professional philosopher is, he tries, when philosophizing, to sink the fact of his temperament. Temperament is no conventionally recognized reason, so he urges impersonal reasons only for his conclusions. Yet his temperament really gives him a stronger bias than any of his more strictly objective premises. It loads the evidence for him one way or the other . . . just as this fact or that principle would. He *trusts* his temperament. Wanting a universe that suits it, he believes in any representation of the universe that does suit it. He feels men of opposite temper to be out of key with the world's character, and in his heart considers them incompetent and 'not in it,' in the philosophic business, even though they may far excel him in dialectical ability.
>
> Yet in the forum he can make no claim, on the bare ground of his temperament, to superior discernment or authority. There arises thus a certain insincerity in our philosophic discussions: the potentest of all our premises is never mentioned.

which itself builds on his 1879 essay "The Sentiment of Rationality":

> Why does [W. K.] Clifford fearlessly proclaim his belief in the conscious-automaton theory, although the 'proofs' before him are the same which make Mr. Lewes reject it? Why does he believe in primordial units of 'mind-stuff' on evidence which would seem quite worthless to Professor Bain? Simply because, like every human being of the slightest mental originality, he is peculiarly sensitive to evidence that bears in some one direction. It is utterly hopeless to try to exorcise such sensitiveness by calling it the disturbing subjective factor, and branding it as the root of all evil. 'Subjective' be it called! and 'disturbing' to those whom it foils! But if it helps those who, as Cicero says, "vim naturae magis sentiunt,"[2] it is good and not evil. Pretend what we may, the whole man within us is at work when we form our philosophical opinions. Intellect, will, taste, and passion co-operate just as they do in practical affairs . . .

The year 2013 rings no differently. David Deutsch calls the Everett interpretation of quantum theory an "implication of science." Yet, where he, David Wallace, and Simon Saunders—to name some of Everett's most striving and eloquent disciples—can see no evidence against such a reading of quantum theory, I can see nothing particular about the theory's formalism that compels the view at all. In fact, I see nothing that even suggests it. In counterpoint: The identities and analogies between quantum theory and Bayesian probability theory that come alive for me, seem to be for them but dead afterthoughts of a formalism handed down from on high. There is something about their mindset that is as foreign to me as mine is to them.

The conceit of this document (as it cannot be otherwise if it is to exist at all) is that *QBism vis naturae magis sentit.* The 2100 or so pages to follow are the only ways I know to convey the varieties of "intellect, will, taste, and passion" needed to make a view like QBism sensible and deemed worth pursuing. Plenty in the pages herein is

[2] "feel the force of nature more"

indeed banter, but taking note of the statement and style, both of the banter and the more seriously considered exegeses, is, as I see it, the most honest way to expose the potentest of QBism's premises. In all, these pages taken together form an expression of one temperament as it confronts a world that will either accommodate it, bend it, or potentially smite it down.

If one were to look for a single most-encompassing statement of QBism's vision of the world—the crucial extract of this whole document—it might well be captured by this passage from page 2058:

> QBism says that every quantum measurement is a moment of creation, and the formal apparatus of quantum theory is an aid for each agent's thinking about those "creatia" she is involved with. But surely a Copernican principle applies just as much to QBism as to any other science. QBism's solution starts by saying the last point just that much more clearly: "Quantum measurement represents those moments of creation an agent happens to seek out or notice." It does not at all mean that there aren't moments of creation going on all around, unnoticed, unparticipated in by the particular agent, all the time. The larger world of QBism is something aligned with James's vision of a pluriverse where "being comes in local spots and patches which add themselves or stay away at random, independently of the rest."

or a little more fully by this one on page 1915:

> Three characteristics set QBism apart from other existing interpretations of quantum mechanics. First is its crucial reliance on the mathematical tools of quantum information theory to reshape the look and feel of quantum theory's formal structure. Second is its stance that two levels of radical "personalism" are required to break the interpretational conundrums plaguing the theory. Third is its recognition that with the solution of the theory's conundrums, quantum theory does not reach an end, but is the start of a great journey.
>
> The two levels of personalism refer to how the "probabilities" and "measurement events" of quantum theory are to be interpreted. With regard to quantum probabilities, QBism asserts that they be interpreted as personal, Bayesian degrees of belief. This is the idea that probability is not something out in the world that can be right or wrong, but a personal accounting of what one expects. The implications of this are deep, for one can see with the help of quantum information theory that it means that quantum states, too, are not things out in the world. Quantum states rather represent personal accounting, and two agents speaking of the same quantum system may have distinct state assignments for it. The second level of personalism appears with the meaning of a quantum-measurement outcome. On this QBism holds with Pauli that a measurement apparatus must be understood as an extension of the agent herself, not something foreign and separate. A quantum measurement device is like a prosthetic hand, and the outcome of a measurement is an unpredictable, undetermined "experience" shared between the agent and external system. Quantum theory, thus, is no mirror image of what the world is, but rather a "user's manual" that any agent can adopt for better navigation in a world suffused with creation: The agent uses it for her little part and participation in this creation.

But these formulations are the fruit of a tree somewhere 10-years-up a very steep slope. They could not have been said at the time of my *Notes on a Paulian Idea*.

[MORE TO COME.]

Much of what is recorded here concerns a fairly major transition in my thought. Once upon a time, I expressed my position with the slogan, "Quantum States are States of Knowledge." But I ultimately realized this phrase was inconsistent with a thoroughgoing Bayesian conception of probabilities—the conception of Frank P. Ramsey, Bruno de Finetti, and Richard Jeffrey. Worse perhaps, it was inconsistent with the idea that physical systems have *no* telepathy!—i.e., that there is no spooky action at a distance. The remediation of these problems required ... This document tracks my thoughts as I tried to formulate a corrective to the conception ... which in turn led the way to *ontological* considerations that were like a hammer to the "block universe" conception of the world.

[MUCH MORE TO COME.]

This time a large fraction of the emails are significantly more technical in flavor and argumentation, though certainly as personal as ever. Thus by necessity, the layout of the book is more continuous in thread than previously.

[MUCH MORE TO COME.]

DISCLAIMERS:

I. This document represents a unique, and hopefully entertaining, method to communicate my more recent foundational thoughts on quantum theory. For precisely this reason, however, it carries a great danger to my friends. It is after all a collection of correspondence. There are two things that should not be mistaken: 1) The potential of my memory to be faulty when reporting the views of others, and 2) that the quotes taken from my correspondents were composed in anything other than a casual manner for *private* use only. With regard to the latter, I assert the right of my correspondents to deny—without apologies!—that their quotes represent accurate accounts of their thoughts. I have tried to guard against misrepresentation by keeping the number of quotes and correspondent-replies to a minimum: The ones that are used, are used mainly as springboards for *my* tendentiousness.

II. Various deletions of text have been made to the original letters. The purpose of the vast majority of these is to spare the reader of the "merely personal" in my life. A smaller fraction are for the sake of protecting the innocent, protecting the correspondents, and protecting the illusion that I am good-natured. The same holds as well for a small number of explicit changes of phrase (in my own writings, *never* the correspondents). In most cases, I have tried to make the process look as seamless as possible, with no evidence that the text may have been otherwise. In my own writings, bare ellipses should be interpreted as punctuation; bracketed ellipses indicate true editorial changes.

III. There is no claim that all the ideas presented here are coherent. The hope is instead that the incoherent ones will earn their keep by their entertainment value.

ACKNOWLEDGEMENTS:

I thank Scott Aaronson, Ingemar Bengtsson, Paul Benioff, Jeffrey Bub, Adán Cabello, Richard Campos, Carlton Caves, Åsa Ericsson, Robert Garisto, Lucien Hardy, Osamu Hirota, Adrian Kent, Eugen Merzbacher, Klaus Mølmer, Ulrich Mohrhoff, Michael Nielsen, Y. Jack Ng, Marcos Pérez-Suárez, Itamar Pitowsky, Arkady Plotnitsky, Damian Pope, Steve Savitt, Ben Schumacher, and Bill Wootters for helping me believe a project like this is not *too* crazy. I thank Marcus Appleby, Hans Christian von Baeyer, Eric Cavalcanti, Greg Comer, Steven van Enk, Andrei Khrennikov, Matthew Leifer, David Mermin, John Preskill, Huw Price, Rüdiger Schack, Maximilian Schlosshauer, and Rob Spekkens for helping me believe it might even be worthwhile.

Beyond all others, however, I thank Blake Stacey for his constant encouragement and the living evidence he gave that the document really might make a difference. With the dozens and dozens of typos he caught at the same time ("samizdata" he called them), the title of "editor-in-chief" would not be out of place for him.

There is a major difference between this collection and my last: It is not so busy with letters and replies to Asher Peres. He is sorely missed. In all, the tone of the book is a little lonelier without him.

Now my own suspicion is that the Universe is not only queerer than we suppose, but queerer than we can suppose.

— J. B. S. Haldane

05-01-01 *In Defense of Interactionism* (to J. M. Renes)

Renesism 1: *I've been reading up on some quantum logic, and finally have some idea of what it is and how it might be useful in this "research direction" – but in some ways cuts against the Bayesian grain, and that might be an opportunity to do some interesting (further) research. I say further because I think our Gleason-like result is a piece in this puzzle; the puzzle being something like "what does quantum logic look like when using POVMs instead of projectors?" That's probably misleading a bit, so "starting from where Hilbert-space-projector quantum logic does, where do POVMs take you? What are the logical structures and rules which differentiate classical and quantum mechanics? How does the weirdness of quantum mechanics arise from these rules and structures?" I'm sure a lot of the answers to these questions are trivial replacements of PVMs with POVMs, but not always.*

I don't know what Carl has said, but I like the sound of your "research direction." I doubt any of the references below will be overly useful, but I met a guy at the quantum information tutorials in Edinburgh who has spent a lot of time generalizing quantum logics to effect algebras. His name is Roberto Giuntini. I just looked up the following articles on Web of Science.

I say I doubt it will be overly useful, because I gathered that, in his heart, he too was looking for the holy grail of most quantum logicians: To find a way of pinning observer-independent properties on the world via algebraic properties of the theory's surface terms (i.e., states, observables, Hamiltonians). In opposition to Carl—I won't say it's heresy—I think that's the wrong way to proceed. I think we'll ultimately find *a quantum reality*, but we'll have to dig deeper than that.

All that said, the reason I like your research direction is because I think understanding the purely algebraic properties of POVMs is an important link nevertheless. I would like to think that quantum mechanics is more about our interface with the world than the world itself ... and that it's at that interface that we'll find our glimpse of a "quantum reality." What is it about the interface that makes our best Bayesian predictions of the quantum mechanical form? That can be an algebraic question just as much as trying to pin naive properties on the world (regardless of how contrived the logic). In that sense, there is some chance of maybe learning something from the Giuntinis of the world.

On another topic—not completely unrelated—I talked to my boss about your summer position here. It's not completely 100% yet, but it's pretty damned close (maybe 99.9%). So, we should have a good summer together.

08-01-01 *Little Miracles* (to R. Jozsa)

I ran across the funniest thing by accident a minute ago. I'll place the announcement below. I especially got a chuckle from the last speaker's talk title. Maybe that's been the problem between you and me all along!

> Conference Announcement
>
> Numbers, Sets and Structures
> University of Bristol
> Saturday 18th November 2000
>
> Speakers:
>
> "The origin and status of our conception of number"
> Bill Demopolous (Western Ontario)
>
> "Can you be sure the number three isn't Julius Caesar?"
> Fraser MacBride (St. Andrews)

"Is there a unique natural number system?"
John Mayberry (Bristol)

"Anti-realists and classical mathematicians cannot get along"
Stewart Shapiro (Ohio State)

08-01-01 *Lunch?* (to S. J. van Enk)

Sorry, but I'm going to try hard not to exist until observed by Norbert.

There was a young man who said, "God
Must think it exceedingly odd
If he finds that this tree
Continues to be
When there's no one about in the Quad."

REPLY
Dear Sir:
Your astonishment's odd:
I am always about in the Quad.
And that's why the tree
Will continue to be,
Since observed by
Yours faithfully,
NORBERT.

09-01-01 *Please Come* (to L. Hardy)

The little blurb below is self-explanatory, and I'm being too lazy to personalize it. But you're in the first round of people I'm contacting. The reference to Montréal refers to the previous meeting I tried to invite you to. I hope you can come to this one; I'm especially eager to talk about your new paper (and I think Mermin is too). Unfortunately, Wootters can't make it, but I'm hoping that some of the other guys (from the previous meeting) can. If you have some grant money to spend, that'd be great, and it will help me get some of the more needy folk there. But most importantly, I hope you can come either way. Please let me know your thoughts as soon as possible. Once I get a better picture of who can make it, I'll start contacting more of the room-and-board crowd.

June 11–16, 2001, there's going to be a conference in Växjö, Sweden titled, "Quantum Theory: Reconsideration of Foundations," and I've been asked to organize a session on "quantum foundations in the light of quantum information" (or at least that's my take on it). I've been given the go-ahead to invite 3–4 people, all expenses paid, and 5 people with local expenses taken care of (but no travel). I'm hoping hard that you'll say yes to being one of the 3–4 (or one of the 5 if you have enough grant money and are feeling generous). In any case, *I'm hoping you'll say yes.* In flavor and constitution, I plan to make the session as much like our little meeting in Montréal as I can (given the larger, more diverse audience of the conference). The other people that I presently know to also be attending are Enrico Beltrametti, Jeff Bub, Arthur Fine, Ed Nelson, Pekka Lahti, and Asher Peres . . . but as a I say there will be a further contingent of quantum information people and a load of others beside that. Please let me know your thoughts at your earliest convenience:

I've been told to get back to the main organizer (Khrennikov) with my recommendations by next Sunday (Jan 14).

Your madly-optimistic-for-the-quantum friend,

Chris

09-01-01 *To Capitalize or Not To Capitalize?* (to S. J. van Enk)

That is the question. If you were me, would you capitalize the Greek letter starting the sentence below?

> The words "quantum state" are used here, just as in the previous formulation: One cannot get away from that. However, there are no unknown quantum states. $\rho^{(N)}$ is known by the experimenter if no one else. More importantly, the experimenter must be in a . . .

Don't you wish you had my troubles?

10-01-01 *Foundation-Sensitive Quantum-Information People* (to A. M. Steane)

I really, really enjoyed my conversation with you in Mykonos this summer: It prompts the invitation below. The blurb should be self-explanatory, so I'm going to be a little lazy and not personalize it. But you *are* in the first round of people I'm contacting; it's just that most of those guys were at a previous meeting Gilles Brassard and I organized this spring. Anyway, I hope you'll come. I think some of your ideas are quite deep and deserve a wider circulation with people who enjoy this sort of thing. To give you a flavor of the sort of people I'm seeking out for this session, I'll also place the *Montréal* meeting blurb further below. (So, don't get confused by there being two conference announcements in this note.) I don't know who I can get yet, but if things turn out like at the previous meeting, I think you'll have quite a bit of fun.

Finally, if you would like to come and have some grant money to spend, that'd be great, and will help me get some of the more needy folk there too. But most importantly, I hope you can come either way. Please let me know your thoughts as soon as possible. Once I get a better picture of who can make it, I'll start contacting more of the room-and-board crowd.

14-01-01 *Title and Abstract for Quantum Tutorials* (to J. E. Mazo)

Title and abstract for the talks (all three) below.

> Title: Enough Quantum Mechanics To Get Up and Running
>
> Abstract: I have a single goal in mind, to get as many people involved and cranking out research in quantum information science as possible. The motivation is self-serving: I really do believe there is nothing more exotic, more interesting, more important than quantum information. These talks (three or so) will be designed with that goal in mind—to get the communication theorist thinking about quantum stuff. If you can come to the lectures with any small memory of linear algebra (what a vector space is, what an inner product is, etc.), then I'll try to get you out with a workable knowledge of

what you might accomplish in the quantum domain. The lectures will be predominantly about the rules of the game from the communication perspective, but they will also be peppered liberally with simple relevant examples—quantum key distribution, quantum teleportation, Bell inequalities (no pun!), etc.

17-01-01 *How About This?* (to A. M. Steane)

That's too bad you can't come. My confirmed list of sessioners is now: Bub, Caves, Hardy, Jozsa, Lahti, Mermin, Peres, Schack, and Schumacher. (Still waiting on Preskill.) Almost surely now, we'll change the dates to June 17-22. You would have been a great addition! I'd really like to get some representation of your paper "A Quantum Computer Needs Only One Universe." So, how about this idea? Do you have a cohort sufficiently versed in the ideas (and convinced of their utility) to carry the torch? If you can't talk on your paper, maybe that person could do just as well. Any recommendations?

17-01-01 *Shannon meets Bohr* (to A. Y. Khrennikov)

Here's where it stands so far. I've drawn up a significantly more detailed synopsis for you. What do you think? I think the handwriting is on the wall as far as this group is concerned: the best dates for the meeting would be June 17–22. Shall we make those dates firm?

As I've told you already, what I've been doing in inviting people is giving them the choice to pay for part of the way out of their own grants. I figure we can get a lot more interesting people that way, and not sacrifice any quality. Indeed, the list is starting to include some of the best of the best in quantum information and still a lot of them are willing to pay their own travel expenses (especially, they say, if it will make for a better meeting).

So, how do your finances look given this new information? Would you like me to pursue some more of my (relevant) friends? Rarely do we find a congenial opportunity to talk about quantum foundations with each other—so this opportunity is quite a nice thing for us. The way I would proceed is roughly according to the list I laid out below. I say, "the more, the merrier!" But *you* are the financier; so it's *your* decision.

I read today about your meeting last Nov-Dec on *Probability in Physics*! It looked fascinating; I wish I had been there.

Anyway, for the present meeting, it looks like Shannon meets Bohr!

17-01-01 *Up Your . . .* (to H. J. Bernstein)

Alley. Up your alley, Herb.
Have a look at this article:

> The Environment and the Epistemological Lesson of Complementarity
> Folse HJ
> Environmental Ethics **15**(4) 345–353 WIN 1993
>
> Document type: Article Language: English Cited References: 23 Times Cited: 1
>
> Abstract: Following discussions by Callicott and Zimmerman, I argue that much of deep ecology's critique of science is based on an outdated image of natural science. The significance of the quantum revolution for environmental issues does not lie in

its alleged intrusion of the subjective consciousness into the physicists' description of nature. Arguing from the viewpoint of Niels Bohr's framework of complementarity, I conclude that Bohr's epistemological lesson teaches that the object of description in physical science must be interaction and that it is now mistaken to imagine that physical science aims to represent nature in terms of properties it possesses apart from interaction.

KeyWords Plus: normative naturalism, intrinsic value, quantum-theory, science

18-01-01 *Indeed I Have* (to A. Plotnitsky)

Plotnitskyism 1: *I hope you have been thinking about Pauli and all in general (naturally, no rush with sending anything).*

Indeed I have, but not nearly to the extent that I had hoped to. Getting established in this new environment has been quite something else. Did I ever write you after Mykonos? I can't find any record of it. OK, in the next note I'll send you a *very* incomplete compendium on Paulian ideas. Perhaps that will help you get better oriented.

In the present note, I'll also put some thoughts prompted by Mykonos. They were in a letter to David Mermin. And then still further below that, I'll place a passage that my note to Mermin refers to, "Genesis and the Quantum". [See 10-09-02 note "Don't Forget Your Problem Sets" to the Communards.] I hope you can sort it all out. It would be interesting to hear to your thoughts. I think there is some connection between the "efficacity" you spoke of and my "Zing!". (I think we even spoke about this in Mykonos.)

By the way, could you send me the full bibliography of your writings on quantum stuff?

Excerpt from 20 July 2000 note titled "Zing!" to N. David Mermin

Let me give you yet another suggestion for reading (that'll you'll probably ignore 2/3 of ... you told me you only read about 1/3 of what I suggest). I really enjoyed this one on my flight home the other day.

> H. J. Folse, "Niels Bohr's Concept of Reality," in *Symposium on the Foundations of Modern Physics 1987: The Copenhagen Interpretation 60 Years after the Como Lecture*, edited by P. Lahti and P. Mittelstaedt (World Scientific, Singapore, 1987), pp. 161–179.

As always, I almost surely liked it because it was saying something I wanted to hear.

Somehow I feel that I had an epiphany in Mykonos. Do you remember the parable of "Genesis and the Quantum" from my Montréal problem set? [See note to Gilles Brassard, titled "Problem Set," dated 15 May 2000.] And do you remember my slide of an empty black box with two overlays. The first overlay was of a big $|\psi\rangle$ (hand drawn in blue ink of course). I put the slide of the box up first, and said "This is a quantum system; it's what's there in the world independent of us." Then I put the first overlay on it and say, "And this symbol stands for nothing more than what we know of it. Take us away and the symbol goes away too." I then remove the $|\psi\rangle$. "But that doesn't mean that the system, this black box, goes away." Finally I put back up the $|\psi\rangle$ over the box, and the final overlay. This one says: "Information/knowledge about what? The consequences of our experimental interventions into the course of Nature."

Well, now I've made another overlay for my black box slide. At the top it asks, "So what is real about a quantum system?" In the center, so that it ends up actually in the box, is a very stylistic version of the word "Zing!" And at the bottom it answers, "The locus of all information-disturbance tradeoff curves for the system." In words, I (plan to) say, "It is that zing of the system, that sensitivity to the touch, that keeps us from ever saying more than $|\psi\rangle$ of it. This is the thing that is real about the system. It is our task to give better expression to that idea, and start to appreciate the doors it opens for us to shape and manipulate the world." What is it that makes quantum cryptography go? Very explicitly, the zing in the system. What is it that makes quantum computing go? The zing in its components!

Anyway, I'm quite taken by this idea that's getting so close to being a technical one—i.e., well formed enough that one might check whether there is something to it. What is real of the system is the locus of information-disturbance (perhaps it would be better to say "information-information") tradeoff curves. The thing to do now is to show that Hilbert space comes about as a compact description of that collection, and that it's not the other way around. As I've preached to you for over two years now, this idea (though it was in less refined form before now) strikes me as a purely ontological one ... even though it takes inserting an Alice, Bob, and Eve into the picture to give it adequate expression. That is, it takes a little epistemology before we can get to an ontological statement.

I looked back at your original Ithaca Interpretation paper, and I'll be bold enough to say that this idea satisfies all your most important desiderata: (1), (2 suitably modified), (3), and (5).

Part of this, by the way, is why I liked so much Folse's paper. Also, believe it or not, for a moment while reading it I thought I could finally "SEE" correlation without correlata. (Not lying.) But then I thought I liked the phrase "Interaction without Interactoids" even more. My wife just thought I was being silly. Maybe you will too.

Arkady's Reply, "Bibliography"

Here is my "quantum-mechanical" bibliography. It only lists books and articles primarily on Bohr and the epistemology of quantum mechanics. There are another dozen or so articles dealing with the relationships among quantum epistemology, philosophy, and literature, as well some reviews in scholarly and popular press (*Chicago Tribune*).

Books:

- *The Knowable and the Unknowable: Modern Science and Nonclassical Thought*, Ann-Arbor, Mich.: University of Michigan Press, forthcoming in 2001. Contains substantial chapters on Bohr and Heisenberg.
- *Complementarity: Anti-Epistemology After Bohr and Derrida*, Durham, NC: Duke Univeristy, 1994.

Articles:

- "Reading Bohr: Complementarity, Epistemology, Entanglement, and Decoherence," forthcoming in the *Proceedings of the NATO Advanced Research Workshop on "Decoherence and its Implications for Quantum Computation,"* eds. Antonios Gonis and Patrice Turchy (Dordrecht: Kluwer, 2001)

- "Quantum Physics and Philosophy 1900–2001," forthcoming in *Disciplinarity at the Fin-de-Siècle*, eds. Amanda Anderson and Joseph Valente (Princeton, NJ: Princeton University Press, 2001)
- "Landscapes of Sibylline Strangeness: Complementarity, Quantum Measurement and Classical Physics," *Metadebates*, eds. G. C. Cornelis, J. P. Van Bendegem, and D. Aerts (Dordrecht: Kluwer, 1999)
- "Techno-atoms: The Ultimate Constituents of Matter and the Question Concerning Technology in Quantum Mechanics," *Tekhnema: Journal of Philosophy and Technology*, Winter-Spring 1999
- "Complementarity, Idealization, and the Limits of the Classical Conceptions of Reality," in *Mathematics, Science and Postclassical Theory*, eds. Barbara H. Smith and Arkady Plotnitsky (Durham, NC: Duke University Press, 1997)

18-01-01 *Berkeley's Clones* (to A. Peres)

Asherism 1: *BTW, can God clone an unknown quantum state?*

Funny that you ask this. I just addressed this question in the paper I'm writing with Caves and Schack:

> There is hardly a paper in the field of quantum information that does not make use of the idea of an "unknown quantum state." Unknown quantum states are teleported [Bennett1993, Experiments1998], protected with quantum error correcting codes [Shor1995, Steane1996], and used to check for quantum eavesdropping [Bennett1984, CryptoExperiments]. The list of uses grows each day. But what can the term unknown state possibly mean? In an information-based interpretation of quantum mechanics the term is an overt oxymoron: For there, quantum states in their essence are states of knowledge and not states of nature [Hartle1968]. If a quantum state is used to describe a system, then it is *known* by someone—at the very least, by the describer himself.
>
> This message is the main point of our paper. If a phenomenon ostensibly invokes the concept of an unknown state in its formulation, then the unknown state had better be a shorthand for a more fundamental situation, even if that more fundamental situation still awaits a complete analysis. This means that, for any phenomenon using the idea of an unknown quantum state in its description, a consistent information-based interpretation of quantum mechanics demands that either
>
> 1. The owner of the unknown state—a further decision-making agent or observer—must be explicitly identified. In this case, the unknown state is just a stand-in for the unknown *state of knowledge* of an essential player that was skipped over previously. Or,
> 2. If there is clearly no further decision-making agent or observer on the scene, then a way must be found to reexpress the phenomenon with the term "unknown state" consistently banished throughout its formulation. In this case, the end-product of the effort will be a single quantum state used for describing the phenomenon—namely, the state that captures the describer's state of knowledge.
>
> The use of unknown states we actually analyze in depth has to do with the measurement technique known as quantum-state tomography [Vogel1989b, Smithey1993,

Leonhardt1995]. The usual description of tomography is this. A device of some sort, a laser say, repeatedly prepares many instances of a quantum system in a fixed quantum state ρ (pure or mixed). An experimentalist who wishes to characterize the operation of the device or calibrate it for future use may be able to perform measurements on the systems it prepares even if he cannot get at the device itself. This may be useful because he may have some prior knowledge of the device's operation that can be translated into a probability distribution over states. Thus learning about the state will also be learning about the device. Most importantly, though, it is assumed that the precise state ρ is unknown. The goal of the experimenter, therefore, is to perform enough measurements, and enough kinds of measurements, on a large enough sample, to estimate the identity of ρ.

This is clearly an example where there is no further player to pin the unknown state upon as a state of knowledge. Any attempt to do so would be quite unnatural: Where would the player be placed? On the inside of the device the tomographer is trying to characterize? [3] The only strategy open to us is the second one listed above, i.e., to banish the idea of the unknown quantum state completely from quantum-state tomography's formulation.

19-01-01 *Industrial Boys* (to A. Kent)

Kentism 1: *But might you want to circulate a criticism of the article itself, independent of the value of its John-component?*

Thanks for the offer, but I think I have to shy away from that. John has always been among my physics heroes. That's why I was so incensed when I found his name attached to (1) mathematical Platonism, (2) some form of an Everett interpretation, (3) a hope for a final theory, and (3) the idea that the observer plays no role in the measurement, ALL in opposition to everything he's written for 30 years. My lashing was a lashing out at Max. I don't want drag John any further through the dirt.

20-01-01 *Sleeping Around . . .* (to G. Brassard)

Maybe I should have completed the title of this note with, "with Shannon and Bohr." Well anyway, you'll understand the relevance of the title when you read the invitation below! I really hope you can come. You, more than anyone, are probably responsible for this session's existence: Without your financing last year, I wouldn't have been propelled into this position of *infamy*!!

[3] This move would be little more respectable than George Berkeley's famous patch to his philosophical system, a difficulty captured engagingly by the limerick of Ronald Knox and an anonymous reply: "There was a young man who said, 'God must think it exceedingly odd if he finds that this tree continues to be when there's no one about in the Quad.' "

Dear Sir:
Your astonishment's odd:
I am always about in the Quad.
And that's why the tree
Will continue to be,
Since observed by
Yours faithfully,
God.

(Nor would I have these continued chances to see my dream come true.) I think your talk on the communication cost of Bell inequality violations would be perfect for this crowd. But on top of that, at least Bub and Hardy (and soon to be many more I think) are taking our ideas about "QM from QKD and no QBC" seriously.

You'll note that Bill isn't in the list below; I already contacted him and he couldn't make it this time. You'll also note that Charlie's not in there either: In this case, it's because he refused to talk about foundations last time! (You did too, but I won't hold that against you.)

So, come!

> Dear friends,
>
> I recently found out that I've gotten another opportunity to gather some friends in an exotic place to thrash out the idea of "Quantum Foundations in the Light of Quantum Information." (This is starting to become a habit for me.) Anyway, this time I've been asked to organize a session at a larger conference in Växjö, Sweden titled "Quantum Theory: Reconsideration of Foundations." The main organizer is Andrei Khrennikov, and he is planning to have 40-50 people attending, with further sessions on Bohmian mechanics, GRW mechanics, and other issues in quantum foundations (Bell inequalities, Kochen-Specker theorems, etc.). Also I've been allowed to ask a small contingent of philosophers.
>
> In flavor and constitution, I plan to make our session much like the meeting Gilles Brassard and I held in Montréal last spring. There the theme was organized around the strong feeling that we'll find the greatest things and technologies to come out of quantum mechanics when we finally grasp the parts of it that make us feel the most uncomfortable. The theory is begging us to ask something new and profound of nature.
>
> This time the list of quantum information invitees (so far) includes: Gilles Brassard, Jeffrey Bub, Carl Caves, Lucien Hardy, Richard Jozsa, David Mermin, Asher Peres, John Preskill, Rüdiger Schack, John Smolin, and Ben Schumacher. The philosophical invitees I'm in charge of trying to get are: Doug Bilodeau, Henry Folse, Itamar Pitowsky, Arkady Plotnitsky, and Abner Shimony. Depending upon how the money holds out, I might be able to call up even a few more in the community. (Also, as I say, there are other sessions and thus other invitees, but I don't know who they are yet.)
>
> I think we'll have a double-edged opportunity at this meeting, so I'm looking quite forward to it. First, we'll get a chance to continue the lines several of us started in Montreal—at that time, the attendees were Bennett, Bernstein, Brassard, Bub, Hayden, Jozsa, Mermin, Schack, Schumacher, and Wootters. But second, we may be able to play the role of educators to a larger community interested in dabbling in these same issues. That is, we will have an opportunity to get them to think of quantum information as a TOOL for exploring quantum foundations.
>
> The dates for the meeting are June 17 to 22. We think this choice will help make for quite a pleasant time: Midsummer's eve is June 21, and Mermin has pointed out that picking wild strawberries in the midnight twilight is huge fun. Furthermore, there are significant local festivities planned around that time of year.
>
> The information I'd like to get from you (as soon as possible!) is:
>
> 1) Can you confirm positively that you would like to come?
>
> and
>
> 2) What kind of financial resources will it take for us to get you there?
>
> a) Full expenses paid?

b) Local expenses paid?
c) Nothing?

Concerning question 2), you can count this letter as an invitation, so feel free to answer any of the three options a), b), or c). However, the more money I can get the invitees to throw into the pot (IF they have it available), the more interesting people I can get to Sweden to keep us entertained. I've been told that I can have 3-4 invitees all expenses paid and 5 invitees with local expenses paid from the quantum information group. You can see that I'm *stretching* my limits! How am I going to do this? I'm *hoping* that a significant number of invitees will be able to volunteer to pay their nonlocal expenses, i.e. their travel expenses. Money is flowing pretty well into quantum information in Canada, the US, and the UK right now; and I do know that at least some of you have a surplus. On the other hand, the most important thing is that you attend, regardless of your funding status.

So please come: I think we'll have a lot of fun. Please let me know your thoughts as soon as you can! The sooner Khrennikov and I can get this preliminary information, the sooner we can start throwing stones at all the other problems.

All the best,

Chris

23-01-01 *It's Really Real* (to the Växjö Invitees)

The main organizer of the Växjö meeting, Andrei Khrennikov, now has all your financial-need information, etc., in hand. The word is, the total session below will go through—physicists, philosophers, and all. You should be hearing from him with an official invitation and conference announcement next week (when he returns from a conference in Italy). So, please mark the dates in your calendars!

Think John Wheeler thoughts!: "I want you ... to jolt the world of physics into an understanding of the quantum because the quantum surely contains—when unraveled—the most wonderful insight we could ever hope to have on how this world operates, something equivalent in scope and power to the greatest discovery that science has ever yet yielded up ..."

Looking forward to seeing you all in Sweden!

Quantum Theory: Reconsideration of Foundations Växjö, Sweden, 17–22 June 2001

Session: *Shannon meets Bohr: Quantum Foundations in the Light of Quantum Information*

The Physicists (Shannon meets Bohr)	Institution	Confirmed Participation
Gilles Brassard	U. Montréal	??
Jeffrey Bub	U. Maryland	yes
Carlton Caves	U. New Mexico	yes
Christopher Fuchs	Bell Labs	yes
Lucien Hardy	Oxford U.	yes

Richard Jozsa	U. Bristol	yes
Pekka Lahti	U. Turku	??
David Mermin	Cornell U.	yes
Asher Peres	Technion	yes
Itamar Pitowsky	Hebrew U.	yes
John Preskill	Caltech	tentative
Ruediger Schack	U. London	yes
Ben Schumacher	Kenyon College	yes, −1st day
John Smolin	IBM Research	yes

The Philosophers (Bohr meets Shannon)	Institution	Confirmed Participation
Doug Bilodeau	U. Indiana	yes
Henry Folse	Loyola U.	yes
Arkady Plotnitsky	Purdue U.	yes
Abner Shimony	Boston U.	??

Student Contingent	Institution	Confirmed Participation
Joe Renes	U. New Mexico	yes
Daniel Terno	Technion	yes

24-01-01 *Split Personality?* (to S. J. van Enk)

Science Desk
New York Times

ESSAY: ‘A Practical Tool,’ But Puzzling, Too
By JOHN ARCHIBALD WHEELER

What is the greatest mystery in physics today? Different physicists have different answers. My candidate for greatest mystery is a question now a century old, “How come the quantum?”

What is this thing, the “quantum”? It’s a bundle of energy, an indivisible unit that can be sliced no more. Max Planck showed us a hundred years ago that light is emitted not in a smooth, steady flow, but in quanta. Then physicists found quantum jumps of energy, the quantum of electric charge and more. In the small-scale world, everything is lumpy.

And more than just lumpy. When events are examined closely enough, uncertainty prevails; cause and effect become disconnected. Change occurs in little explosions in which matter is created and destroyed, in which chance guides what happens, in which waves are particles and particles are waves.

Despite all this uncertainty, quantum physics is both a practical tool and the basis of our understanding of much of the physical world. It has explained the structure of atoms and molecules, the thermonuclear burning that lights the stars, the behavior of semiconductors and superconductors, the radioactivity that heats the earth, and the comings and goings of particles from neutrinos to quarks.

Successful, yes, but mysterious, too. Balancing the glory of quantum achievements, we have the shame of not knowing "how come." Why does the quantum exist?

My mentor, the Danish physicist Niels Bohr, made his peace with the quantum. His "Copenhagen interpretation" promulgated in 1927 bridged the gap between the strangeness of the quantum world and the ordinariness of the world around us. It is the act of measurement, said Bohr, that transforms the indefiniteness of quantum events into the definiteness of everyday experience. And what one can measure, he said, is necessarily limited. According to his principle of complementarity, you can look at something in one way or in another way, but not in both ways at once. It may be, as one French physicist put it, "the fog from the north," but the Copenhagen interpretation remains the best interpretation of the quantum that we have.

Albert Einstein, for one, could never accept this world view. In on-again, off-again debates over more than a dozen years, Bohr and Einstein argued the issues – always in a spirit of great mutual admiration and respect. I made my own effort to convince Einstein, but without success. Once, around 1942, I went around to his house in Princeton to tell him of a new way of looking at the quantum world developed by my student Richard Feynman.

Feynman pictured an electron getting from point A to point B not by one or another possible path, but by taking all possible paths at once. Einstein, after listening patiently, said, as he had on other occasions, "I still cannot believe God plays dice." Then he added, "But maybe I have earned the right to make my mistakes."

Feynman's superposed paths are eerie enough. In the 1970's, I got interested in another way to reveal the strangeness of the quantum world. I called it "delayed choice." You send a quantum of light (a photon) into an apparatus that offers the photon two paths. If you measure the photon that leaves the apparatus in one way, you can tell which path it took.

If you measure the departing photon in a different way (a complementary way), you can tell if it took both paths at once. You can't make both kinds of measurements on the same photon, but you can decide, after the photon has entered the apparatus, which kind of measurement you want to make.

Is the photon already wending its way through the apparatus along the first path? Too bad. You decide to look to see if it took both paths at once, and you find that it did. Or is it progressing along both paths at once? Too bad. You decide to find out if it took just one path, and it did.

At the University of Maryland, Carroll Alley, with Oleg Jakubowicz and William Wickes, took up the challenge I offered them and confirmed that the outcome could be affected by delaying the choice of measurement technique – the choice of question asked – until the photon was well on its way. I like to think that we may one day conduct a delayed-choice experiment not just in a laboratory, but in the cosmos.

One hundred years is, after all, not so long a time for the underpinning of a wonderfully successful theory to remain murky. Consider gravity. Isaac Newton, when he published his monumental work on gravitation in the 17th century, knew he could not answer the question, "How come gravity?" He was wise enough not to try. "I frame no hypotheses," he said.

It was 228 years later when Einstein, in his theory of general relativity, attributed gravity to the curvature of spacetime. The essence of Einstein's lesson can be summed up with the aphorism, “Mass tells spacetime how to curve, and spacetime tells mass how to move.” Even that may not be the final answer. After all, gravity and the quantum have yet to be joined harmoniously.

On the windowsill of my home on an island in Maine I keep a rock from the garden of Academe, a rock that heard the words of Plato and Aristotle as they walked and talked. Will there someday arise an equivalent to that garden where a few thoughtful colleagues will see how to put it all together and save us from the shame of not knowing “how come the quantum”? Of course, in this century, that garden will be as large as the earth itself, a “virtual” garden where the members of my imagined academy will stroll and converse electronically.

Here, a hundred years after Planck, is quantum physics, the intellectual foundation for all of chemistry, for biology, for computer technology, for astronomy and cosmology. Yet, proud foundation for so much, it does not yet know the foundation for its own teachings. One can believe, and I do believe, that the answer to the question, “How come the quantum?” will prove to be also the answer to another question, “How come existence?”

26-01-01 *Report: Wallace, ‘Worlds in the Everett Interpretation’* (to J. N. Butterfield, C. Pagonis, and D. Wallace)

Anyone who knows me knows that I am rather down on attempts to interpret quantum mechanics along Everett-like lines. I think the most funny and telling statement of this in the present context is that, whereas Mr. Wallace speaks of “Everettians,” I often speak of “Everettistas.” Thus, I am almost surprised that you sent me this paper to referee.

My difficulties come not so much from thinking that an Everett-like interpretation is inherently inconsistent or that parallel worlds tax the imagination too much. It’s more that this line of thought strikes me, at best, as a complete dead end in the physical sense. At worst, I fear it requires us to tack on even more ad hoc structures to quantum theory than we already have. (Here, I’m thinking of a preferred basis for the Hilbert space and a preferred tensor-producting of it into various factors.) For these reasons, among umpteen others, I have always been inclined to an epistemic interpretation of the quantum state. Doing this has helped me (personally) to focus the issue to asking, “What is this *property* of the quantum world—i.e., reality—that keeps us from ever knowing more of it than can be captured by the quantum state?” To that extent, I consider myself something of a realist who—just as David Deutsch—takes the wavefunction absolutely seriously. *But* absolutely seriously as a state of knowledge, not a state of nature. I do well believe we will one day shake a notion of reality from the existing theory (without adding hidden variables, etc.), but that reality won’t be the most naive surface term floating to the top (i.e., the quantum state). When we have it, we’ll really have something; there’ll be no turning back. Physics won’t be at an end, but just at the beginning. For then, and only then, will we be able to recognize how we might extend the theory to something bigger and better than quantum mechanics itself.

All that said, you’re going to be surprised by my evaluation of this paper. Without hesitation, I recommend you publish it! Of all the things I’ve read on Everett-like interpretations over the years, this paper has struck me as the most reasonable of the lot. This is a nice paper. It changed none of my views, but it caused me deep pause for thought. What better honor can one have from a sparring partner?

I am not in a position to judge whether the paper is a significant step forward over the many Saunders papers it cites—I’ve never read any of them—but I do know this much: I have walked away from three of Simon Saunders' talks and not had a clue what he was talking about. So, even if my evaluation (as an outsider) of the paper's technical merit leaves something to be desired, I think Mr. Wallace's paper clearly serves a purpose within our community. The analogies between the Everett-like structure he proposes and the spacetime of general relativity are indeed intriguing and worthy of thought. For me personally—whatever their ultimate merit—they give a new stone on which to hone the arguments for an epistemic interpretation of the quantum state.

Let me just make a few minor comments to round out this report.

1) I very much enjoyed the discussion: "So there are no theory-neutral observations: rather, there is an existing theory in terms of which our observations are automatically interpreted, and which we must take as our starting point when interpreting the theories of physics." I've seen a discussion like this before, and it probably should be cited. Here are two references from my personal archive:

- W. Heisenberg, *Physics and Beyond: Encounters and Conversations*, translated by A. J. Pomerans (Harper & Row, New York, 1971), pp. 63–64. Heisenberg reports Einstein as having once said the following to him:

  > It is quite wrong to try founding a theory on observable magnitudes alone. In reality the very opposite happens. It is the theory which decides what we can observe. You must appreciate that observation is a very complicated process. The phenomenon under observation produces certain events in our measuring apparatus. As a result, further processes take place in the apparatus, which eventually and by complicated paths produce sense impressions and help us to fix the effects in our consciousness. Along this whole path—from the phenomenon to its fixation in our consciousness—we must be able to tell how nature functions, must know the natural laws at least in practical terms, before we can claim to have observed anything at all. Only theory, that is, knowledge of natural laws, enables us to deduce the underlying phenomena from our sense impressions. When we claim that we can observe something new, we ought really to be saying that, although we are about to formulate new natural laws that do not agree with the old ones, we nevertheless assume that the existing laws—covering the whole path from the phenomenon to our consciousness—function in such a way that we can rely upon them and hence speak of "observation."

  This is discussed further in:

- M. Jammer, "The Experiment in Classical and in Quantum Physics," in *Proceedings of the International Symposium, Foundations of Quantum Mechanics in the Light of New Technology*, edited by S. Kamefuchi, H. Ezawa, Y. Murayama, M. Namiki, S. Nomura, Y. Ohnuki, and T. Yajima (Physical Society of Japan, Tokyo, 1984), pp. 265–276.

2) Equation 1: There's a typo. "Atom decayed" also appears in the second term of the superposition.

3) Section 10 (the big table). This may have been my favorite part of the paper. But I would do this: Put the relativity column on the left and the Everett column on the right. Somehow, I found it much easier to read in that manner. It just seemed more natural to recognize a feature in relativity first, and then look for the analogous feature in Everett.

4) There's a typo in the fifth entry of that table. The words "choice of choice of" appear in the right-hand column.

27-01-01 *The Test Particle* (to D. Wallace)

I presume by now you've seen my thoughts on your Everett article. I meant it all; it's a very nice paper. I'd like to encourage you to place the article on the `quant-ph` archive. I'd like to refer some of my friends to it to the get a debate going. Having the paper easily accessible will help get that off the ground.

One piece of analogy (or disanalogy) that you didn't explore very much is the geodesic. Is there an analogue to the geodesic in your Everettian system? One thing that strikes me is that you might start seeing a conceptual divergence here. It's not clear to me that one can concoct a good notion of "test particle" for this game: even adding the smallest system possible to an existing multiverse (I hate that term) doubles its Hilbert space dimension (acting as if the Hilbert space is finite to begin with).

31-01-01 *Ah Midsummer . . .* (to R. Jozsa)

Thanks for the report on Butterfield. I just refereed a paper by David Wallace (for Butterfield's journal) on a variant of many worlds. It's a paper that Butterfield is very sympathetic to. The impressive thing about it was that maybe it made more sense than anything else I've read on the idea. So I accepted it for publication. I made it very clear that I continue to think that MWI is a dead-end, contentless idea. But I feel morally obligated to think that only of (what might be) their best shot!

31-01-01 *Corrections FUCHS Manuscript 060103PRA* (to *Physical Review A*)

Along with this note, I will fax back my corrections listed directly on the page proofs. All page numbers below refer to the marked up proofs. On the faxed copy, all modified pages are marked with a star in the bottom right corner.

The vast majority of your changes improved the readability of the paper. I thank you for making them. However, please note that I am fairly adamant about my remarks concerning pages 1 and 4, which have turned into something of a bone of contention because of a previous experience. Please consider my point of view with respect.

<u>Page 1)</u>

b) First sentence of abstract. I wish Physical Review would review its policy of blindly deleting all uses of the word "new" in titles and abstracts. Sometimes authors make use of this term for exactly the opposite of self-aggrandizing purposes. In my original draft I started with the sentence:

> "In this paper we give a new way to quantify the folklore notion that quantum measurements bring a disturbance to the system being measured."

You changed it to:

> "In this paper we provide a way to quantify the notion that quantum measurements bring a disturbance to the system being measured."

Written in this manner (without any extra qualification) it makes the authors appear arrogant. Any reader who knows anything whatsoever of quantum mechanics will think with disdain, "As if that's never been quantified before?!?!" Having said my piece, however, I will accept your deletion of the word "new."

What I cannot accept is your complete deletion of the word "folklore." It plays an important role in that sentence, and I ask that you replace it in its adjectival form "folkloric." The original word (barring only its mistaken grammatical form) was placed there quite carefully. It conveys the idea that we are speaking about something that is taken to be common knowledge, even when it has never been quantified. Quantifying it is the point of our paper. "FOLKLORE: the traditional beliefs, myths, tales, and practices of a people." Physicists, being human, are as susceptible to folklore as anyone else. You write, "Author–Please use more literal, meaningful modifiers." It was meant to be taken literally: there is no word that captures the concept better.

The fight over this word is a funny one with *Physical Review*. Asher Peres and I in our paper PRA **53**, 2038 (1996) had to fight for it in our opening sentence then. Finally Bernd Crasemann (then editor) accepted our point. Here is the original conversation, drawn from my email archive:

Peres:

> Dear Sirs:
>
> I just received the proofs of this article, and I am shocked that the fourth word of the first paragraph, "folklore", was changed into "convention" by the copy-editor, who added a comment "we favor more literal and accurate terminology". The authors have carefully chosen the word "folklore" because it has, in the present context, a slightly derogative meaning. This is exactly the message we want to convey to the readers of this article. I understand that the role of a copy-editor is to correct typos, style and grammar errors, and the like. There should be no distortion of the original meaning of the text. The authors, not APS or AIP, are responsible for the contents of their article.
>
> Please confirm that you are willing to accept the term "folklore" that was chosen by us. In case of a negative answer, we shall have to reconsider whether to publish our work in *Physical Review*, or withdraw it and submit it to another journal (we would prefer *Physical Review*).

Crasemann:

> You convincingly justify your use of the word "folklore" and we will certainly let it stand, even though it is not listed in the index of your admirable book, *Quantum Theory: Concepts and Methods*, which sits on my desk and has been a source of great edification.
>
> Permit me, however, to rise in defense of our staff's unceasing struggle to guard the integrity of the journal's scientific language. It was not a copy editor, but a Senior Assistant to the Editor, endowed with enviable Sprachgefuehl, who suggested the change in an effort to expunge unduly colloquial terminology. While no one is perfect, our colleagues in the Editorial Offices do a truly outstanding job safeguarding the journal's style.

I see no reason why the decision should be different this time around.

Page 2)

a) Second paragraph, third sentence. I originally wrote, "If there were a set of hidden variables underneath ..." You changed it to "If there is a set ..." This question was meant to be a hypothetical, and as such the verb should be "were." There is no question in my mind that there *are no* hidden variable underneath quantum mechanics. Please replace "were."

Page 3)

a) Second paragraph, sixth sentence. I wrote "What is novel here is that the encoding ..." You changed "novel" to "interesting," again charging that I should use more literal wording. "NOVEL: strikingly new, unusual, or different." "INTERESTING: arousing or holding the attention." Novel is the appropriate word for that sentence (describing a discovery of 1970); please reinstate it.

Page 4)

a) Second paragraph, fifth sentence. I accept your point that the phrase "founding fathers" is a colloquialism. However, substituting "original description" does not capture the proper idea either. Please replace "founding fathers" with "common folklore" (in line with my remarks above).

b) Third paragraph, first sentence. Again, please substitute "folklore" for "the founding fathers."

Page 12)

a) Sentence just above Eq. (16). You changed "... one can think of the interaction as causing the system to further unitarily evolve to" to "... to evolve further unitarily to." I understand you don't want me to split my infinitive, but "unitarily evolve" is the proper atomic verb. Please change the phrase to "... to unitarily evolve further to."

Page 13)

a) First paragraph, second to last sentence. Indeed "get a handle on" is a colloquialism, almost a Texanism. But "comprehend" doesn't capture the right idea either. Please replace the sentence with, "Finally, it stands to reason that if we can delineate the tradeoff ..."

Page 15)

a) Second paragraph, third sentence. I wrote, "When this obtains, the Shannon ..." You wrote, "When this answer is obtained, the Shannon ..." Completely different meaning. Please replace it with, "When this is the case, the Shannon ..."

Page 19)

a) Very top of page. Consistency is the hobgoblin of my small mind. 99.9% of all "non" words in the English language are nonhyphenated. Check a *Webster's* dictionary; check an *American Heritage* dictionary. It seems only in the physics community that this standard rule is broken. Please reinstate "nonnegative" in place of "non-negative."

31-01-01 *Tomography* (to S. J. van Enk)

The second reference below sounds a lot like it's doing what you say?

- K. Vogel and H. Risken, "Determination of Quasiprobability Distributions in Terms of Probability Distributions for the Rotated Quadrature Phase," Phys. Rev. A **40**, 2847 (1989).
- D. T. Smithey, M. Beck, M. G. Raymer, and A. Faridani, "Measurement of the Wigner Distribution and the Density Matrix of a Light Mode Using Optical Homodyne Tomography: Application to Squeezed States and the Vacuum," Phys. Rev. Lett. **70**, 1244 (1993).
- U. Leonhardt, "Quantum-State Tomography and Discrete Wigner Function," Phys. Rev. Lett. **74**, 4101 (1995).

01-02-01 *Oh Translator* (to S. J. van Enk)

Can you translate the German in this [quote of E. T. Jaynes]?

> For some sixty years it has appeared to many physicists that probability plays a fundamentally different role in quantum theory than it does in statistical mechanics and analysis of measurement errors. It is a commonly heard statement that probabilities calculated within a pure state have a different character than the probabilities with which different pure states appear in a mixture, or density matrix. As Pauli put it, the former represents '... eine prinzipielle *Unbestimmtheit*, nicht nur *Unbekanntheit*'. But this viewpoint leads to so many paradoxes and mysteries that we explore the consequences of the unified view, that all probability signifies only human information.

Steven's Reply

Literally it says

> a principle undeterminedness, not just unknownness.

where principle here is used as an adverb meaning something like fundamental.

Does that help?

01-02-01 *Zoom, Zoom, Zoom* (to G. Brassard)

Can you come, can you come, can you come??!?!?!?!

01-02-01 *Zing, Zing, Zing* (to G. Brassard)

Please come, please come, please come!!

02-02-01 *Zub, Zub, Zub* (to G. Brassard)

Please come, please come, please come!

02-02-01 *Zurek Criticisms* (to A. Kent)

Considering the careful critic that you are, you must have at some point written up your thoughts on Zurek's view of the quantum interpretation problem (to the extent that he has a well-defined view). Where can I find that? Alternatively, do you know of any other good critique papers by others along those lines?

05-02-01 *The Eerie Parallel* (to A. Kent)

Kentism 2 : *[Functionalism is] a view which has little to recommend it except a pleasing sense of answering a deep question with no work, and so naturally has become very widely held and respected among philosophers of mind. In this, it eerily parallels the Everett interpretation. It is only fitting that the two should be combined into a grander exercise in question-begging.*

At times in the past I've found myself wanting to be able to write like Mark Twain, and like William James. Both had this way of putting things—very different ways—that made me shiver from seeing the truth in their thoughts. Today I found myself wanting to be able to write like you!

06-02-01 *Interesting Coincidence* (to A. S. Holevo)

I'm writing up a paper (finally!) on this quantum de Finetti stuff you saw in Cambridge two years ago. And while building the bibliography, I had to place the following two contiguous entries:

- A. S. Holevo, "Information-Theoretical Aspects of Quantum Measurement," Prob. Info. Trans. **9**, 110 (1973).
- E. Prugovečki, "Information-Theoretical Aspects of Quantum Measurements," Int. J. Theo. Phys. **16**, 321 (1977).

I cited them for different reasons, and the two papers have quite distinct contents, but isn't it funny how the citations fell next to each other!

06-02-01 *Zoink!, Zoink!, Zoink!* (to G. Brassard)

Will you come? Will you come? Will you come?
(Every time I do this I have visions of the video version of *Horton Hears a Who.*)

07-02-01 *GHZM* (to N. D. Mermin)

Weren't you the first person to show that there's something weird about the state $000 + 111$ (even though everyone calls that a GHZ state)? If so, can you give me the full reference for that paper: including title and page numbers. If no, can you still give me the full reference for *that* paper: including title and page numbers.

David's Reply

Very scholarly of you to notice. The GHZ state is not in the GHZ paper. But they deserve the glory. I only constructed my version after hearing about their result and thinking that there ought to be a simpler way to make the same point. (Standing on the shoulders of GHZnts.)

I wrote about GHZ in two places. One is a *Physics Today Reference Frame* column (the only Reference Frame column I know of to receive citations in the technical literature) where I launch the sloppy scholarship by suggesting that GHZ invented the $000+111$ version of the argument as well as the general idea; the other's an AJP article.

- "What's Wrong with These Elements of Reality?," Phys. Tod., 9–11, June, 1990.
- "Quantum Mysteries Revisited," Am. J. Phys. **58**, 731–734, 1990.

There was a reason for my sloppy scholarship, by the way. I was quite enchanted with what I had boiled their argument down to and realized that if I attributed it to them, I could praise it extravagantly. But if I presented it as mine, I'd have to be boringly objective.

07-02-01 *The Scholar and the Cut* (to N. D. Mermin)

Merminition 1: *Very scholarly of you to notice.*

I am nothing if not a scholar. (Too bad I haven't yet been a good physicist too. I keep waiting for the day . . .)

07-02-01 *Wow!* (to A. Plotnitsky)

Yesterday I received the package you mailed to me! I can't express how grateful I am. I never imagined you would send me your book!! I'll make you a promise: I'll work very hard to digest all of it before meeting you again. I feel that a lot of our thoughts run fairly parallel, but I know that I have a lot of room for growth. (You, by the way, couldn't have gotten a better endorsement in my eyes than that John Wheeler was interested in your book.)

07-02-01 *Reports and Chutzpah* (to A. Kent)

Kentism 3: *I gather you'd already read David's article: maybe in fact that prompted the Zurekian query?*

Yeah, I was pretty open with my report. Might as well share it with you too; I'll paste it below. [See 26 January 2001 entry titled "Worlds in the Everett Interpretation" in *Coming of Age with Quantum Information*.]

But, no, that's not what prompted my Zurekian query. That was prompted by the paper I'm writing for the NATO meeting last summer. (I'm a little late!) The title will be "Quantum Foundations in the Light of Quantum Information," and mostly it will be devoted to laying out my program (rather than reporting results). But because the meeting was on decoherence and its connection to foundations, I thought it behooved me to say in a crisp way that it has *no* connection to foundations before going into my own spiel.

09-02-01 *A Little GHZM with Your States, Sir?* (to S. L. Braunstein)

I was thinking about a conversation we once had, and it dawned on me that you're probably the only one I dare tell this joke to. You once asked me for confirmation that David Mermin was actually the inventor of the three-particle GHZ state: GHZ, in their original paper, only talked about a four particle state. (I'll place the full story of this in David's words below.) [See 07-02-01 note "GHZM" to N. D. Mermin.] Anyway, I was toying with the idea of calling the three-particle GHZ state the GHZM state—maybe you once did too?—but how do you think that would end up being pronounced? "`!@?$`" is the first thing that comes to mind . . . but we can't have that at professional conferences!

10-02-01 *Historical Accuracy* (to N. D. Mermin)

While I'm digging for complete historical accuracy . . . Can you give me the complete reference for the very first appearance of GHZ's four-party state. Was it some AJP article including Shimony? There must have been something before that.

In any case, can you give me the complete reference including the title of the paper. Sorry to keep bugging you.

David's Reply

> The very first GHZ paper was: "Going Beyond Bell's Theorem", in *Bell's Theorem, Quantum Theory, and Conceptions of the Universe* (! — conceptions of the laboratory would have been good enough for me), ed. M. Kafatos (Kluwer Academic, Dordrecht, The Netherlands, 1989) pp. 69–72.
>
> The AJP article you mention is "Bell's Theorem without Inequalities", Daniel M. Greenberger, Michael A. Horne, Abner Shimony, Anton Zeilinger, Am. J. Phys. **58**, 1131–1143 (1990).

10-02-01 *Our Time with Brick and Keech* (to D. B. L. Baker)

You know, the years I spent with you during our youth make you partly to blame for this! I just wrote the following two footnotes for a paper by Caves, Schack and me, slated to appear in the *prestigious American Journal of Physics*. Tell me if you get the joke. The greatest mark of success will be if you (and readers like you) get it ... but the editor doesn't and therefore lets it slip past his red pen.

Let me know.

- `\bibitem{Mermin1990}`

  N. D. Mermin, "What's Wrong with These Elements of Reality?," Phys. Tod. **43**(6), 9 (1990); N. D. Mermin, "Quantum Mysteries Revisited," Am. J. Phys. **58**, 731 (1990). Though Mermin was the first to point out the interesting properties of this three-system state (following the lead of Ref. `\cite{Greenberger1989}` where a similar four-system state was proposed), we call attention to the pronunciational perils of calling the state a "GHZM state" and, thus, defer to the more common label GHZ.

- `\bibitem{Greenberger1989}`

  D. M. Greenberger, M. Horne, and A. Zeilinger, "Going Beyond Bell's Theorem," in *Bell's Theorem, Quantum Theory and Conceptions of the Universe*, edited by M. Kafatos (Kluwer, Dordrecht, 1989), p. 69.

12-02-01 *AMS Abstract* (to me)

Title: The Power of Generalized Measurements (POVMs)

Abstract: It has become customary in quantum information theory to think of "generalized measurements" or "positive-operator valued measures" (POVMs) as a derivative concept. This is because it is known that a POVM can always be built up from a standard von Neumann measurement on an ancillary system that has previously interacted with the target system. In this talk we point out the utility of taking the POVM as a basic notion. This strategy greatly reduces the difficulty of proving many very basic theorems in quantum mechanics and gives a deeper insight into why "entanglement" has the exact structure that it does.

14-02-01 *Shannon and Bohr* (to E. Merzbacher)

Since I haven't heard back from you concerning the "Shannon meets Bohr" meeting, I'm going to assume that you cannot come. In any case, our funds are fairly exhausted now. But I would have loved to have had you there, especially to expand on this wonderful thing you wrote me in 1999:

Merzbacherism 1: *For a long time I have thought about writing an essay on what is meant by the term "physical system", including some history of that slippery concept. I'll probably never do it, but your opinion piece has brought this matter back to my mind.*

Do it some day! You'd automatically have an audience of at least one. (That's something I cannot say for some of my papers!)

17-02-01 *Saturday with Some Jazz* (to A. S. Holevo)

Holevo-ism 1: *The conference was interesting, among people you know were Milburn, Massar, van Dam, Werner, ... Quite remarkable was great interest from classical probabilists and mathematical statisticians to learn quantum information. Eurandom is a good place and we should keep it in mind. ... The highlight was supposed to be the lecture of a Nobel-price winner 't Hooft .... The point of his lecture was that on Planck distances, where gravitational interaction becomes important, one may convert to nonlocal hidden variables in place of quantum theory. It was interesting to see how classical prejudices are strong even in the most distinguished physicists' minds.*

Thanks for the report of the Europhys conference. Indeed your remark about 't Hooft was most interesting. Today I am taking a leisurely day, thinking about philosophical things and compiling further my Bohrish-Paulian compendium (I now have 355 references), and thus thinking about such things.

We had a very busy week here at Bell Labs. Chris King gave a wonderful talk, and much of Jim Mazo's information theory group was in attendance. Mary Beth outlined a proof of the equality conditions for the strong subadditivity and this led to some good discussion about notions of Markov chains for quantum states. Serap and Gerhard gave a talk about "quantum coding" for commutative alphabets. And then while Peter Shor was visiting, Emina Soljanin presented what she thinks is a proof of the achievability of (your) χ in the noncommutative case. (Recall that Barnum and several of us proved χ to be a lower bound; M. Horodecki also proved it independently.) Unfortunately I had to miss that talk. Finally, I gave my final tutorial talk on basic quantum mechanics (from the quantum information slant) to Mazo's group; when I return from Japan I will start a set of tutorials on quantum information proper (for the smaller, more prepared audience).

17-02-01 *My Bohr-Pauli Compendium* (to K. Barad)

Your quantum writings have been brought to my attention by Herb Bernstein and Mike Fortun, and I wanted to tell you that your one article that I did read was wonderful! (I'll place the passages that took me the most below.)

Mainly I'm writing this letter, though, in hopes that I can get you to send me some more of your writings or at least fill in the missing information for the two references (far) below. Any way you can help would be most appreciated. I am compiling a bibliographical compendium of sensible writings about quantum mechanics, and I would like to include all your work there.

- K. Barad, "A Feminist Approach to Teaching Quantum Physics," in *Teaching the Majority: Breaking the Gender Barrier in Science, Mathematics, and Engineering*, edited by S. V. Rosser (Teachers College Press, New York, 1995), pp. 43–75.

> The Newtonian worldview is compatible with an objectivist epistemology, in which the well-prepared mind is able to produce a privileged mental mirroring of the world as it exists independently of us human beings. That is, what is "discovered" is presumed to be unmarked by its "discoverer." The claim is that the scientist can read the universal equations of nature that are inscribed in [God's] blackboard: Nature has spoken. Paradoxically, the objects being studied are given all the agency, even and most especially when they are seen as passive, inert objects moving aimlessly in the void. That is, these cultureless agents, existing outside of human space-time, are thought to reveal their secrets to patient observers watching and listening through benignly obtrusive instruments. Notice that agency is not attributed to human beings; once all subjective contaminants have been removed by the scientific method, scientists simply collect the pure distillate of truth.
>
> The Newtonian worldview is still so much a part of contemporary physics culture that it infects the teaching of post-Newtonian physics as well. That is, the stakes are so high in maintaining the mirroring view of scientific knowledge that quantum physics is presented as mysticism.

and

> Notice that particular experimental arrangements can be used to give more or less definite meaning to each of the complementary variables, but due to the lack of object-instrument distinction . . . it is not possible to assign the value obtained to the object itself. The "property" being measured in a particular experimental context is therefore not "objective" (that is, a property of the object as it exists independently of all human interventions), but neither is it created by the act of measurement (which would belie any sensible meaning of the word *measurement*). Bohr speaks of this "interaction" between "object" and "instrument" as a "phenomenon." The properties then are properties of phenomena. That is, within a given context, classical descriptive concepts can be used to describe phenomena, our intra-actions within nature. (I use the term *intra-action* to emphasize the lack of a natural object-instrument distinction, in contrast to *interaction*, which implies that there are two separate entities; that is, the latter reinscribes the contested dichotomy. . . . That is, the ambiguity between object and instrument is only temporarily contextually decided; therefore, our characterizations do not signify properties of objects but rather describe the intra-action as it is marked by a particular constructed cut chosen by the experimenter (see Ref. [Barad95] for more details).
>
> The notion of "observation" then takes on a whole new meaning according to Bohr: "[B]y an experiment we simply understand an event about which we are able in an unambiguous way to state the conditions necessary for the reproduction of the phenomena" (quoted in Ref. [Folse85], p. 124). According to the analysis of the previous section, this is possible because, in performing each measurement, the experimenter intervenes by introducing a constructed distinction between the "object" and the "measuring device" (e.g., deciding whether the photon is part of the object or the instrument). The claim is that unambiguous, reproducible measurements are possible through the introduction of constructed cuts. Notice that "[n]o explicit reference is made to any

individual observer": Different observers will get the same data set in observing any given phenomenon. Therefore, reproducibility, not some Newtonian notion of objectivity denoting observer independence, is the cornerstone of this new framework for understanding science.

For Bohr, the uncertainty principle is a matter of the inadequacy of classical description. Unlike the "mirroring" representationalism inherent in the Newtonian-Cartesian-Enlightenment framework of science, scientific concepts are not to be understood as describing some independent reality. A post-Newtonian framework sees these constructs as useful (i.e., potentially reproducible) descriptions of the entire intra-action process (the phenomenon, which is context dependent by definition), not of an isolated object. The implications of this finding are profound. In Bohr's own words:

> The extension of physical experience in our own days has ... necessitated a radical revision of the foundation for the unambiguous use of elementary concepts, and has changed our attitude to the aim of physical science. Indeed, from our present standpoint, physics is to be regarded not so much as the study of something a priori given, but rather as the development of methods for ordering and surveying human experience. (Bohr, Ref. [Bohr63c], p. 10)

In other words:

> These facts not only set a limit to the extent of the information obtainable by measurements, but they also set a limit on the meaning which we may attribute to such information. We meet here in a new light the old truth that in our description of nature the purpose is not to disclose the real essence of [physical objects] but only to track down, so far as it is possible, relations between the manifold aspects of our experience. (Bohr, Ref. [Bohr63a], p. 18)

and

Bohr's philosophy of physics involves a kind of realism in the sense that scientific knowledge is clearly constrained, although not determined, by "what is out there," since it is not separate from us; and given a particular set of constructed cuts, certain descriptive concepts of science are well-defined and can be used to achieve reproducible results. However, these results cannot be decontextualized. Scientific theories do not tell us about objects as they exist independently of us human beings; they are partial and located knowledges. Scientific concepts are not simple namings of discoveries of objective attributes of an independent Nature with inherent demarcations. Scientific concepts are not innocent and unique. They are constructs that can be used to describe "the between" rather than some independent reality. (Why would we be interested in such a thing as an independent reality anyway? We don't live in such a world.) Consideration of mutually exclusive sets of concepts produces crucial tensions and ironies, underlining a critical point about scientific knowledge: It is the fact that scientific knowledge is socially constructed that leads to reliable knowledge about "the between"—which is just what we are interested in. This shifting of boundaries deconstructs the whole notion of identity: Science can no longer be seen as the end result of a thorough distillation of culture. There is an author who marks off the boundaries and who is similarly marked by the cultural specificities of race, history, gender, language, class, politics, and other important social variables. Reproducibility is not a filter for shared biases. In stark contrast to the objectivist representationalism that is usually transmitted to students, the new framework inspired by Bohr's philosophy of physics is robust and intricate. In particular, there is an explicit sense of agency and therefore accountability. And so I refer to this Bohr-inspired framework, which shares much in common with central concerns in contemporary feminist theories, as "agential realism."

Karen's Reply

Thank you for your interest in my work. As per your request, below is a list of some of my other articles further elaborating Bohr's philosophy-physics. I hope you find these useful.

21-02-01 *There Are No Quantum States* (to A. Peres)

Asherism 2 : *There are no quantum states (in a relativistic theory). Therefore it is pointless to discuss collapse, there is no EPR paradox, etc. What the theory is about is propagators (or rather superpropagators = completely positive maps) from initial preparation to final observation. However, an explicit evaluation of these superpropagators is best done by introducing fake notions (quantum states), just as we use a vector potential in electrodynamics, or a spacetime metric in general relativity, because it is cumbersome not to use these gauge dependent objects. I don't know what these ideas will bring, but at least I have an impression that now I understand better.*

My thesis, paradoxically, and a little provocatively, but nonetheless genuinely, is simply this:

QUANTUM STATES DO NOT EXIST.

> The abandonment of superstitious beliefs about the existence of Phlogiston, the Cosmic Ether, Absolute Space and Time, ..., or Fairies and Witches, was an essential step along the road to scientific thinking. The quantum state, too, if regarded as something endowed with some kind of objective existence, is no less a misleading conception, an illusory attempt to exteriorize or materialize the information we possess.
>
> — *the ghost of Bruno de Finetti*

21-02-01 *There Are No Quantum States, 2* (to A. Peres)

Asherism 3: *Where did you write that?*

I've never put it in real print yet, only in my philosophical samizdat. Maybe I'll find a way to get it into real print soon.

What am I up to? Too much and not enough at the same time!

21-02-01 *A Reference* (to P. Pearle)

If I were going to cite one (and only one) reference on spontaneous collapse ideas, which one should it be? I just want something, even a popular exposition, that can serve as a point of departure for my readers.

To give you a flavor of what I'm looking for I cited the following in connection with the Einselectionists, the Bohmians, the Everettistas, and the Consistent Historians.

1. W. H. Zurek, "Decoherence, Einselection and the Existential Interpretation (The Rough Guide)," Phil. Trans. R. Soc. Lond. A **356**, 1793–1821 (1998).

2. J. T. Cushing, A. Fine, and S. Goldstein, editors, *Bohmian Mechanics and Quantum Theory: An Appraisal*, (Kluwer, Dordrecht, 1996).

3. D. Deutsch, *The Fabric of Reality: The Science of Parallel Universes—and its Implications*, (Allen Lane, New York, 1997).

4. R. B. Griffiths and R. Omnès, "Consistent Histories and Quantum Measurements," Phys. Today **52**(8), 26–31 (1999).

26-02-01 *THE Book* (to D. P. DiVincenzo)

I just wrote to Barbara explaining what a heel I was for forgetting to ask how she made it home during the big snow storm (after her interview here). But I'm also a heel for not writing earlier to thank you for the wonderful Jammer book you bought me. I really, really appreciate it. It is THE classic in quantum foundations.

27-02-01 *Claude Shannon's Death* (to the "Shannon meets Bohr" Invitees)

To those friends I contacted for the "Shannon meets Bohr" session in Växjö:

We at Bell Labs were all deeply moved yesterday to learn of Claude Shannon's death over the weekend. Like for many Alzheimer's patients, however, we knew that it may have been a blessing in disguise. You can read more about Shannon's life in the *New York Times* obituary section today.

Some weeks ago, I found myself using the following words for a recommendation letter I was asked to write:

> As it turns out, today January 16, we had a dedication ceremony at Bell Labs for a bronze bust of Claude Shannon, the founder of classical information theory. That struck me as symbolic. Since joining the laboratory, I have been asking myself over and over what role I might play in furthering the legacy of Shannon?

Those words hold just as true for me for this midsummer's meeting. Let us use information theory as a sword and finally defeat this mystery of the quantum.

28-02-01 *History's Mysteries — A Real One!* (to family and old friends)

Dear Family and Friends (mostly from my old home town ... I'm too embarrassed to tell my colleagues),

I likely made a good fool of myself, but if you have cable TV, you might be on the lookout for my ugly mug on the History Channel the week of March 12. I got the announcement below from them. The time 8pm may be referring to California time, I don't know. They interviewed me for about an hour—stuff to do with quantum teleportation—but I suspect they're going to use only a minuscule amount of that footage. Steven Weinberg and Jeff Kimble will also be making appearances in the capacity of "official, knowledgeable scientists."

> We have an air date!! The show will air on the History Channel on the show, 'History's Mysteries: The Philadelphia Experiment' Monday, March 12 at 8pm. For more show information, you can access the History Channel web site at
>
> `www.thehistorychannel.com`
>
> The show will repeat throughout the week and you can get that air info from the web site.

06-03-01 *Pauli-ish Compendium* (to H. Atmanspacher)

I am compiling a rather large compendium to be titled, "The Activating Observer: Resource Material for a Paulian-Wheelerish Conception of Nature," and will ultimately be submitting it to the journal *Studies in History and Philosophy of Modern Physics*. Perhaps the subject of the compendium needs no explanation given the title. It presently has about 400 items listed in it.

In any case, I wonder if I can ask of your assistance. In the compendium, I presently have you listed with three titles:

- H. Atmanspacher, "Wolfgang Pauli und die Alchemie," Zeitschrift für Parapsychologie und Grenzgebiete der Psychologie **34**, 3–32 (1992).

- H. Atmanspacher, H. Primas, and E. Wertenschlag-Birkhäuser, eds., *Der Pauli-Jung-Dialog und seine Bedeutung für die moderne Wissenchaft*, (Springer, Berlin, 1995).

- H. Atmanspacher and H. Primas, "The Hidden Side of Wolfgang Pauli: An Eminent Physicist's Extraordinary Encounter with Depth Psychology," J. Consc. Stud. **3**, 112–126.

Unfortunately, I have not been able to obtain these materials. Might I ask you to send me copies of these papers (in the case of the book, maybe you wrote an introduction)? Also, if there is anything else you've written on the subject since then, I would be most appreciative if you could send that too. I will place my professional address below.

I obtained your email address from Andrei Khrennikov who just placed me on the advisory board to his ICMM in Växjö. I am in Germany at least once a year to visit my wife's parents in Munich; perhaps I will get a chance to visit with you sometime during such a visit (the next will be in August or September).

Harald's Reply

I am happy to give you a list of publications of mine on Pauli, see below. Copies of the articles will be sent to you.

Concerning the title of your project, it is somewhat unclear to me why you connect Pauli so tightly with Wheeler. You will have your reasons to join those names. Personally, I would not connect Pauli and Wheeler on a more than superficial level. Maybe you have insights which I am lacking.

Whenever you are in Germany, please let me know if you see a chance to come to Freiburg. As I spend some part of my time in Munich, it's possible we can meet there as well.

07-03-01 *Wonderful* (to M. A. B. Whitaker)

Thank your for your kind invitation to speak at the Belfast meeting. I am flattered, and of course I will make time on my calendar to be there. Indeed "Quantum Foundations in the Light of Quantum Information" has been one of my pet peeves lately, and I have spent quite a bit of energy in promoting that direction in our community. (First organizing a small meeting in Montréal last year with Brassard, and then a small meeting in Sweden this year.) I think there is probably no way quantum information will make a deeper contribution to physics than in finally bringing to a satisfactory conclusion the foundation problem.

So please mark me down for a talk—I have a pretty good one now devoted solely to this idea that not many in the foundations community have seen—and please keep me abreast of the further developments.

07-03-01 *Pauli and Wheeler* (to H. Atmanspacher)

What a wealth of information! Thank you so much. I didn't realize that you had written so extensively on Pauli! If only I could read German! But, still, your sending those things will be most useful: with the help of some friends I will be able to get the abstracts and some key pieces of the text translated for inclusion into the compendium.

You ask why I connect Pauli and Wheeler so tightly? Well, really the whole document is centered around a theme to do with the potential "malleability" of our world. I use Pauli and Wheeler as two figureheads, but really the document is much more about the overall theme. There is also much material on Bohr, quite a lot on Rosenfeld, stuff to do with ideas about *evolutionary* physical laws à la Peirce, Bergson, James, etc., a sprinkling of historical things on alchemy, and so forth. I'll place the (present) abstract and two quotes (one by Pauli, one by Wheeler) below to show why I've chosen those two men as figureheads.

Thank you again for your help!

09-03-01 *Banach Conference* (to D. Petz)

Thank you for the invitation to speak at the Banach Center meeting. I am flattered that you would think of me in this regard. If I were to give a talk there I would try to make sure that the subject was more along the lines of "Some Nontrivial Theorems in Quantum Mechanics" rather than as in my previous visit!! Beside visiting you again, I would be specially intrigued to meet Csiszar and discuss his "secrecy capacity" in the quantum context.

May 21–26 is just potentially possible for me.

13-03-01 *FYI – The History Channel* (to S. K. Stoll)

Stollicism 1: *On a related topic, is it true you gave an interview to Swedish media about teleportation of "souls"? I'm puzzled.*

Why do you ask? It wasn't to the Swedes, it was before that. It may have been a Japanese crew. I tried to explain that what is teleported is the quantum state, not a material object. And of course, they said, "What's that?" And I said, "It's more like the soul than the body." Or some such ting.[4]

Did I actually make an appearance on the show? Or did they completely cut me?

I'm in Tokyo right now. Akira came for Steven's and my talks. That guy is amazing: It took him a two hour trip each way, just to come sit through our talks. Friday we're going to go visit his laboratory. He's an associate professor at U. Tokyo now.

13-03-01 *Is Nice nice?* (to S. L. Braunstein)

What's the business about below? It seems they put my name on their flyer before I had a chance to answer them. Oh well. A little extra advertisement can't hurt. Now we'll just have to see whether I'm free during that time. Thanks for promoting me.

Is Nice a nice place? I'm in Tokyo right now. Charlie Bennett and I are sharing a room, and both up with jetlag. The lights are off and the laptops are glowing. A little like two fireflies in the night.

Sam's Preply

Dear Dr. Touddaint and Dr. Plet,

[4]Actually it was a Brazilian television crew. On 7 November 1998, I wrote to Asher Peres, "Teleportation has surely grasped the media's attention. Wednesday a Brazilian television crew came here and shot 1.5 hours of footage of the lab, Kimble and me. All that to make a five minute TV segment on some prime-time show. The interviewer assured me that 70 million people would be seeing my face and hearing my thoughts. It's funny, but when they told me that, all I could think of was the poor sick woman who sent Charlie Bennett a police report of some minor accident she had had about ten years earlier. She had read enough of Wheeler's thoughts on quantum mechanics—with phrases like, "reality is a function of the community of communicators," etc.—to think that if not more people knew about the smallness of the accident, it might turn into something really big and horrible. I thought, "I'm not starting to feel any more real yet. I wonder if it'll happen when the viewers actually see the film?" Oh well, I guess I don't know what it means to feel real anyway! The interviewer was fixated on whether the soul would also get carried over by a teleportation device. I'm sure my remarks will go over well in a Catholic country!"

Mr. Anders Hansson was correct about my interest in giving a presentation at DASIA 2001, unfortunately, other commitments have been made before I knew what dates were involved.

Might I suggest an alternative (whom I have approached):

- Dr. Chris Fuchs at Lucent
  cafuchs@research.bell-labs.com

His especial interests are quantum cryptography, which I think you would find very interesting; he is is also an excellent speaker and would be worth getting to come.

Sincerely,

Sam Braunstein

16-03-01 *Jammin' Jammer* (to H. Barnum)

Thanks for thinking of me. Actually, I was just given a copy of Jammer's 1974 book (*The Philosophy of Quantum Mechanics*) by David DiVincenzo. But I don't have Jammer's 1966 book yet (*The Conceptual Development of Quantum Mechanics*). I'm not completely sure which one you were thinking of.

And by the way, thanks for sending me a report on Jeff Bub's seminar. I was dancing a little jig for a week after.

17-03-01 *RCFoC* (to J. B. Lentz)

Thanks for the article. I'm still in Japan. I'll be here until Thursday. The History Channel show was an episode of History's Mysteries. The title was something about "The Philadelphia Experiment," some silliness about a supposed teleportation of a navy ship from Philadelphia to Norfolk, VA sometime in WWII. From what I understand, of the hour-long interview they gave me, they only used about a minute of the footage (at most).

17-03-01 *Pounding Rice Cakes* (to H. Barnum)

The allusion is this: One of my greatest eye-opening experiences was in learning that when the Japanese look at the moon they see a rabbit pounding rice cakes. Ever since being told that, I've been able to see it too. It's plain as day. Thirty-three years of not seeing it once, and then, boom, someone tells me of it and I see it all the time. Likewise, I'll bet the next big step in physics will only require that we see something right here in front of us. It'll be something no big multi-billion dollar particle accelerator will be needed for. We just have to figure out how to take note of it. I'm banking that a hint is already written down in the quantum.

18-03-01 *The Copenhagen Picnic* (to H. J. Folse)

Folsesm 1: *What is it that you're looking for in the Archives? I spent six months going through them 26 years ago. Of course there's more there nowadays. But I doubt that there is any undiscovered gold to find, and if there is it's deeply buried.*

Ultimately, I plan to dig deeper into whatever can be found in the US repositories you mentioned, but for the present Ben and I thought it might make a nice picnic with which to end our time in Scandinavia.

What am I looking for? Basically, just fun historical tidbits to do with this train of thought I've been telling you about. You never know what you might find ... especially when seen through "prepared" eyes. If I need to pull out an official reason for being there, I can use this large compendium I'm putting together—if it doesn't create too much copyright trouble, I plan to have it appear in *Studies in History and Philosophy of Modern Physics*. And I'm sure I can get any number of letters vouching for my historical integrity: you perhaps?, Mermin, Butterfield (editor of SHPMP), or maybe some more appropriate people if I think harder.

Speaking of the compendium, would you like to see it as it stands? It's now got about 400 references in it and a nonnegligible amount of annotation. It stands presently at 80 pages. I'm projecting about 500 references and 150 pages for the completed project. There's a whole lot of editing left to be done, but you might find it fun even at this stage. And maybe you can tell me about any glaring omissions that you know of.

For the present, let me attach a note I wrote you on my way to Japan. You never answered my two questions, even though you replied to later emails. So maybe you never got it.

From a 09 March 2001 note to Henry Folse, "The Right Choice"

Sorry for my long delay in getting back to you. I'm off to Japan in about five hours for two weeks, and *trying* to get things tied up here before leaving has made the week pretty hectic.

Anyway, the most important message I wanted to tell you is that I'm gettin' damned happy I invited you to Växjö. Reading your papers has been a really pleasant experience. I think I hit my first dozen last night at about this time. (But maybe the bigger question is, why am I up at this time?!?) Below, I'll place my Folse compendium as it stands—every word typed in lovingly with my own little fingers! Of course, I have a few quibbles with some things I've read, but I think I'll save my comments until I've read the complete body of work. 27 years is a long time, and you could well have changed your mind about some things: I'll give you the benefit of the doubt for now.

Folsesm 2: *I should certainly warn you that very few in this community agree much with my reading of Bohr.*

I couldn't care less about that: I like it (or most of it), and that's all that counts for me. Besides, I've read Bohr myself—fairly carefully I've always thought—and your view significantly coincides with my memory of that.

Folsesm 3: *I'm more concerned about my lack of knowledge of anything about information theory.*

You need not be too concerned, but of course it wouldn't hurt you to do a little reading on the side if you've got some time. Somewhere below, you wrote:

> In describing the phenomena of observational interactions, quantum theory describes them as being caused by the interactions between the observing systems and microsystems. The fact that we can form no representation, no mechanical picture, of the atoms on which the mechanistic description of

> the phenomenal world is based, hardly reveals that we are ignorant of what these entities *are*. Rather it testifies to what we have learned about them – that they cannot be so represented – through explorations of the atomic phenomenon in which their strange behavior is revealed to human experience.

It is my strongest opinion that the great fruits of quantum information and computing get at precisely this point ... and in spades! The point is that this "nonrepresentability" in actual fact boils down to a positive statement rather than a negative one. So it would do you well to learn a little about our field. (And, luckily, most of what we do is not abstruse stuff: it's just basic quantum mechanics, viewed mostly from a new point of view with a new set of goals in mind.) Where to start? Maybe a good place would be three "recent" *Physics Today* articles:

1. Gottesman and Lo, "From Quantum Cheating to Quantum Security," PT November 2000 (don't have the page numbers)
2. Preskill, "Battling Decoherence: The Fault-Tolerant Quantum Computer," PT June 1999, p. 24
3. Bennett, "Quantum Information and Computation," PT October 1995, p. 24 (interesting coincidence)

If you get that far, let me know, and I'll suggest a couple of really *mild* technical articles that'll be worth their weight in gold in insight.

But why do I think it would do you well? Because I think you have an honest heart. And, because while I believe Bohr and his gang certainly started to point us in the right direction, I think we have a long, long technical way to go before we can claim a particularly deep understanding of the quantum structure. Here's how I put it in exasperation to David Mermin once:

> What's your take on this passage? Can you make much sense of it? What does he mean by "providing room for new physical laws?" What "basic principles of science is he talking about?" What five pages of derivation are lying behind all this business?
>
> It nags me that Bohr often speaks as if it is clear that the structure of quantum theory is derivable from something deeper, when in fact all the while he is taking that structure as given. When did he ever approach an explanation of "Why complex Hilbert spaces?" Where did he ever lecture on why we are forced to tensor products for composite systems? It's a damned shame really: I very much like a lot of elements of what he said, but as far as I can tell all the hard work is still waiting to be done.

The issue in my mind is *not* to *start* with complex Hilbert space, unitary evolution, the tensor product rule for combining systems, the identification of measurements with Hermitian operators, etc., etc., and *showing* that Bohr's point of view is *consistent* with that. Instead it is to start with Bohr's point of view (or some variant thereof) and see that the *precise* mathematical structure of quantum theory *must* follow from it. Why complex instead of real? Why unitary, rather than simply linear? Indeed, why linear? Why tensor product instead of tensor sum? And, so on. When we can answer *these* questions, then we will really understand complementarity.

I'm banking my career on the idea that the tools and issues of quantum information theory are the proper way to get at this program.

OK, I've got to get some sleep. I have this dream that I'm going to get work done all the way to Japan. But if I don't get some sleep, I'll certainly be kidding myself.

Henry's Reply

Yes, if you have some particular theme to look for beforehand, then you can perhaps improve your chances of finding something of interest. Actually when I first started exploring the Archives my interest was totally different, and I probably didn't see many things that might strike me as important now. My original target was Heisenberg, not Bohr, and my original interest was the influence of Kantianism on German scientists, not realism or interpreting quantum theory. I thought of Bohr as a positivist, but when I started reading more stuff, I came to believe that Bohr had been seriously misrepresented by philosophers in general, and so I ended up going in this direction. Also they're probably in a lot better order today than they were then. At that time Bohr's last secretary, Fru Hellman, was still very much alive and running the show. She had personal knowledge of much of the files, but beyond that there was just a list of file names and dates. I'm sure at that time there were a lot of pages of manuscripts that were more or less misidentified or otherwise inscrutable. It was really an old-world European kind of thing. The last time I was there it seemed they had made a lot of progress, but still had a ways to go. I'd be interested to see how modern they might be nowadays. I imagine I'll go thru Copenhagen prior to Sweden; I'm afraid I have to get home ASAP after the conference is over.

18-03-01 *Hello from Tokyo* (to J. D. Sanders & L. Sanders)

Here's a funny story about Cuero. The last time I was in town, Kiki and I dropped in to the little bookshop/coffeeshop on Main street. I picked up an old copy of Arthur Eddington's *Our Mysterious Universe* for 50 cents. When I bought it, I told the lady—and this is a true story—"You know, this is the first book I ever bought in Cuero!" I had bought comic books in Cuero as kid, but never a real book (even a paperback). All my real books had come from Victoria and the like. But there was another weird coincidence. That night there was an author there having a book signing. It turned out, she works in Morristown (where I live presently) and lives in Murray Hill (where I work presently). A small world, and it keeps getting smaller!

20-03-01 *The Transcript Archive* (to B. W. Schumacher)

That is a really nice site!

Thanks again for coming to Japan. Charlie, Steven, and John are all gone now. Only I'm left. Things are much quieter now, and I am starting to get back to the hard job of writing some things down.

Ben's Preply

This is pretty exciting stuff.

I've been looking into the Archives for the History of Quantum Physics (AHQP) stuff. There is a web site at which one can find out more:

`http://www.amphilsoc.org/guides/ahqp/`

> Included is a list of everyone about whom there is material in the AHQP, including interviews. There are copies of the transcripts in the U.S. at various institutions, but it would of course be much cooler to visit them at the Bohr Institute.

22-03-01 *Nonorthogonal States* (to R. W. Spekkens and J. E. Sipe)

I just pulled up your new paper, `http://arxiv.org/abs/quant-ph/0003092`. It looks like it's going to be interesting even for nonmodal people!

It dawned on me when I saw your title this morning—I'm jetlagged greatly just having got back from Japan—that maybe I never told you about my paper: C. A. Fuchs, "Nonorthogonal Quantum States Maximize Classical Information Capacity," Phys. Rev. Lett. **79**(6), 1162–1165 (1997).

(You can also find it on `quant-ph`.) It shows that there is a certain sense (motivated in an operational way by information transmission problems) in which nonorthogonal states are sometimes more stable against noise than orthogonal ones. Peter Shor, John Smolin, and I even have examples now where it is best to pull the states from a set of linearly dependent ones!

I don't know if these examples have any impact on your proposed ontology, but it might be worth thinking about.

By the way, you misspelled Wootters.

24-03-01 *Annoyed* (to S. K. Stoll)

I'm back from Japan now, and I decided to finally watch that history channel thing this morning at 4:00 AM! You're right, I certainly do wish I had never been on it.

Stollicism 2: *In the last 5 minutes of the program, the photography of the lab was great, they show that first, along with a panning shot of the "Unconditional Quantum Teleportation" paper, with voice over and a clip of you saying something like, "this experiment is so fantastical that it is almost in the realm of science fiction ... " (I kid you not). Then it has a clip of Jeff explaining how technically it is impossible to teleport a material object in the foreseeable future because of the massive bits of information necessary to do so, or some such. Then the narrator says something about how Einstein started all this talk of teleportation and it flips backs to you explaining that his '35 paper was an argument against quantum mechanics.*

More precisely, I said:

> "This is something that is so fantastic ... scientifically ... at this point in time that it almost is in the realm of science fiction."

But that was targeted not at Akira's experiment; it was about that silly ship teleportation stuff. They certainly gave a sense though that I was talking about Jeff's lab. Then the other thing about Einstein really grates. The larger part of my career is devoted to debunking the idea that entanglement is about "spooky action at a distance." It is just about information: what information Alice and Victor can obtain about Bob's site. The only thing that is teleported in quantum teleportation is Victor's *predictions* ... from being about one particle to being about another. But that is not only the larger part of my career, it was the larger part of my interview!! And they just dropped that completely. They played up this "spooky action" stuff, and that is just the opposite of what I had intended.

I live and I learn.

26-03-01 *Home Sweet Home* (to O. Hirota)

I apologize for my delay in sending you word of my safe arrival. Since arriving in New Jersey, most of my time has been spent in trying to wake up, battling a small cold, and becoming reacquainted with my family. I've hardly looked at email at all.

There is no need to thank *me* for *my* involvement in the Tokyo party. I don't deserve that honor. We all owe *you* many thanks for giving us this wonderful opportunity. I had a tremendous time, and was struck once again by the inner strength of the Japanese culture. I also particularly thank you for helping to get me out of trouble my final day there. My daughter became so happy with her "Japanese gifts"; it was an opportunity I would have been ashamed to miss.

To continued progress in quantum information!

26-03-01 *Big Daddy on the Way* (to H. J. Folse)

I arrived back in my office today to find your newest mail to me. Thanks so much for going to that trouble.

In the next email, I'll send you a PostScript file of "The Activating Observer"—the compendium I told you about. Please keep in mind that it is a very tentative version … full of typographical errors, gaps, and other inanities. In particular, the Introduction is still very much under construction. I may well take out some of the nasty things I said about Whitehead for instance.

As of yesterday, I believe I only have about three of your papers to go reading-wise! It's been a very nice experience. In particular, over the weekend, I enjoyed your 1978 paper "Kantian Aspects of Complementarity." In this connection, I have quite a pressing question for you. Do you happen to have the full text of all the letters between Bohr and Pauli on the phrase "detached observer?" (The ones I know of from your paper are dated 15 February, 2 March, and 25 March 1955. But maybe there are more.) If so, have you (or someone) translated those texts into English? When you open my compendium, you'll see why I'm particularly interested in this. Those texts would be an invaluable addition to it.

Thanks again for going to such trouble for me.

26-03-01 *Clifton Proposition* (to N. D. Mermin)

Have you thought about this? [See 02-04-01 note "Present State of Thought" to R. Clifton.] I've thought about combining contributions from Montréal and Växjö as a *small* possibility, but then I was thinking as the target journal our new one on quantum information. But as I say, I was only thinking of this in a small way: most of my thoughts were purely self-serving … namely, using it as a way to extract Schumacher's "Doubting Everett" paper from his head. (Bennett with his Everettista fatigues was really getting on my nerves in Japan last week: there's only so many days I can room with such a person! Ben was my only breath of fresh air.)

David's Reply

> All my life I have conscientiously declined invitations to edit anything and have never regretted it. I'm inclined not to abandon that successful policy at this late stage, but I told Rob Clifton (who incidentally is one of the more solid philosophers of quantum mechanics) that I'd chew it over with you in Växjö this June.
>
> On the other hand a volume that was Montréal+Växjö might be a useful contribution to western civilization. I like the idea of it being in Hist Phil Sci, because it would reach

a bunch of readers who ought to be more interested in this subject than they currently are. (Look at the profound effect you had on Bub.)

I don't think there's any hurry with this.

29-03-01 *French Philosophers* (to J. M. Renes)

Do you remember you once told me about a French philosopher who said something like: neither the subject is real on its own, nor the object is real on its own; only their interface is real. Or some such thing. Can you give me a reference to that?

29-03-01 *There's At Least One More* (to H. J. Folse)

Looking through your book (I picked up a copy from `Powells.com`), I found at least one more letter in that exchange on the "detached observer" that I'm interested in. It's dated 11 March 1955, from Pauli to Bohr.

I sure hope you have copies of these letters in their entirety! (And I keep my fingers crossed that you've translated them.) This is quite exciting to me.

Unfortunately, I'm going to have to slow down on my metaphysical project for the time being. The mundane matters in my life are starting to pile up for the month. Too many papers that desperately need finishing and—more frighteningly for me—I've got to meet with the president of Bell Labs in three weeks. He's asked for a pitch on where we as a company should be going with quantum information. The philosopher meets the executive: that ought to be pretty.

Henry's Reply, "Bohr-Pauli Exchange"

You're quite right that this an interesting exchange between Bohr and Pauli. I suspect that many have ignored them because of the late date.

The letters are in English and typed, but at least on one Pauli inserted several comments in handwriting. Since it's about 15 pages or so, I've photocopied and mailed all four of them to you at your Bell Labs address. The copies are too poor to scan very easily. The Pauli letters are photocopies of the originals; the Bohr letters are photocopies of Bohr's carbon copies.

Hope you enjoy reading them.

W. Pauli, letter to Niels Bohr, dated 15 February 1955, photocopy obtained from the Niels Bohr Institute via Henry Folse.

Dear Bohr,

It is with great pleasure that I received your nice letter and above all, the text of your lecture on "Unity of Knowledge". The general outlook of it is of course the same as mine. Under your great influence it was indeed getting more and more difficult for me to find something on which I have a different opinion than you. To a certain extent I am therefore glad, that eventually I found something: the definition and the use of the expression "detached observer", which appears on page 10 above of your lecture and which reappears on page 13 in connection with biology. According to my own point of view the degree of this "detachment" is gradually lessened in our theoretical explanation of nature and I am expecting further steps in this direction.

1) As you will see in the reprint on my lecture on "probability and physics", which I have sent to you, it seems to me quite appropriate to call the conceptual description of nature in classical physics, which Einstein so emphatically wishes to retain, "the ideal of the detached observer". To put it drastically the observer has according to this ideal to disappear entirely in a discrete manner as hidden spectator, never as actor, nature being left alone in a predetermined course of events, independent of the way in which the phenomena are observed. "Like the moon has a definite position" Einstein said to me last winter, "whether or not we look at the moon, the same must also hold for the atomic objects, as there is no sharp distinction possible between these and macroscopic objects. Observation cannot *create* an element of reality like a position, there must be something contained in the complete description of physical reality which corresponds to the *possibility* of observing a position, already before the observation has been actually made." I hope, that I quoted Einstein correctly; it is always difficult to quote somebody out of memory with whom one does not agree. It is precisely this kind of postulate which I call the ideal of the detached observer.

In quantum mechanics, on the contrary, an observation hic et nunc changes in general the "state" of the observed system in a way not contained in the mathematically formulated *laws*, which only apply to the automatical time dependence of the state of a *closed* system. I think here on the passage to a new phenomenon by observation which is technically taken into account by the so called "reduction of the wave packets." As it is allowed to consider the instruments of observation as a kind of prolongation of the sense organs of the observer, I consider the impredictable change of the state by a single observation—in spite of the objective character of the result of every observation and notwithstanding the statistical laws for the frequencies of repeated observation under equal conditions—to be *an abandonment of the idea of the isolation (detachment) of the observer from the course of physical events outside himself.*

To put it in nontechnical common language one can compare the role of the observer in quantum theory with that of a person, who by its freely chosen experimental arrangements and recordings brings forth a considerable "trouble" in nature, without being able to influence its unpredictable outcome and results which afterwards can be objectively checked by everyone.

Probably you mean by "our position as detached observers" something entirely different than I do, as for me this new relation of the observer to the course of physical events is entirely *identical* with the fact, that our situation as regards objective description in "this field of experience" gave rise to the demand of a renewed revision of the foundation for "the unambiguous use of our elementary concepts", logically expressed by the notion of complementarity.

2) Passing now from physics to other sciences like psychology and particularly biology I am most interested in your approach, which certainly seems to me to go in the right direction. Without entering a discussion of the dependence of such concepts as "[art?]", not only on the state of motion but

also on the psychological attitude of the observer, I am very much looking forward to your article on the organic evolution which you announced in your letter.

In discussions with biologists I met large difficulties when they apply the concept of "natural selection" in a rather wide field, without being able to estimate the probability of the occurrence *in a empirically given time* of just those events, which have been important for the biological evolution. Treating the empirical time scale of the evolution theoretically as infinity they have then an easy game, apparently to avoid the concept of purposiveness. While they pretend to stay in this way completely "scientific" and "rational", they become actually very irrational, particularly because they use the word "chance", not any longer combined with estimations of a mathematically defined probability, in its application to very rare single events more or less synonymous with the old word "miracle". I found for instance *H. J. Müller* very characteristic for this school of biologists (see also his recent article "Life" in *Science*, issue of January 7, 1955, which certainly contains very interesting material), but also our friend Max *Delbrück*. With him this is combined with vehement emotional affects and a permanent thread to run away which I interpret as obvious signs of overcompensated doubts.

You can imagine how much better than "natural selection" sounds for me "natural evolution" which I never heard before from you and which you use now on page 19 of your lecture. I hope that your announced article will tell us more about your use of the latter concept.

Concluding this letter, I add some remarks about your sentence on page 14 concerning the "medical use of psychoanalytical treatment in curing neurosis". I am quite glad about this sentence, as logic is always the weakest spot of all medical therapeuts, who never learned the rigorous logical demands of mathematics.

Historically the word "the unconscious" was used by German philosophers of the last century, particularly by *E. von Hartmann* [also E. G. Carus], developing further older allusions of Leibniz and Kant. The Psycholamarckist *A. Pauly*, on whom we spoke already, quoted von Hartmann in 1905 (Freud was not known to him), when he called processes of biological adaptation, already in plants, an "*unconscious* judgement of the psyche of the organisms". In this way however, only a new name was introduced, which did not explain anything. Freud was the first who made practical applications of the unconscious replacing hereby this word by "subconsciousness", which you also apply. With this change of the word Freud wanted to emphasize that all "contents of the subconsciousness" were earlier in the consciousness and had been suppressed ("verdrängt") afterwards. In this way Freud's subconsciousness was like a bag containing a finite number of objects. The purpose of the psychoanalytical treatment was therefore to make this bag again empty by upheaval of the suppression.

To this restricted concept of subconsciousness among others C. G. Jung is in opposition since about 1913. He reestablished the older word the unconscious of the philosophers emphasizing that every change of consciousness for instance in a medical treatment, backwards also changes the unconscious, which therefore can never be made "empty of contents", only a small part of which has ever been in consciousness. The aim of the medical treatment according to Jung and his school is therefore the establishment of a correct and sound "equilibrium between consciousness and the unconscious", like an equilibrium between two powers. This process in which this equilibrium is reached and reestablished, they also call "the assimilation or interaction of the unconscious to the consciousness".

I only refer here historically a situation without identifying myself with this kind of terminologies, which seem to me rather far from logical clarity. The Jung school is more broad minded than Freud has been, but correspondingly also less clear. Most unsatisfactory seems to me the emotional and vague use of the concept of "Psyche" by Jung, which is not even logically self consistent.

I am very glad about the prospect of a visit in Copenhagen in the autumn of this year, when also your 70th birthday will be celebrated. Francas treatment is not yet finished entirely, but she is much better and there is much hope, that she also will be able to go to Copenhagen this next time.

With all good wishes from both of us to yourself, Margrethe and the whole family,

yours old,

W. Pauli

[PS:] Where your lecture on "Unity of Knowledge" will be printed in case I would like to quote it?

N. Bohr, letter to Wolfgang Pauli, dated 2 March 1955, photocopy obtained from the Niels Bohr Institute via Henry Folse.

Dear Pauli,

On my return from the CERN meeting in Geneva, I am writing to thank you for your letter of February 15th. It was very good of you to write me so carefully about your reaction to my article and, as always, you touch upon a very central point. A phrase like "detached observer" has of course like all words different linguistic and emotional aspects, but using it in connection with the phrase "objective description", taken as theme of the discussion on Unity of Knowledge, it had to me a very definite meaning. In all unambiguous account it is indeed a primary demand that the separation between the observing subject and the objective content of communication is clearly defined and agreed upon. The aim of the article is just to stress that this condition is indispensable in all scientific knowledge, including biology and psychology, while in art as well as in religious belief one allows oneself to neglect or rather tacitly to shift such separation. In this connection, the historical information in your letter about the use of terminology by psychologists was very valuable to me, and I was glad that you on the whole sympathize with my approach. Indeed, contrary to what some of our common friends seem to believe of me, I have always sought scientific inspiration in epistemology rather than mysticism, and how horrifying it may sound, I am at present endeavoring by exactitude as regards logic to leave room for emotions.

It is on this background that it seems to me very important that we fully understand each other in questions of terminology. Of course, one may say that the trend of modern physics is the attention to the observational problem and that just in this respect a way is bridged between physics and other fields of human knowledge and interest. But it appears that what we have really learned in physics is how to eliminate subjective elements in the account of experience, and it is rather this recognition which in turn offers guidance as regards objective description in other fields of science. To my mind, this situation is well described by the phrase 'detached observer', and it seems to me that your reference to our controversy with Einstein is hardly relevant in this connection. Just as Einstein himself has shown how in relativity theory 'the ideal of the detached observer' may be retained by emphasizing that coincidences of events are common to all observers, we have in quantum physics attained the same goal by recognizing that we are always speaking of well defined observations obtained under specified experimental conditions. These conditions can be communicated to everyone who also can convince himself of the factual character of the observations by looking on the permanent marks on the photographic plates. In this respect, it makes no difference that in quantum physics the relationship between the experimental conditions and the observations are of a more general type than in classical physics. I take it for granted that, as regards the fundamental physical problems which fall within the scope of the present quantum mechanical formalism, we have the same view, but I am afraid that we sometimes use a different terminology. Thus, when speaking of the physical interpretation of the formalism, I consider such details of procedure like 'reduction of the wave packets' as integral parts of a consistent scheme conforming with the indivisibility of the phenomenon and the essential irreversibility involved in the very concept of observation. As stressed in the article, it is also in my view very essential that the formalism allows of well defined applications only to closed phenomena, and that in particular the statistical description just in this sense appears as a rational generalization of the strictly deterministic description of classical physics.

I am eager to learn your reaction to these points as I feel that it is essential, not least for the approach to the wider problems on which we are working, to be as precise as possible in terminology, and above all to avoid any vagueness as to the demands of objective description. It was a great joy to learn that we can expect a visit of you and Franca in the autumn and perhaps there is an opportunity of meeting you even earlier, since I am invited to give a talk in Basel at the end of March on the general epistemological problems.

With kindest regards and best wishes to you both from us all,

Yours, in every way, old

W. Pauli, letter to Niels Bohr, dated 11 March 1955, photocopy obtained from the Niels Bohr Institute via Henry Folse.

Dear Bohr,

I find your letter of March 2nd very youthfull, which is just the reason that it is not easy for me to answer. Although we have the same view "as regards the fundamental physical problems which fall within the scope of the present quantum mechanical formalism" and although I agree with some parts of your letter, the situation is now complicated by your use in a publication of a phrase like "detached observer" (without comment!) which I used already in some publications in a very different way. I believe that this should be better avoided to prevent a confusion of the readers[5] and I don't cling at all to particular words myself. I also felt, already before your letter arrived, that my brief characterisation of the observer in quantum theory as "non-detached" is in one important respect misleading. As is well known to both of us, it is essential in quantum mechanics that the apparatus can be described by classical concepts. Therefore the observer is always entirely detached to the *results* of his observations (marks on photographic plates etc.), just as he is in classical physics. I called him, however in quantum physics "non-detached", when he chooses his experimental arrangements.[6]

I shall try to make my point logically clear, by defining my concepts, replacing hereby the disputed phrase by other words. As I was mostly interested in the question, *how much informative reference to the observer an objective description contains*, I am emphasizing that a communication contains in general *informations on the observing subject.*

Without particularly discussing the separation between a subject and the informations about subjects (given by themself or by other persons), which can occur as elements of an "objective description", I introduced a concept "degree of detachment of the observer" in a scientific theory to be judged on the kind and measure of informative reference to the observer, which this description contains. For the objective character of this description it is of course sufficient, that every individual observer can be replaced by every other one which fullfills the same conditions and obeys the same rules. In this sense I call a referency to experimental conditions an "information on the observer" (though an impersonal one), and the establishment of an experimental arrangement fulfilling specified conditions an "action of the observer"—of course not of an individual observer but of "the observer" in general.

In physics I speak of a detached observer in a general conceptual description or explanation only then, *if it does not contain any explicit reference to the actions or the knowledge of the observer.* The ideal, that this should be so, I call now "the ideal (E)" in honor of Einstein. Historically it has its origin in celestial mechanics.

There is an important *agreement* between us that we find Einstein not consequent in this formulation of the "ideal E". Indeed, there is no a priori reason whatsoever to introduce here a difference between the *motion* of the observer on the one hand, and the realization of specified experimental conditions by the observer on the other hand. If Einstein were consequent he had to "forbid" also the word coordinate system in physics (as not being objective). That the situation in quantum mechanics has a deep similarity with the situation in relativity is already shown by the application of mathematical groups of transformation in the physical laws in both cases.

In this way I reached the conclusion to distinguish sharply between the "ideal of an objective description" (meaning science) on the one hand (which

[5] An explaining remark about it in your *new* article would be most welcome!

[6] I still believe today that this more restricted use of my terminology is very good and that it has been unhappily obscured in your article in a non-logical way!

I warmly supported just as you do) and the "ideal of the detached observer" on the other hand (which I rejected as much too narrow).

What really matters for me is not the word "detached", but the more active role of the observer in quantum physics, which is already implied in your [consideration?] of the "indivisibility of the phenomena and the essential irreversibility involved in the very concept of observation". According to quantum physics the observer has indeed a new relation to the physical events around him in comparison with the classical observer, who is merely a spectator: The experimental arrangement freely chosen by the observer lets appear *single* events *not* determined by laws, the ensembles of which are governed by *statistical* laws.[7] It is not relevant to me, if you say the same thing using *different* terminologies (but please use [essentially?] different words than I). They will only confirm my statements again as all these statements on the observer are part of an "objective description".

I confess, that very different from you, I do find sometimes scientific inspiration in mysticism[8] (if you believe that I am in danger, please let me know), but this is counterbalanced by an *immediate* sense for mathematics. The result of both seems to be my kind of physics, whilst I consider epistemology merely as a logical comment to the application of mathematics in physics.[9] Thus when I read a sentence as "how to eliminate subjective elements in the account of experience" my immediate association is "group theory" which then determines my whole reaction to your letter. Although the first step to "objectivity" is sometimes a kind of "separation", this task excites in myself the vivid picture of a superior common order to which all subjects are subjected, mathematically represented by the "laws of transformations" as the key of the "map", of which all subjects are "elements".

I hope that it will be possible to find a terminology which will turn out to be satisfactory for both of us, but it is no hurry with it. I propose to resume this discussion only when your new article will be ready, which I am eagerly awaiting. It will show me your terminologies in more general cases of objective descriptions, of which I am most interested in the application to biology, in connection with your new expression "natural evolution".

From March 16th till about 27th I am away in Germany and Holland and when I come back I hope either to see you or to hear from you (I wrote to Basel to get informations on your lecture there).[10]

Hoping that you will in the future (just as I do myself) enjoy the enrichment coming from the different kind of access to science by different scientists, expressed in different, but not contradicting terminologies, I am sending, also in the name of Franca, all good wishes to yourself, to Margrethe and to the whole family,

[7]In this way we obtain just the logical foundations of an "*objective* description" of the incidents (Ein begriffe) which the quantum mechanical observer makes within his surroundings with his experimental arrangements. Attention: there is *no* logical contradiction between a word like "trouble" and a possibility of its objective observation and description.

[8]By the way: the "Unity" of everything has always been one of the most prominent ideas of all mystics.

[9]We are here *both* in our letter in a realm of information on the writing subject, which do *not* belong to the "objective content of the communications".

[10]Meanwhile I heard from P. Huber in Basel, [Fierz is in the United States], that your lecture there is on March 30. On this date I am very glad, because I shall be back from my trip by then. Paa Gensje!

as yours complementary old

W. Pauli

N. Bohr, letter to Wolfgang Pauli, dated 25 March 1955, photocopy obtained from the Niels Bohr Institute via Henry Folse.

Dear Pauli,

Thanks for your letter of which I was glad to see that even if I am old you do not feel that I am yet so petrified that we cannot have such animated and fruitful discussions as in our younger days. You are certainly right that, as regards many personal utterances, in my letters like in yours, we are not detached onlookers, although of course we have so much in common that it is a pure discussional accident which words, like mysticism or logical systematism, the one or other of us uses for mutual educational purposes. I also read with great pleasure your beautiful Columbia radiolecture which I had not seen before. Of course, I appreciate the background for your use of the phrase "detached observer" on that occasion, but in my article I was using the phrase in a more generalized (or, if you prefer, more limited) sense suited to point to the characteristics of our position in science and art.

To characterize scientific pursuit I did not know any better word than detachment, especially in connection with psychological studies. As regards quantum mechanics and biology, I wanted to stress the difficulties which even in these fields have had to be overcome to reach the detachment required for objective description or rather for the recognition that in such field we meet with no special observational problem beyond the situations of practical life to cope with which the word "observer" has been originally introduced. To my mind, the lesson was merely that continued exploration of the regularities of nature only gradually should teach us of the necessary caution in looking for unambiguously communicable experience. As you, I am of course prepared to change terminology when it is clear that this will promote common understanding, but before any of us decides on such steps, I wish to call your attention to the pure scientific aims I have perhaps not sufficiently clearly presented in my article.

To make myself more clear, I may for a moment remind of the days of socalled "classical" physics and "critical" philosophy, when in the description of the course of events the role of the tools of observation was disregarded and spacetime coordination and causality were considered a priori categories. You are certainly right that Einstein is not consequent when speaking of the ideal of detached observer and neglecting his own wisdom of relativity, which Eddington poetically described by the picture of how long man traced a footprint in the sand until he recognized that it was his own. Seriously, I mean that you are yourself as inconsequent in stressing the difference in such respect between classical and quantum mechanics. It is true that, before the epistemological aspects of the observational problem were so widely cleared up, a certain confusion was prevalent, but after the thorough lesson which we have received, the whole situation including that of classical mechanics appears in a new light. Though in a vast field of experience one could neglect the interaction between what was regarded as separate objects of investigation and tools of observation, one often overlooked our reach of interfering with the course of events through our freedom of choosing the experimental arrangement. Indeed, in those days, relying upon the deterministic and reversible character of the mechanical description, one might rather have thought that such influencing within a large scope was possible in unlimited detail.

On the basis of the recognition of the limited divisibility of elementary phenomena we have, however, obtained a more generalized description embracing new fundamental regularities of nature, the orderly comprehension of which in principle implies statistical account even as regards reversibility, and which for the exhaustion of knowledge demands mutually exclusive experimental arrangements. The point which I especially wanted to stress in the article is that, just by avoiding any such reference to a subjective interference which would call for misleading comparison with classical approach, we have within a large scope fulfilled all requirements of an objective description of experience obtainable under specified experimental conditions. The freedom of the choice of the experimental arrangement is indeed common to classical and quantum physics and, considering all aspects of the situation, we may say that in both cases a sharp separation between the "observer" and the "phenomena" is retained. The difference is only that in quantum phenomena we have for their definition to include the description of the whole experimental arrangement and that we have less possibility of influencing the course of events.

Still, if the study of natural phenomena were exhausted by simple experience, one might not take questions of terminology too serious, at any rate within the scope in which order is already obtained. I want, however, to challenge you whether you really mean that, in the description of proper biological phenomena, we have to do with an even greater interference with events on the part of the observer than that you want to stress in quantum mechanics. To my mind, the situation is entirely opposite, since the characteristics of our position in biological studies is just the impossibility without excluding the display of life to arrange the experimental conditions required for well defined mechanistic description. It is of course true that physiological research just consists in studying the reactions of the organisms to experimental conditions open to our choice, but it appears to me to be practical as well as rational to include such reactions under varied specified conditions in an exhaustive account of organic life. A further point which in this connection is on my mind is to stress that, in the description of the characteristic properties of the organism, reversal of events is logically excluded, and just this circumstance is of course of fundamental importance for speaking of "natural evolution".

I do not know if I in any such respect was able to make the essential points sufficiently clear in my article, but I am glad that, quite apart from our present dispute, you were not unsympathetic with my striving for a unified attitude to the scientific description of that nature to which we belong and in the exploration of which we step by step have been reminded of fundamental general aspects of our position as observers, which only in limited fields may be disregarded. I shall here not go further in repeating things which are not new to any of us and leave the battle about the word "detached" to our meeting in Basel in preparation of which I only wanted to remind of our resources for defence as well as attack, irrespective of the word "old".

With kindest greetings from home to home,
and på gensyn,
Yours ever

02-04-01 *Present State of Thought* (to R. Clifton)

Good to finally meet you. (Though I think I've had some email with one of the students in your seminar.) Sorry to reply so late to your note, but I wanted to hear Mermin's thoughts first. I'll just paste in the exchange we had below: The conjunction of the two notes captures my present state of thought pretty well. Mermin, I see, does have a good point. And since I do already have promises for three papers (beside one that I could write), it might be worthwhile running in this direction. We'll let you know something at the end of June, maybe just at the start of your new tenure.

Rob's Preply

> My name is Rob Clifton and, as of July 1st, I will be the new chief editor of the journal *Studies in History and Philosophy of Modern Physics*. Jeremy Butterfield, my predecessor, has told me that you might be interested in guest editing a special issue of the journal devoted to the conceptual implications of quantum information theory, computation theory or both. To my mind, this is an excellent idea. Are you still interested? I've also mentioned the idea to David Mermin, with the thought that you and he could perhaps guest edit the issue together. Might that work?

07-04-01 *Operational Approaches* (to R. W. Spekkens)

Spekkensism 1: *I've been trying to become better acquainted with quantum information theory. For this and other reasons, I became interested in determining how the axioms of quantum mechanics appear in an* entirely *operational language. I noticed that most attempts at axiomatization (for instance those found in the standard textbooks) commit themselves to some degree of realism, assigning dynamical variables to particles, etc. Only Peres' book seems to be entirely operational in its approach. Are there other places where one can find a strictly operational axiomatization of quantum mechanics?*

You can also look at the books by Karl Kraus and Günther Ludwig. But I don't think their efforts are very convincing (though complex they certainly are). Still another source might be the book by Paul Busch and coauthors; I think it's called *Operational Quantum Mechanics*.

Spekkensism 2: *The impression I now have is that the task of deriving the axioms of quantum mechanics from a few physical principles is a task that one can hope to carry out entirely within an operational approach to the theory, the physical principles being operational principles. So it seems to me that this project can proceed pretty much independently of whether one can find a satisfactory realist interpretation. Is this in line with your thinking?*

Somewhat. You can find much more about my foundational thoughts (though in a somewhat nonorganized form) at my website: `http://www.its.caltech.edu/~cfuchs/lwl.htm`.

Spekkensism 3: *Anyhow, it's fascinating stuff. Is there any chance you'd be willing to come to Toronto to give a talk on this or other research?*

I'm pretty much tied up until the Fall, but then I should have plenty of time to travel again. So I'd love to come to Toronto possibly in that time frame. Let's keep in touch on this.

10-04-01 *Rudolph/Sanders/Teleportation* (to H. J. Kimble & H. Mabuchi)

If you look at `quant-ph` today, you'll find a new little production by Steven and me—`quant-ph/0104036`—that we think pretty much clears up the trouble brought about by Rudolph and Sanders. More than that, we think it clears up quite a few other things as well: namely, how laser light can be used most generally as a source for quantum information experiments. The point is a simple one and a basic one: There is a useful difference between thinking about the quantum state on the inside of the laser cavity and the quantum state on the outside. So, in a way, we're hoping the paper also gets attention outside of the circle of teleportation defenders—it's almost the kind of thing that ought to be in the classroom (if we say so ourselves).

In the end, Rudolph and Sanders dissolved most easily: We were still quite confused the last time we talked to you (though we didn't feel it then). Laser light can be used to generate continuous-variable entanglement after all (and you certainly did it in the Furusawa et al. experiment), it's just in the form of *distillable* entanglement. It's much better than "entanglement of assistance" in the sense that you don't even have to recover the laser cavity to recover the entanglement. And even better than that, you don't even have to distill it to do continuous-variable quantum teleportation! So everything appears to be safe with those aspects of the experiment.

I had previously mentioned to you the possibility of writing a comment to PRL, following an earlier suggestion by Hideo concerning the same but for *Physics Today*. In light of the almost trivial solution in the end, that possibility is starting to fade from my mind. But maybe I'm still open to entertaining some thoughts—I'm not ready to shut the door completely yet. Tell me what you think of our new paper, and I might revise my disposition accordingly. We'll see, but right now, like I say, I'm starting to get disinclined to the idea. (I'm not sure what Steven's thoughts are.)

Anyway, that's it. Wishing you both the best in sunny Southern Cal,

15-04-01 P_E (to A. Peres)

Asherism 4: *Please give me a reference for the formula for* P_E *in terms of* $\mathrm{tr}(\rho_1 - \rho_2)$.

You meant in terms of $\mathrm{tr}|\rho_1 - \rho_2|$, of course. The reference is:

- C. A. Fuchs, "Information Gain vs. State Disturbance in Quantum Theory," *Fortschritte der Physik* **46**(4,5), 535–565 (1998). [Reprinted in *Quantum Computation: Where Do We Want to Go Tomorrow?*, edited by S. L. Braunstein (Wiley–VCH Verlag, Weinheim, 1999), pages 229–259.]

The paper is listed on quant-ph as `9611010`. I had originally submitted it for the proceedings of PhysComp96 in *Physica D*. After waiting a ridiculously long time with no sign of movement from the editors, I finally withdrew it and submitted it to the special issue of *Fortschritte*.

Kiki, Emma and I are in Texas for the Easter holidays. I believe I had forgotten the meaning of the words humid, muggy, and sultry!! They've come back to me now with a force that won't be forgotten!

18-04-01 *Op-Ed* (to A. Peres)

I'll paste the entry from my dictionary below on the word op-ed. (It's a common term in America.)

I'm glad that all is well with your family. Kiki, Emma, and I are just back from a week in Texas. I finally submitted the old quantum de Finetti paper to `quant-ph`—it only took me two years! It will appear tomorrow morning. You may have an interest in it; it is one of my better pieces of work (conceptual *and* technical). Petra has already expressed an interest in it. You might get her to give you a report on it. van Enk and I also gave a technical application of the result in `quant-ph/0104036`, "The Quantum State of a Laser Field." (It was nice to see that it could be used in the real world of quantum information bickers!) That may interest you as well.

19-04-01 *Warsaw Wait* (to R. Jozsa)

Jozsa-ism 1: *Anyhow it'll be great to catch up in Warsaw. Have you seen the amazing papers of Koashi/Imoto recently on* `quant-ph`*? Certainly among the best papers for some years!!...*

Yes, I have ... and I agree with you completely. (I wrote Koashi telling him the same.)

I'll come to Warsaw if I can. The main issue is funding. Despite the pre-history of big bucks at Bell Labs, Lucent has fallen on hard times—you warned me!—and there are no travel funds for this year. I've been put on an "expenses-paid invitation only" alert. So I hope I can come. I'll talk about my stuff with Sasaki if I do. (Now I've just got to finished the damned paper for him! I'm a week late.)

Charlie's talk on "time travel" was less interesting than you might think. I took grave issue with it, and didn't like it. (But I bet that makes you want to hear about it even more now.)

Have fun in Japan. I'm glad you're finally getting to see the cherry blossoms.

19-04-01 *CVs and Samizdats* (to A. Peres)

Asherism 5: *Meanwhile it seems to me that I found a method for secure quantum bit commitment. It is so simple that I can't see what can go wrong.*

That is always dangerous. Have you tried very hard to apply the standard Mayers-Lo-Chau attack on it? Steven van Enk and I were able to break the "definitive" QBC protocol of Horace Yuen within about 5 minutes of discussion in just that way.

Asherism 6: *Aviva and I plan to be at ITP UCSB from Aug 13 till Sept 29. Shall we have the pleasure of seeing you?*

No, I will not be there. They didn't accept my application because I listed a time window of less than four weeks availability.

My mother-in-law leaves today to go back to Germany. She has been at our house since April 4 visiting. Also though, while we were away in Texas, she completed painting the walls downstairs and up the stairwell. I'm very thankful for all that she's done, but having extra duties of conversation have been time consuming for me. Now that she's gone, I intend to work like gangbusters to get at least one more paper on the web before April is out (a paper by Sasaki and me). Also I intend to post my big quantum samizdat on May 10; Mermin is writing a foreword for it presently. Getting it together is an exhausting and painstaking affair, making sure that there are no places where I put my foot in my mouth (where I don't want to, that is). It is 300+ pages at this stage. I will send a copy to you and a few other friends pretty soon asking for permission to quote you in a small number of places. I think no one need worry though: I have worked very hard to make it safe and tasteful.

19-04-01 *CVs and Samizdats, 2* (to A. Peres)

Asherism 7: *I have a paper by Chau and Lo on my desk, another on the table near it, and also one by Brassard et al. I have some difficulty understanding them but eventually I'll find out.*

Maybe the best place to look for an easy understanding of this idea is Jeff Bub's paper. I'll put the abstract below. He really tried to be very didactic in that paper.

I'll tell you more about the samizdat in a couple of days.

> `quant-ph/0007090`
> The quantum bit commitment theorem
> Authors: Jeffrey Bub
> Comments: LaTeX, 25 pages. Forthcoming in *Foundations of Physics*, May 2001
>
> Unconditionally secure two-party bit commitment based solely on the principles of quantum mechanics (without exploiting special relativistic signalling constraints, or principles of general relativity or thermodynamics) has been shown to be impossible, but the claim is repeatedly challenged. The quantum bit commitment theorem is reviewed here and the central conceptual point, that an 'Einstein-Podolsky-Rosen' attack or cheating strategy can always be applied, is clarified. The question of whether following such a cheating strategy can ever be disadvantageous to the cheater is considered and answered in the negative. There is, indeed, no loophole in the theorem.

19-04-01 *Quantum de Finetti* (to D. Petz and Other Friends)

Dear friends who I recall having shown some interest in quantum de Finetti issues:

My coauthors and I have finally gotten off our lazy duffs and written up our work of two years ago on a quantum analog of de Finetti's theorem on exchangeable probability assignments. The paper appeared on the Los Alamos Archive today:

`http://xxx.lanl.gov/abs/quant-ph/0104088`.

Apologies to all for the long delay,

> Title: Unknown Quantum States: The Quantum de Finetti Representation
> Authors: Carlton M. Caves, Christopher A. Fuchs, Rüdiger Schack
> Comments: 30 pages, 2 figures
>
> Abstract:
> We present an elementary proof of the quantum de Finetti representation theorem, a

quantum analogue of de Finetti's classical theorem on exchangeable probability assignments. This contrasts with the original proof of Hudson and Moody [Z. Wahrschein. verw. Geb. 33, 343 (1976)], which relies on advanced mathematics and does not share the same potential for generalization. The classical de Finetti theorem provides an operational definition of the concept of an unknown probability in Bayesian probability theory, where probabilities are taken to be degrees of belief instead of objective states of nature. The quantum de Finetti theorem, in a closely analogous fashion, deals with exchangeable density-operator assignments and provides an operational definition of the concept of an "unknown quantum state" in quantum-state tomography. This result is especially important for information-based interpretations of quantum mechanics, where quantum states, like probabilities, are taken to be states of knowledge rather than states of nature. We further demonstrate that the theorem fails for real Hilbert spaces and discuss the significance of this point.

22-04-01 *An Apple and a Commitment* (to A. Peres)

I printed out your paper and quickly skimmed it while I was eating my apple for lunch. Forget about the cryptic details of cryptology, your paper is in fundamental contradiction to the HJW result. I'm sorry, but I think that squashes your protocol. Read below, and then look up the paper, and I think you'll understand.

I am really sorry about this.

Back to my other project, the samizdat. I'll write you more details about that in a few days. And thanks for getting me an invitation to Israel Dec 17–21 (or at least I suspect you were behind it).

Review of:
Lane P. Hughston, Richard Jozsa, and William K. Wootters,
"A Complete Classification of Quantum Ensembles Having a Given Density Matrix,"
Physics Letters A, Vol. 183, pp. 14–18, 1993.

Abner Shimony likes to say that entanglement gives rise to "passion at a distance." He does this because when Alice performs a measurement on A of an entangled system AB, *something* changes for B, BUT that change cannot be used for the purpose of communication with a Bob at B. If you ask me, this is language that is just asking for trouble; it is language that is poised to confuse a generation of new physicists. Something indeed does change for B, what Alice can *say* of it. But it is nothing more than that; to think that it is truly a physical change with respect to B alone—especially one that is so contrived as to not lead to communicability—is to open up a sink hole. We are dealing here with changes of states of knowledge.

Within this context, it is quite reasonable and quite interesting to ask how many different ways Alice's knowledge can change. Depending upon which measurement Alice wishes to perform on A, there will be any of a number of different state assignments for B that follow from that. What are they, and what are their probabilities? This is the main question addressed in this little paper. It has a very clean answer: a state assignment can be created for B from a measurement on A if and only if that state falls within a pure-state decomposition of the marginal density operator of B. Moreover, the probabilities of Alice's measurement outcomes correspond precisely to the probabilities of the ultimate state assignments.

This result, it turns out, is not of purely academic interest. It has had a wide range of application in several more applied problems in quantum information: it is crucial for the proof that no quantum bit commitment schemes exist, it plays a crucial role in proving the exact expression for the entanglement of formation for two qubits, and it is crucial for defining the notion of the entanglement of assistance. This theorem is one that all quantum information theorists should have incorporated into their tool bag.

Can more be said? Actually, it turns out that this result even has some historical significance. For, unknown to the authors above, the same question was raised and even partially answered by Erwin Schrödinger in a 1936 paper! [E. Schroedinger, "Probability Relations between Separated Systems," Proc. Cam. Phil. Soc. 32, 446–452 (1936).]

24-04-01 *Endo, Exo* (to A. Peres)

Asherism 8: *You are an inexhaustible source of references. The terms "exophysical" and "endophysical" were coined by Primas (I believe). Do you know when and where? Or could you find Primas's email (he is at ETH in Zurich, I know nobody there). I'll need these terms when my current research with Danny will bear fruit. This may take a long time, at least several days.*

You flatter me. Actually I think David Finkelstein first invented the words. The story of that is written down somewhere. I think it is probably in:

- H. Primas, "Endo- and Exo-Theories of Matter," in *Inside Versus Outside: Endo- and Exo-Concepts of Observation and Knowledge in Physics, Philosophy and Cognitive Science*, edited by H. Atmanspacher and G. J. Dalenoort (Springer-Verlag, Berlin, 1994), pp. 163–193.

At times like this, I dearly miss my old paper collection. I had thousands of papers copied, and I could just turn to my file cabinet and find the answer.

My memory is awfully weak on this, but I think there is even a letter of Finkelstein's published somewhere. If it's not in the volume above, try

- O. E. Rössler, *Endophysics: The World as an Interface*, (World Scientific, Singapore, 1998).

Of this reference, I had written a note to myself: "This is a strange little book, full of crazy ideas, but still perhaps some are worth further scrutiny."

As I recall, though Primas uses the same words as Finkelstein, he had opted to do something odd with their meanings in relation to Finkelstein's. (I think he may have even *reversed* their meanings!)

I hope that helps.

26-04-01 *Short Replies* (to A. Peres)

Asherism 9: *Indeed I found in the proceedings of the 1990 Joensuu conference Primas's talk, where he refers to a 1983 paper by the Finkelsteins. I also found the talk of Schroeck, where he uses the acronym POVM.*

I procrastinated during my lunch hour the other day (lately I've been taking no lunches at all), and dug up the Primas article I told you about. He gives a full history of the terms there and their variations of usage: In particular, his is different from Finkelstein's. The references he gives are, first Rössler,

- O. E. Rössler, "Endophysics," in *Real Brains, Artificial Minds*, edited by J. L. Casti and A. Karlqvist (North-Holland, NY, 1987), pp. 25–46.

then Finkelstein,

- D. Finkelstein, "Finite Physics," in *The Universal Turing Machine. A Half-Century Survey*, edited by R. Herken (Kammerer & Unverzagt, Hamburg, 1988), pp. 349–376.
- D. Finkelstein, "The Universal Quantum," in *The World of Contemporary Physics*, edited by R. F. Kitchener (State University of New York Press, Albany, 1988), pp. 75–89.

Primas, in fact, writes: "A pertinent distinction referring to internal vs. external viewpoints has been introduced by Otto Rössler and David Finkelstein under the notions 'endophysics' and 'exophysics', respectively." And he gives the references above.

26-04-01 *Mysticism and Logic* (to N. D. Mermin)

Merminition 2: *You never replied to my comment on it: that you were getting close to Schrödingerian mysticism. I suspect the only difference (if it is a difference) is that you say the observer is in the world while Schrödinger — this is a cartoon version of what he says but is hard to resist in the current context — says that the world is in the observer. Both of you say (with Pauli) that they cannot be separated.*

But there is a big difference: Schrödinger's view was not contingent on quantum mechanics. He said the same things before and after its construction.

... Though I guess I've heard the same accused of Bohr.

26-04-01 *The Anti-Deutsch* (to R. Pike)

Remind me again of the PR guy I'm supposed to talk to before interviewing and such. I keep forgetting his name.

Discover magazine wants me to insult the many-worlds interpretation of quantum mechanics next week, and I'm more than happy to do it. (What that really means is that they'll want to make Deutsch the shining good guy, and me the bad guy. I'm sure it'll turn out that way, but somehow, someway, someone has got to say that this view is nonsense.)

26-04-01 *Your Interview Request* (to T. Folger)

Yes, I should be able to talk to you Monday or Tuesday of next week. (Tuesday is preferred, but even Wednesday is fine.) As Asher suggested, I too would suggest that you read our articles before we talk. I'll send them both to you now to make that more convenient. I would especially encourage you to read the smaller "reply to critics" article [Physics Today **53**(9), pp. 14 and 90 (2000)] (after reading the original) in preparation for the thing you say below:

Folgerism 1: *More specifically, I hope to discuss how most physicists take a very utilitarian attitude towards quantum theory, and tend to avoid considering what the theory might have to tell us about the fundamental nature of reality.*

From your choice of words in this, you hint very much that you've already talked to David Deutsch. He seems to have it in his head that there is only *one* way to extract a scientific point of view of Nature out of quantum theory: namely, his way (a many-worlds view). But I find that view essentially contentless, whether he wants to call it scientific or not.

You will not find me saying that quantum mechanics teaches us nothing about the nature of Nature. Just the opposite: I would say it has taught us a lot, and there is still a load more to learn (just by contemplating quantum mechanics alone). But we will never see the greatest things the theory has to offer if we first shut our eyes to its greatest lesson: That is, that the terms in the theory are not about a *free-standing* reality. Rather they are concerned with our interface with the world. We are part of Nature—an inextricable part when it comes to the constructions of our descriptions of it—and that has to be reckoned with. That is the great lesson of the quantum.

If I had one thing to do over again in the original article with Asher, I would have inserted the words "free-standing" in front of every instance of the word "reality" to make that absolutely clear. I would also have done it in an effort to keep people like Deutsch from taking it out of context.

26-04-01 *Tuesday Afternoon* (to T. Folger)

Tuesday afternoon will be fine.

Rereading the last note I sent to you, I realized that you wouldn't be able to have a clue what the last sentence of it was about:

> I would also have done it in an effort to keep people like Deutsch from taking it out of context.

The "it" in this refers the following exchange, which I recently inserted into a big thing I'm writing up on the quantum foundations. Let me paste that in for you:

> AUTHOR'S NOTE: In my *Physics Today* article "Quantum Theory Needs No 'Interpretation'" with Asher Peres, there is a passage that says the following:
>
>> Contrary to those desires, quantum theory does *not* describe physical reality. What it does is provide an algorithm for computing *probabilities* for the macroscopic events ("detector clicks") that are the consequences of our experimental interventions. ...
>
> This passage (usually taken out of context) has been found distasteful by several readers. At least one of those readers was Alvaro Carvalho, and at least one reader of Carvalho was the iconic many-worlds activist David Deutsch.[11] I know this because Michael Nielsen forwarded to me Carvalho's posting of 12 July 2000 and Deutsch's reply of 16 July 2000 from the electronic bulletin board `Fabric-of-Reality@egroups.com`. Carvalho writes:
>
>> For those who have not read the Letter: "Quantum theory needs no 'interpretation'" by C. Fuchs and Asher Peres (Physics Today -March 2000), here are some short excerpts (with comments...): [...]
>>
>> "Contrary to those desires, quantum theory does not describe reality ..." I wonder what it can possibly describe. Is there anything else beyond reality?
>
> While Deutsch responds:

[11] It probably goes without saying, but perhaps I should have said "many-worlds activist and Star Trek fan." See `http://www.qubit.org/people/david/David.html` for details.

> No, but that's not what they think. They think it describes our observations, but that we are not entitled to regard this as telling us anything about a reality beyond our observations. Why? Just for the Bohring old reason that they don't like the look of the reality that it would describe, if it did describe reality. Why? – I have many speculations, but basically I don't know. I don't understand why.
>
> It's sad enough when cranks churn out this tawdry old excuse for refusing to contemplate the implications of science, but when highly competent physicists – quantum physicists – dust it off and proudly repeat it, it's a crying shame.

In bemusement, I forwarded these quotes to David Mermin, who responded with:

Merminition 3 : *Funny, there was this English Bayesian, Tony Garrett, who said more or less the same thing about anybody who had given up the search for hidden variables. And I suppose there's a sense in which many worlds, insofar as it can be made coherent, is the ultimate hidden variables theory.*

This comment spurred the following note on my part . . .

26-04-01 *The Itch, the Burn, the Fire* (to N. D. Mermin)

Oh, how I itch to put these in the samizdat too . . . But I won't do it! A man is nothing if he can't control his itches. (And besides, enough is enough.) [See 26-04-01 notes "Your Interview Request" and "Tuesday Afternoon" to T. Folger.]

26-04-01 *Memory Lane* (to G. Brassard)

I just took a walk down Memory Lane and I'm wondering how you're doing: I just skimmed all 214 notes I've written you since 8 May 1997! "Why?," you must be asking. I'm putting together compendium of all my q-foundational emails, and I'm leaving no stone unturned. You ought to see this book—it's really turning into something. Mermin is writing a Foreword for it, and I'll go public with it pretty soon. (But I'll be sending you a preliminary draft of it before then.)

I *do* hope you'll come to Växjö. People are really taking this idea seriously that you and I have promoted. I think you'll be quite pleased with what you get to see, hear, think about, and take part in if you come. The quantum is waiting to be explained (and extended)! And I think our ideas really are on the right track.

So, come. I'll bring a little single-malt for us.

27-04-01 *You Say Relate-a, I Say Relata* (to N. D. Mermin)

Did you ever run across anyone else using the word "correlata?" The excerpt of a note below to Howard Barnum shows that we were once worried about that.

In the mean time, I have seen old papers by Henry Folse where he essentially says that Bohr's point of view is "relation without relata" . . . and he really does use the word relata. I've been meaning to tell you about that.

I'll dig up some relevant Folse quotes and send them to you in the next email.

27-04-01 *Folse Quotes with "Relata"* **(to N. D. Mermin)**

From: H. J. Folse, "The Copenhagen Interpretation of Quantum Theory and Whitehead's Philosophy of Organism," Tulane Stud. Phil. **23**, 32–47 (1974)—

> While Whitehead and classical physics are in sympathy with regard to experience as the starting point for natural philosophy, there is a dramatic difference with respect to the manner in which the two define "nature." In the materialistic world-view of classical physics, nature is the *object* that *causes* our experiences; what we experience are observables correlated with the primary and secondary properties of material substances that exist without the aid of experience. For Whitehead, however, "nature is that which we observe in perception through the senses." Nature is not the cause of experience; it is the field of experience itself. On this point Whitehead's philosophy insists: we are not concerned with discovering the concrete object which is the objective cause of experience, the nature of which is known in abstract concepts; we are instead concerned with explicating the origins of our abstractions by reference to the concrete factors nature revealed an experience. Thus Whitehead claims that
>
> > we have nothing to do with the ultimate character of reality. It is quite possible that in the true philosophy of reality there are only individual substances with attributes, or that there are only relations with pairs of relata .... Our theme is Nature ... we confine ourselves to the factors posited in the sense-awareness of nature ....
>
> Against the traditional view of science, the Copenhagen Interpretation finds complete agreement with Whitehead's intention:
>
> > As a final consequence, the natural laws formulated mathematically in quantum theory no longer deal with the elementary particles themselves but with our knowledge of them ... we can no longer view "in themselves" the building blocks of matter which were originally thought of as the last objective reality ... basically we can only make our knowledge of these particles the object of science.
>
> It is important to note that when Heisenberg refers to "knowledge" he is not calling upon a conceptual abstraction but rather the experiences of investigators in their experiments. Since what is involved in this agreement between Whitehead and quantum theory is a redefinition of the concept of "nature" and since physics seeks to "explain" nature, it is not surprising that Bohr should call for "a reconsideration of our attitude towards the problem of physical explanation." Such a reconsideration is precisely the goal of Whitehead's philosophy.

and

> In undertaking a metaphysics which would take the professed empiricism of science seriously and yet offer a conceptual elaboration of nature, Whitehead offers us an ontology of "events" as the real termini of our experiences in sense-awareness. Each event is an "actual entity" which is a concresence of prehensions of all previous events. In a "prehension" the prehending event brings within itself with a certain determinate "subjective form" the prehended event as an objective datum entering into the process that makes up the life of the prehending event. In this process the prehending event

"becomes" while the prehended event achieves "objective immortality" and "perishes." There is no hylomorphic structure to the actual entities of this ontology; there is not "something that endures," material substance, and something which the enduring thing "has," properties, that can change. What is, is events, and events do not endure, they happen. In a prehension an event reaches out to "feel" other events; thus an actual entity "acts." Activity, not endurance, is the basic ontological status of entities in the philosophy of organism.

Since the actual entity has no hylomorphic structure, what is experienced is not properties standing for the object experienced, but rather the actual entity itself. Experience does not reveal nature mediately, but immediately. The task of science is not to explain nature through an appeal to a conceptual representation of it, but rather to explain a conceptual representation through an appeal to experience. In this way the philosophy of organism is a "critique of abstractions" and the fallacy of misplaced concreteness has been avoided.

and

If we endorse the materialistic ontology, then Bohr's position is totally unacceptable, but on the Whiteheadian view his ideas follow quite naturally. The common point, as has been stressed, is that both positions are interested in a reformulation of the doctrine of physical explanation by an appeal to direct experience. However, where Whitehead analyzes experience in general, Bohr, as a physicist, is interested in only a small set of experiences, namely those observations in which a measurement of a microsystem takes place. Whitehead protested against the idea of experience as experience of an impassive object "out there" related at each precise instance in time to a subject that in no way reached out to modify the object experienced. Since at each instance the subject is allegedly related to the object in a perfectly determinate way, there is no becoming *within* an experience; becoming can only be the succession of experiences, one following, instant after instance in a continuum, upon the other. If nothing becomes within the instant, nothing happens; there is no activity in experience. Experience, on this view, is quite literally, a point instant in time in which nothing happens. Against this notion Whitehead's process view holds that the essence of an experience is the *activity* of the prehending or experiencing entity.

This crucial role of activity in experience is the cornerstone for the compatibility between Bohr's Copenhagen position and Whitehead's view. While Whitehead appeals to the logical absurdity of the materialistic doctrine, Bohr appeals to a physically confirmed theoretical assumption, namely, the quantization of action. The introduction of the quantum of action into physical theory requires that in a measurement the system being measured and the system performing the measurement share for finite period of time at least one indivisible quantum of action; in other words, that they are in *interaction*. In speaking of "isolated systems" classical physics used an idealization or abstraction which was tolerable within the limits of accuracy relevant to large objects, but this abstraction is inapplicable and leads to ambiguities if used in microphysics. Thus complementarity gives a critique of abstractions.

The direct fit between Bohr's interpretation of physics and Whitehead's metaphysics can be seen best if we express the measurement interaction in terms of Whitehead's vocabulary. An experimental situation is a prehending in which the measuring system prehends or measures a certain other actual entity or society of such entities. The measuring apparatus itself is a society of actual entities, i.e. a nexus of mutually prehending entities each having a specific subjective form of prehending such that all share in common a defining characteristic that is determined by the function and application of the measuring instrument. The measurement itself is an event, i.e. an actual occasion in which the society forming the measuring system prehends the measured system with a certain definite subjective form determined by the whole of the experimental setup. If the experimental setup is changed, that the society of events constituting the measuring system will prehend the measured system with a different subjective form and the objective immortality achieved by the prehended entity will differ accordingly.

On the classical view the fact that microphysical entities which are all theoretically represented as being in the same state will in one observational setup appear as particles and in another appear as waves seems highly perplexing. On the Whiteheadian view, there is nothing remarkable in this fact, for what is "measured" is not an *isolated* system, but an entity that is the coming together of its relations to everything else, including the entities of the measuring system and the situation in which the two interact. Thus Bohr also emphasizes "the impossibility of separating the behavior of atomic objects from the interaction of these objects with the measuring instruments which serve to specify the conditions under which the phenomena appear."

Bohr often speaks of the above conclusion as the impossibility of separating subject from object, and he held that "but this situation in physics has so forcibly reminded us of the old truth that we're both onlookers and actors in the great drama of existence." Such a conclusion is precisely what Whitehead advocates in his account:

> The fundamental concepts are activity and process .... The notion of self-sufficient isolation is not exemplified in modern physics. There are no essentially self-contained activities within limited regions .... Nature is a theater for the interrelations of activities.

The point intended these passages is not that "subjectivity" in the usual sense has intruded into scientific explanation, but merely that like the notion of an "isolated system" the idea of an object distinctly separate from a subject is an abstraction or idealization which omits the factor of the interaction between systems.

From: H. J. Folse, "What Does Quantum Theory Tell Us About the World?," Soundings **72**, 179–205 (1989)—

> Thus we find a way to relate the *philosophers'* question about realism to the *scientists'* concerns about the systems described by quantum physics. If a neutral observer were to follow the discussion between realists and their opponents when it comes to quantum theory, and then is asked to whom to award the palm, one reasonable reply would be to say, "No decision can be made until we first know what is this 'something more' that realists want me to believe and anti-realists find so unacceptable?" Answering this question is the job of a contemporary philosophy of nature, and it is precisely here that the realist interpretation of quantum theory finds itself most embarrassed.

and

> This classical account of how we know the nature of reality behind the phenomena relies on the presupposition that knowledge requires the "truth" of theoretical statements to reside in a *correspondence* between at least some terms in these statements and the properties of independently existing entities. This correspondence account of

> truth implied that the resulting "spectator theory of knowledge" stipulates the *objective* knowledge must describe reality in terms of the properties actually *possessed* by an independent reality. (To be sure, even in a classical account, observation involves an interaction between observing and observed systems, thus what is recorded in an observation is strictly speaking a *relation* between the interactors, as even the Ancients well understood. But insofar as this interaction involves systems that can be defined as existing in separate mechanical states, such relations entirely supervene on the *possessed* properties of the relata, and thus can be "reduced" to them.) According to this outlook, the "objectivity" essential to *scientific* knowledge is guaranteed by the fact that classical mechanics makes it possible to provide a description of the object which eliminates any reference to the observer as a physical system interacting with the object to produce the "observations" on which that description is based. Thus the "subject" is "detached" from the object by treating the "observer" (*qua* physical system) as mechanically isolated from the "observed" object. In this way the observer is treated as a "ghost spectator" and any physical effect of observation is eliminated from the account in order that the description can be considered as referring to a physical world existing apart from observation.

and

> This was justified on its view because "observation" in the Cartesian framework refers to an event in the cognitive domain, *i.e.*, the human "mind," and thus even though the careers of spatio-temporal substances are the "cause" of this observation, it cannot be described as a *physical* interaction. The Cartesian ideal which pictures what the universe would look like even if no one was there to look at it is the viewpoint of a ghost spectator who pilots without physical effort his corporeal submarine through a space-time sea.
>
> In a quantum-era philosophy of nature this dualist approach to observation must be thrown out. The empirical starting point of science is the description of a phenomenon through a very specialized set of concepts in which that phenomenon is described as an observation of a neutrino or a quasar. Thus the description of observation as interaction which was exactly what had to be *left out* in the classical account now becomes exactly *what it is* that is described in the quantum description of microphysical reality.
>
> For this reason the realistic interpretation of quantum physics requires not only that we discard the spectator account of knowledge, but it also denies the presupposition that "truth" refers to a property of statements and exists in virtue of a reference relationship between terms in these statements and the properties of an independent reality to which these terms correspond. Now we learn that in physics we characterize an independent reality *not* by attributing properties to some substantial entity which is imagined to possess those properties apart from our interaction. Instead we characterize it through the phenomena which occur in our interactions with it. Truth, then, is not a property of statements but a property of the whole theoretical structure which allows us to predict those sorts of phenomena, and such a theoretical structure has that "truth" in virtue of its power to predict successfully precisely those phenomena in which we are said to observe these objects.
>
> The collapse of the hope for a hidden-variables theory which would preserve the separability of the states of mechanically isolated systems, and the dispelling of the myth that quantum physics was conceived in an anti-realist spirit now make it necessary to take seriously a philosophy of nature which represents real microentities as the seats of

objective potentials for interaction. Such a philosophy of nature will no longer characterize as ontologically fundamental those primary properties which characterized the classical body. Material objects are not vast collections of tiny extended bodies, Democritean atoms or Cartesian *rei extensae*. In breaking the presumed link between the primary properties of the classical mechanistic framework and those properties which are conceived to be ontologically fundamental, the quantum revolution point towards a philosophy of nature which "atomizes" not bits of matter, but elementary processes of interaction.

From: H. J. Folse, "Ontological Constraints and Understanding Quantum Phenomena," Dialectica **50**, 121–136 (1996)—

> The discourse of physics speaks about physical systems by attributing properties to them in two distinct ways. Insofar as physics is an empirical science it must be possible to describe physical systems as objects of *observation*. Insofar as the "explanation" of the observable properties offered by physics entails deductions from theory which are confirmed by observation, it must also be possible to attribute properties to physical systems on the basis of theory. Although the resulting distinction between "observational" and "theoretical" properties is of course deeply entrenched in the philosophical literature, the relations presumed to hold between them rest on often tacit ontological presuppositions which the quantum description shows to be idealizations acceptable at the macrolevel but not at the microlevel.

and

> The quantum theoretical description of atomic systems was born in the attempt to devise mechanical models of the chemical "atom" as a complex physical system composed of subsystems of the (then held to be) truly atomic "elementary particles." The hope that mechanistic atomism could provide an ontological basis for understanding a wide variety of phenomena traced to the behavior of the chemical "atom" seemed a rationally attainable goal because of the (then) well corroborated assumption that the classical state of an isolated system obeys strictly deterministic laws. However, the discovery that initiated the quantum revolution was the theoretical parameter of "action" could formally explain the relevant phenomena only by being theoretically represented as "quantized." This discovery in turn implied that in the obsevational interaction there is a kind of *wholeness* which precludes attributing a classical mechanical state to the observed object as an isolated system immediately (or any time) after the interaction. Consequently while the properties in terms of which the classical mechanical state is defined can be predicated as *observable*—i.e. relational—properties of the empirical object, these same properties cannot unambiguously be predicated of the isolated system as *theoretical*—i.e. possessed—properties. Thus there is a crucial difference between the ways in which classical and quantum descriptions of the phenomena allow us to attribute properties to systems in the discourse of physics.

and

> Assuming that there are a plurality of individuals in nature, an ontology must provide a means for individuating them from each other. This need for a principle of individuation entails that ontological discourse requires that at least some "fundamental" properties must be *possessed* absolutely by the entities of which they are predicated.

> To see why this is so, consider that if no properties were possessed, then all properties would be relational. But in this case there would be no way to individuate the relata as distinct entities between which the relation is said to hold. Indeed, the supposed relation could not be external between the relata, but becomes a relation "internal" to the complex whole of the supposed relata. But to say that a relation is internal to a nonreducible whole, is in effect to say that the whole, treated as an individual, possesses a certain property. So we are back to the need for possessed properties.

27-04-01 *Primrose Lane* (to G. Brassard)

Brassardisme 1: *I'm not yet saying no, but the chances of my coming are slim. Alas! Please forgive me and think of me again in the future.*

In other words, you *are* saying no. OK, I understand. But you will be sorely missed.

Brassardisme 2: *By the way, I have about 2.5 times more money to spend than in the "gobs and gobs" era! Any fresh ideas how to deal with this?*

Having gobs and gobs, and 2.5 times that(!), is a good thing. I'll think hard about a postdoc for you. Would you be willing to take someone like me? (I.e., someone with zero knowledge of computer science and cryptology?) Or do you want to stick on a more traditional basis this time?

In the mean time—you knew I would say this!—what say you about "QFILQI-2"? (It may not even be such a bad thing in the eyes of the computer scientists: Larry Schulman recently organized a small meeting like this at Caltech. Watrous gave an excellent talk there.) We could do it bigger, better, a fresh set of people (with old standbys too), if you wish. Or we could keep it small and cozy. The point is, the time is ripe, and people—good people—are starting to take these issues seriously. I could lean hard on everybody for a conference proceedings this time. Think about it.

Your old scheming friend,

30-04-01 *Rudolph/Sanders/Teleportation, 2* (to H. J. Kimble)

I'm glad you're waiting to ask your scientific questions. I'm running ragged trying to get a big symphony finished. Stay tuned to `quant-ph` May 10: I think it's likely to be the biggest submission ever. (Single spaced, 400+ pages, no figures!)

01-05-01 *Samizdat Revealed* (to A. Peres)

I finally reveal the samizdat! I'll do it mostly by tacking on a form letter that I wrote for some of the more sensitive cases of my quoting frenzy. Perhaps if you read that first, what I am about to write will make more sense.

The samizdat is a collection of some of my deepest and most forward-looking thoughts on quantum theory: it's the kind of stuff that cannot appear in a scientific journal because it is not science *yet*. Nevertheless I do not think it is all worthless—that is the main reason for my wanting to make it public. Life is short, and I want to do as much as I can in this lifetime to advance physics. Inspiring others to think about deeper things is part of what I now view as my mandate.

What I would like to ask of you is for you to follow the instructions below for getting a preview of the thing. In your case, actually, I believe I have quoted nothing sensitive: You will find no surprises. But I do very much crave your approval for the 71(!) times that I do quote you. (They are all clearly denoted as Asherisms, followed by a number.) You *by far*, had the greatest influence on this document and my letters to you alone take up about 90 pages! No other correspondent comes close. (There are even two separate chapters devoted to you.) Also I guess what I am searching for is a kind nod of tolerance for the chapter titled "Diary of a Carefully Worded Paper." Beside my point of general emphasis below about reading the Disclaimers, please do read the introduction to the DCWP chapter. I think you will find it pleasing in regard to our mission as teachers.

This document, despite its nonstandard character, is quite a serious work, I believe. And some quite serious people think that of it (Bub, Mermin, Caves, Nielsen, etc.). Worried slightly that you might not approve of my inclusion of the DCWP chapter, I had hoped that David Mermin would first share his Foreword with you—I believe he will laud the chapter there. Unfortunately he is holding on to it until the original deadline I set for him, but he did write me to tell you this:

Merminition 4: *If you want you can tell him I've been working hard on a foreword which there's no way I would have done if I didn't take your project extremely seriously and think the Samizdat well worth making public.*

So, that's about it from me. I hope I don't crash your computer. And I hope I hear some happy words from you tomorrow.

Form Letter

May 10 will be the first anniversary of the Cerro Grande fire entering the township of Los Alamos. The 400+ families that lost their homes that night will all likely commemorate the event in their own way. For myself, I plan to do what I usually do on special occasions: share my sins with the wider physics community. In this case, it will be in the form of a posting (to the Los Alamos archive) of a 400+ page book of my quantum foundational emails. I am in cahoots in this with David Mermin, who is writing a foreword for the thing.

In two or three days, I plan to start requesting proper approvals from my correspondents for the quotes of theirs I would like to use. To make it easier on everyone, I hope to have a name index in place before then (listing not only the quotes but my conversations with others about their thoughts). But in a couple of cases, I wanted to get pre-approvals even before that. Yours is one of them. The main questionable thing in connection to you is that I would like to include ___________. I hope you will say "yes" as it adds much to the theme. [In your case Asher, there is nothing really questionable; the only outstanding feature is its sheer mass.]

In either case I hope you can tell me your thoughts on this as soon as possible. I would really be very grateful. Trying to meet the anniversary date makes it such that I (and Mermin) are working around the clock.

Here's what to do:

1. Go to my website `http://netlib.bell-labs.com/who/cafuchs/index.html` and download the PostScript file titled, Wacky File #1. The file is very large (3.5 megabytes or so), so do not do this over a modem; use Ethernet only. Furthermore, don't bother to print it out; when it is complete I will send you a bound copy. Use only a screen viewer for your reading (unless you want to kill a lot of trees).
2. Read the Introduction page (so you get a deeper feel of what I'm aiming for), then read the Disclaimers and Acknowledgements on the following page. The Disclaimers are *especially* important in connection to your contribution.

3. In the Table of Contents, find your section and skip over to it. There you'll find the material I'm talking about. [In your case Asher that is Chapters 14 and 15 in the present version.]

If you say that I should not use any of the direct quotes, I will delete them before my larger approval request. But as I say, it adds much to the theme. [More importantly Asher, in your case you are the backbone of the book.]

Thanks for everything.

02-05-01 *Commitments and Burdens* (to J. Bub)

I dug up a good tidbit from '96, especially in connection to you. I'll send you a pointer once I get the new (internal) posting out. I think it hints at a new—maybe more interesting—twist to the foundational value of the bit commitment issue. ...

Well maybe I oversold it, but there is certainly a thought there that I had completely forgotten about. The places to look are the second two notes in the chapter on Michael Nielsen. [See chapter on Nielsen in *Coming of Age with Quantum Information*.] What I found interesting was that my feelings were a bit equivocal about the possibility of a no bit commitment theorem at the time. What I really seemed to think important was that quantum mechanics have the possibility of providing a provably secure digital signature. Things were muddled in my head at the time though, because I didn't seem to understand fully that the two protocols might not be equivalent.

Anyway, there it is. The further thing that I find intriguing is that Dan Gottesman slipped me a preprint by himself and Ike Chuang the other day where they *think* they have a provably secure digital signature scheme (that does not rely on bit commitment, of course). (One glitch remains in the proof.) So, putting the two together, it's just food for thought.

Enjoy London! (If you see Rob Spekkens there, tell him to look at the samizdat: all the answers to his teleportation questions are there.)

03-05-01 *Lyme Disease Newsletter* (to J. W. Nicholson)

God, even if I don't have the disease, I've got the symptom: I had *not* noticed that they used "entitled"!

Here's a good one that Mermin caught me at: I used to flaunt when I really wanted to flout. Apparently I'm not the only one: it is labeled as a "usage problem" in the *American Heritage* dictionary.

04-05-01 *Fermat* (to J. Preskill)

Preskillism 1: *If you make some copies, I'll buy one from you. You can even mark it up ...*

"I have found a truly marvelous proof that quantum mechanics is a law of thought. But this margin is too small to contain it ..."

05-05-01 *Author's Reply* (to A. Peres)

Thank you for your "referee's report".

Asherism 10: *Circa line 20200, you write "It is the theory which decides what we can observe". I remember hearing these words from von Weizsäcker in Joensuu in 1987. What is the reference? Who said that to whom?*

In the samizdat I write:

> Here's an idea attributed to Einstein by Heisenberg that I love. It captures an extremely important point (in this fuller version that is not quoted so often):
>
> > It is quite wrong to try founding a theory on observable magnitudes alone. In reality the very opposite happens. It is the theory which decides what we can observe. You must appreciate that observation is a very complicated process. The phenomenon under observation produces certain events in our measuring apparatus. As a result, further processes take place in the apparatus, which eventually and by complicated paths produce sense impressions and help us to fix the effects in our consciousness. Along this whole path—from the phenomenon to its fixation in our consciousness—we must be able to tell how nature functions, must know the natural laws at least in practical terms, before we can claim to have observed anything at all. Only theory, that is, knowledge of natural laws, enables us to deduce the underlying phenomena from our sense impressions. When we claim that we can observe something new, we ought really to be saying that, although we are about to formulate new natural laws that do not agree with the old ones, we nevertheless assume that the existing laws—covering the whole path from the phenomenon to our consciousness—function in such a way that we can rely upon them and hence speak of "observation."

The whole paragraph of thoughts is meant to be a paraphrase of Einstein. He had told this to Heisenberg on a walk, after Heisenberg's talk in Berlin. The time period was sometime strictly between Heisenberg's discovery of matrix mechanics and his discovery of the uncertainty principle. He claims that that conversation was his main motivation for searching for "something like" an uncertainty principle.

05-05-01 *Full Reference* (to A. Peres)

- W. Heisenberg, *Physics and Beyond: Encounters and Conversations*, translated by A. J. Pomerans (Harper & Row, New York, 1971), pp. 63–64.

Also quoted in:

- M. Jammer, "The Experiment in Classical and in Quantum Physics," in *Proceedings of the International Symposium, Foundations of Quantum Mechanics in the Light of New Technology*, edited by S. Kamefuchi, H. Ezawa, Y. Murayama, M. Namiki, S. Nomura, Y. Ohnuki, and T. Yajima (Physical Society of Japan, Tokyo, 1984), pp. 265–276.

This paper contains some absolutely wonderful material about the experimenter's role in varying experimental initial conditions and about how that is an essential piece in the construction of scientific theories.

08-05-01 *Depth* (to N. D. Mermin)

By the way, I find the opening sentence of this paragraph extremely deep sounding! Is that what I've been talking about all this time?!?!

Merminition 5: *The real issue is nothing less than how you and I can each construct a representation of the manifold aspects of our individual experiences (loosely known as a world), and the constraints that my representation imposes on yours, and vice-versa. By focusing explicitly on the strange information-processing capabilities inherent in the quantum mechanical description of physical reality, the new discipline of quantum information offers an opportunity to put on a sound foundation what was only hinted at in the convoluted prose of Bohr, the facile sensationalism of Heisenberg, the aphorisms of Pauli, and the poetic mysticism of Schrödinger. If it hasn't occurred to you that this is the real justification for your quantum information-theoretic pursuits, then you owe it to yourself to pause and peruse these pages.*

08-05-01 *No Irony* (to N. D. Mermin)

Merminition 6:

> [CAF wrote:] By the way, I find the opening sentence of this paragraph extremely deep sounding! Is that what I've been talking about all this time?!?!

I detect irony.

No, that's my current take on how what you're doing will ultimately bring coherence to the Ithaca Interpretation. I actually thought it might irritate you. And perhaps it has.

No irony at all. Go back and read "Fuchsian Genesis" in Comer's chapter. What the heck do you think it's about? I just thought you said it in a particularly masterful way.

10-05-01 *Leibnizian Thoughts* (to N. D. Mermin)

Merminition 7: *I know Fuchsian Genesis and its variations almost by heart at this point, but I didn't think that was what I was saying. I wasn't thinking of the constraints in terms of your information gathering requiring my information loss. I had in mind something more like a static situation. Not very well defined (or I'd be done). But maybe it's the same thing. Will think about it.*

I'm just rambling. Here's a thought from my drive in to work a minute ago.

Given what you say above, maybe you should go back and read about Leibniz's monads again (just like someone else had once suggested to you).

Thinking about that led me back to the phrase "correlata without correlation." And thinking about that lead me to a thought I had never thought before: how ridiculously Cartesian the relative state interpretation is! There is res extansa (maybe I should call it res physica to be more careful), and there is res cogitans. And the only way the two "interact" is by the happenstance—you sold me on the word—of appearing in a Schmidt decomposition of some wave function! Deutsch's multiverse boils down to about the same thing as a modern-day pineal gland.

10-05-01 *The Easy Part* (to N. D. Mermin)

I'll give you a bonus: a scotch, a beer, and comments. Unfortunately for the bulk of the comments, you will have to wait until Monday or Tuesday. I have pledged to my wife to have the computer completely turned off tomorrow for Mother's Day.

A serious problem is that the PostScript you sent me will not print. [...]

In the meantime, let me comment on footnote 5, because that's easy. Yeah, you're right—I think—that the usual textbooks don't emphasize the Born rule in the setting of bipartite systems. However, I myself have always been reluctant to take the "collapse postulate"—i.e., that after a measurement, a system is left in an eigenstate of the observable—simply because it is not true generally. The state of the system after a measurement depends in a detailed way on the precise form of the measurement interaction, and even upon whether the observer kept all the information available to him. (Remember, for me, a quantum state is a state of knowledge; and no one has the right to say that I can't throw away some of my information, etc.) There is one setting, however, where one can make something close to the collapse postulate come alive: and that is in considering measurements on subsystems of a total whole.

Below I'll place the "axioms" for quantum theory that I used in a tutorial on "Basic Quantum Mechanics" for a DIMACS meeting in 1997. Anyway, axiom 5 in particular emphasizes the point above, and comes close to the point you were trying to make. Though notice, in contrast to you, I was silent on what happens to the state on system S_1.

About an overall assessment, you're going to have to wait until I can print out the thing and view it properly.

The DIMACS Meeting Axioms

Quantum Axiom 1

A *quantum system* is any domain of physical inquiry or manipulation.

Maximal states of knowledge about such a system are in a bijective correspondence with operators

$$\Pi = |\psi\rangle\langle\psi| \quad \text{with} \quad \langle\psi|\psi\rangle = 1$$

for $|\psi\rangle$ in some Hilbert space $\mathcal{H}$.

$$\Pi = \text{“the quantum state”}$$

Quantum Axiom 2

The most precise manipulation of a quantum system that can arise without learning anything new of it corresponds to a map of the form

$$\Pi \longrightarrow U\Pi U^\dagger$$

where U is unitary.

Quantum Axiom 3

Each question that can be asked of a system corresponds to a set $\{P_1, \ldots, P_k\}$, $k \le \dim\mathcal{H}$, of operators with

$$\begin{aligned} P_i P_j &= \delta_{ij} P_j \\ \sum_j P_j &= I\ . \end{aligned}$$

The index j labels the outcomes.

When state is $\Pi = |\psi\rangle\langle\psi|$, outcome j can be expected to occur with probability

$$p(j|\Pi) = \mathrm{tr}\Pi P_j = \langle\psi|P_j|\psi\rangle \ .$$

Quantum Axiom 4

Maximal states of knowledge about a composite system $\mathcal{S}_1 \oplus \mathcal{S}_2$—the components with Hilbert spaces $\mathcal{H}_1$ and $\mathcal{H}_2$—are in bijective correspondence with all

$$\Pi = |\psi\rangle\langle\psi| \quad \text{with} \quad \langle\psi|\psi\rangle = 1$$

where

$$|\psi\rangle \in \mathcal{H}_1 \otimes \mathcal{H}_2 \ .$$

When $|\psi\rangle \neq |\alpha\rangle|\beta\rangle$, the state $|\psi\rangle$ is said to be *entangled*.

Quantum Axiom 5

Suppose $\mathcal{S}_1 \oplus \mathcal{S}_2$ consists of two noninteracting systems (e.g. spacelike separated systems) and $|\psi\rangle \in \mathcal{H}_1 \otimes \mathcal{H}_2$ is of the form

$$|\psi\rangle = \sum \sqrt{p_i}|e_i\rangle|\psi_i\rangle \ , \qquad \sum_i p_i = 1$$

for some orthonormal set $|e_i\rangle \in \mathcal{H}_1$, and $|\psi_i\rangle \in \mathcal{H}_1$ with $\langle\psi_i|\psi_i\rangle = 1$. (The $|\psi_i\rangle$ need not necessarily be orthonormal).

Then a measurement of $\{|e_i\rangle\langle e_i|\}$ on $\mathcal{S}_1$ revealing outcome k leaves the observer in a maximal state of knowledge about $\mathcal{S}_2$:

$$\mathrm{state}(\mathcal{S}_2|k) = |\psi_k\rangle\langle\psi_k| \ .$$

10-05-01 *Your Questions on de Finetti and Diffusion* (to R. W. Spekkens)

I still don't have enough time to come out of the water. But let me surface to get a breath of air: I've got NATO pounding on me for a paper, and I've got a meeting with the president of Bell Labs Monday. That combined with getting the big samizdat on `quant-ph` this morning has been killing me. Literally, only 3-4 hours of sleep each night for the past two weeks. (That kind of thing takes its toll on an old man; I'm not young like you and Terry any more.)

Spekkensism 4: *I enjoyed reading your paper on the quantum de Finetti theorem. I'm quite interested in the mathematical result, but I'm not sure I agree with the way you've interpreted it. In particular, your view that quantum states are states of knowledge doesn't make sense to me.*

Let me first see if I properly understand what your view is not. *It seems to me that it is not an operational view. This actually surprises me because I somehow got the impression that you were an operationalist (perhaps because I take Asher Peres to be an operationalist and you wrote that* Physics Today *article together). My understanding of operational approaches to quantum mechanics is that they take quantum states to represent preparation procedures (for instance, the setting on a dial on some apparatus). If an observer has only partial information about which of a set of preparation procedures was implemented, it seems to me that an operationalist should describe this observer's* *state of knowledge by a probability distribution over density operators. I get the feeling from reading your paper that you would agree with my characterization of operationalism as distinct from your view, given that you come down against interpreting the density operator as "the description of the 'true' preparation procedure". Have I got that right?*

You state that "the quantum state is a representation of the observer's knowledge of a system". What I don't quite get is what you mean by 'knowledge of a system'.

But you provide the first example of how the samizdat can serve me. (By samizdat, I mean the paper cited below.) Let me give you pointers for where to look in there. Three places: In the Brassard chapter, read the introduction to the problem set for the Montréal meeting. Also look at Proto-Problem #3. Jeffrey Bub has been big on precisely this question too. So read his chapter. Finally, there is plenty of material on your question in Chapter 23, "Diary of a Carefully Worded Paper."

Spekkensism 5 : *This actually surprises me because I somehow got the impression that you were an operationalist (perhaps because I take Asher Peres to be an operationalist and you wrote that* Physics Today *article together).*

You were perceptive to notice a difference between Asher and me. We had to fight that one out. See Chapter 23.

Spekkensism 6 : *Although I have not yet fully thought through your arguments in the "quantum state of the laser" paper, it isn't clear to me that the quantum de Finetti theorem is applicable to the state of a laser, since the finiteness of any laser's coherence time seems to imply a lack of infinite exchangeability.*

I know I still need to write Terry, but I've just going bonkers timewise. People with bigger hammers have been hitting on me. Phase diffusion has little to do with the issue: in that paper, we *ignored* phase diffusion (for the propagating beam) just as Terry and Barry do in their paper. That of course is an approximation. Our argument is about a proof of principle: namely without phase diffusion (as Terry and Barry), there is after-all entanglement in a Kimble kind of set up (in contrast to Terry and Barry): the *distillable* entanglement is equal to what was believed to be the case before, but then it was mistakenly identified as *pure* entanglement. Terry and Barry's great contribution was in getting us to recognize that. Taking into account phase diffusion will—as you say—invalidate infinite exchangeability. But I imagine (actually, that's too weak, I really should say *know*) that the flavor of our conclusion will remain intact: there will still generally be distillable entanglement (on some time scales), it will just be degrading as time goes on. An interesting, but probably hard calculation, would be to work that out explicitly. There is already a lot known about partial exchangeability classically: see the concluding remarks in our de Finetti paper. Combining that with estimates of coherence times, etc., in the present case is the path that needs to be taken.

I guess I'll CC this to Terry and also Steven van Enk: chances are strong that I'll be (completely) dropping out of the email scene for a couple of weeks again. Have a look at the beast below.

```
quant-ph/0105039 [abs, src, ps, other] :
Title:  Notes on a Paulian Idea:  Foundational, Historical, Anecdotal
   and Forward-Looking Thoughts on the Quantum
Authors:  Christopher A. Fuchs, (with foreword by) N. David Mermin
Comments:  504 pages including introduction, table of contents, and
```

```
   index of names; no figures

This document is the first installment of three in the Cerro Grande
Fire Series.  It is a collection of letters written to various
colleagues, most of whom regularly circuit this archive, including
Howard Barnum, Paul Benioff, Charles Bennett, Herbert Bernstein, Doug
Bilodeau, Gilles Brassard, Jeffrey Bub, Carlton Caves, Gregory Comer,
Robert Griffiths, Adrian Kent, Rolf Landauer, Hideo Mabuchi, David
Mermin, David Meyer, Michael Nielsen, Asher Peres, John Preskill,
Mary Beth Ruskai, Rüdiger Schack, Abner Shimony, William Wootters,
Anton Zeilinger, and many others.  The singular thread sewing all the
letters together is the quantum.  Some of the pieces are my best
efforts to date to give substance to an evanescent thought I see
rising from the field of quantum information---I call it the Paulian
idea.  To the extent I have communicated its misty shadow to my
correspondents and seen a twinkle of enthusiasm, it seemed
worthwhile to expand the jury on this anniversary occasion.  (612kb)
```

10-05-01 *The de Finetti Theorem and the Samizdat* (to A. G. Zajonc & K. Jagannathan)

(Could one of you also forward this note to Bob Romer, I don't have his email address. Could one of you give me his email address?)

I've been meaning to write you for some time to tell you that the last talk I gave at Amherst has finally made it onto paper. You can find it on `quant-ph` now; I'll put the citation below. [See "On Unknown Quantum States: The Quantum de Finetti Representation Theorem," `http://xxx.lanl.gov/abs/quant-ph/0104088`.] We think it's a fundamental and pretty nice little result, and does clear up quite a bit for those who want to take the wave function as a state of knowledge, rather than a state of nature. We tried to make the paper chock full of motivation, so even if you don't read the technical parts I think you'll still get something out of it. (In fact, for that reason, we submitted it to AJP, so maybe Bob has already seen it. I don't know whether he sees all the papers that come through there at an early stage of the game or not.)

Also, I put something else on the web today that you saw an extremely early version of (during my first interview trip, I think). I've been calling it the samizdat. I think you might enjoy browsing parts of it. (Actually Arthur makes a couple of appearances in there.) David Mermin wrote a very nice foreword for it. I have this dream (hope) that it'll somehow have an impact on the community, but it *is* probably too big for that. ["Notes on a Paulian Idea: Foundational, Historical, Anecdotal & Forward-Looking Thoughts on the Quantum (Selected Correspondence)," `http://xxx.lanl.gov/abs/quant-ph/0105039`.]

My wife and I very much want to spend a few days at the Bennetts' house this spring. I'll try to drop by the college when I'm in town and see what you fellows are up to.

10-05-01 *No Tests: I'm Beat!* (to A. Cabello)

Cabello-ism 1: *More LaTeX typos for the next edition: García, Álvaro (if it is a Spanish name). I have sent about 10 e-mails recommending your work. It is great!!!*

Thanks for the word of encouragement! And also thanks for already helping me catch some typos: I didn't realize that I should TEX your name as Adán. I will fix that in the next edition.

Anyway, the main goal here is to try to Copenhagenize people, but with a modern twist. I think accepting Copenhagen-like ideas is the first step in a great journey—not an end to the road—and that's what I'm trying to turn people on to. Thanks for showing that people are really starting to read the thing!

11-05-01 *Tot Dinsdag* (to S. J. van Enk)

van Enkism 1: *Congratulations on your submission that surely will make you even more famous!*

You made a spelling mistake: you misspelled infamous.

Robert Garisto, that assistant editor I know at PRL, wrote me that it is the "Many Letters Interpretation of Quantum Mechanics." (Actually, with hindsight now, I wish I would have written him a letter before/during our submission.)

11-05-01 *No Worry, Just No Time* (to A. S. Holevo)

I am sorry that my silence has alarmed you. I did not recognize that your request for a fax was an urgent matter. Things have just been very hectic for me in trying to get my large samizdat onto `quant-ph` in time for the anniversary of the Los Alamos fire. I have only been sleeping about 3–4 hours per night for the last two weeks, while trying to get it compiled. (It is a very big manuscript, 504 pages, so you should wait until I can give you a bound copy before attempting to read very much of it. However, you might enjoy reading David Mermin's foreword to it from your screen. I have never been so flattered. It is `quant-ph/0105039`.)

On top of that though, NATO has been putting much pressure on to complete my paper for them. (And also withholding $1,000 of my reimbursement unless I get it submitted.) So, I have had to multiplex in that way too.

So, there is nothing to worry about, I have just been very strained.

11-05-01 *Shannon Meets Bohr* (to P. Pearle)

I put a large samizdat about quantum foundation things on `quant-ph` yesterday. (Mermin wrote the foreword to it.) Parts of it, I think, you might enjoy. Other parts, though, are certainly going to irritate you. (So I apologize in advance.) In connection to your own point of view about quantum mechanics, you might have a read of the "Jeffrey Bub Chapter" and branch out from there.

11-05-01 *Sigh of Relief* (to B. W. Schumacher)

Great to hear you're definitely coming. (It seems the only definite dropout will be Brassard; Preskill is still in superposition.) And great to hear your term is coming to an end: Maybe you'll have some time for some leisure reading! My big samizdat appeared on `quant-ph` yesterday (with a foreword by Mermin). You and Mike Westmoreland might enjoy perusing some of it. I'll put the abstract below.

Ben's Reply

> Mike and I did notice your samizdat, though I haven't had time to read it. Sounds like great incindiery fun — which is perhaps appropriate, given the title …
>
> Your fellow bomb-thrower,

12-05-01 *The Observer in the Quantum Experiment* (to B. Rosenblum & F. Kuttner)

Last night I read your recent paper on `quant-ph` with the same title as above. [See `http://arxiv.org/abs/quant-ph/0011086`.] It was enjoyable reading, and I am in substantial agreement with significant parts of it.

I did however get the impression (from some of your choices of words near my citation and at the end), that you would not have guessed that I would say such a thing. Quite the opposite! That is what my paper with Asher Peres was about, albeit it in a somewhat subdued way and despite its provocative title. For, though we did write,

> Contrary to those desires, quantum theory does not describe physical reality. What it does is provide an algorithm for computing probabilities for the macroscopic events ("detector clicks") that are the consequences of our experimental interventions.

the word "interventions" is prominent there. It is there precisely to refer to the paragraph previous to it where we write:

> To begin, let us examine the role of experiment in science. An experiment is an active intervention into the course of nature: We set up this or that experiment to see how nature reacts.

The word "nature" is a stand-in for all the "stuff" of the world. The issue is whether the theory gets at a free-standing reality rather than only our interface with nature. I opt for the latter: i.e., that the theory is indicating to us that there simply is no free-standing reality (at least now that we are on the scene).

I believe we say this more clearly in our follow-on paper C. A. Fuchs and A. Peres, "Quantum Theory – Interpretation, Formulation, Inspiration: Fuchs and Peres Reply," *Physics Today* **53**(9), pp. 14, 90 (2000).

In any case, I say these kinds of things from many, many different angles in my recently posted samizdat. Given your paper, I think you might enjoy perusing it a bit. It emphasizes many of the same points as you. Maybe the first places to look are Chapter 14, a letter to Bob Griffiths, and also the beginning of the Montréal problem set starting on page 85. I'll place the full reference below.

13-05-01 *Early Morning Sneaking* (to N. D. Mermin)

Kiki's still asleep, so I snuck in here for a while. It looks like I can view this version just fine. I presume therefore I can print it out too, but that will have to wait until tomorrow when I get it to a printer.

Merminition 8: *The way you state it would lead most readers to think that it holds only for special states of the composite system.*

Yes, you're probably right about that. But I certainly meant your version of it rather than the misreading of it.

Merminition 9: *I've never seen an argument that it's implied by 3, and am glad to see that you too state 5 as an independent assumption. Does anybody else? Or has anybody showed that it is implied by 3? Or produced a counterexample that satisfies 3 but not 5?*

It certainly cannot be derived from 3 as I have it stated. That only addresses probabilities, not state changes. 5 only addresses state changes, not probabilities. (In this version of Gleason's theorem that I'm writing up, there is a slight connection between the probability rule and the form of quantum state changes, but that's a pretty advanced matter that need not enter this discussion: in particular because it views quantum mechanical measurement as *nothing more* than a state-of-knowledge change.)

Does anybody else take 5 as an independent assumption? Now, that you mention it, I guess I never have seen anyone else state it that way. I do remember Bill Wootters in the audience at that meeting, combing his beard with his fingers, and looking intent as if the talk were actually interesting (remember it was a tutorial on basic quantum mechanics). That's the only place I've ever presented that talk where there was someone who knew quantum mechanics in the audience. But I don't remember ever having this conversation with anyone else but you: so there may well be a similar development out there, but I haven't seen it.

Kiki should be up any minute now: I'd better get going.

14-05-01 *Today's Meeting Canceled – Future of Quantum Information Processing* (to N. D. Mermin)

The easiest way to answer is below: I am so relieved! (Arun had to have his gall bladder taken out. In his own way he's probably relieved too.) BTW: do you know any of the others in the list?

Among other things, I found out last night—middle of the night—that there's been a load of work done on quantum cryptography over optical fiber networks (by Paul Townsend and the like at BT, now owned by Corning, our competitor). If I can swing it all, these are papers I need to digest (just a little at least) before meeting the big cheese.

Thanks for the developing interest in my life: it certainly helped the samizdat out.

Whose Knowledge? (I saw the title of your Växjö talk.) My answer: anyone old enough to have a driver's license and write down a density operator. (Actually, one probably doesn't need a driver's license, but it might be safer that way.)

15-05-01 *Many Letters + One More* (to R. Garisto)

Garistoism 1: *I read a few pages from your intriguing e-book and thought I'd send you a response. Although not tied to it, as you know I have some fondness for the Many-Worlds Interpretation (MWI). Although we will probably never agree about the MWI, I will say a few words in its defense anyway.*

First of all, to be glib, and to make a point, I will refer to your e-book as the "Many Letters Interpretation". It is a beautiful and complex mixture of information, but it is essentially impossible to follow without a table of contents or index. And like all compilations, superpositions if you will, it makes sense when one uses the index to apply culling conditions on it, say, all pages which mention me (I note I am equal to Aristotle ☺).

My point is that the MWI says that the world is a beautiful mosaic which makes no sense until one imposes the human viewpoint of a classical world. Once one applies the culling condition "all parts of the quantum which are consistent with me existing and having had my last thought", the mosaic falls into focus and the world is conceivable to the human mind.

Is this a slight to art, poetry, or free will? I say that it is not. There are certainly exponentially small areas of the quantum (notice how I am avoiding assuming that this quantum info is actually embodied (rather than simply described) by "the wave function"? I should surely get brownie points for that ☺) . . .

You certainly do. And thanks so much for the appellation "Many Letters Interpretation" — I like it! (I have a feeling this won't be the last I hear of it.) If there is a Chris Fuchs in another world who sways more toward MWI, I hope you meet him eventually. Then maybe the two of you could confront me in a way that might just make some headway! (My wife tells me I only listen to myself.)

With many thoughts (to match my many letters),

15-05-01 *Many Letters + One More, 2* (to R. Garisto)

Garistoism 2: *Nah, it would be no fun if you agreed with me on everything.*

In fact, it's necessary for the very notion of reality itself. Here's how I just wrote it for an article that I'm writing (in an attempt to distill the samizdat to a paper-sized statement).

> [S]urely, the existence of [the] world is the primary experimental fact of all, without which there would be no point to physics or any other science; and for which we all receive new evidence every waking minute of our lives. This direct evidence of our senses is vastly more cogent than are any of the deviously indirect experiments that are cited as evidence for the Copenhagen interpretation.
>
> — *E. T. Jaynes, 1986*

> The criticism of the Copenhagen interpretation of the quantum theory rests quite generally on the anxiety that, with this interpretation, the concept of "objective reality" which forms the basis of classical physics might be driven out of physics. . . . [T]his anxiety is groundless . . . At this point we realize the simple fact that natural science is not Nature itself but a part of the relation between Man and Nature, and therefore is dependent on Man.
>
> — *Werner Heisenberg, 1955*

There are great rewards in being a new parent. Not least of all is the opportunity to have a close-up look at a mind in formation. I have been watching my two year old daughter learn things at a fantastic rate, and though there have been untold numbers of lessons for her, there have also been a smidgen for me. For instance, I am just starting to see her come to grips with the idea that there is a world independent of her desires. What strikes me is the contrast between this and the concomitant gain in confidence I see grow in her everyday that there are aspects of existence she actually *can* control.

The two go hand in hand. She pushes on the world, and sometimes it gives in a way that she has learned to predict, and then sometimes it pushes back in a way she has not foreseen (and may never be able to). If she could manipulate the world to the complete desires of her will, I am quite sure, there would be little difference between wake and dream.

But the main point is that she learns from her forays into the world. In my more cynical moments, I find myself thinking, "How can she think that she's learned anything at all? She has no theory of measurement. She leaves measurement completely undefined. How can she have any true stake to knowledge?"

Hideo Mabuchi once told me, "The quantum measurement problem refers to a set of people." And though that is a bit harsh, maybe it also contains a bit of the truth. With the physics community making use of theories that tend to last between 100 and 300 years, we are apt to forget that scientific views of the world are built from the top down, not from the bottom up. The experiment is the basis of all that we know to be firm. But an experiment is an active intervention into the course of nature on the part of the experimenter; it is not contemplation of nature from afar. We set up this or that experiment to see how nature reacts. It is the conjunction of myriads of such interventions and their consequences that we record in our data books.

We tell ourselves that we have learned something new when we can distill from the data a compact description of all that was seen, and, more tellingly, when we can dream up further experiments to corroborate that description. This much can never change or science ceases to be science. It is the minimal requirement of what we shoot for in science. If, however, from such a description we can *further* distill a model of a free-standing "reality" independent of our interventions, then so much the better. I have no bone to pick with reality. It is the most solid thing we can expect from a theory. Classical physics is the ultimate example in this regard. It gives us a compact description, but it gives us more.

However, there is no logical necessity that this worldview always be obtainable. If the world is such that we can never identify a reality independent of our experimental interventions, then we must be prepared for that too.

16-05-01 *Reference* (to P. Busch)

Can you give me the complete reference for your paper, "Resurrection of von Neumann's No-Hidden-Variables Theorem" (including page numbers)?

I've been meaning to write you for some time to tell you that Joe Renes, Kiran Manne, Carlton Caves, and I came across essentially the same proof of a "a Gleason-like theorem for POVMs" as you did. We were getting all set to write it up as a Phys. Rev. Lett., when I leaked some word of it to David Mermin. He remembered your paper and pointed me toward it ... and sure enough! So, we never published it. (And I think it shattered poor Joe's research life.) But now I'm going to review it in a longish expository piece, so I want to get the reference right.

I'll put below the paragraph I'm just working on where the citation makes its first appearance. I hope you're OK with the wording of that. I just wanted to make sure Joe recovers even some small something for his effort.

I hope I'll see you at the Belfast meeting in September.

The structure of the remainder of the paper is as follows. In Section 3 "Why Information?," I reiterate the cleanest argument I know of that the quantum state is solely an expression of information—the information one has about a quantum system. It has no objective reality in and of itself. The argument is then refined by considering the phenomenon of quantum teleportation. In Section 4 "Information About What?," I tackle this common question head on. The answer is, "nothing more than the potential consequences of our experimental interventions into nature." Once freed from the notion that quantum measurement ought to be about revealing traces of some preexisting property (or beable, one finds no particular reason to take the standard account of measurement (in terms of complete sets of orthogonal projection operators) as a basic notion. Indeed quantum information theory, with its emphasis on the utility of generalized measurements or positive operator-valued measures (POVMs), suggests one should take those entities as the basic notion instead. The productivity of this point of view is demonstrated by the beautifully simple (Gleason-like) derivation of the quantum probability rule found recently by Paul Busch and, independently, by Joseph Renes and collaborators. In Section 5 ...

16-05-01 *Principle Theory* (to J. Bub)

Can you give me the full citation of your paper "Quantum Mechanics as a Principle Theory?" (Including starting and ending pages.)

Thanks. I'm citing that paper for the question "Information About What?" in regard to my view that the quantum state is solely subjective information. (I'm trying to distill the essence of the samizdat into about a 40 page paper: I'm about 25 pages toward it now. I'm really hoping it's finished long before Växjö. But I write so damned slowly!)

16-05-01 *Amicable Banter II* (to R. Jozsa)

Jozsa-ism 2: *Thanks for your message — I would not object to that inclusion into your volume of correspondence (but I wonder if our amicable banter would really be of value/interest to a wider readership!?...).*

More seriously, I've found that the thing (in scaled-down preliminary versions) turned out to be a surprisingly effective means for getting my (forming) point-of-view across. To see Bub, for instance, make a 180 degree turn even after writing his two books on quantum logic, was the most shocking thing. Similarly to see the dents I've made in David Mermin, John Preskill, Lucien Hardy, and a few others went a long way toward giving me some courage. Amicable banter is kind of like a sugar coating that helps the medicine go down.

I keep counting on the day that you'll see I'm not a complete fool, only a partial one (but maybe one not completely worth dismissing). It may or may not happen: but you remain my friend and sparring partner as always.

Looking forward to some beers and a little rest in Warsaw!

17-05-01 *Voracious Readers* (to J. Bub)

I found the information on the reference I needed. So, no need to reply on that. But in the process of finding it, I found a new paper of yours that I had never seen.

I'd like to see that! Can you send it to me?

J. Bub, "Indeterminacy and Entanglement: The Challenge of Quantum Mechanics," Brit. J. Phil. Sci. **51**: 597–615 (2000).

Abstract: I explore the nature of the problem generated by the transition from classical to quantum mechanics, and I survey some of the different responses to this problem. I show briefly how recent work on quantum information over the past ten years has led to a shift of focus, in which the puzzling features of quantum mechanics are seen as a resource to be developed rather than a problem to be solved.

17-05-01 *Pre-Irritation Irritation!* (to P. Pearle)

Pearley Quote 1: *I shall now get it out and get irritated! But perhaps not. I was amused by your article with Peres in* Physics Today *about quantum theory needing no interpretation—amused because I have over the years come across this point of view promulgated in one guise or another many times and I always wonder, if that is so obvious, why there is a continual necessity, starting with Bohr (so you are in a great tradition, for polemics against any other point of view).*

No, that is a very good point, and I am trying to tackle that issue head on in the present paper I'm writing. Let me send you the very much incomplete, preliminary draft right now. The first four sections are particularly important for what you say above. And I just want to show you I've thought about that!

So drop the samizdat for the moment! And go to this pre-irritation irritation. I think you'll find I'm not so flaming as you think I might be!

It's attached below as a PostScript file. If you need it in a different format, let me know.

18-05-01 *Finally!* (to P. W. Shor)

Sasha and I just put together the stuff below for Fred Roberts' request. Why don't you make any corrections/additions you deem appropriate and then forward it to Fred. I'm sure we missed some people on the potential invitee list, but maybe this is enough to get started . . . and maybe you can remember some others that ought to be on it.

Sasha and I will both be gone next week. (I'll be in Warsaw.)

Please CC us whatever you send to Fred.

Title:
Capacities and Coding for Quantum Channels

Abstract:
In 1973 the information theorist J. R. Pierce wrote for the 25th anniversary of Claude Shannon's original paper, "I think that I have never met a physicist who understood information theory. I wish that physicists would stop talking about reformulating information theory and give us a general expression for the capacity of a channel with quantum effects taken into account." Today, 28 years later, Pierce might still be saying the same thing! For though there has been an explosion of activity in understanding quantum channel capacities in recent years, Pierce had no feeling for the breadth of the question he asked: associated with a quantum channel, one can speak of its capacity for sending classical information, its one-way capacity for sending truly quantum information, its two-way quantum capacity, its entanglement-assisted classical capacity, its secrecy capacity, and the list of distinctions is still growing. This tutorial and workshop will be devoted to all aspects of

quantum channel capacity and coding, from code-construction techniques to bounds on capacities and error exponents.

Potential Invited Speakers: (NOT FOR PUBLIC VIEW YET)

Rudolf Ahlswede	(Bielefeld)
Alexei Ashikhmin	(Bell Labs)
Howard Barnum	(LANL)
V. P. Belavkin	(Nottingham U.)
Charles H. Bennett	(IBM Research)
Toby Berger	(Cornell U.)
Gilles Brassard	(U. Montreal)
Rob Calderbank	(AT&T Research)
Nicolas Cerf	(Brussels)
Thomas Cover	(Stanford)
Imre Csiszar	(Budapest)

19-05-01 *Golden Ages of the Quantum* (to E. Merzbacher)

I'm just off to an information theory meeting in Warsaw. But I'm so happy—and I wanted to tell you—I also just finished the fine book you gave me about the early years of the Bohr Institute. (Now I can use the flight to work rather than read.) Thanks once more for the nice book collection.

Let me also tell you about something I put on the Los Alamos archive last week. You might be interested it, as it also documents a little bit of the history of quantum mechanics (both of the old golden age and the new golden age). David Mermin wrote a foreword for it. I'll put the abstract below. [See *Notes on a Paulian Idea: Foundational, Historical, Anecdotal and Forward-Looking Thoughts on the Quantum*, `quant-ph/0105039`.]

25-05-01 *Quantum Axiomatics* (to C. H. Bennett)

Bennettism 1: *Have you read the new papers by Aerts et al. on repairing "defective" axioms of quantum mechanics? Are they worth reading?*

That's a very strange question coming from you Charles Bennett. No, I haven't looked at that: I am in Warsaw right now, with very limited email access and essentially no web access. I'll look at it when I'm back in the states next week and get back to you.

You know (or ought to know) that my only trouble with the axioms is that we have to deal with them at all. I.e., that we don't seem to have clear-cut way to pose the theory without invoking them. (As one might say that we do when it comes to special relativity.) My clearest statement yet on that point is made in the paper attached (I am in the middle of writing it, so it's not complete). But read the first two sections and tell me whether it stirs you at all. Or does it still leave you limp?

26-05-01 *The Warsaw Cafe* (to N. D. Mermin)

I'm on the last day of my trip to Poland, writing you from a little place with blue tablecloths and yellow flowers. Mostly I'm writing you again to thank you again: maybe one of these days I'll say enough is enough, but not yet. The week had its ups and downs. The biggest up was seeing an audience of classical information theorists light up to the idea of quantum cryptography. The biggest down was a collection of conversations with [Professor X] about the samizdat. It seems to eat at him that I broke the rules of academia in this way, and that I would put such rubbish on the net for "self-glorification." One night I got so depressed, I found myself opening up your foreword and reading it again. It did me a world of good, and got me through the night. I knew that without you I would not have had the courage to carry out the project in the first place. What I didn't know was that I would need you even after it was completed. Thanks again from the bottom of my heart.

The NATO paper has—of course!—gotten delayed again by this little outing.[12] I know that Gonis views me as one of the most evil men alive. But if it's not too arrogant, I think it might turn out pretty good over all. There is a fine line between trying to shock people into action and going too far, and I know I'm just playing it by ear. The manuscript just reached the 32 page mark. Once I get to the stage of having the "collapse rule argument" completely written down, I'll send the preliminary version your way: you seemed the most interested in that part of it.

My off hours here have been devoted to going through Rosenfeld with the same thoroughness that I gave Folse (and will eventually give Plotnitsky). I copied down a little passage for you. If I'm not mistaken, it's Rosenfeld's way of *trying* to say what you were *trying* to say in one of the sentences in the Foreword:

> And now comes the last great surprise: it turns out that in describing atomic phenomena one particular picture cannot suffice: according to the circumstances we are obliged to make use of several quite different pictures; one can only describe the atomic world, as it were, from one point of view at a time, and the prospects it offers from various angles are so different that they cannot be fused into one single picture in the usual sense.
>
> This situation has given atomic physicists occasion for fascinating reflections upon the very essence of human cognition, which I shall not enter upon here. I just wanted to mention it as a concluding touch in the picture of the atomic physicist that I have attempted to outline. I scarcely venture to hope that I have succeeded in giving an adequate insight into his methods of work, but perhaps I have managed to persuade you that the secret weapons that have secured him such brilliant triumphs are persevering toil and common sense.

Plotnitsky, by the way, wrote me the most wonderful letter comparing his reading of Bohr to Folse's. He also included a load of analysis on Pauli and Wheeler. You should see the size of it: it almost makes my samizdat look like small cakes. Most surprising though: it's one of his best pieces of writing I've seen yet! (I actually understand a thing or two: that used to take an actual face-to-face conversation.)

But now my coffee's gone, and I've got to start contemplating the taxi ride to the airport. I'll be in touch again soon.

26-05-01 *Your Correspondence* (to Y. J. Ng)

Thanks for the warm reception of my samizdat. I'm just flying back from a meeting on (predominantly classical) information theory in Poland. The reception of quantum cryptography was

[12] This refers to C. A. Fuchs, "Quantum Foundations in the Light of Quantum Information," in *Decoherence and its Implications in Quantum Computation and Information Transfer: Proceedings of the NATO Advanced Research Workshop, Mykonos Greece, June 25–30, 2000*, edited by A. Gonis and P. E. A. Turchi (IOS Press, Amsterdam, 2001), pp. 38–82. Also `quant-ph/0106166`.

wonderful: I could really see the enthusiasm for the idea building as the audience started to understand what it is all about.

I hope to write you some comments on your black hole paper (early) this summer. It is an important issue, and I'm glad you've turned your mind to it. Sometimes I wonder (but not nearly so strongly as in the quantum case) if one might pose a similar program for general relativity as I did in the beginning page of the samizdat (i.e., the one immediately following Mermin's foreword, with Preskill's question). That is to say, might one be able to find a natural information theoretic justification for the principle of equivalence, etc. If one could, then one might immediately find a new point of connection between GR and QM ... one that may have been passed over before.

26-05-01 *Sitting in Zurich* (to E. Merzbacher)

Thank you for your encouraging letter on the samizdat. The reactions of course have been varied, but on the whole those who are writing me seem to think they might get something out of it. I truly do want to see all this commotion about quantum mechanics "not making sense" disappear before my daughter goes to college. Life is too short to be confused for too very long.

I'm trying to condense the program of the samizdat into a single paper (of about 40 pages). It is being written for a NATO meeting I attended last summer whose hidden undercurrent was quantum foundations. With some luck I'll be able to get it on the web by the end of next week. I'll put the abstract below (to see if I can whet any more of your interest). (Beside that though, the paper will have a couple of very basic theorems that might interest you in their own right: it's time for me to get a little longer on analysis and a little shorter on poetry again.)

It sounds like you've been going to the New York theater much more than I have! That's a real shame for me, considering I'm only 32 miles away!

> In this paper, I try to cause some good-natured trouble. The issue at stake is when will we ever stop burdening the taxpayer with conferences and workshops devoted—explicitly or implicitly—to the quantum foundations? The suspicion is expressed that no end will be in sight until a means is found to reduce quantum theory to two or three statements of crisp *physical* (rather than abstract, axiomatic) significance. In this regard, no tool appears to be better calibrated for a direct assault than quantum information theory. Far from being a strained application of the latest fad to a deep-seated problem, this method holds promise precisely because a large part (but not all) of the structure of quantum theory has always concerned information. It is just that the physics community has somehow forgotten this.

26-05-01 *The Activating Observer on Hold* (to B. Rosenblum & F. Kuttner)

Thanks for your nice letter. I hope you will be patient with my reply. In fact I am putting a paper on the web probably at the end of the week (or at the end of the following week, latest) that I believe will answer your questions. If it still does not, then we can pick it up from there.

Things have been immensely busy for me lately and I've had to cut my email drastically. I'm writing to you as I'm flying back from Warsaw. (Most of my email is in fact limited to what I can do on a plane now, for the time being at least.)

Thank you for the invitation to speak at your university. I am in California from time to time (to visit Caltech etc.). I'll try to give you a heads-up when the next trip goes into the planning stage.

Bruce and Fred's Preply

Thanks for your email and the friendly comments. You're right, we would not have guessed that you would be in substantial agreement with significant parts of our argument. But in rereading your opinion piece with Peres and the other stuff you referred us to, we can see how we are not—necessarily at least—far apart.

We too might agree that "quantum theory needs no 'interpretation'." After all, the interpretations of quantum theory arise because of the measurement problem, which can be seen as the apparent intrusion of the observer. Our main thesis is that this apparent intrusion arises in the quantum experiment, logically prior to the quantum theory. If so, no mere interpretation of the theory can ever resolve this problem.

I'm puzzled though. Is the position you advocate (a version of) the Copenhagen interpretation? Your opinion piece ends with implying that all that quantum mechanics need be is a useful guide to the phenomena around us. That sounds much like Bohr's "Science is not about nature but only about what we can say about nature," which more or less seems to capture the Copenhagen spirit. In a sense, of course, the Copenhagen interpretation is not really an interpretation. (Peierls objects to the term "interpretation" because, according to him, Copenhagen is the only way to understand quantum mechanics.) Might, however, what you advocate be seen as close to Mermin's extreme rendering of Copenhagen: "Shut up and calculate!"?

You do say that you would be the last to claim that the foundations of quantum theory are not worth further scrutiny. But then the example you give (a search for minimal sets of physical assumptions) seems to advocate a rather narrow range of scrutiny. Reading other things you have written—including your comment on our piece—we'd have thought that you would welcome more far-reaching investigations. Are we wrong?

While we don't think mere interpretation can resolve the measurement problem, we do believe there likely is a real problem—that Nature may be trying to tell us something we can't yet understand. And, moreover, interpretations may have a role in addressing it.

As we see it, the role of interpretation can be two-fold: Interpretations can suggest new physical phenomena to address the measurement problem. For example: Bohm's suggested deeper levels and implicate order; interpreting collapse to be a physical phenomenon motivates the GRW and Penrose speculations; many worlds has suggested non-linear terms connecting worlds; and extending von Neumann, Stapp has a physical theory of consciousness.

Interpretations, on a yet grander scale, may suggest new world-views. The presently dominant Newtonian world-view, still the basis of much of our thinking and attitudes, is, of course, fundamentally flawed. Insignificant for all practical purposes, perhaps, but world-views go beyond practical purposes. This may all be well outside the realm of physics. But physics may be encountering something of great concern beyond physics—as it has in the past.

You say your opinion piece was motivated by a concern that the airing of various interpretations of quantum mechanics "may lead some readers to a distorted view of the validity of standard quantum mechanics." If you mean the readers of articles in *Physics Today*, AJP, and the physics research journals, that is not a concern that would worry us. Most of our colleagues are completely immunized against that problem by their courses in quantum mechanics and by their continued work with the discipline.

We'd have two different concerns. The first is that by ignoring the enigma that Nature presents us with, physics may just miss something truly important—albeit, perhaps, something beyond what is normally regarded as physics. (And we, personally, have the feeling that by concentrating solely on interpretations of the quantum theory, physics may indeed be missing something.)

A second concern is that the secret that physics has a problem is out. There is no way to honestly present the measurement problem to someone not brainwashed by a serious course in quantum mechanics in a way that doesn't leave them feeling that some mysterious spookiness is involved. To the extent that physicists don't develop these ideas among themselves and present them properly to the interested wider public, others less knowledgeable—or, worse, badly motivated—will become even more the major communicators than they now are.

After all this talk about the measurement problem, we feel like noting that when we teach quantum mechanics we spend almost zero time on the enigma. Aside from some, likely missed, offhand comments, nearly all of our own students are probably as brainwashed as most. They concentrate on what will be on the exams (and I can't blame them).

To some good extent we feel that you generally agree with much of what we say here. Reading some of the very interesting stuff you directed us to, it seems you take the issue quite seriously. (Your "daytime" publications also look very interesting.)

Which brings me (BR) to ask if you are likely to be in the California area during the next academic year. If so, would you be able to come to Santa Cruz for a colloquium? (Unfortunately, our limited colloquium budget permits few invitations from the east coast.) We'd love to hear from you.

27-05-01 *Mohrhoff* (to A. Peres)

Asherism 11: *Have a look at* `quant-ph/0105097`*. You'll probably enjoy it.*

I am home finally! And, I have now seen what you were talking about. You were right, it looks like it might be interesting. (I only read the first page quickly.) I remember that Mohrhoff impressed David Mermin in the past, but the last time I saw one of his papers I couldn't get through it. Have you read this one?

Do you think people will one day write such mean things about my samizdat? (I'm starting to get frightened that they might!) I've now, by the way, received 19 responses to the samizdat's posting. Only two of them have been overtly negative. Yesterday, on the other hand, I found a very flattering one from Eugen Merzbacher. Things like that keep my spirits high, and help build the belief that I may have done something worthwhile.

I read your paper with Danny yesterday on the flight. I will formulate a response to it tomorrow. As for the rest of today, I am going to spend some time with my family; they will be waking up soon. I think I will try to find an IHOP to take them out for a pancake breakfast.

28-05-01 *The Morristown Coffee Tank* (to N. D. Mermin)

Thanks for the cheering letter. I'm back in Morristown now, tanking up for the morning. No, I haven't seen the 't Hooft thing.

Merminition 10: *But if it happened to get two readers who appreciated its literary merits, do you think its subsequent appearance in PRL would make me a laughing stock in the quantum-info community? This worries me. Please advise.*

Yes, I can see that that might be a worry.

Here's how I opened my first talk in Warsaw the other day:

> Well I'm going to do something unexpected; I'm going to change the category of my talk from a research talk to an expository talk. I hope the organizers will forgive me; it just seemed I could make the talk more relevant that way. ... You know, I referee a lot of papers. [Someone in the audience yelled, "You're the one?!?"] And for a while, whenever I thought a paper's content was skimpy, I would describe it as a "didactic" paper in my anonymous referee reports. The implication was that the paper was merely instructive, rather than of research value. But that led me to a little trouble, because I sometimes write my colleagues directly to insult their papers. And I found that I was using the word didactic in my emails too! You can guess I was eventually caught! ... Anyway, today's talk will be a didactic one, and I have one goal in mind ...

Let me withhold judgment until I see the revamped version. PRL has been publishing so much crap lately, and turning down some rather good pieces—like Paul Busch's Gleason-like derivation—that they might do well to publish a good didactic one. And also, you might convince me that it's more than that with this new prose.

28-05-01 *Card-Carrying Greens* (to C. H. Bennett)

I'm back in Morristown now. Thanks for the (unusually long) note. I can see that I continue to leave you limp!

Bennettism 2: *Were you a Green? Did you really believe there was no difference between Gore and Bush?*

No, I wasn't a Green. And, I didn't believe that there would be no difference in the *consequence* of having Gore versus Bush in the White House.

But I do believe it of the quantum campaigns. And I do believe the reason there continues to be money in quantum foundations research is because the arguments all center around almost-invisible variations of the same thing.

Bennettism 3: *Nice introduction and motivation of the problem, especially the math vs physics versions of special relativity. However, in your table on Quantum Axioms and Imperatives, the one with the redundant right column, it seems to me you beg the question with "give an information theoretic reason".*

If I'm on the right track, the two columns really will be redundant. So, that's a good sign.

Bennettism 4: *Isn't information theory, no less than linear algebra, a branch of mathematics, rather than a branch of physics?*

But rarely is a branch of mathematics laid down without a more fuzzy kind of motivation working in the background. The fuzziness comes first, the formalization comes next. But the meaning and the value of the final construct—i.e., the final formal system—remains in the fuzziness. What I'm really asking us to do in that paper is to lay open the motivation for why we have the particular structure we do in quantum mechanics. If I had to place a bet, it would be that the answer will be found along information-theoretic or decision-theoretic lines. You undersell those fields in not realizing that they have a significantly firmer grip on their origin than quantum mechanics does. (Remember Rüdiger's nice presentation of the "dutch book" argument for the probability calculus in Montréal last year? As I recall, you appeared, at least mildly, impressed. That is the flavor of things I'm hoping for for quantum mechanics.)

Bennettism 5: *And when you ask for a physical explanation, what do you mean by "physical"? It's like pornography—you can't define it but you know it when you see it.*

I know you meant to be sarcastic with this, but, roughly, yes. Yes, we will know it when we see it: the nagging, nasty feeling that something is missing from our worldview will disappear (at least in this avenue of science). Funding for quantum foundations meetings will—by community choice—dry up. One could argue that one's pet interpretation—like the Everett program, for instance—is already virtually there ... if the rest of the community would just stop being stubborn! But I just don't think the rest of the community will stop being stubborn until the essence of the theory can be taught to a junior high student. (Your Everett interpretation is not there, except in the trivial sense of saying "all possibilities equally exist" ... which one could have just as well have said of classical physics, asserting that every initial condition is equally valid.)

Bennettism 6: *You could say that the special relativity example, despite its patent physicality, is really a geometric axiom asserting that spacetime behaves like a Minkowski space rather than a Euclidean one. So how much worse is it to have a bunch of axioms saying that states behave like rays in a Hilbert space? To me quantum mechanics is a more essentially mathematical and less physical part of physics than special relativity is. In that regard it is more like thermodynamics, which concerns the macroscopic consequences of microscopic reversibility, and would apply in any world, for example a 2 dimensional classical-mechanical world, a discrete cellular automaton world, or a 5-dimensional special-relativistic world, as long as the underlying dynamics was reversible.*

You will find little disagreement with me about part of this: i.e., that quantum theory shares a lot with thermodynamics in its range of applicability. But that is precisely why I would call quantum mechanics more a "law of thought" than a "law of nature." Just as Boole did of probability theory. And just as Jaynes did with (classical) statistical mechanics. (In fact, either of you two—i.e., you or Jaynes—might just as well have written your quote above.)

You might say, and I suspect you will say, the distinction I draw between "nature" and "thought" is only a semantic one. But I don't believe that: I think it is precisely in making that distinction clear (and operational) that we have a chance of closing the quantum foundations debate and moving on.

Physical theory is about two things: what is and what we know (or what we believe). It's the process of putting the two things together that gives a prediction in any practical setting. Quantum theory, interestingly, seems to be a nontrivial jumble of those two things. I think that is a rather deep statement about the world, and one that we have not yet come to grips with.

I hope you'll read the whole paper from beginning to end when I finally post it. You know that I crave your respect. But I know that I have to earn it.

28-05-01 *Letters: the Long and the Short* (to A. Plotnitsky)

Thank you so much for the amazing letter! I haven't read the whole thing yet, but I've read enough to know that definitely going to get something out of it. Very impressive. When I get in to the office tomorrow, the first thing I'm going to do is print it out so I can read it properly.

Let me also alert you to something I posted on quant-ph a couple of weeks ago. The citation is below. [See *Notes on a Paulian Idea: Foundational, Historical, Anecdotal and Forward-Looking Thoughts on the Quantum*, `quant-ph/0105039`.] It's the thing I've been calling the samizdat: I don't know whether I've mentioned it to you. You might enjoy parts of it.

Arkady's Preply

> First of all, I apologize for being out of touch since receiving the latest version of your "Compendium," but a busy end-of-semester schedule and too many pending (and some past-all-deadline) commitments have intervened. I have managed, however, to finish reading the expanded version of the "Compendium" in the meantime, which, a bit slow as it was (in part because I also used the occasion to visit some of the things you cite), actually provided a kind of refuge. I have by now a rather extended set of notes that nearly amounts to a small "compendium" of its own. I have, however, distilled a kind of commentary out of them over the last few days, which I thought I would pass on to you. (At your request, I also append in the end a few typos and other small glitches that I have noticed, although, as I was paying much more attention to the content, I could have easily missed others.)
>
> This commentary started as a much shorter set of remarks on some of Henry Folse's work, which your cite extensively and which especially attracted my attention, since of the works that you mention it deals with Bohr most extensively and since I am already familiar with. (By contrast, I was not familiar with D. J. Bilodeau's work, which you cite extensively as well and which I found, I take it in agreement with you, to be among the better commentaries on most subjects he addresses.) My thought, however, quickly moved to more general concerns, prompted by other things (many of them quite extraordinary) that you cite and by my own thinking about the differences among Bohr's, Pauli's, and Wheeler's views (with some of Heisenberg's ideas, my current special interest, added to the mix), and developed into the argument to follow. I shall, nevertheless, start with some comments on Folse's work, as a convenient entrance to this argument. For the sake of convenience, I shall mostly restrict myself to citing your "Compendium" (hereafter referred to as "Fuchs").
>
> Folse is among the more assiduous readers of Bohr, and his more recent readings seem to me to improve on his 1985 book, *The Philosophy of Niels Bohr*, which I read when working on *Complementarity* and on which I comment there, along with Dugald Murdoch's and Jan Faye's readings of Bohr. I must especially commend Folse on commenting (he is one of the very few who has done so) on the significance of Bohr's new conception of atomicity, specifically in his "Niels Bohr's Concept of Reality," in Pekka Lahti and Peter Mittelstaedt's *Symposium on the Foundations of Modern Physics 1987: The Copenhagen Interpretation 60 Years after the Como Lecture* (Singapore: World Scientific, 1987), which you mentioned in one of your emails and which you cite in your "Compendium" ("Fuchs," #135, p. 27). Folse's interpretation of this conception and, in part correlatively, of Bohr's epistemology as a whole in this article and elsewhere is, however, quite different from the one that I have tried to pursue in my own recent

articles. I have no quarrel with Folse's insistence on Bohr's "realism"; and he has good reasons for this argument, given some arguments against Bohr. The question is what form this "realism" takes and the areas and limits within which such concepts can apply to Bohr's view.

In my view, while there is a place for some realism in Bohr's interpretation of quantum mechanics, I cannot think of any concept of reality that could, in my interpretation of his interpretation, apply at the ultimate (quantum) level of description. Nor, accordingly, can I think of any form of realism attributable to Bohr's view of nature at this level, except of course that he believed that what we call "quantum objects" exist. How could one deny this, given that no concept of reality applies to such "objects"? To what would such concepts be inapplicable, then? And what would be responsible for the effects on the basis of which one would argue for this inapplicability?

Folse does not quite see Bohr's epistemology in terms of classical (knowable) effects, manifest in measuring instruments (or in other macro-phenomena) of nonclassical (unknowable) efficacities, defined by the interaction between quantum objects and measuring instruments, even though he (rightly) stresses the significance of this interaction, specifically for Bohr's concept of phenomenon. The lack of this or (one can think of different ways of handling the situation) a comparable epistemology sometimes prevents him from following Bohr's key concepts (such as "phenomenon" or "atomicity") and arguments to their limit. It also leads him to certain critical arguments against Bohr that are in fact, or in effect, answered by Bohr, for example, those concerning the identity of atomic systems ("Fuchs," #146, p. 31; #149, p. 33) or "properties" ("Fuchs," #149, p. 33).

On the first point, concerning the identity of atomic systems, I would argue as follows. One can have, and, in my view, Bohr does, a perfectly logically and data-wise consistent argument, whereby all individuality, identification (say, of electrons) and so forth are defined in terms of possible effects upon measuring instruments, without appealing to the properties or identity of quantum objects themselves. Bohr, incidentally, never says and, in my view, would not say, as Folse does, in reading him, that "complementary 'wave' and 'particle' phenomena are *complementary phenomenal appearances of the same atomic system*" ("Fuchs," #146, p. 31; Folse's emphasis). Both types of appearances are, of course, possible, but at least two experiments, and hence two different systems, rather than "the same system," would have to be involved in order to obtain two complementary phenomena. I leave aside, for the moment, further qualifications as concerns the possibility, or, as the case may be, impossibility, of a "wave" appearance of any given atomic system (defined, again, in terms of effects or phenomena, by a given initial detection or/as preparation). This may appear a bit too pedantic, but it may be shown that these nuances have major epistemological implications, for example, in the EPR case, implications sometimes missed by Folse.

On the second point concerning "properties," Folse is not wrong in saying that, in interpreting quantum physics, one cannot avoid speaking of "properties" at least at some level. One cannot, however, quite see this point, as Folse does, as indicating a problem in or even incompleteness of Bohr's argument. It is clear that all quantum-mechanical phenomena in Bohr's sense do possess "properties," classical-like properties, at the level of effects and indeed are defined by such properties, without—this is almost the whole point of Bohr's concept of phenomenon—the possibility of attributing any properties to quantum objects themselves or their behavior.

Let me note that David Mermin's argument concerning "correlations without correlata" may be generalized to "relations without relata" and related to Folse's remarks on properties. I might be bringing David's view closer to Bohr's than he himself has in mind, but one can see Bohr's argument in these terms in the following sense. While in classical physics observable phenomena (in the usual sense) can be properly *related* to and *correlated* with the observable properties of actual objects, in quantum mechanics, in Bohr's interpretation, observable phenomena can only be *correlated* with the behavior of quantum objects. It is not possible to establish the correlata of such correlations at the quantum level as properties of quantum objects or of their behavior, whether the quantum objects under observation or the quantum stratum of measuring instruments, through which the latter interact with quantum objects. This impossibility is intimated already in Bohr's original criticism of Heisenberg's "microscope" thought experiment in Heisenberg's original uncertainty relations paper of 1927, although it took the EPR argument and then a decade or so for this point to crystallize. It is this impossibility that eventually led Bohr to his redefinition of the term phenomenon in terms of the effects of the interactions between quantum objects and measuring instruments upon the latter (and thus, as effects, configurable in terms of classical physics properties of measuring instruments), something, again, under-appreciated by Folse.

What I find most problematic, however, is that Folse, in the essay in question and elsewhere, appears to attribute to Bohr the suspension, at least a possible suspension, of locality and to contrast Bohr's and Einstein's positions on this point, with obvious implications for Bohr's interpretation of EPR-type experiments. This argument is, I would argue, difficult to sustain, if possible at all, as opposed to the argument that Bohr and Einstein held sharply contrasting views concerning the independent (local) reality of physical description at the level of quantum objects. It is true, that, in this essay, Folse, following Don Howard's argument (which you cite as well, "Fuchs," #189, p. 41), attempts to assimilate Einstein's position on reality to his position concerning locality. This attempt is, in my view, not altogether successful, on either Howard's or Folse's part, although I do agree that the connection between reality and locality in Einstein's thought should indeed by explored further. I shall not address this subject here, since it is not required for my argument concerning Bohr's interpretation and specifically his view of locality (which derives from the overall argument outlined below). Bohr's interpretation is local and is in part designed to respond to Einstein's arguments concerning locality by offering a local interpretation of quantum mechanics. I do not think that one could even argue that Bohr's view is open as concerns the possible nonlocality of quantum physics. (I entertained such a possibility myself at some point, a few years ago, but a relatively quick "reality check" of Bohr's argument showed that even this weaker argument is difficult to sustain.) From this standpoint, I find Folse's (or Howard's) parallel assimilation of Bohr's wholeness (indivisibility) of phenomena to "nonlocality/nonseparability" problematic. This is a crucial, perhaps uniquely central point, since, in my view, it is Bohr's concept of wholeness of the phenomenon in his sense that enables the locality of his interpretation, rather than allows for even the possibility of nonlocality.

Indeed, if one reads the passage from Folse's essay that you cite, it may appear that by "separability" (of Einstein's concepts of reality) and, conversely, "nonseparability" (of Bohr's concept of reality), Folse refers, respectively, to the possibility of an unambiguous reference to the properties of quantum objects independently of—"separately" from—their interactions with measuring instruments vs. the impossibility thereof. The former is indeed desired by Einstein, while the latter is argued for by Bohr and defines his concept of the wholeness (indivisibility) of phenomenon in his sense, which is to say, his concept of phenomenon, since all phenomena are indivisible in this sense. Of course, by invoking "nonseparability" Folse has this indivisibility in mind as well. It is clear from the essay as a whole, however, that he also means by "nonseparability" more than merely "indivisibility" in this sense, in view of the two assimilations just mentioned, that of Einstein's view toward locality (which is possible, or at least is worth exploring) and Bohr's position toward a form of nonlocality, which is, I would argue, untenable. He means by it primarily (a form of) nonlocality. It is true that, in the passage you cite (and in general) Folse separates "locality" and "separability." First, however, he clearly argues that Bohr, in contrast to Einstein, does not see "locality" (rather than only "separability") as the necessary condition of "physical reality," which is incorrect in any event. Secondly, "separability" is first established by Folse as a form of nonlocality and only then is linked to Bohr's wholeness/indivisibility of phenomena. "Separability" appears to be seen by him as a physical independence of spatially separated and physically disconnected events, on which, I would argue, both Einstein and Bohr equally insist, and which Bohr also argues to be possible in view of his interpretation. Locality and nonlocality are seen in terms of, respectively, the impossibility and the possibility of instantaneous physical connections between spatially separated physical objects. It is clear, however, that nonseparability would make it, at least in principle, possible to use the resulting mutual dependence of spatially separated entities to create nonlocal connection, even if undetectable physically. Hence, it may be seen as a form of nonlocality, which makes it, again, unacceptable to both Einstein and Bohr (in the present reading).

In other words, while applied to the standard version and specifically to Bohr's interpretation of quantum mechanics, and thus making *both* nonlocal, Folse's view is ultimately that of proponents of Bohm's theory, which of course uses a different formalism. You will recall that in some versions of Bohmian mechanics, nonlocality, that is, violation of relativity, is never manifest, but is nevertheless always a strict mathematical consequence of theory. Folse's view is not unique, of course; for example, Henry Stapp argues for the nonlocality of quantum mechanics, which argument is, at least, unpersuasive, as his recent exchange with David Mermin shows as well, and of Bohr's view, which argument is simply untenable. The point is of considerable significance for the recent debates. The nonlocality of complementarity and, especially, of quantum mechanics itself, whether at the level of the data (such as the EPR correlations) or of the formalism would erase arguably the most crucial difference between the standard and Bohmian mechanics.

Folse's reading of Bohr's argument as, at least, tolerant of nonlocality (rather than his argument concerning Bohr's realism) was for me the main problem when I originally read the article (and a couple of his related pieces) a few years back. Perhaps I am becoming over-concerned with locality. A Bohmian I know (a philosopher, not a physicist) once asked me why I give so much importance to locality (leaving aside my argument that Bohr insists on it just as much as Einstein does). What if locality were not true at the ultimate level? This is of course not inconceivable in principle, even though so many things currently in place would have to go wrong (which has, however, happened in physics). I replied by repeating Einstein, when asked a similar question concerning the validity of general relativity, which of course safeguards locality as well: "Then, I would be sorry for the Lord." I guess it is all about the beauty of relativity. In any event, your email and, then, your "Compendium" prompted me to revisit Folse's argumentation and my own, ultimately opposing, argument, which I shall now sketch. It uses my argument in "Techno-Atoms" and in my Mykonos paper as background, but the main points should be clear, especially given the preceding argument. I shall comment on the question of reality first.

Here is my view of Bohr's position, which (perhaps, as I shall explain, taken a notch further) is also my own. Bohr does not and, for the reasons explained above, could not deny the existence—and in this, but only in this sense, "reality"—of quantum objects, nor (in contrast to the positivist or, to be cautious, naively positivist view) the relevance of the question. What he does deny is that any concept of reality, that is, of the properties and behavior of quantum objects, conceived on the model of classical physics is applicable to them, while such a concept is germane to classical physics, and is retained by Bohr at the level of measuring instruments. Indeed, which is equally crucial for Bohr, within certain limits, such concepts are germane in quantum physics, especially insofar as classical physics plays a role in quantum theory: the correspondence principle in its various incarnations; the classical description of measuring instruments and of the effects of their interactions with quantum objects upon them; and so forth. Thus, reality is suspended only as concerning the ultimate objects of description but is retained at the level of their effects upon what can be described in the realist way, such as the macro-world around us and, specifically, the measuring instruments involved in quantum physics. Heisenberg's "new kinematics" of his first paper introducing quantum mechanics already epistemologically reflects this argumentation and, while influenced by Bohr in turn, may well be the ultimate source of Bohr's conception.

This view appears to me to be close to Asher Peres's and your own position both in your article and your replies to letters in *Physics Today*. In truth, however, the best I can say about some of those letters would be to repeat Pauli's remarks on the commentary by the editors of *Nature* prefacing Bohr's article introducing complementarity (a much reworked version of the Como lecture): "*sancta simplicitas*." (As I was perusing your "Compendium," I have read and, in some cases, reread some of Peres's articles and his book on quantum mechanics, many of which I found quite helpful.) Some among the key aspects of Folse's argument concerning Bohr's realism are consistent with this view as well. Thus, he writes: "According to Bohr's concept of reality, real entities are entities that have power to interact, and in interacting, to produce the phenomena that comprise the natural world" ("Niels Bohr's Concept of Reality," "Fuchs," #135, p. 28). This is correct, although, again, it does not sufficiently discriminate, in the way Bohr does, between the classical and quantum levels of description (or, in the quantum case, undescribability), since this statement would apply to both, which may have been Folse's point. The differences, however, are hardly less crucial. In other words, here, too, Folse does not fully explore or take advantage of the finer structure or layering of the architecture of phenomena in Bohr's sense, which leads to a number of problems in his argumentation (such as those mentioned above).

Now, although Bohr does not present his argument in so general a way in his writings and perhaps does not take it that far (for most of his purposes he did not need to), it appears that one can take a step further here, to what may be called "the strong Copenhagen interpretation." Rather than only anything conceived of by analogy with classical physics, more radically, no conceivable concept of reality, or even any concept of "existence," or "object" and "quantum" (the latter originating in classical physics, to begin with) or, in dealing with multiple systems, possibly even "local" or "nonlocal," is applicable to "quantum objects." I would like to add that this impossibility of applying either determination, "local" or "nonlocal," at the quantum level does not mean that anything is nonlocal at the quantum level, and of course allows for the locality of all possible effects. By the same token, this view is different from those versions of hidden variables theories, in which the locality of all observable effects would be maintained as well, but which configure the underlying quantum reality as nonlocal. In accordance with this view quantum objects and behavior, including the ultimate nature of the interactions between them and the classical world (the world amenable to description in terms of classical physics) may be beyond our perceptive and conceptualizing capacities. It is through a refinement of these capacities that we constructed the conceptuality and mathematization of classical physics, even if (this is somewhat more complicated) not mathematics itself.

This last point, coupled to the strong epistemological position just outlined, "the strong Copenhagen interpretation," also suggests a better approach to Bohr's famous and often misunderstood insistence on the inevitability and necessity of using classical concepts in quantum mechanics. Bohr's argument to that effect is at the core of Schrödinger's letter to Bohr, which, as you say, "continues to haunt [you]" ("Fuchs Compendium," #200, pp. 43–44). You are, of course, not alone. This apparently excessive emphasis on the necessity of classical physical concepts appears to have been one of the most haunting aspects of Bohr's arguments for complementarity throughout the history of its reception. I think, however, that, eloquent as his letter is, Schrödinger misunderstands Bohr on this point, as do most other critics of Bohr. I shall spare you a reading of the letter itself, although such a reading would be instructive on several counts. Part of my argument concerning Bohr and quantum mechanics all along has been that the significance of reading in physics is often underestimated, and this concerns as much the works of Bohr's key critics as those of Bohr himself, notoriously demanding and inattentively read, by critics and admirers alike, as his writing is.

Indeed I am not certain whether Schrödinger sufficiently examined Bohr's overall argument, which is, I think, imperative in order to understand Bohr's point in question. In accord with his argumentation as here outlined, Bohr's argument is, more or less, as follows. Measuring instruments and their behavior, and, accordingly, the effects of the interactions between quantum objects and these instruments upon the latter, must be described in the classical manner in both physical and, correlatively, epistemological terms, while quantum objects and their behavior cannot be described at all, by any means, classical or other. This, let me reiterate, is not the same as saying that the behavior of measuring instruments under the impact of their interaction with quantum objects is described classically, while that of quantum objects themselves is described quantum-mechanically. In Bohr's view, quantum mechanics describes nothing, but only predicts the outcome of the interactions in question; and, again, most crucially quantum objects and processes, including those involved in the interaction between a quantum object under investigation and the measuring instruments involved in that investigation, are not describable by any means. Otherwise, among other things, it may not be possible to maintain locality, for example, in the case of the EPR correlations. The presence of this circumstance in quantum physics, which Bohr sees as uniquely significant to the difference between classical and quantum theory, is crucial to the rigorous description of any experiment, which hardly makes its manner classical—within Bohr's interpretation. In other words, Bohr (his reply to EPR is crucially at stake in this exchange) argues that we do have an interpretation of quantum mechanics, as complementarity, that is both complete and local, which, accordingly responds to the

EPR argument (it also specifically accounts for the specific experiment in question, or for "quantum correlations," as we say now). I shall return to the question of interpretation presently. For the moment, my main point is that Schrödinger does not quite see Bohr's point that the distinction in question is also necessary for locality, or, it appears, even completeness, and hence he missed the essence of Bohr's reply. He thought the question posed by the EPR unresolved and that new "concepts" (and perhaps even new mathematics accompanying them) were necessary. Bohr, by contrast, saw that old concepts could be used to solve the problem and to provide an interpretation of quantum mechanics as both complete, within its limits, and local. Einstein, by and large (there are some further nuances concerning locality), accepted this point, and rejected Bohr's interpretation on epistemological grounds. The epistemology rejected by Einstein was defined by Bohr's view that in quantum physics the classical description or describability in general of measuring instruments co-exists with the irreducible indescribability of quantum objects (and hence, the impossibility of classical-like reality at the quantum level). Schrödinger liked none of this epistemology either, but it appears that in his letter, or perhaps elsewhere, he does not get that far.

At this further juncture, the question becomes whether it is possible to find an interpretation or possibly a new theory (both Einstein and Schrödinger, and sometimes even Bohr, under-appreciate this crucial distinction) that is more epistemologically palatable, including by virtue of being local. Nonlocality would be epistemologically as unpalatable to Einstein or Schrödinger as the impossibility of a realist description at the quantum level. Ultimately, both appear to be nearly ready to give up on causality, but not locality and realism, which moreover they see as linked, in contrast to Bohr, who, accordingly, saw no such need, and, by and large, regarded the debate to be over. The question itself remains, I would argue, unanswered, whether by means of old or, as Einstein and Schrödinger thought possible, new physical concepts. Bohm's hidden variables offer an old-style alternative, but it is nonlocal, and Einstein did not like it on both grounds—the old conceptuality and the nonlocality of the theory. Einstein and Schrödinger looked for new (nonclassical) physical concepts to reinstate the epistemologically classical (realist and preferably causal) local theory. Bohr, by contrast, while seeking to preserve locality found a way to use classical concepts, but at the cost of a loss of classical epistemology or, it depends how one sees this philosophically, as a way, as a fringe benefit, of discovering the nonclassical epistemology. As part of this process he invents quite a few new philosophical concepts, such as complementarity. For the moment, I refer by "complementarity" to complementary physical description or experimental arrangements—mutually exclusive and hence never applicable simultaneously, yet both necessary for a comprehensive theoretical account—rather than to the overall interpretation of quantum mechanics.

The fact that, within Bohr's interpretation, quantum objects and their behavior are not, and cannot be, described by either classical or quantum-mechanical means, or, again, ultimately by any conceivably means, is crucial to Bohr's appeal to classical concepts, which link is usually missed by Bohr's opponents, Schrödinger among them, and indeed by most other commentators on Bohr, critical or sympathetic. For it follows that, whatever physical concepts we can ever conceive of could not be applicable for describing or even imagining, providing a (visualizable) intuition, *Anschaulichkeit*, concerning the properties of quantum objects and of their behavior. ("Pictorial visualization," often used, including by Bohr, in English is adequate and part of what is at stake, but is not quite accurate and strong here, as opposed to the German term, used by both Heisenberg and Bohr, while the Danish word, used by Bohr, is very close to German.) From this perspective, we may even define as *classical* whatever is conceivable and can serve for the purposes of a realist (and especially causal) *physical* description. Mathematical formalism (such as that of quantum mechanics, which cannot be seen as descriptive in this sense, already by virtue of its dependence on complex numbers, as Bohr observed on several occasions) is another question; and Bohr never speaks of any limits in this respect. Naturally, there are limits to what degree this type of mathematics, even two-dimensional complex Hilbert spaces (used in the case of spin) or indeed the field of complex numbers (the complex plane), let alone infinite-dimensional spaces of quantum mechanics, are available to our spatial intuition. (Even if they were, though, and I do not think they are, we still could not use them to describe the behavior of quantum objects, or indeed anything physical; hence Bohr's appeal to mathematical "abstractions" in quantum mechanics, in contrast to classical physics.)

Bohr does not perhaps entirely deny that new concepts could be and are being developed, but only that, no matter what new concepts or mathematical tools ("abstractions") we can and must develop, they will not bring us closer to describing or imagining the behavior of quantum objects. This argument would of course only remain valid unless the nature of the available experimental evidence drastically changes (say, uncertainty relations or locality would be no longer valid), or, I would add (Bohr might be a bit less cautious here), unless a different consistent and complete local interpretation of quantum mechanics or an alternative local theory is found. As Bohr says:

> Such argumentation does of course not imply that in atomic physics, we have no more to learn as regards experimental evidence and the mathematical tools appropriate for its comprehension. Indeed it seems likely that the introduction of still further abstractions into formalism will be required to account for the novel features revealed by the exploration of atomic processes of very high energy. The decisive point, however, is that in this connection there is no question of reverting to a mode of description which fulfills to a higher degree the accustomed demands regarding pictorial representations of the relationships between cause and effect [which obtains in classical physics]. (*The Philosophical Writings of Niels Bohr [PWNB]*, 3 vols. [Woodbridge, Conn.: Ox Bow Press, 1988), vol. 3:6)

One might indeed speak here of any pictorial representation, assuming that we could intuit anything in noncausal terms, which Wittgenstein, for example, if not already Hume and Kant, and certainly, Nietzsche questioned. In other words, there is a kind of (en)closure—enclosure and closure (not the same as "end")—of physical (or of course other) concepts, defined by our perceptual and conceptual capacities, and perhaps ultimately linked to biological and evolutionary nature. We cannot reach beyond this (en)closure, and we must depend on and (as both Bohr and Heisenberg grasped) can greatly benefit from this (en)closure even in our thinking about quantum objects, but, at the same time, this—beyond this (en)closure—is also where, in this interpretation, the nature of quantum objects and their behavior lies, forever hidden from us. The latter placement of the quantum is, again, in this interpretation, itself a consequence of the effects of the interaction between quantum objects and the classical world (including measuring instruments) upon the latter, effects whose understanding is, accordingly, within this (en)closure and is available to us. Classical physics is a refinement of these capacities, and there is of course a question of how far it reached on that road, but it would not affect the argument, here presented, concerning placing quantum objects beyond this limit in Bohr's interpretation, no matter how much further such a refinement reaches. Perhaps it defines, if not the end of this road, a certain limit, a "closure," indicating that we can only go so far and only along certain lines, perhaps incrementally infinitely, but the limit and the closure are implied, even if not expressly determined. Possibly, it is quantum physics that establishes this limit. Bohr's position on this point is not altogether clear, except, as the above statement suggests, on the point that quantum mechanics is beyond this limit, beyond the "cut." (I am of course not using this term in its strictly quantum-mechanical sense, but one can contemplate certain links between both usages.) As explained above, the overall argument just outlined remains, perhaps against Bohr's view (one can read him either way), conditioned by the particular interpretation here adopted, the strong Copenhagen interpretation, that is, such are epistemological consequences of this interpretation, on interpretation necessitated in part by the locality requirement.

Thus, Schrödinger, just as Einstein, wants new concepts to return to the epistemologically classical models in physics, which would mathematically represent, in however idealized a way, independent and, it appears, causal physical reality. By contrast, according to Bohr's interpretation (in this strong form), the appeal to classical concepts, beyond the practical role, reflects the impossibility of having such models. The abstractions (in many ways, and indeed, as Bohr anticipated, ever more radical) of the quantum-theoretical mathematical formalism, from the original quantum mechanics to the field theories of the current standard model, enable excellent, even if only statistical, predictions under these conditions. This is a kind of miracle, and an epistemological enigma, since, in contrast to classical physics, there appears to be no physical justification why they do so, and in this interpretation there cannot be, in part because the interaction between quantum objects and measuring instruments is itself quantum and subject to the same nonclassical epistemology.

From the present perspective, Bohr's interpretation, which may be called "reciprocal-interactive," appears as somewhat different from Wheeler's more or, at least, still more, "participatory" or "observer dependent" view of the quantum world, which may be ultimately closer to Pauli's, although, in my view, it is uneasily suspended between Bohr's and Pauli's views. The question is rather subtle and I should only make a few "background" points against which it could be considered, rather than addressing it as such, since to do it justice would require an engagement with Pauli and Wheeler on a much greater scale. One cannot, however, stop short of anything but admiration for the grandeur of Wheeler's vision, which is well conveyed in your selection of quotations, let alone the works themselves cited.

I would like to comment briefly on Wheeler's discussions of the delayed-choice experiment, such as that in "Law without Law" (in J. A. Wheeler and W. H. Zurek, *Quantum Theory and Measurement* and elsewhere, for example, in "'A Practical Tool,' But Puzzling Too," *New York Times*, 12 December 2000, which you cite, "Fuchs," #383, p. 74). His analysis does not appear to me (perhaps I miss something) sufficiently to take into account the architecture of phenomena in Bohr's sense. I, again, refer most especially to the wholeness-indivisibility of phenomena, in view of which we cannot attribute any properties, such as wave-like or particle-like ones, to quantum objects themselves even when a phenomenon becomes, using Bohr's term favored by Wheeler, "registered" as the result of an observation. This view would help to refine Wheeler's argument that our observation of certain quantum events that took place in the past, possibly a very distant past, in no way influences what had happened at the time of such events, even though we have a (delayed) choice in setting our equipment. This choice allows us to "observe" a different "past event" depending on a given setting. Wheeler accurately puts the same type of quotation marks throughout his discussion. Or, one can put it more accurately, and it is, I think, here that Wheeler's analysis could be refined and, I think, it would be by Bohr, as appears from his statement on or anticipating the delayed choice setup in *PWNB* (Vol. 2, p. 57), cited by Wheeler and Zurek in *Quantum Theory and Measurement* (p. 778). The choice in question allows us to create different phenomena in the sense of what will have classically manifest itself in our measuring instruments at the time of measurement (see, for example, Wheeler's design in "Law without Law," *Quantum Theory and Measurement*, p. 193), without, however, claiming anything concerning the properties of quantum objects or of their behavior. For example, we can make no claim as to how the photons in question in Wheeler's design actually traveled before leaving their traces in our measuring instruments. By the way, Wheeler's article in *The New York Times*, which you cite, contains, in my view, an inaccurate statement, unless Wheeler's whole interpretation is off, at least as against Bohr's. Wheeler says: "if you measure the departing photon in a different [and mutually exclusive] way (a complementary way), you can tell if it *took both paths at once*" ("Fuchs," #383, p. 74; emphasis added). My understanding (which follows Bohr's and most other versions of the Copenhagen Interpretation) is that in such cases we *cannot know* through which route the photon has passed. This lack of knowledge is reflected in the effects of the experiment, such as, once we repeat the experiment with a large number of photons, the interference-like pattern on a silver screen in the double-slit experiment. (In the other complementarity observation measurement case we can establish through which "route" the photon travels.) In "Law Without Law," Wheeler's puts "routes" in all cases in quotation marks (*Quantum Theory and Measurement*, p. 192), which may imply only a symbolic assignment of routes. Even so, I am not altogether happy with his usage of "both routes" in ever speaking of a single photon without qualification.

Nor could we argue, counter-factually, concerning what could or would have happened to the same photon, if we had set our equipment differently. Indeed, it appears that we cannot use counterfactual logic of that type in quantum mechanics without reinstating nonlocality, even though we can, of course, speak of different possible outcomes of future experiments, or of possible, that is, possibly obtainable, information concerning future events without introducing nonlocality. This delayed-choice experiment seems to invite the former (counterfactual) reasoning, and Wheeler needs all the help he can get from Bohr to escape its traps, nonlocality included, but, to his great credit, by and large he manages to do so.

In sum, we can never "see" what happened with quantum objects as such in the past, nor argue, it follows, always counterfactually, on the basis of what would have but did not happen. We can only predict (with certain probability) what will happen in future experiments we can perform, future effects of the interactions between quantum objects and measuring instruments upon the latter, on the basis of previously performed experiments and previously observed or measured effects of the same type.

From this viewpoint, one can speak of the "constitutively participatory measurement" in, and defining, quantum physics, or indeed of "the activating observer," as you do. I am not sure, however, in what sense one can speak, as Wheeler does of a "participatory universe," even if in quotation marks and even if designating that the sense in which the universe is "participatory" is "strange" ("Law without Law," *Quantum Theory and Measurement*, p. 194). Unless, of course, he merely means that it is the universe that participates in these interactions, but the latter would be equally true in classical physics. "The activating observer" would indeed be more accurate, since, while there is some reciprocity to these relationships, they are not exactly symmetrical.

While I am on the subject, let me point out that Pauli, in my view, also misses certain key nuances of Bohr's concept of phenomenon and his argument concerning the indivisibility of phenomena. Thus, I cannot agree (nor I think would Bohr), in any event not without further qualifications (not offered by Pauli and not apparent from the article as whole), with the following statement in "Phenomenal and Physical Reality": "[E]very act of observation is an interference is of undeterminable extent, with the instruments of observation as well as with the system observed, and interrupts the causal connection between the phenomena preceding and succeeding it" ("Fuchs," #257, p. 56). There is no such "causal connection," or there would not be in Bohr's view of the situation, and, in all rigor, there is never either a phenomena (in Bohr's sense) of either preceding or succeeding an act of measurements, but only such acts. Each such act gives rise to a phenomenon (no phenomena could appear otherwise) and such acts rarely, if ever, can present any "sequence." Instead they entail repetitions using different quantum systems. It seems to me that Pauli here thought of "phenomena" in terms of reference to the properties of quantum objects, or in any event he does not sufficiently elucidate the point. If, however, he did think in this way, he could not have properly or at least in full measure understood Bohr's counter-argument to EPR and related arguments by Einstein, since Bohr's argument does not work unless it is assumed that all observable quantities or references to physical attributes pertain to measuring instruments and only to them. The immediately following sentence in Pauli's elaboration, "The gain of knowledge by means of an observation has as a necessary and natural consequence the loss of some other knowledge," is not altogether accurate either. At the very least, one should, I think, say "the loss of other possible knowledge." The point might, again, seem minor, but everything here is in finer micrological details and nuances.

As concerns the "participatory universe," I would say, in general, that such statements as nature "responds" (the quotation marks are imperative) to the kind of questions we ask (no quotation marks are necessary), and hence is defined by the latter participation on our part, can only be used metaphorically and, even then, with much caution. We "participate" in nature only within the limits of our interaction with it, for example, by means of scientific experiments, even though this "participation" can take us far, as our knowledge, or what we learn we cannot know, is concerned. Of course this participation also defines any conceivable view of reality, or, again, the impossibility thereof, we can have, for example, the possibility of describing much (not all!) of the macroworld in terms of classical physics, or (this difference is crucial in the present context) using quantum physics to learn how the quantum micro objects affect the macro world. (Some quantum effects, such as those manifested in Josephson's devices, can of course appear at the macro level, but they would still be due to the micro constitution of nature.) The so-called "unreasonable" (we merely exclude other things as ineffective) "effectiveness of mathematics" belongs only to this level, as do certain archetypal correspondences (which attracted Pauli). Heisenberg, in his later view (although one finds anticipations of it in his earliest works), combined both of these ideas and refined their application closer to Bohr, in arguing as follows:

> If we attempt to penetrate behind this reality [the spatio-temporal reality of classical physics, or of our perception, to begin with] into the detail of atomic events, the contours of this 'objectively real' world dissolve—not in the mist of a new yet unclear idea or reality, but in transparent clarity of mathematics whose laws govern the possible [the outcome of experiments?] and not actual [what actually happens?]. It is of course not by chance that "objective reality" is limited to the realm of what Man can describe simply in terms of space and time. At this point we realize the simple fact that natural science is not Nature itself, but a part of the relation between Man and Nature, and therefore depends on Man." ("Fuchs," #176, p. 38)

This is not quite the way I (or, I think, Bohr) would put it, as my interpolating parentheses indicate, but it is essentially correct and, in its own way, admirable and philosophically appealing (Heisenberg clearly speaks here with a broader audience in mind). In any event, the ultimate "workings" of "nature" are in no way participatory in the present view, even though, and because, they make any participation on our part possible. By contrast, quantum mechanics, as a mathematical-experimental science of nature, is irreducibly participatory. It appears to me that (for perhaps different reasons) both Pauli and Wheeler blur this difference, or want to dispense with it. I prefer, however, to refrain from any definitive claim, since on a further reading this "appearance" or suspicion may yet dissolve. Some of Heisenberg's elaborations, such as the one cited above, may seem to be a form of the mathematical Platonism of nature, while in fact they are not. Plato's own view is yet another story and may even be closer to Heisenberg's and Bohr's than it appears, as Folse, incidentally, suggests by juxtaposing Democritus's and Plato's atomism, although I am, again, not in agreement with his reading of Bohr's atomism itself ("Fuchs," #129, pp. 25–26).

A (in my view) related remark by Heisenberg that you cite is also important here: "It is quite wrong to try founding theory on observable magnitude alone. In reality the very opposite happens. It is the *theory* which *decides* what we can observe. You must appreciate that observation is a very complicated process" ("Fuchs," #177, p. 38; emphasis added). One must qualify Heisenberg's point here (actually it is Einstein's). First, "the theory" ought to refer to much more than a given mathematical apparatus, but instead to the whole conceptual framework of which the latter is a part, and indeed one may need to speak of a broader "plane of mental immanence" where these concepts emerge (I am not sure one can call this plane "theory") that shapes "the theory." Second, it would be more accurate to say that the theory *shapes* what we observe and *decides* what observations are included, unless, again, we refer by the "theory" to a broader plane of immanence, just mentioned, in which case the theory might indeed be seen as *deciding* here. The remainder of the (important) elaboration that you cite might be shown to illustrate this point.

The main point that I want to make is as follows. The view here expressed by Heisenberg may appear to be in conflict with Heisenberg's approach in his first paper on quantum mechanics, to which he clearly refers here, and stressed the "magnitudes, which in principle are observable," in other words, more or less individual quantum effects in the above sense. The effects, rather than properties of quantum objects and of their behavior, that became subject to his "new kinematics." There is no contradiction, however, and, as is well known and well documented, Einstein's point concerning the theory deciding what can be observed, was indeed was guiding Heisenberg in his work. For his theory was not founded on such magnitudes alone; nor of course was Bohr's complementarity. Heisenberg's famous, but not always carefully read, opening statement (a kind of abstract, but much more than that) is worth citing: "The present paper seeks to establish a basis for theoretical quantum mechanics founded exclusively upon *relationships* between quantities [magnitudes] which are *in principle* observable" (emphasis added). "Relationships" is the key word here, and the title of the paper was, we recall, "On Quantum-Theoretical Re-Interpretation of Kinematic and Mechanical Relations." "In principle" is quite crucial too, for, no matter how theory-laden and how complicated the processes of observation, the magnitudes in question could, in principle, be observed and, as it were, "kinematized," while the classical-like physical (and ultimately any) properties of quantum objects and of their behavior could not. In other words, even leaving aside for the moment the theory-laden character of all conceivable data (equally including that of classical physics), dealing with such, "in principle observable," magnitudes is not the same as founding the theory on them, and Heisenberg's paper was not doing the latter. While working with the available data of quantum physics (such as the Rydberg-Ritz formulas and the Bohr frequency relations), his theory qua theory was founded above all on Bohr's correspondence principle. The latter was used to argue both that for large quantum numbers the data becomes the same as it would be in a classical case, at least as far as predictions are concerned (the description could, in all rigor, no longer be the same). The principle was also used to argue, in part correlatively, that the equation should be formally the same as those of classical mechanics, the Hamiltonian equations. (For large quantum numbers these of course would give correct predictions classically.)

It is this combination, this "lethal combination" (as far as classical physics is concerned), that leads to most remarkable properties of quantum mechanics, such as Bohr's probability rules, uncertainty relations, and so forth, and mathematically (in part correlatively) the irreducibility of complex numbers and replacing functions with operators as the kinematical and dynamical variables of the theory. Both Dirac's and von Neumann's schemes are more or less automatic translations of Heisenberg's matrix mechanism. Indeed, Heisenberg's stroke of genius (not altogether unprepared by, among others, Bohr, but a stroke of genius nevertheless) was itself a founding theoretical move. That is, this arrangement of the relationships between observable magnitudes, made moreover into complex, rather than real, numbers (never observable as such), into infinite matrices is already *theory*, not observation. (You may also recall that these matrices must be infinite in order to derive uncertainty relations.)

I, once again, apologize for not having enough to say on Pauli. To me, his statement, which you cite from his essay "Matter" (but the statement, with minor variations, recurs throughout his lectures): "Like an ultimate fact without any cause, the *individual* outcome of a measurement is, however, in general not comprehended by laws" ("Fuchs," #251, p. 54), has always been his greatest and most significant statement on quantum theory. Indeed, it may well have been also on much that is beyond it, perhaps ultimately on life, or life/death, the randomness of whose occurrences, including in his own life, Pauli (I could hardly doubt this), was also contemplating here. But then, Pauli appears to have been reluctant to separate life and quantum theory, anymore than Kepler wanted to separate it from his music of the cosmic spheres, either of which would indeed be difficult to do, at least in their own cases.

These are a few more or less immediate thoughts prompted by reading your "Compendium," and clearly the stakes continue to be as enormous as ever, after three quarters of a century of debates, which may never end, and the reasons (I can think of several) why they may not end are worth considering, but cannot be addressed here. I am, once again, grateful to you for allowing me to read it, and of course for putting it together. As I said, the work, while seemingly consisting of citations, has a life and argumentation of its own, not reducible to the sum of citations, if indeed we can ever sum them up. Perhaps, my sense of it is best captured by my reaction to Wheeler's remarks in his letter to Carrol Alley: "Today, the physics community is bigger and knows more that it did in 1939, but it lacks the same feeling of **desperate** puzzlement. I want to recapture that feeling for us all, even if it is my last act on Earth" ("Fuchs," #380, p. 73). Whether with Wheeler's (and Pauli's) help or not, I think your "Compendium" does bring the right sense of deep puzzlement, or perhaps better of profound complexity, whose resources are far from exhausted, and we have yet barely touched the epistemology of quantum field theories. I am not sure one needs, at least at this point (perhaps ever) to feel desperate, or even **desperately puzzled**. Perhaps one needs more resolve to move forward from where quantum mechanics has already brought us and, of course, use what it gave us, in physics and philosophy alike—*increscunt animi, virescit volnere virtus*, the spirit grows, strength is restored by the wounds it receives, as Niezsche would have it. One can hardly doubt that quantum mechanics inflicted one of the deepest wounds upon the spirit of physics; but physics survived, and more than merely survived; and, this is part of Nietzsche's meaning, what does not kill us sometimes (not always) can make us stronger. In my view (I know that not everyone shares it, but I think that Bohr would), in this case it did. Naturally, one could hardly doubt this either, this growth will bring us, it has already, new, yet deeper puzzles and puzzlement, but they will be, and some already are, new.

29-05-01 *'Typo in Note 6' and 'Worst of All'* (to N. D. Mermin)

Wootters! Wootters!

There are two t's.

29-05-01 *Bayes and Lorentz: Never the Twain Shall Meet* (to A. Peres)

I still owe you some comments on your paper. I guess in the end, I don't have much to say. I agree with its content of course. Not least of all, because you taught me long ago that the correct analogy is between quantum states and Liouville distributions, and not between quantum states and phase space points. For me, that means that both objects—quantum state and Liouville distribution—are subjective entities, and can therefore be changed by the whims and the fancies of the observer. Their valuations are not tied to physics per se. The learning of information always presents just such an opportunity: there is no law of physics that says that all observers must agree in their Liouville distributions for a given system. Measurement can lead to very nice inequities in that regard: an application of Bayes' rule is not Lorentz invariant, but then again it is not even *observer* invariant. We apply it when we gather information; we don't apply it when we don't.

But the question, I must ask is: what new point did you make in this paper? What did you say here that was not clearly in your mind when you wrote the RQM paper, for instance? (I can even find our discussion of similar points in the samizdat, pp. 270–276.) The answer to those questions don't come out clearly in your present exposition.

29-05-01 *No Miracles* (to A. Peres)

Asherism 12: *Exophysical agents are essential, and most people tend to sweep them under the rug.*

Yeah, you might say my *Notes on a Paulian Idea* is about looking under the rug.

29-05-01 *Substantiation* (to N. D. Mermin)

What particular piece in the paper directly substantiates the sentence: "It is possible to eliminate all couplings between the source and the destination because quantum qubits have a richer range of logical capabilities than do classical bits."

Have you tried explicitly walking through all your circuits with a classical Liouville distribution rather than a quantum state? That is to say, in Fig. 2 for instance, let $|\psi\rangle$ stand for a (Bayesian) probability distribution over $|0\rangle$ and $|1\rangle$, rather than a pure quantum state. Then you would have a classical state-swapping circuit: where the word state now means without doubt "state of knowledge."

What goes break and where goes break in getting from figure 2 to figure 10 in such a classical setting? Well, nothing of course, because we know that teleportation also works for mixtures. But it does probably mean that some components in the circuit are probably more "quantum" than they need to be to carry out such a classical project. (I.e., the project of teleporting a classical state of knowledge, via purely classical resources.)

Can you pinpoint where that occurs? It has now struck me that your view of teleportation may be a good laboratory for sussing that out. I'm warming up as a referee.

Today Renes arrives, and this evening Caves arrives, and ... and next Tuesday I have committed myself to lecturing on Holevo's channel capacity result, and—between all of that—somehow, someway, some pig (Charlotte's web), I must complete the NATO paper. I keep hoping for a miracle: none occurs.

You've never read it, I know, but you should read it: de Finetti's paper "Probabilismo," written in his youth while in a fascist fervor. Have the mental strength to divorce it from the fascism, and you will find it is an absolutely wonderful piece: B. de Finetti, "Probabilism," Erkenntnis **31**, 169–223 (1989). [See also R. Jeffrey, "Reading *Probabilismo*," Erkenntnis **31**, 225–237 (1989).]

I've come to think of the NATO paper as my own Probabilismo. I just wish I had the youthful fervor.

31-05-01 *Quotes and Barbells* (to H. J. Folse)

No, there is never a worry in quoting me. I say right things, and I say wrong things, but I never say anything without the intention of lifting the veil of the quantum. I am more than happy to be quoted if my right/wrong thing contributes to that.

We don't have a program worked up yet: Unfortunately, both Khrennikov and I have been hugely tied up for the past weeks. But we started the process yesterday—in fact—so maybe something will come out by mid-next week. In any case, I'm fairly sure at this stage you can count on a 30 minute talk. I think we all can; there have been several additions to the conference (Bernstein, Greenberger, and several others) even though a few dropped off the list (Shimony, Brassard, Preskill).

I printed out my samizdat for the first time yesterday. It's a frightening thing, seeing it bend the table. I don't suppose you've had any luck in retrieving it. Maybe I'll just break down and send you loose-leaf copy of it. Can you send me your mailing address so I make sure I send it to the right place.

03-06-01 *Quotes* (to me)

- "Only those who will risk going too far can possibly find out how far one can go."
  – T. S. Elliot

- "Opportunity is missed by most people because it is dressed in overalls and looks like work."
  – Thomas Edison

06-06-01 *Comments and Answers* (to N. D. Mermin)

Wow. Thanks again for the very thorough reading! (And concern over my welfare.)

I reply to all your comments below. You've certainly left me hungry for more.

Merminition 11: *I didn't really get the epigraph ("imprimatur") and the apparent explanation of it on p. 2. Is that a coy reference to the bad-boy tone?*

Which meaning of coy did you have in mind?

1. Tending to avoid people and social situations; reserved.
2. Affectedly and usually flirtatiously shy or modest.
3. Annoyingly unwilling to make a commitment.

Merminition 12: *What is an Einselectionst? (p. 2.) Everything else is familiar, but, irritatingly, it's the one school you don't explain in footnote 2. Is this a (bad) joke you're playing on the reader?*

I'm letting that one stand: it was meant to be a little insulting. I can't figure out what their views are.

Merminition 13: *p. 2. You should think twice about sentences like "If I am ever going to get ... someone else's war." I know it's true, that physics would be a lot more fun if people weren't trained to hide such sentiments, etc. But it does have a certain self-indulgent quality.*

Stripped away with surgical precision ...

Merminition 14: *p. 4. Say the whole thing: 1) the speed of light IN EMPTY SPACE is [constant,] independent of the speed of its source. (Einstein did not say "is constant" — it's not necessary.) Keep "is constant" if you like, but why leave out his "in empty space" — that's crucial.*

Oh, alright!

Merminition 15 : *Bottom of p. 4. Can you explain classical E&M to a junior high-school student giving the essence, not the mathematics? Classical mechanics? Thermodynamics? I've always thought relativity was special that way.*

No. Not yet. Maybe. Me too. I.e., I consider E&M much more like the setting of a particular Hamiltonian within QM: And I wouldn't expect a high-school student to be in a position to understand why we have chosen the particular Hamiltonians that we have in any practical situation. Since the overarching belief here is that "quantum mechanics is a law of thought" (with an almost trivial side-input of honest-to-god physics), it strikes me as being in a category much more like relativity. In the words of J. Bub, it is a "framework theory."

Merminition 16 : *Also p. 5, I've been meaning to ask you: why is H a vector space if the scalars are real or complex, but a module if they are quaternions? As I remember "module" has a precise meaning — maybe having to do with the scalars lacking inverses — which is not satisfied if they're quaternions. Isn't H still an ordinary vector space?*

According to Adler's book, it is a module. Why one makes such a distinction, I don't know: I just followed convention.

Merminition 17 : *Is footnote 5 on p. 7 a little too cute? [Just asking.]*

Let me think about this one. I added the footnote first as a joke to myself. But then I decided I sort of liked it. The motivation came from Bennett having no clue about what imagery I was trying to convey with zing.

Merminition 18 : *p. 11. I find your brief knee-fortifying rejoinder to Penrose somewhat of an anticlimax. If you had added explicitly that the answer to Penrose is that it's all about the RELATION between Alice and the qubit (even without invoking correlations without correlata) I would have thrown away my Ace bandage.*

Yeah, I thought it was a bit of an anti-climax too. I continue to search for ways to strengthen my rejoinder to Penrose and Jozsa (the z comes first).

But indeed you and I differ on the climaxes we seek. As far as I can tell, you seem to seek a predominantly static worldview. I want to see true becoming ... I think.

Perhaps I said something closer to what you'd like me to say presently in the Samizdat, pages 407–408 (in a note titled Penrose Tiles). Have a read of that, and tell me whether that meshes with what you would have liked to hear. Who knows, I may well reconsider (based on the old text).

Merminition 19 : *p. 11. I'd never seen so direct a statement of correlations (between Man and Nature) without correlata in Heisenberg before. Nice quote. Where's it from?*

W. Heisenberg, "The Development of the Interpretation of the Quantum Theory," in *Niels Bohr and the Development of Physics: Essays Dedicated to Niels Bohr on the Occassion of His Seventieth Birthday*, edited by W. Pauli with the assistance of L. Rosenfeld and V. Weisskopf (McGraw-Hill, New York, 1955), pp. 12–29.

> The criticism of the Copenhagen interpretation of the quantum theory rests quite generally on the anxiety that, with this interpretation, the concept of "objective reality" which forms the basis of classical physics might be driven out of physics. As we have here exhaustively shown, this anxiety is groundless, since the "actual" plays the same decisive

part in quantum theory as it does in classical physics. The Copenhagen interpretation is indeed based upon the existence of processes which can be simply described in terms of space and time, i.e. in terms of classical concepts, and which thus compose our "reality" in the proper sense. If we attempt to penetrate behind this reality into the details of atomic events, the contours of this "objectively real" world dissolve—not in the mist of a new and yet unclear idea of reality, but in the transparent clarity of mathematics whose laws govern the possible and not the actual. It is of course not by chance that "objective reality" is limited to the realm of what Man can describe simply in terms of space and time. At this point we realize the simple fact that natural science is not Nature itself but a part of the relation between Man and Nature, and therefore dependent on Man. The idealistic argument that certain ideas are *a priori* ideas, i.e. in particular come before all natural science, is here correct. The ontology of materialism rested upon the illusion that the kind of existence, the direct "actuality" of the world around us, can be extrapolated into the atomic range. This extrapolation, however, is impossible.

Merminition 20: *p. 11. "wake and dream"? waking and dreaming?*

I left that alone. The *American Heritage Dictionary* has a huge usage note associated with "wake." I took that to give me license, plus I like the flow of it.

In general, I think that paragraph is the deepest part of the whole paper. It is the Paulian idea.

Merminition 21: *p. 13. Gleason derives the state-space structure? What do you mean? He talks about projections. What are they projecting on? What does "tr" mean? Isn't the state-space structure already there? You yourself begin by saying "Let P_d be the set of projectors associated with a . . . Hilbert space . . . "*

$$\text{state space structure (for me)} \quad = \quad \text{convex set of density operators}$$

The Hilbert space you are talking about—again for me—only has significance in that it defines the set of potential measurements. The quantum state, and with it the state-space structure, is a secondary notion.

But I will try to ward off confusion by adding the definition above to the text.

Merminition 22: *p. 16. "sum total OF ways" I wrote in the margin around here that noncontextuality for POVMS seems to be an enormously stronger assumption than noncontextuality for projections . . .*

Yes. But so what? The point is—physically—the assumption is equally deep for both notions of measurement. Noncontextuality IS Bayes' rule. (Or just about so much.) It's just that applying it to POVMs actually gets you somewhere (without having the mathematical skills required to solve one of Hilbert's problems).

06-06-01 *The Haunting* (to N. D. Mermin)

You have this habit of haunting me: even when I say I'm not going to listen to you, I end up listening to you. Demon!

Einstein was the master of clear thought. I have already expressed my reasons for thinking this in the arena of electromagnetic phenomena. Likewise, I would say he possessed the same trait when it came to analyzing the quantum. For even there, he was immaculately clear and concise in his expression. In particular, he was the first person to say in absolutely unambiguous terms why the quantum state should be viewed as information (or, to say the same thing, as a representation of one's knowledge).

06-06-01 *Reading de Finetti* (to H. M. Wiseman)

Carl Caves is visiting Bell Labs, and yesterday he shared with me some correspondence he's had with you about the quantum de Finetti paper. Thanks a million for the interest!

I just wanted to make one comment on one of your comments. You asked about the deeper reasons for my mean-spirited, off-hand remark about "for a stretch of the imagination … ".

Wisemanism 1: *But of course the Bohmian particles behave in a nonlocal way, so this means that our experience must be capable of nonlocal influence. That is, we cannot rule out faster-than-light information transfer, if information is transferred when a being becomes conscious of it. (Is this a reasonable concept of information transfer? What a tangled question! I will assume it is.) So in fact Bohmian mechanics is not even compatible with relativity, unless conscious systems are constrained somehow so as not (or at least with vanishing probability) to have nonlocal effects. This seems an ad-hoc hypothesis and even if it can be shown to work for us, I don't see how it could be proven in general.*

Actually, something like this has been one of my longer-standing pet peeves with Bohm theory. In particular, I've always thought it absolutely contrived that the nonlocal components in the theory could not be made use of. That they could not be turned into a technology, say. In that capacity, the Bohm theory seems to me to be no deeper than saying "God wills each and every event in our quantum world." It is true that the theory has a sheen of equations—which a religion normally doesn't have—but beyond that, I see no great difference. Somehow the mere possibility of writing down an equation has been deemed to be an acceptable state of affairs in the Bohmian community. But if the parameters in that equation cannot be set by the experimentalist (with a sufficient amount of effort), then, in my mind, it is no different than a burning bush proclaiming, "I am that I am."

Now, not all Bohmians, believe that the particle trajectories cannot be controlled at all. Antony Valentini is a notable exception. And he has also studied the non-uniqueness of the trajectory equation at length, hoping one day to put the various options to experimental test. (I don't have any references for his papers, but I see he has at least one paper on `quant-ph`: So you can probably find references therein.) But it has been my experience that the vast majority of the Bohmians (or the Goldstein, Duerr, Albert flavors thereof) see no need to go to the trouble of actually calculating a particle trajectory. It is enough, for them, to believe it exists.

I had not realized before that you have an interest in quantum foundations. Lately I've been trying to energize the community to think hard about "quantum foundations in the light of quantum information" and have organized two meetings to that effect. (One in Montréal last year, and one coming up in Sweden at the end of next week.) There is a good chance that Brassard and I will be doing still another in Montréal next summer. If you have an interest in coming, I'll surely make sure that you get an invitation.

06-06-01 *Bohm and the Burning Bush* (to H. M. Wiseman)

Wisemanism 2:

> [Chris said:] Somehow the mere possibility of writing down an equation has been deemed to be an acceptable state of affairs in the Bohmian community. But if the parameters in that equation cannot be set by the experimentalist (with a sufficient amount of effort), then, in my mind, it is no different than a burning bush proclaiming, "I am that I am."

But that is because you have such a strong instrumentalist philosophy (is that a fair description?). I'm in favour of giving a theory a fighting chance of producing its own interpretation. After all, wasn't gas theory criticised on your sorts of grounds a century or so ago?

No, most of the gas laws were found empirically at first. Then theory was tested quite well, by working explicitly in new regimes of pressure, temperature, etc. Quantum theory, too, has been tested empirically. We have means of preparing quantum states and checking how they evolve. We don't have the same means—so we are told by Goldstein and company—for (Bohmian) particle positions.

Wisemanism 3: *But I'd certainly like to understand an informational view of QM (and stat mech too, for example; do you think they are related?) better.*

Yes. That was a good bit of the point of the de Finetti paper.

07-06-01 *Frost* (to N. D. Mermin)

Just found this in my quote of the day:

> Poetry is a way of taking life by the throat.
>
> Robert Frost (1874-1963), U.S. poet. Quoted in: Elizabeth S. Sergeant, *Robert Frost: the Trial by Existence*, ch. 18 (1960).

I see you wrote me a note last night at 10:17. I'll have a look at it.

07-06-01 *The Mud of von Neumann* (to N. D. Mermin)

Merminition 23:

> [CAF wrote:] Forget about the larger Hilbert space. It is artifice. It is only historical accident that has confused us for so long.

Now that I've added the discovery of POVMs to my discovery of the moons of Jupiter I'm less inclined to object to this. Indeed, I'd like it to be so. But if I give you a resolution of the (2 dimensional) identity for a single qubit into 17 positive operators, can you always tell me how to set up a corresponding procedure with 17 distinct outcomes without enlarging the system to one described by a larger Hilbert space?

The point is: If I give you a resolution of the (2 dimensional) identity for a single qubit into 2 projection operators, can *YOU* always tell me how to set up a corresponding procedure with 2 distinct outcomes without enlarging the system to one described by a larger Hilbert space?

Von Neumann didn't know how. He introduced the notion of a "measurement model," enlarged the Hilbert space, and got us into the muddle most of us are still in today. Now, people like Zurek are going around trying to justify the "pointer basis" on von Neumann's ancillary Hilbert space by enlarging it still further (and calling it "the environment"). And I'm sure you'll recall that von Neumann himself did even more dastardly things.

You just have to get into a different mindset. My attitude is it's time to cut the Gordian knot. That's what Section 4 and 5 are about. To the extent that one admits a mystery to the standard (von Neumann, orthogonal projection-valued) notion of measurement, one gains *nothing* by holding tight to it. One might as well transfer the mystery to the POVMs and be done with it. The advantage of the POVMs is that they are a conceptually simpler structure: the old von Neumann notion is just a horribly contorted surface of constraint within that beautifully smooth space. What is a measurement? A refinement of one's state of knowledge, full stop. Any refinement whatsoever? Yes, any refinement.

Let me give you a homework exercise. (Now I'm going to sound like Gottfried.) Go back to a classical setting where you have a probability distribution $p(h, d)$ over two hypotheses. Marginalizing over the possibilities for d, you obtain an initial state of knowledge $p(h)$ for the hypothesis h. If you gather an explicit piece of data d, then, using Bayes' rule, you should update your knowledge about h to $p(h|d)$. The question is this: Do you not find that transition $p(h) \longrightarrow p(h|d)$ a mystery you should contend with? Does it not bother you that if someone asked you for a *physical description* of that transition, you would be at a loss for words? I mean, after all, one value for h is true and always remains true. One value for d is true and always remains true. There is no transition for those variables. The transition is in your knowledge (or belief, if you will). Should we not have a detailed theory of how the brain works before we can trust in the validity of Bayes' rule? (I ask that rhetorically of course.) Should we close all the gambling houses in Nevada, on the suspicion that they know better of Bayes' rule (and its limitations) than we do and have been using that to their (nondisclosed) advantage all along?

In my view, recognizing the ridiculousness of the rhetorical question is the *first* step to freedom. Now we've got a long haul to go, but at least we're out of the parking lot.

I think I'll CC this note to Caves (across the hall) since parts of it seem to be a point of contention between us too.

07-06-01 *Modules Over a Division Ring* (to N. D. Mermin)

Actually, I picked up the word "module" in a footnote of Adler's, where he explains that he is going to flout convention and call the object a "quaternionic Hilbert space." (Or, maybe he said vector space instead.)

Anyway, "quaternionic module" does square with the definitions in Mac Lane and Birkhoff's book *Algebra*.

p. 134: "A division ring is defined to be a non-trivial ring (not necessarily commutative) in which every non-zero element has a two-sided multiplicative inverse. A commutative division ring is thus the same thing as a field. An example of a non-commutative division ring is furnished by the quaternions ..."

p. 190: "A module is an additive abelian group whose elements can be suitably multiplied by the elements from some ring R of 'scalars.' ... This chapter will be concerned with general properties of modules over arbitrary rings; special properties of modules over fields ('vector spaces') will be studied in the next chapter."

p. 253: "We have already noted that most of the properties of vector spaces (modules over a field) are shared by modules over a division ring. As the most important example of such a division ring we now construct the ring of quaternions."

I would like to know what cherished property of vector spaces goes bust with quaternionic modules ... but I just don't have the time for that now.

07-06-01 *Two Go Bust* (to N. D. Mermin)

Actually Mac Lane and Birkhoff say that only two of their theorems in Chapter 7 "Vector Spaces" fail for modules over a division ring. But I haven't been able to locate the theorems, and I think I'm going to have to give up for now.

07-06-01 *The Mud of Mermin* (to N. D. Mermin)

Merminition 24:

> [CAF wrote:] The point is: If I give you a resolution of the (2 dimensional) identity for a single qubit into 2 projection operators, can *YOU* always tell me how to set up a corresponding procedure with 2 distinct outcomes without enlarging the system to one described by a larger Hilbert space?

Yes, I can. (That's why I picked that example.) The two orthogonal projections are necessarily of the form $(1 \pm n \cdot \sigma)/2$. *So all you do is find a Stern-Gerlach magnet and rotate it so its axis is along* n. *(I'm taking my qubit to be associated with the magnetic degree of freedom of a spin 1/2 particle that I can shoot between the poles of the magnet whenever I please. Tricky to do, of course, but not conceptually challenging.)*

Your rejoinder didn't faze me a bit. I just go to that same fine machinist who built your Stern-Gerlach device, and ask him to cut me two very good and very small mirrors, add the tippiest tip of glue to one of them, pass it through a dilute solution of just the right chemicals (so that just the right amount sticks to the glue). Et voila! In THEORY you CAN call such a thing an "atom in a cavity," that allows a $J = 0 \longrightarrow J = 8$ multipole transition (in principle) to be excited by a tenuous beam of light. We then apply a magnetic field and shine some auxiliary lasers in to "check" which of the 17 sublevels was "actually" excited.

I ask the machinist, "Did you feel particularly different when you worked for me than when you worked for Mermin?" He says, "Well you do pay better! But I promise you my prices were set by strictly objective criteria: I had to roam the earth to find that exotic chemical, and believe you me, that machining job was no easy task." I ask him, "Well, did you at least feel particularly quantum?" Just a guess, but I suspect he'll look at me with the same blank stare of the students on page 15 of my draft.

Merminition 25:

> [CAF wrote:] von Neumann didn't know how. He introduced the notion of a "measurement model," enlarged the Hilbert space, and got us into the muddle most of us are still in today. Now, people like Zurek are going around trying to justify the "pointer basis" on von Neumann's ancillary Hilbert space by enlarging it still further (and calling

> it "the environment"). And I'm sure you'll recall that von Neumann himself did even more dastardly things.

I basically agree with all of this but I don't think it has much to do with the question I asked you, which was how to describe on the down-to-earth unphilosophical laboratory (FAPP) level how to set up an experiment whose distinct outcomes correspond to the distinct positive operators. I can think of ways to do it, but if I want to describe them in the language of QM I need a larger Hilbert space to do it. I want to know how to do it in a way that refers only to the original qubit, analogous to what I told you above.

You're just not getting the point. There is no difference in principle, between the machinist's fine work for you and his even finer work for me. But von Neumann, silly von Neumann, invoked extra Hilbert space for both jobs. At least he was consistent. You're not being consistent. What do you think the Stern-Gerlach device is if it's not extra Hilbert space (in the von Neumann view)?

Merminition 26 :

> [CAF wrote:] Let me give you a homework exercise. ...

Again, very nice, but it has nothing to do with what I was asking you.

No, it has everything to do with what you are asking. You're just causing me to drag you in kicking and screaming. The point is: You don't need to invoke physics to make sense of Bayes' rule. A part of the quantum confusion has come about precisely because people have wanted to invoke "physics" to make sense of quantum collapse. It hasn't happened in 75 years, and it's not going to happen now—or at least that's my bet. In your Stern-Gerlach example you explicitly throw away the issue of "where the outcome comes from." (Von Neumann tried to answer that issue but botched it.) But your example is precisely on the right track: you don't need to ask where the outcome comes from for Bayes' rule, and you don't need to ask it for the quantum.

Now I've got to go to lunch, and then try to recover from all the work I did NOT put into the paper today. I hope though that these notes I'm writing you are clearing a little bit of the mud away.

09-06-01 *Nope* (to H. J. Folse)

Folsesm 4 : *I'm less hopeful than you that conferences such as next week's in Växjö will cease — or at least if they do cease it will be because these questions have been answered* **for once and for all**. *I suspect we suffer from the historical delusion that back in the* **old days** *of "classical physics" there was a clear cut conception of what the universe was like and how we had knowledge of it. And what we'd like is a quantum era substitute. But of course a moment of historical realism tells us that back in the old days the philosophical significance of the "***classical*** mechanical conception of the universe" was just as much controversial as is the "***quantum*** mechanical conception of the universe" today. Such questions tend more to get* **outdated** *than answered.*

Nope. I don't believe in "for once and for all" for anything. I'm just looking to clarify quantum mechanics enough so that its foundation stops being a burden to thought. Then we'll be in a position to move on to the next step in physics, with all of the wonderfully mysterious things it entails. Sort of like laying down special relativity, so we'll finally have a fighting chance of discovering general relativity.

I'm still working on the silly NATO paper after all. I've de-ego-ized the introduction quite a bit, and added more discussion on the analogy between Bayes' rule and quantum collapse than I thought I'd have to. But Mermin has been reading it carefully—that's why I made those changes—and though its slowing me down, it's certainly helping the paper. I'll bring a copy of the final to Sweden.

I'm keeping my fingers crossed that the rain will subside on your end of the world.

10-06-01 *Answers* (to N. D. Mermin)

Merminition 27: *Before I torture myself making sure that the converse really holds, I need a little more education in the formalism. [...]*

So I'm putting myself in the place of your student on p. 16 and I'm looking for a simple example where the standard postulate you've dropped doesn't hold, so I can see for myself whether it makes a difference. What could be simpler than the POVM

$$E_b = p(b)I$$

where I is the identity and the $p(b)$ are non negative probabilities that sum to 1. Now I look at your rule for $P(b)$ and it tells me that $P(b) = p(b)$, independent of the density matrix of the system. So I raise my hand and ask why you call that a measurement when it doesn't tell you a damn thing about the system.

You will not say, "Ah, that's because the POVM you picked corresponds to the case where you turn on no interaction between the system and the ancilla, so of course the measurement of the ancilla tells you nothing about the system." You will not say that because (a) the point is to eliminate the ancilla and (b) to say nothing more about "measurement" than is in your table.

My guess is you will say that some POVMS are more informative than others and I have picked a particularly bad one (just as picking I for my observable is a particularly bad choice under the standard rules).

Yes.

Merminition 28: *So then I say, "So there is some figure of merit for POVMs associated with how well their outcomes discriminate among various density matrices for the system? Could it be that the postulate you have dropped is there because it somehow maximizes this figure of merit?"*

There are two ways in which a POVM can be informative. 1) Suppose you have a density operator ρ for a system, and you know that someone else has a density operator ρ_i for that same system—where ρ_i falls within some fixed decomposition of ρ. You just don't know which value of i he happens to be using (outside of some prior probability). Therefore, you perform a measurement in an effort to obtain information about his i: this is the scenario of classical communication. 2) There is no extra player, there is simply ρ. However, you are dissatisfied with how little you can predict of a random measurement in the future, given that very mixed state ρ. So you perform a measurement now, in the hope that you can say more about a random measurement in the future. That is to say, by performing a measurement, you can reduce the mixedness of a state ... and in that sense a measurement can be informative.

Unfortunately, I do not say a lot about 1) in this paper outside of the paragraph you cite below. I do say a lot about 2) though. It sounds like you haven't read through that.

Of course some measurements will be better or worse for each of these tasks. In some examples of 1), you most certainly have cases where NON-vNM POVMs are required. As regards 2), I haven't thought about it enough: i.e. suppose you wanted to changed your mixedness from amount x to amount y. Could you always do that with a sufficiently well-chosen vNM?

Your example of $p(b)I$ is bad for both these tasks. Call it a "measurement" if you will. I keep thinking "intervention" or "act" is better, but I'm not going to change 75 years of ingrained language.

Merminition 29: *Could it be that the postulate you have dropped is there because it somehow maximizes this figure of merit?*

That would be interesting if it were the case. But I don't know of any ways in which it is true.

Merminition 30: *Is there some way to measure the ability of povms to discriminate among all the possible density matrices a system might have which shows that pvms are the most sensitive? Or, conversely, is there some natural measure of discriminatory ability for which a povm that is not a pvm does better. (I seem to remember an example in Peres — possibly even in your paper — where a three outcome povm tells you more about something or other than any possible pvm.)*

Systems don't have density operators; people ascribe density operators. But what you have in mind is 1) above.

Actually, there is at least one more interesting way to think about a POVM as being informative of a density operator. (This way is more conceptual than the two above, however.) The space of Hermitian operators is a d^2 dimensional vector space. It turns out to be possible to find POVMs with precisely d^2 linearly independent elements. For such measurements, the probabilities $P(b) = \mathrm{tr}(\rho E_b)$ uniquely specify ρ. You could of course do the same task by (conceptually) measuring $d+1$ standard observables ... like the three Pauli operators in the $d = 2$ case. But counting the total number of outcomes for this case (and lumping the whole thing into a single POVM if you will), you would have $d^2 + d$ outcomes. Thus there are "minimal informationally complete POVMs" if you move outside the von Neumann paradigm. And that too makes POVMs special over von Neumann ones. (You can read about these kinds of POVMs in our quantum de Finetti paper.)

Merminition 31: *A second question. I'm on page 20, and a student again. My povm has only one outcome (which always occurs, again, independent of the initial density matrix rho). It is just $E_1 = I$. How am I to understand the enormous range of possible final density matrices? This would appear to be a measurement from which I learn nothing. Yet it has an enormous capacity for altering the density matrix, which encapsulates my knowledge. What's going on?*

There are good interventions, and there are bad interventions. For your example $E_1 = I$ there are no ameliorating ways to do it. You can never end up with an increase in the purity of the state describing the system.

Merminition 32: *Your ground rules forbid you to tell me that the enormous range of outputs have to do with the fact that I've turned on an interaction that has entangled the poor system with an arbitrarily chosen ancilla, so of course, if I've paid attention to what I've done to it, the poor density matrix will change even if I subsequently perform no test on the ancilla. But what do you tell me?*

The word intervention really is better than measurement. (Did you read the "Penrose Tiles" section I sent you to?) Some ways I can act on the world now will help me predict the consequences of my actions in the future. Some ways will not. Quantum theory gives us the full range.

12-06-01 *Something I Wrote Once* (to R. Obajtek)

Below is something I wrote a couple of years ago. I reread it this morning. You do understand the implication of the Wheeler quote? It's solely about self-confidence.

Let's just get started on your research project this morning.

> Undergraduate Research and Quantum Information
>
> When I was an undergraduate at The University of Texas I had the opportunity to be associated briefly with the research group of John Archibald Wheeler. Two things about Wheeler's style made a great impression on me. First, he viewed research for both graduates and undergraduates in precisely the same light: It's a frying pan and you've just got to jump into it! It got him results, and it trained a generation of excellent theoretical physicists. The second thing came in a question-answer session at the end of a seminar. Someone in the audience asked, "Do you see a difference between the students at Princeton and the students at UT?" His answer was just as clean and as simple as it should have been, "Yes I do; the students at Princeton *know* they're smart. Next question."
>
> If you want to know my philosophy of how to advise research, then you need go no further than the paragraph above. Great discoveries are waiting to be made at all levels of science. And if there ever was a frying pan to jump into for the undergraduate, it is quantum information. Some of the greatest discoveries of our field have been very literally at the level of a third-year undergraduate quantum mechanics course. There is not a student who has studied Vol. III of *The Feynman Lectures on Physics* who could not have discovered quantum teleportation for himself. There is not a student at that level who could not have discovered the idea behind quantum cryptography. Wonderfully, these are not isolated incidents: there is a sense in which they define what the field is about. The field is about looking at quantum mechanics in a new way and wringing everything we can from it. The only tool a student really needs for a start in quantum information is to *know* that he's smart.
>
> The bulk of present-day research in quantum information is truly an interdisciplinary effort. Take quantum mechanics, computer science, information theory, and linear algebra, put them in a bowl and mix. Because the field is in its infancy, the use of undergraduate-level ingredients from each of those disciplines is far from exhausted. There is just so much fun work to be done; one cannot help but be thankful for the army of eager, questioning undergraduates that will teach their professors so much.

15-06-01 *New Flight, New Letter* (to D. B. L. Baker)

A new flight, a new letter to you, and still none in return since my last. Do you ever read your email anymore? I'm on my way to Växjö—pronounced Vexsher by the Danish but not the Swedes; no English speaker alive can pronounce it like the Swedes—via Stockholm via London. Of course, the flight took off an hour late and now I'm going to have a tight squeeze on my connection.

Do you ever read your email anymore? I'll ask you again: How are things going? How's the little one? Did you get the play area built that you were planning? How's your significant(?) other doing? How's your love life? How's your intellectual life? How's your health? How's the stroke recovery progressing? How's the heat in Texas? How's your mom? How's your sister? How's your niece and nephew? How's the job going? What's the general feeling in Texas since G.W.'s taking office? Does it still upset your stomach? (It does mine.)

Do you ever read your email anymore? Have you tried a new wine lately? Do you have any picks you should tell me about? Have you done any barbecuing in a while? (I wish I had.) Do you ever get to Austin? Have you heard any live music of late? (I wish I had.) Did you get your taxes in on time?

Do you ever write your email anymore? (Did I get you with that one?) Have you heard from Michael D. in a while? (I haven't.) Do you know whatever happened to Terry? Do you know if he really moved to Florida? Do you know why I'm asking you this? (I don't.) Any other gossip of Cuero? Any dreams of ever going to Turkeyfest again? (I don't suppose I have any.)

Do you ever read your email? Are you still driving the same car? (I guess not.) Are you still leasing a car? (I bet so.) Were you hit very hard with the Allison rains? (I suspect not.) Do you ever read your email anymore?

Do you remember the time I backed out of your driveway on French St. and hit a car parked across the street? Do you remember the time you and I went to Port A in your Fiat just after you got it? Do you remember the allure of the Pat Magee shirt? Do you remember the time I met Pat Magee? Do you remember the time we went to Troll Bridge and you beat your head on the roof of your car? (Or was it my car?) Do you remember the time we left Linda Henderson's trunk open in Houston and it rained? Do you remember the time we sat in your car, parked in front of my house, and listened to an interview with Rush? (Or was it my car? And was it Rush?) Do you remember the time we tried to find our way to the beach by following the signal of C-101? Do you remember the time we were going to see Simon and Garfunkel and the hurricane came? Do you remember how eerie it was in Cuero with all the refugees hanging out in the high-school parking lot? Do you remember the blonde-haired girl who kept a diary and whose father worked at Texas Eastern? (I bet you do.) Do you remember the blonde-haired girl at UT orientation that I never had the nerve to talk to? Do you remember Donna Slack? (Is my statute of limitations out yet?) Do you know whatever happened to Wendy G? Do you know whatever happened to the girl that married Warner Scott (briefly)? Or was that Scott Warner? Or Scott Hamilton? Scott Henry! (Didn't I make that mistake before?)

Do you ever read your email!?! Do you remember the wonderful taste of Malt Duck on an early morning cruise? Do you recall why we thought we were the deepest thinkers in Cuero, TX? (Besides it being a small world?) Do you remember the wonderful three day party we had at your house on French St? Do you remember who came? (Do you remember who went?) Do you remember The Nails? Do you remember Debbie D? (Or was that two D's?) Do you remember the time you helped me write a paper for Linda H? Do you still scorn me for getting so many kudos on that?

Do you remember our graduation day? Can you tell I'm going to a quantum foundations conference? Do you remember Craig Calk? (Some things never leave us.) Do you know whether Grunt ever became a dentist? Do you remember the Rudolf christmas special? Do you ever think of the girl you dated at UT? (I can't think of her name right now.) You used to. But do you anymore? And while I'm at it: Do you ever read your email anymore?

Do you miss our old days? When we hadn't grown so far apart? (Read your email every now and then.) Do you ever think of the Cuero Country Club? With Gaye K. and Sheri T? Do you think they could possibly look the same still? Do you ever get to Stubb's BBQ anymore? Do you think life is finite? Or unbounded? Do you remember a time some policeman in Cuero told me I was glassy-eyed and I told him that that was my contact lenses? Do you remember the dry hamburgers you grilled for Kiki and me once? Do you remember the time you came to Montréal? Could you forget the Vampire Lounge?

Dinner time.

Three little wines, each by my doorstep. Swinging sweet song. A melody pure and true . . . Do you ever read your email?

Do you remember our first week at UT? Do you remember the week before that? Do you remember how we drove through the middle of Gonzales the day we left Cuero? Do you remember the night we slept in the lawn of the Methodist Church? Do you remember the Hobo Pack? Do you remember Don Billings? Do you recall the time the cat shit behind your bed and you wouldn't remove the evidence? Do you remember your trip to Alaska with your uncle? Do you remember any Simon and Garfunkel songs from beginning to end? Do you remember the worn circle on the back pocket of Art Garfunkel's jeans in *Concert in the Park*?

Do you remember any Madonna videos? Do you remember what you told me about Rumble Fish? Do you ever read your email anymore? Did you ever understand why I mailed you that menu from a restaurant in Italy? Do you remember the good life? Do you ever think about the Cuero Livestock Show? Do you think Brett Wright's belly is bigger than mine? (You know, he and I share the same birthday.)

Did you know that Laura Lee had no eyebrows? Did you ever notice at the time? Did you have a look at my book on the web? Did you ever pay that outstanding ticket you owed in some county near Houston? Do you still watch Ally McBeal? Dharma and Greg? M*A*S*H? Saturday Night Live?

Do you ever think of Janet Reno's waddle? (Richard Fish does.) Do you still pull evening shifts? Or is it a 9 to 5 job now? Do you still read so much? Do you think "a mind is a terrible thing?" Do you remember the Moulin Rouge? Do you ever wish you could recover it all? All of what? Do you ever get scared when a jet starts bobbing up and down 30,000 feet over the ocean? (I do, and I am now.)

Do you ever think of the Swedish Bikini Team? (Not me.) Do you remember Mad Dog and Beans? Captain Quackenbush's? The Fajita King? Uma Thurman? Conan's Pizza? The GM Steakhouse? The Doll House? Bunk Brantley? Ken Adams? Lisa Adams? The chubby and skinny sisters that lived nearby? Vitalis hair tonic? Caskey Realty? Life on Long Island?

Do you ever download your email? Do you ever play the state lottery? Do you remember the ferry to Port A? And, who could forget Greta? (She was Swedish, wasn't she? Tell me it *is* so.) Do you think there is a god in heaven? Do you think there is a heaven? Do you ever go to church anymore? Do you remember John Hinckley Jr.?

Have you prayed for my sins? Have you ever confessed to yours? Twilight Zone. Brando. Helicopters. Napalm? Frog? American Legion? Deputy Sheriff Bobby Roberts? Charlie's Angels? The Mighty Mightor? Sealab 2020? Moby Dick? Buck Sralla? Can you forget the Thanksgiving morning I knocked on your door? (Or was it the Friday after?) Can you forget the girl from Yorktown? (I don't think you knocked on my door.) Can you remember a life before children? Can you remember Immanuel Kant? Can you remember the Square One? (I just remember Elvis.) And speaking of Elvis, can you remember an Icehouse in Houston, TX? Elvis the Pelvis. You know he had a brother, don't you? Enis.

Do you remember Octogafest? The morning after? The Butthole Surfers? Do you remember the mystical side of Coleto Creek? Do you remember a swim in Fox Crossing? Could you forget the Meyersville Country Club? The graduation party the year before ours? Could you forget Spider Man? Sandy Boehne? (I've forgotten how to spell her name.) Life on Long Island? (Again?) I must know: Do you ever read your email? Can you find the reply button? Is it spiked with needles and pins? Poison tips? Deadly fungus? Fly paper? The scent of a woman?

Do you think there is life on Mars? Do you think there is permanence? Do you think Bill Clinton's hands are big? Is there any connection between a Woody and a woody? (Some things are better left unasked.) Have you ever worn a trench coat in San Francisco? Have you ever read a Ginsberg poem? Can you remember the poutine in Montréal? Are you afraid of fires? Could you forget the Vampire Lounge? (Never!)

Yeah, I did that on purpose. Benny Williams? His mat headed, blonde headed, bicycle riding girlfriend? My crush on her? My obsessive idealism? Your cynical realism? My love of Marx? Your belief in "human nature"? Her name was Kathy—it finally came to me. Do you think the Gonzales girl ever graduated from college? The one you did the skinny dipping with? Do you think Ricky Bluntzer ever amounted to anything?

Do you ever eat chicken fried steak any more? Do you have a clear vision? Do you have clear vision?!?! Do you see the difference? (Pun intended.) Can you answer all these questions? Will you answer all these questions?

Good night old friend,

PS. Do you ever read your email anymore?

25-06-01 *Bohr and Bits* (to H. J. Folse)

It was wonderful to meet you finally. But, my deepest regret of the meeting was in not getting a chance to really talk to you! I think I should dig up a way to drop by Loyola sometime.

I'm in London right now, slowly working my way back home, taking care of some delinquent tasks, and adding some more words to my compendium. So, let me send you a little reminder. When you get back from your vacation, can you send me a more complete copy of the paper:

- H. J. Folse, "The Formal Objectivity of Quantum Mechanical Systems," Dialectica **29**, 127–136 (1975).

Also, if you could supply me with the full list of editors for the volume below (including a description of the needed diacritical marks), that'd be greatly appreciated.

- H. J. Folse, "Realism, Idealism, and Representation in the Description of Nature," in *Avartuva ajatus: Julkaisutoimikunta*, edited by U. Ketvel and ?? (Luonnonfilosofian seuran, Espoo, 1999), pp. 73–77.

I'm shooting to get a completed version of the compendium out before the end of the year.

Also I'm getting much closer to giving you some feedback on all your papers. That should arrive in the form of a longer letter sometime in the coming month. My remark after your talk was a hint of the general difficulty I'm having with your version of Bohr. If I can ask enough testing questions to prod you into trying describe "the quantum postulate" (and a few other things) from a new angle, then maybe I will be filling a useful task.

Caves and I really enjoyed the format of your "Bohr's Best Bits." In particular, the boldface to let us know what you thought was most important, while keeping the remaining text to build a context.

27-06-01 *Gleasons, and Me at AT&T* (to H. Barnum)

Barnumism 1: *I must apologize for still having only skimmed the paper you gave me to read. I really liked the Gleason's theorem for POVMs. I used to think such a thing would be superfluous except for 2D, since we have it for orthonormal frames in 3D and hence, by extension, for POVMs in 3D and higher. The lack of it for the rationals didn't bother me because I always thought the difference between the rationals and the reals is "unphysical." (I think we discussed this business a bit in Los Alamos in the fall of '99, and in fact you guys may have had the theorem by then, and it was part of the discussion.) One would need to use some kind of continuity of states (sets of probability distributions for each possible measurement) in the way we represent them. This would* *impose continuity of frame functions as a requirement, which I think is reasonable despite the fact that Gleason can do without it. Now I never tried to think about what that would do in the rational case (I guess maybe one could define continuity there?). But I think it might well require that frame functions on the rationals extend continuously when the rationals are embedded in the reals.*

Now I think the POVM version is really quite important (just how important, I am still trying to decide). It provides another, perhaps better, way of getting at this sort of issue. The thing is that the unphysicality of the difference between the rationals and the reals is closely related to the idea that we can never measure a true orthonormal frame ... we always measure a fuzzed version of it. All measurements are measurements of POVMs. So, in a sense, what should really be proved is a Gleason's theorem whose proof uses only finite strength (in the terminology of you & Kurt Jacobs) POVMs*. I.e., one which holds for the physical model in which* all *measurements are finite strength POVMs. So one should look at your proof and Busch's and see if they only use finite strength POVMs. (It seems like it ought to be possible to modify them to do so, if not.)*

Yes, it will still work there. The finite strength measurements simply corresponds to the set of POVMs but with the boundary removed.

Barnumism 2: *Here's an interesting idea to explore within the Bayesian/operationalist view of quantum theory. Okay, states are essentially (whatever else they may correspond to) summaries of our knowledge about a system insofar as it's relevant to predictions of future measurement results. Measurements (POVMs) similarly have a subjective aspect: what measurement we think we're performing depends on the "state" (subjective) of the apparatus we start out with, and* our beliefs about *the interaction dynamics, etc ... I think some of that subjectivity is irreducible, in that we won't want to say "well, we didn't know what POVM we were doing, but now we do". We can sometimes* view *some POVMs as "convex" combinations of some others, in a sense such that we learn both which of the sub-POVMs was done, and the result of the sub-POVM. But that, ex ante, is still the original POVM.*

So, the fuzz in a fuzzy measurement results from our incomplete knowledge.

Watch out: you'll start to tweak Carl's greatest fears with this.

27-06-01 *Invitation* (to A. Y. Khrennikov)

Khrennikovism 1: *I also plan to work in the direction of p-adic [Gleason] theorem, but it is not so simple as we discussed ...*

I'm really glad to hear this. More than anything, I would like to get down to the bottom of why this theorem works. It works for the reals, but not the rationals. What crucial new property comes into play there? It also seems to work when the field is the algebraic numbers. So, it is not just having a completion of the rationals that makes it fly. The more examples/counterexamples we have, the more clear the picture will become.

Khrennikovism 2: *I plan to write a paper in that I shall criticize your Bayesian approach to quantum probabilities. But I think it would be not so bad. You could reply and there could be a good exchange of viewpoints.*

In a way I'm glad to hear this too. Every opportunity for a clarification of the crucial issues is a welcome opportunity. One thing I hope you will keep in mind though in building your criticism is that: Even though Caves, Schack and I see no escape from a subjectivist account of quantum probabilities, that does not mean we strive for a subjectivistic account of Nature. The issue is, instead, that quantum mechanics seems to be a jumble of epistemic and ontological entities. The task we see is to disentangle those two aspects of the theory, with the main goal being to lay bare the ontological content. Getting straight the epistemological nature of quantum probabilities—we believe—is the first step toward a greater goal.

I will write you some notes on your context-dependent probabilities before the day is out tomorrow.

28-06-01 *Amherst-Area Visit* (to A. G. Zajonc & K. Jagannathan)

I will be in the Amherst area July 1–3. Would either of you be interested in my dropping by the college for a short visit? (July 2 would probably be the best date for that, but the morning of the third would be OK too.) I could also give an impromptu talk if there's any interest: I've recently been involved in three very foundational theorems that might titillate you. (I'll put a trouble-making abstract below that I wrote recently for a quantum foundations conference.)

> Title:
> Quantum Foundations in the Light of Quantum Information Theory
>
> Abstract:
> In this talk, I hope to cause some good-natured trouble. The issue at stake is when will we ever stop burdening the taxpayer with conferences and workshops devoted—explicitly or implicitly—to the quantum foundations? The suspicion is expressed that no end will be in sight until a means is found to reduce quantum theory to two or three statements of crisp physical (rather than abstract, axiomatic) significance. In this regard, no tool appears to be better calibrated for a direct assault than quantum information theory. Far from being a strained application of the latest fad to a deep-seated problem, this method holds promise precisely because a large part (but not all) of the structure of quantum theory has always concerned information. It is just that the physics community has somehow forgotten this.

28-06-01 *Context Dependent Probability* (to A. Y. Khrennikov)

Khrennikovism 3: *It was nice to meet you in Växjö and discuss fundamental problems of quantum theory. Unfortunately, I have the impression that my presentation on Contextual Probabilistic Interpretation of quantum theory was not so clear for participants (conversations during lunches and dinners). I try to present my views as short and clear as possible.*

Thank you for valuing my opinion on your ideas; I am flattered. So I treated the problem in a conscientious manner: I downloaded and read three of your papers (`quant-ph/0103065`, `0105059`, and `0106073`).

I am indeed quite intrigued by the possibility that quantum mechanics may be nothing more than a calculus for comparing probabilities when the experimental context cannot be deleted from the results it brings about. In vague philosophical terms, I think this is precisely the kind of idea Bohr, Heisenberg, and Pauli were bandying about in constructing their interpretation of quantum mechanics. It is certainly the kind of notion Bohr was trying to get at with his emphasis on "complementarity." So I would welcome a more precise way (a mathematical way) of expressing the essence of all this. I myself have been attracted to this sort of thing for a long time: it is a large part of the thread connecting my "Notes on a Paulian Idea"—that is, that the observer sets the context, and, in the words of Pauli, cannot be "detached" from what he finds. Also you can find discussions of it in Sections 4 and 8 of the large paper I was circulating at the conference, "Quantum Foundations in the Light of Quantum Information." I say all this to make it clear that I am more than sympathetic to your program.

However, as much as I would like to tell you otherwise (because you are my friend), I do not see that your present formulation of the problem moves very far toward quantum mechanics in a convincing way. There are problems on at least two levels.

Maybe the most devastating and immediate is your move between Eqs. (5) and (6) of `quant-ph/0106073`. (I'll focus on that paper for specificity since I did not see you make a stronger argument in either of the other two papers.) You write:

> The perturbation term $\delta(\mathcal{S},\mathcal{S}')$ depends on absolute magnitudes of probabilities. It would be natural to introduce normalized coefficient of the context transition ...

The question anyone will ask is, "Why is this natural?" What compels the precise form of the normalization other than that it forces the equation to look of a more quantum mechanical form. Why did you choose the square root rather than the third root, say? Indeed, why not divide by the absolute value of δ, or the exponential of δ, or any other combination of functions one could pull out of a hat? To put it not so gently, it looks as if you built the desired answer in at the outset, with little justification otherwise.

The second level of my problem is that, even if you do get this far, how do you make the further step to vector space representations of quantum mechanics? Why are observables POVMs and not other exotic entities? What leads us to the starting point of Gleason's theorem? Etc., etc.? I don't see that you have enough structure to do that. But more importantly, until you have done that I would have to say that your theory remains fairly empty in making a connection to quantum mechanics. Too empty.

The way I view the problem presently is that, indeed, quantum theory is a theory of contextual probabilities. This much we agree on: within each context, quantum probabilities are nothing more than standard Kolmogorovian probabilities. But the contexts are set by the structure of the Positive Operator-Valued Measures: one experimental context, one POVM. The glue that pastes the POVMs together into a unified Hilbert space is Gleason's "noncontextuality assumption": where two POVMs overlap, the probability assignments for those outcomes must not depend upon the context. Putting those two ideas together, one derives the structure of the quantum state. The quantum state (uniquely) specifies a *compendium* of probabilities, one for each context. And thus there are transformation rules for deriving probabilities in one context from another. This has the flavor of your program. But getting to that starting point from more general considerations—as you would like to do (I think)—is the challenge I haven't yet seen fulfilled.

I very much hope that I have not offended you with these comments. I greatly respect your program. But because of that I want much from it. I want it to stretch our understanding. John Wheeler used to say, "We must make as many mistakes as we can, as fast as we can, or we'll never have a hope of gaining a true understanding!" I let that philosophy rule my research life. Thus I can only commend you for your exploration, and hold the strongest hope that something firm will come from it with a little more work and contemplation.

28-06-01 *The Oblique Observer* (to N. D. Mermin)

You haunt me so that I wake up in the middle of the night just to spar with you. It's this damned noncontextuality of quantum probabilities. If one walks into the game with the *firm* belief that a quantum state is a state of knowledge, then noncontextuality is almost a given. That, in part, is what my section "Whither Bayes' Rule?" is about. Moreover, all questions about instantaneous signaling through quantum-state change just become silly: such questions spring solely from a wrong-headed view.

But, you do not walk into this game with the firm belief that a quantum state is a state of knowledge. So I am forced to work to win your approval. In the end, with clarity achieved, your demands will have been a great gift. Right now, they are just annoying.

In any case, this leads me down the path of the oblique observer. There is a way in which a von Neumann-like view of measurement may be a virtue. That is, a view of measurement where, to make it go, I first introduce an ancilla to interact with the system. Then I introduce a second ancilla to interact with the first ancilla because I didn't know how to solve the measurement problem at the new level. Then I introduce a third ancilla, and so forth. Von Neumann went to this extreme because he was chicken to let the mental update that is a measurement fall outside of physics (as Thomas Bayes would have). So, he piled up superobserver after superobserver, just so there would always be an outside view. But so be it: Let us glean what we can from this freedom of our descriptions.

The main point is this: You pick any measurement (any POVM) you wish for some system, and I can always think of a way to get at that measurement in an indirect way. That is to say, I can always delay my cutting of the Gordian knot until I get to a system with no residual causal link to the one I'm really interested in. In language I don't like, it means I can always induce the "physical collapse" somewhere else. I can always push the measurement to an arena where you would take the noncontextuality assumption (on the system of interest) as a given. My direct measurement on an ancilla serves only to refine my knowledge about the actual system: the actual system cannot care how I came to that refinement, or, indeed, if I ever pursued refining my knowledge at all.

You get my point—with that much repetition, you'd better. This gives rise to a vague idea that perhaps you can help me elicit into reality. (And save me some torture that you are the root of.) Forgetting about the precise structure of quantum mechanics, why should we not view all observations as oblique observations? Whose philosophy ever dreamt that we had *direct* access to the minutest details of the world in the first place? (I'll paste in the great Heisenberg/Einstein quote below so you'll have quick access in case you wish to remind yourself of it—especially the fourth, fifth, and sixth sentences.)

Moreover, coming back to quantum mechanics in particular, what is to keep me (in my derivation of the tensor product rule) from thinking of the two separate observations as each concerning the opposite system? The question is, can one get some quantitative mileage from this. At least that's the question on my mind as the sun is rising. Any thoughts?

It's a good thing you left the Växjö before Friday's lunch. The boiled potatoes were ridden with rocks: I lost an eighth of a molar in the process! What was your overall impression of the meeting (good and bad)?

28-06-01 *The Kettle Black* (to N. D. Mermin)

I'm just reading through a friend's comments on my NATO draft. Just after my equations 65–67, where I write, "The resemblance between the process in Eq. (66) and the classical Bayes' rule of Eq. (38) is unmistakable," he writes: "Seems to me contrived — you want to find a resemblance and then you find it."

Thinking back to one of his recent productions, I think "Boy, that's the pot calling the kettle black!"

But aside from that, I do seem to be impressing less people with this result than I would have thought. Is it my presentation, or is it really the substance? This result, in particular, is the one I'm most pleased with in the paper, but it gets the coldest reception. You've never yet told me your truest thoughts on that section. I'd like to hear them.

29-06-01 *Alex Favor* (to D. R. Terno)

I wonder if I might ask a favor of Alex. Could you ask her if she would be willing to type in the linguistic analyses she made at the Växjö meeting? She thrilled me to no end by telling me how consistent my language patterns were in my talk. (Consistency is what I'm striving for!) Most importantly, I'd like to see how some of the other attendees fared in this regard. (I'm always willing to learn by others' mistakes!)

29-06-01 *Opinion* (to S. J. van Enk)

Do you have an opinion on this as my abstract for the NATO paper on `quant-ph`? I'll drop by your office in a little bit.

> This paper reports three almost trivial theorems that nevertheless appear to have significant import for quantum foundations studies. 1) A Gleason-like derivation of the quantum probability law, but based on the positive operator-valued measures as the basic notion of measurement (see also Busch, `quant-ph/9909073`). This theorem works both for 2-dimensional vector spaces and for vector spaces over the rational numbers (where the standard Gleason theorem fails). 2) A way of rewriting the quantum collapse rule so that it looks almost precisely identical to Bayes' rule for updating probabilities in classical probability theory. And 3) a derivation of the tensor-product rule for combining quantum systems (and with it the very notion of quantum entanglement) from Gleason-like considerations for local measurements and classical communication on bipartite systems.

02-07-01 *Objective Properties* (to D. G. Chakalov)

Thank you for all the interest you've shown in the papers I have been involved with. I commend you in your efforts to get to the bottom of what's going on in our world. But I cannot believe it very likely that distinct new kinds of *physics* arise in our brain processes. Instead the road I have chosen to develop is making sense of quantum mechanics (as a theory predominantly of inference) from *within* quantum mechanics. I understand that your road is distinct: but life is short, and one has to make a cut or one will certainly never get anywhere. My own direction may turn out to be completely wrong, but I have decided to pursue it with dogged determination and not to get derailed.

I wish you luck in your own pursuits.

02-07-01 *Making Good Sense* (to J. Finkelstein)

Finkelsteinism 1: *I enjoyed reading your latest "quantum states are states of knowledge" manifesto,* `quant-ph/0106133`*. I do have sympathy for that point of view, but I would like to put my two-cents-worth in by remarking that it is not quite fair to imply that experimental results such as those of Scarini et al. which you cite furnish ADDITIONAL support for it. ...*

It is certainly important to confirm the standard quantum predictions under as wide a set of circumstances as possible, but that confirmation does not distinguish between alternative interpretations all of which agree with the prediction. For example, neither I nor (I believe) you are advocates of the many-worlds interpretation. But some folks are, and those folks would have expected Scarini, Zbinden, Gisin etc to have found exactly the results that they did find. Therefore I would say that the many-worlds interpretation has the same (small) degree of plausibility after these experiments as it did before.

Would you agree?

Thanks for the note! Yes, I guess I would (though only to the small extent that I think many-worlds is coherent in the first place). But there are two things working in the background. 1) Probably plain sloppiness on our part in our wording. And 2) the fact that Rüdiger is (presently) more conciliatory to MWI than Carl and I are. He sees Bayesian probability as holding a place even in their interpretation. (A rough cartoon is: In their interpretation, the universal wave function serves an ontologic role, while the relative states in a Schmidt decomposition with respect to an observer's mind serve the same epistemic role we ascribe to them.) We should probably either remedy 1) or make 2) more clear, or both. We'll have to huddle for that.

Finkelsteinism 2: *(And also by pointing out that the experiment with detectors in relative motion was reported in Zbinden et al. (*`quant-ph/0007009`*), rather than in your ref. 2.)*

That's probably my screw-up: I just assumed (from a search through SciSearch) that Ref. 2 was the published version of Zbinden *et al.* I presume you're telling me it's not. Is there some history here that we should be aware of? Or a different published reference?

Finkelsteinism 3: *I enjoyed reading your latest "quantum states are states of knowledge" manifesto ...*

And there's still another one coming: it should have appeared on `quant-ph` today. I hope you'll read it too. This one's a solo flight by me (titled "Quantum Foundations in the Light of Quantum Information"). (BTW: Don't let the sober sounding abstract on `quant-ph` fool you; I'm as loquacious and philosophical as usual on the inside.)

Jerry's Reply

My understanding of the history is as follows:

1. H. Zbinden, J. Brendel, W. Tittel, and N. Gisin, `quant-ph/0002031` and *Pramana-Journal of Physics* **56**, 349 (2001) [two somewhat different papers] discuss the results with moving detectors, and also claim the lower limit on the velocity of 10^7c.
2. A more detailed version of the above is H. Zbinden, J. Brendel, N. Gisin, and W. Tittel (note permuted authors), `quant-ph/0007009`, published as *Phys. Rev. A.* **63**, 022111 (2001).

3. The paper you cite (*Phys. Lett. A* **276**, 1 (2000)) is the published version of V. Scarini, W. Tittel, H. Zbinden, and N. Gisin, `quant-ph/0007008`. Here they consider the velocity in the frame of the cosmic microwave background, and claim a lower limit of (only!) $1.5\times10^4 c$.

02-07-01 *quant-ph/0106133* (to R. Schack)

I would only temper what you just said by making one addition:

Schackcosm 1: *Actually, I believe that the relative state an observer in some branch of a multiverse* [has no choice but to assign] *to, say, a qubit has a very natural interpretation as a state of knowledge.*

The lack of free choice is important there, and to that extent the whole scheme is non-Bayesian. Bayesian probabilities are never fixed by edict. In a way, this is just a fancy version of David Lewis's principal principle.

Top of the mornin',

03-07-01 *Epistemic Probabilities and Zing* (to U. Mohrhoff)

I have just started to read your new paper.

Mohrhoffism 1: *Epistemic interpretations of quantum mechanics fail to address the puzzle posed by the occurrence of probabilities in a fundamental physical theory. This is a puzzle about the physical world, not a puzzle about our relation to the physical world.*

I would appreciate hearing any thoughts you might have on my own newest: `quant-ph/0106166`. In particular, whether you think the ideas (or the research direction) supported there might temper your statement above? In a sense, it was written with precisely that purpose in mind.

04-07-01 *Carts and Horses* (to U. Mohrhoff)

Mohrhoffism 2: *I hate to dash your hopes ...*

Your pet idea that quantum information theory holds the key to the mother of all mysteries is understandable, you being a quantum information theorist, but it reminds me of something someone wrote about the father of all mysteries, consciousness. Everyone concerned with it (neuroscientists, psychologists, philosophers, AI-ers, etc) thinks that his/her particular field holds the key, so a baker would think that the secret of consciousness lies in the éclair. What would a baker think about the puzzle posed by the occurrence of probabilities in a fundamental physical theory?

You confuse the cart with the horse. I was attracted to a career in quantum information—and it can be documented—precisely because I had wanted to express quantum foundations problems in information theoretic terms all along. This was a process that started long before your publicational record and, indeed, long before Shor's factoring algorithm. But, you say what you did because it is the easy thing to say.

I will read and remark on your papers in due time, despite A) your arrogance, and B) the offensiveness of your letter. If there is something in your ideas, then it will be worthy of note regardless of its source.

[But see 16-07-01 note "Insults" to S. J. van Enk.]

04-07-01 *Invitation, 2* (to A. Y. Khrennikov)

Khrennikovism 4: *Yes, this is very well! However, for me, the only bridge between "reality" and our subjective description is given by relative frequencies . . .*

But there other ways to make the bridge: this is what gambling situations (like the Dutch-book argument that Schack spoke about) are about. They give a NON-frequency *operational* definition to probabilities. Subjective probabilities make their *objective* mark on the world by specifying how an agent should act when confronted with them.

04-07-01 *Context Dependent Probability, 2* (to A. Y. Khrennikov)

Khrennikovism 5: *P.S. But! How can you unify contextuality with subjective probability?*

I just don't see this as a problem. In choosing one experiment over another, I choose one context over another. The experiment elicits the world to do something. To say that the world is indeterministic means simply that I cannot predict with certainty what it will do in response to my action. Instead, I say what I can in the form of a probability assignment. My probability assignment comes about from the information available to me (how the system reacted in other contexts, etc., etc.). Similarly for you, even though your information may not be the same as mine. The OBJECTIVE content of the probability assignment comes from the fact that NO ONE can make *tighter* predictions for the outcomes of experiments than specified by the quantum mechanical laws. Or to say it still another way, it is the very existence of transformation RULES from one context to another that expresses an objective content for the theory. Those rules apply to me as well as to you, even though our probability assignments WITHIN each context may be completely different (because they are subjective). But, if one of us follows the proper transformation rules—the quantum rules—for going to one context from another, while the other of us does not, then one of us will be able to take advantage of the other in a gambling match. The one of us that ignores the structure of the world will be bitten by it!

04-07-01 *Gleason* (to A. Y. Khrennikov)

I still need to answer your question about Gleason. You can read about the POVM version of it in the section "Information About What?" of my new paper "Quantum Foundations in the Light of Quantum Information". But then the better places to look are the papers by Cooke, Keane, and Moran cited there, and also the paper by Pitowsky. It is those versions of the Gleason theorem that I am particularly interested in, in connection to the question of p-adic numbers.

04-07-01 *Book Reminder* (to the Los Alamos Historical Society)

Kiki and I thank the Historical Society for their kind offer. Our time in Los Alamos and our loss of everything material is something the family will have to reckon with for another generation: there will be no getting around explaining the fire to our two children.

Please send the books to our new home address below.

05-07-01 *Standing Up and Saying YES* (to J. Finkelstein)

Thanks for the comments. I welcome any that you send me!

Finkelsteinism 4: *This is not really any objection to what you have written, but the story you tell on page 10 might produce even WEAKER knees with the following modification: Suppose that Alice, instead of choosing ANY state $|\psi\rangle$ for her qubit, makes her choice from a finite and previously-agreed-upon set. She broadcasts the result of her measurement, but keeps her choice a secret, except that she reveals her choice in a sealed envelope which she sends to Chris (who initially leaves it sealed). Bob performs the appropriate Pauli rotation, then he makes a guess as to which state Alice chose, and performs a yes-no measurement with that guess; he communicates his guess, as well as the yes-no result, to Chris.*

Chris can now open the sealed envelope; if it happens that Bob's guess was in fact correct, then the result must have been "yes". So, if one wanted to be contrary (and of course I do not) one might say that, although when the yes-no measurement was performed nobody knew that the guess was correct, and although Alice did not "take the time to ... interact with it", nevertheless the qubit had "the power to stand up and say YES all by itself".

I agree, this does sound even more dramatic. And maybe I will start using it in my presentations. But the point remains the same: it is Bob's action that elicits a consequence.

You can see, I keep dreaming (modern) alchemical thoughts. Below. From: W. Heisenberg, "Wolfgang Pauli's Philosophical Outlook," in his book *Across the Frontiers*, translated by P. Heath, (Harper & Row, New York, 1974), pp. 30–38.

> The elaboration of Plato's thought had led, in neo-Platonism and Christianity, to a position where matter was characterized as void of Ideas. Hence, since the intelligible was identical with the good, matter was identified as evil. But in the new science the world-soul was finally replaced by the abstract mathematical law of nature. Against this one-sidedly spiritualizing tendency the alchemistical philosophy, championed here by Fludd, represents a certain counterpoise. In the alchemistic view "there dwells in matter a spirit awaiting release. The alchemist in his laboratory is constantly involved in nature's course, in such wise that the real or supposed chemical reactions in the retort are mystically identified with the psychic processes in himself, and are called by the same names. The release of the substance by the man who transmutes it, which culminates in the production of the philosopher's stone, is seen by the alchemist, in light of the mystical correspondence of macrocosmos and microcosmos, as identical with the saving transformation of the man by the work, which succeeds only 'Deo concedente.'"

> The governing symbol for this magical view of nature is the quaternary number, the so-called "tetractys" of the Pythagoreans, which is put together out of two polarities. The division is correlated with the dark side of the world (matter, the Devil), and the magical view of nature also embraces this dark region.

and

> When, in the spring of 1927, opinions on the interpretation of quantum mechanics were taking on rational shape and Bohr was forging the concept of complementarity, Pauli was one of the first physicists to decide unreservedly for the new possibility of interpretation. The characteristic feature of this interpretation—namely, that in every experiment, every incursion into nature, we have the choice of which aspect of nature we want to make visible, but that we simultaneously must sacrifice, in that we must forego other such aspects—this coupling of "choice and sacrifice," proved spontaneously congenial to Pauli's philosophical outlook. In the center of his philosophical thinking here there was always the wish for a unitary understanding of the world, a unity incorporating the tension of opposites, and he hailed the interpretation of quantum theory as a new way of thinking, in which the unity can perhaps be more easily expressed than before. In the alchemistic philosophy, he had been captivated by the attempt to speak of material and psychical processes in the same language. Pauli came to think that in the abstract territory traversed by modern atomic physics and modern psychology such a language could once more be attempted . . .

05-07-01 *Invitation, 3* (to A. Y. Khrennikov)

Khrennikovism 6 : *I think that there is some mystification in such a direct use of subjective probabilities. Do you really believe that you choose probabilities in gambling situation by your personal belief? I think you (and everybody) do in the following way: you have some experience with gambling (frequency!) and use this experience to introduce "subjective" probabilities.*

No, I think it is just the opposite: people almost never use frequency data as the determiners of their information in any common situation. Instead they use symmetry. If someone presents me with a coin that I have never seen before, then after a quick examination, I will likely *ascribe* a 50/50 probability to its coming up heads *simply* because I have no reason to believe otherwise. But if Danny Greenberger is the tosser of it, I know that he has the skill to make it look superficially as if it were being tossed in a haphazard fashion but it will still come up heads every time. The 50/50 ascription is not a property of the coin! It is simply a property of ignorance.

05-07-01 *QIC010531 (fwd)* (to S. J. van Enk)

van Enkism 2 : *I really get irritated by report I, you?*

Yes. We should probably just tackle it head on, pointing out how it is irrelevant.

Let me share some of my recent insults to cheer you up. Below is a letter I sent yesterday and for which I received profuse apologies today. What really annoyed me was that he insulted me for 24 kilobytes worth of email (in front of Peres and Mermin), and then at the end of it, had the audacity to say, "I trust you will find that we are striking consonant chords." So, I decided to strike *his* chords.

05-07-01 *Par Avion* (to H. J. Bernstein)

I just received your phone reimbursement. Thanks!

And thanks for coming by Charlie's the other day. What I really need to do the next time I come up, is just spend a day visiting you and visiting ISIS. Would you guys like to hear a talk from me? In fact, Kiki and I didn't get nearly as much (book) shopping time in as we had hoped to (mostly because of my Hirota duties): So, we might just come for another visit very soon. We'd probably just stay in a hotel in Amherst or Northampton or something to maximize our free time. What's your summer schedule like? What might be a good time for us to visit?

Charlie dismays me at times, calling my efforts to clean up quantum mechanics "theology." Strangely, it does hurt—I guess because I respect him so much. For instance, I doubt he'll even look at my latest paper just because he doesn't like the goal I have in mind. But there are some meaty theorems there that he might find useful . . . if he wouldn't just shut himself off to my trains of thought. Getting something like this from Holevo maybe makes it even harder:

> I downloaded your recent `quant-ph/0106166`. It has several interesting observations, but I like particularly the argument concerning derivation of tensor product of Hilbert spaces from the measurement statistics.

There are two great information theorists in my life, but only one of them will read my papers.

06-07-01 *Stamina!* (to S. Aaronson)

Thanks for the note! I'll give you a longer reply later. But in the mean time:

Aaronsonism 1 : *Anyway, I finished (!!!) "Notes on a Paulian Idea." Your shamelessness in mixing quantum physics, philosophy, and your personal life is an inspiration; maybe it will encourage other scientists to try something similar.*

Am I to take this to mean that you actually read the whole thing? If so, I'm shocked! I never imagined anybody would read the whole thing.

Scott's Preply, "Notes on a Preskillian Meeting"

> Remember me from Bell Labs? I'm at Caltech now, and tonight was at Preskill's group meeting where Andrew Landahl spoke on your "Quantum Foundations" paper. I thought you might want to know some highlights.
>
> - We took a vote on whether humans have free will or are mere machines. Machines won, 7-5.
> - Preskill defended the view that one can be an Everettista and still agree with most of your thesis that quantum states are states of knowledge. I think his argument was that wavefunctions are indeed mathematical constructs, but we can use them to describe those "branches of the multiverse" that interest us.
> - Andrew presented an imaginary dialogue in which he and Einstein chide you for holding that interventions in the world just tell us about the likely results of further interventions (I don't know if that's your position). Preskill said to Andrew, "you and Einstein certainly hit it off!"
> - Andrew expressed concern for your daughter, after quoting the comment that she has no theory of measurement.

Anyway, I finished (!!!) "Notes on a Paulian Idea." Your shamelessness in mixing quantum physics, philosophy, and your personal life is an inspiration; maybe it will encourage other scientists to try something similar.

I was struck by the recurrent question, why complex Hilbert spaces and not real (or quaternionic) ones? Someone ought to write a semipopular article about this issue. It seems analogous to asking why space has 3 visible dimensions and not 2 or 4, as opposed to the dozens of more nebulous questions one could ask about space.

Do you know of an argument for complex Hilbert spaces that doesn't rely on dimension-counting under tensor products (i.e. the Goldilocks Principle)? What about this: if we think time is continuous, then for all operations U, there should exist a V such that $V^2 = U$. Let U be a phase flip; then V must involve complexes.

The obvious objection is, why are phase flips possible? For example, in real quantum mechanics with arbitrary rotations but no phase flips, every operation does have a real square root. One response is that a phase flip in n dimensions can always be simulated by a rotation in $n+1$ dimensions. But since this rotation maps the n-dimensional subspace onto itself, it must (we can declare!) have a square root that also maps the subspace onto itself. That forces us to complex numbers.

It's 5AM and I'm going to sleep.

Scott's Reply

[**Chris said:**] "Am I to take this to mean that you actually read the whole thing?"

Well, I skipped some repetitive parts and extended quotations, but besides that yes. I think if condensed to, say, the best 200 pages, it would be worth publishing as a book. The jacket could say, "Just like *The Fabric of Reality* by David Deutsch ... except antithetical in its philosophical stance, and funnier!"

09-07-01 *Quantum Optics, San Feliu* (to K. Mølmer)

I just got a quote for a flight from Newark to Barcelona. It was $1182 (including taxes, etc.). That comes to about 1394 euros.

Mølmerism 1: *P.S. I started reading some of your letters in the compilation that you put on* `quant-ph`. *At first I thought: what a nut case, thinking that anybody should take an interest in such stuff, but after reading a bit, I got really impressed, and now I only regret that life is too short to read both your letters and William James. As a comment to Mermin's preface: I also had the kind of nice feeling long time after having read his paper that you describe.*

Thanks for the soothing words about the samizdat. I've gotten a lot of nice reactions (from about 25 people). My very best PRL in contrast maybe got 2! So, in the end, it has seemed worth it.

09-07-01 *The O'bleak Observer* (to N. D. Mermin)

Merminition 33: *You should not dismiss my feeling that you've not adequately justified your assumption about noncontextuality as merely a manifestation of a regretable atavistic tendency to reify the quantum state.*

The "oblique observer" note was a concession, not a dismission. It is evidence that I am taking your point very seriously (even though I'd rather being out playing with the other kids).

Merminition 34: *The question you're evading is what it means for one and the same positive operator E to appear in many different POVMS.*

No, I don't think I'm evading it. It means that those various interventions or ways of gathering data—those POVMs—physically diverse though they may be—all lead to at least one common possibility for what my knowledge can be updated to (modulo the unitary readjustment).

09-07-01 *More O'bleakness* (to N. D. Mermin)

Merminition 35:

> CAF Said: Moreover, all questions about instantaneous signaling through quantum-state change just become silly: such questions spring solely from a wrong-headed view.

No! The signalling has nothing to do with quantum-state change. (We've been through this before.) If Bob and Alice share a large number of identically prepared pairs, then a very reasonable requirement is that the statistical distribution of outcomes Bob gets from his members of the pairs cannot depend on what Alice chooses to do to her members. (If it did Alice could send useable unmediated signals to Bob.) Again, this has nothing to do with how you like to think about probabilities or quantum states. I offered this to you as an example of a situation in which you can, in fact, justify the non-contextuality of certain probabilities by appealing to an independent physical requirement (no remote signalling).

I hold firm in my opinion. It has *everything* to do with how you like to think about (quantum) probabilities. If you think the probabilities are subjective expectations for the local consequences of one's experimental interventions, then the question never arises.

However, granting you a little distrust for that, the point about oblique observations is that one might always be able to think of a quantum measurement as being enacted on a system other than the intended one. This would give your point above a natural means for being used to justify noncontextuality for *all* quantum measurements.

Again, I'm starting to feel awfully comfortable with noncontextuality as the very simplest generalization of Bayes' noncontextuality. It is the very glue that puts measurement outcomes into Hilbert space in the first place. (Otherwise we might just draw out an exhaustive list of one-outcomed, two-outcomed, three-outcomed measurements etc., etc., and never even suppose a connection between them.) But I offer the above as an effort to go in the direction you want me to.

10-07-01 $V^2 = U$ (to S. Aaronson)

Aaronsonism 2: *Do you know of an argument for complex Hilbert spaces that doesn't rely on dimension-counting under tensor products (i.e. the Goldilocks Principle)? What about this: if we think time is continuous, then for all operations U, there should exist a V such that $V^2 = U$. Let U be a phase flip; then V must involve complexes.*

I have heard some arguments not based on dimension counting. Go to Adler's book[13] and Wheeler's paper[14], both referenced on page 125 of the samizdat.

1. In the first case it is that the generators of unitary time evolution cannot then be observables.
2. In the second case it is that uniform distributions of pure states only lead to uniform distributions on the probability simplex of a fixed observable in the complex H space case.

Your argument is new to me. It might be worth writing it up properly if some reference in Adler's book hasn't yet discussed it.

Thanks again for the note on John's meeting. (And reading the samizdat!)

10-07-01 *My Recent Foundations Posting* (to J. D. Malley)

Thank you for your pleasant letter. Indeed, good hearing from you again: I trace that my last email from you was in 1996 when you were reading my PhD thesis.

I've gotten a lot of good feedback on this paper.

I checked out the Geisser book as soon as I got your letter. His attitude to parameter estimation is particularly relevant for a debate Carl Caves and I are embroiled in presently. And he raises some points similar to ones I've heard from Rüdiger Schack. So, that was a very useful reference.

Let me reply briefly to your comments.

With regard to (1), this can be posed in a purely Bayesian way through use of the "quantum de Finetti representation theorem." Maybe my description of it was too brief in the present paper. You can find a significantly longer elaboration of it in my paper with Caves and Schack, `quant-ph/0104088`.

With regard to (2), yes, true enough. But there is definitely a quantum analogue—a noncommutative analogue—to it if one only uses conditional states of knowledge (never joint). That is what my "Whither Bayes' Rule?" section is about.

With regard to (3), agreed. (This, in large part, is my present debate with Caves . . . but in the specific context of "unknown Hamiltonians.")

With regard to (4), I'm not sure I understand this. If you're suggesting that my point of view on the quantum foundations will be more interesting if it suggests some new experiments, then I most certainly agree. Unfortunately, I'm not there yet.

Jim's Preply

> Thanks for the thoroughly enjoyable and very readable account of your take on quantum foundations and its connections with information theory (e.g. `quant-ph/0106166`, 29 Jun 2001).
>
> I thought you might find it interesting to learn that your essential ideas have, it would seem to me, been the subject of much research in the statistical community for many years, though not with quantum things in mind. Specifically, there is a school of thinking which argues that as parameters in a model are generally not observable, they therefore should not be the focus of statistical inference. Instead, it is argued that making predictions should be the real purpose of inference, and to this end one should use Bayes' theorem to construct the "predictive posterior distribution." I think

[13] S. L. Adler, *Quaternionic Quantum Mechanics and Quantum Fields*, (Oxford University Press, 1995).

[14] J. A. Wheeler, "The Computer and the Universe" *International Journal of Theoretical Physics* **21**(6/7), 557–72 (1982).

this strategy accords quite well with the quantum foundations argument you're making under your imprimatur.

Prominent among those making this argument has been Seymour Geisser at the U. of Minnesota (`geisser@stat.umn.edu`). See for example, his textbook

- S. Geisser (1993), *Predictive Inference: An Introduction* (Chapman & Hall).

As background for predictive inference in a more general context you could consult

- A. H. Welsh (1996), *Aspects of Statistical Inference* (Wiley); see pp. 34–35.
- B. P. Carlin and T. A. Louis (2000), *Bayes and Empirical Bayes Methods for Data Analysis* (2nd edition) (Chapman & Hall); see pp. 20–21.

Finally I'd like to add four, small comments:

(1) given an unlimited amount of data (or, take a limit as sample size increases) the density operator is known with arbitrary accuracy, so in this sense is, finally, itself observed;

(2) use of Bayes theorem in any quantum setting is often a slippery business, since its rigorous derivation requires joint distributions for all observables: the events A and B that are outcomes in an experiment, and from which one constructs conditional probability $Pr(A|B)$, does not lead to a valid Bayes theorem unless the observables commute.

(3) it is not clear to me that the predictive posterior ever leads to any inference that is unique to its formulation—any inference obtained about parameters in a model can be considered as useful intermediates to prediction.

(4) any change in emphasis or construal of the quantum primitives has greatest interest only when new experiments are suggested, and the predictive posterior does not in itself suggest new experiments.

Again, thanks for the well-written and nicely organized discussion of this important topic.

10-07-01 *Replies on a Preskillian Meeting* (to A. J. Landahl)

Wow, what a set of notes! Thank you all for the interest in my silly efforts. This is a little unexpected.

Landahlism 1: *The talk was a smash. It went much better than I was expecting, causing much discussion. (As you know, some of the people in our group are rather reticent, so that's really saying something.)*

I am so glad to hear that. It is really very flattering.

Landahlism 2: *At the end of the talk, Sumit decided to go up to the chalkboard and take a poll, the topic and results of which I'll leave as a surprise, as I imagine John will tell you about them himself. (If he doesn't, just e-mail me back and I'll let you know.)*

I presume this is the poll Scott mentioned. I'll say more about that later.

Landahlism 3: *I also mentioned your program to establish an information-theoretic foundation for all the laws of quantum mechanics (and physics?) in this section. This proposal met with much skepticism from the audience. I'm somewhat sympathetic to your cause (certainly more so than some of our denizens!), but I don't believe that all of physics has an information theoretic description. For example, where would the (dimensionful) physical constants enter into this scheme (like Planck's constant and the speed of light)? I don't see how they could enter unless they define what physical dimensions are, which is rather peculiar.*

I really am very flattered by all this attention, but I do get dismayed when I can't seem to get the most important point across to my readers. Even sympathetic readers! Because of this, I have spent months and months trying to clarify and refine my presentation. But for some reason it is amazingly difficult to get the point across. At the very least I need people to understand what I want *before* they declare that they disagree with it. (Disagreeing with it would *then* be fair enough.) The sentences above seem to convey that you haven't gotten to the level of understanding what I want. How can the following sentences be consistent with what you say above?

1. Abstract, penultimate sentence.

   This method holds promise precisely because a large part (but not all) of the structure of quantum theory has always concerned information.

2. Section 1, last paragraph.

   Our foremost task should be to go to each and every axiom of quantum theory and give it an information theoretic justification if we can. Only when we are finished picking off all the terms (or combinations of terms) that can be interpreted as information—subjective information—will we be in a position to make real progress. The raw distillate that is left behind, miniscule though it may be, will be our first glimpse of what quantum mechanics is trying to tell us about nature itself.

3. Section 2, last paragraph.

   The world is sensitive to our touch. ... The whole structure of quantum mechanics—*it is speculated*—may be nothing more than the optimal method of reasoning and processing information in the light of such a fundamental (wonderful) sensitivity.

4. Section 3, penultimate paragraph, page 9.

   The complete disconnectedness of the quantum-state change rule from anything to do with spacetime considerations is telling us something deep: The quantum state is information. Subjective, incomplete information. Put in the right mindset, this is *not* so intolerable. It is a statement about our world. There is something about the world that keeps us from ever getting more information than can be captured through the formal structure of quantum mechanics. Einstein had wanted us to look further—to find out how the incomplete information could be completed—but perhaps the real question is, "Why can it *not* be completed?"

5. Section 5, last two paragraphs.

   Perhaps the structure of the theory denotes the optimal way to reason and make decisions in light of *some* fundamental situation, waiting to be ferreted out in a more satisfactory fashion.

   This much we know: That "fundamental situation"—whatever it is—must be an ingredient Bayesian probability theory does not have. There must be something to drive a wedge between the two theories. Probability theory alone is too general of a structure. Narrowing it will require input from the world about us.

6. Section 7, last two paragraphs.

   The quantum de Finetti theorem shows that the essence of quantum-state tomography is not in revealing an "element of reality" but in deriving that various agents (who agree some minimal amount) can come to agreement in their ultimate quantum-state assignments. This is not the same thing as the stronger statement that "reality does not exist." It is simply that one need not go to the extreme of taking the "unknown quantum state" as being objectively real to make sense of the experimental practice of tomography.

   One is left with the feeling ... that perhaps this is the whole point to quantum mechanics. That is: Perhaps the missing ingredient for narrowing the structure of Bayesian probability down to the structure of quantum mechanics has been in front of us all along. It finds no better expression than in the taking account of the limitations the physical world poses to our ability to come to agreement.

I certainly believe there are some things within quantum mechanics that are beyond our subjective description. As in your example, Planck's constant could well be one of them. The dimensionality d of a Hilbert space is another one I feel fairly confident of. That number characterizes something intrinsic to a system. To that extent, it is not something that can be information-theoretic in origin.

Landahlism 4: *To press your point more forcefully in the future, you might consider rephrasing the special relativistic axioms themselves in a more information-theoretic light.*

But it doesn't seem to me that special relativity is overtly about Bayesian or information theoretic concerns in the way that quantum mechanics is. So I wouldn't want to express those axioms in a more information-theoretic light.

Landahlism 5: *Conclusion: quantum information theorists need to get out more!*

Yes! (And I speak for myself too.)

Landahlism 6: *At least I got a good groan from John Preskill when Alice flipped Bob a quarter for the "two bits" of classical communication she sent him.*

I got a similar groan from Mermin when he first read the end of Section 3. BTW, footnotes 8 and 9 are not typos; several people have asked me about that.

Landahlism 7: *In The Future section I talked about Gleason's theorem for POVMs and expressed my concerns about Emma's future psychological counseling given that you already are pressing her for a theory of measurement. None of us understood what the quote you ascribed to Hideo actually meant, which I suppose I should ask Hideo about. Do you understand it? It sure sounds amusing.*

The point is, Emma gets by without a theory of measurement, and we should all learn something from that. It is the people who think that knowledge acquisition, or better, belief acquisition, must arise from a detailed dynamical theory that are the problem.

The point of view taken here is that "detailed dynamical theories" are theories of *inference*, and therefore lie outside of the process of knowledge acquisition. This does not bar quantum theory from making contact with the REAL world—the world that was here long before man ever arose (see points about reality below)—it just means that one is not going to find it in the dynamics.

Landahlism 8 : *In the Learning section, I went over your argument for quantum collapse being a kind of Bayesian conditioning. I understand the analogy you drew here, but I hardly believe this makes quantum collapse any more gentle of a process. That's because I don't believe Bayesian conditioning is "gentle." While it's true that one can express the classical process as "plucking" a term out of a sum over conditional probabilities, the change in probabilities can be quite dramatic: the change can be from nearly zero to one in a single step!*

Fair enough. Perhaps I overplayed the imagery. The point I really wanted to emphasize is that quantum collapse can be thought of as predominantly a refinement of one's knowledge.

Landahlism 9 : *I also don't understand the meaning of the "mental readjustment" step in the quantum process. Is this just a change-of-basis for the description of the state? Is it something more or less than this? If that's all it is, then I really don't like this phrase "mental readjustment" at all.*

The track I'm on is that quantum state change is essentially Bayesian updating of knowledge, but with the proviso that the things we have to do to update our knowledge are (generally) not without effect on the world. This must be taken into account in some way. That the updating is Bayesian-like has a trace in quantum mechanics through Eqs. (57) and (58). That we still have to take into account our knowledge of our invasiveness, this has a trace in Eq. (59). That is the "mental readjustment"—i.e., taking into account what we know about our own invasiveness. (I agree, I should have found a better word for it.) When we know that our knowledge acquisition could not have physically affected the system it was concerned with, then we need do nothing whatsoever beyond Bayesian updating. Eq. (64) is an example of that.

Landahlism 10 : *I finished the Learning section by sketching how "typical von Neumann entropy" as an uncertainty measure increases after every measurement. A question I had in your argument was why the integration is done over only von Neumann measurements. I looked over your original paper on this subject and didn't find an answer there either. Some mention is made of projective measurements being "maximally predictive," but I'm not totally convinced by this argument. I suspect that the true reason for restricting attention to these measurements is technical. A measure over POVMs doesn't exist, so one can't integrate over them. Wouldn't life be so much nicer if there were one! Is this the true reason for the von Neumann measurement restriction?*

Your suspicion is correct. My choice was no deeper than that.

Landahlism 11 : *I spent most of my time discussing the Correlations section. I went in detail over your proof of what I called "Gleason's theorem for Classically Semilocalizable Operations (CSOs)" in deference to the terminology introduced in a recent paper by Beckman et al. Personally, I thought it was cool that the tensor product arose out of noncontextuality and the measurement model. John Preskill wasn't so impressed — he believes that the tensor product will arise out of any reasonable model of measurement which has the property of locality. (I.e where neither Alice's nor Bob's local actions can meaningfully impact the other.) He may be right, but for me that isn't the point. The point for me is that the proper way to view Gleason's theorem is as a machine. The input to the machine is the measurement model and the output of the machine is the state space structure and the probability law.*

Indeed you did get the point. Thanks. The point is, how much of the structure of quantum mechanics can we shove into the simple choice: "measurements = POVMs." How much of quantum mechanics is really independent of that choice? There has been a hell of a lot of work trying to reduce all of quantum mechanics to the assumption of unitarity. I'm trying to go the other way.

Landahlism 12 : *What especially excites me about this point-of-view its potential impact on quantum field theory. The main point of the Beckman et al. paper is that causal measurements and localizable measurements are not one in the same. Wouldn't it be interesting to see what happens when we impose only causality on our measurement model and send it through the "Gleason machine?" What do you suppose the resultant structure of the state space would be?*

If I understand you correctly, Mermin in his talk in Montréal and Sweden has been wondering something very similar. In fact, he would like to see the quantum probability rule AND the tensor product rule arise out of the idea that measurement cannot give instantaneous signaling. He doesn't yet feel comfortable with my (Gleason's) noncontextuality assumption. Yours is a good question; I'll try to have a look at that paper.

Landahlism 13 : *On the whole I portrayed your "party platform" as the statement that "Quantum states are states of knowledge about the consequences of future interventions."*

That statement, as it stands, is true.

Landahlism 14 : *In particular, those consequences aren't consequences to reality, but rather consequences to states of knowledge about even further future interventions.*

That statement, as it stands, is not. (Do you not see the difference?!?!)

Landahlism 15 : *In this worldview Bayesian agents don't work to align their predictions with an underlying reality.*

They would if they could, but they don't because they can't. Realizing this—it seems to me—is the first step to understanding what the quantum world is about.

Landahlism 16 : *Instead they work to align their predictions with each other. It is as if reality in this picture is solely the agreement of predictions!*

I'd be interested to hear if you believe that this is a fair characterization of your party's platform. After reading this paper, I came to the conclusion that you didn't believe in reality at all. (Or at best I thought you believed reality = knowledge.) John Preskill tells me you believe otherwise, namely that there is a reality, which surprised me.

Yeah, you botch it pretty badly there. John is right. See my diatribe under C) above. But, let me also add to that:

1. Section 4, first paragraph.

   I have been watching my two year old daughter learn things at a fantastic rate, and though there have been untold numbers of lessons for her, there have also been a sprinkling for me. For instance, I am just starting to see her come to grips with the idea that there is a world independent of her desires. What strikes me is the contrast between this and the concomitant gain in confidence I see grow in her everyday that there are aspects of existence she actually *can* control. The two go hand in hand. She pushes on the world, and sometimes it gives in a way that she has learned to predict, and sometimes it pushes back in a way she has not foreseen (and may never be able to). If she could manipulate the world to the complete desires of her will, I am quite sure, there would be little difference between wake and dream.

This wispy little piece is the closest I've been able to come to giving substance what I call "the Paulian idea." See my "Notes on a ...", page vii. The world must have some impredictability about it, otherwise we would never be able to say we have seen any trustworthy trace of a reality.

Landahlism 17: *I'm curious to hear what you believe reality is.*

Me too. The idea is not well formed yet. Perhaps this accounts somewhat for people not getting my point that the first part of attempting to identify what is real in the quantum world is to identify what is subjective and governed by "laws of thought." We should do that because that's the easier part of the program. Contemplating what's left behind is when the real fun will begin.

People are too used to seeing gurus (like Deutsch or Mohrhoff) sit on high and declare what reality *is*. My goals are more modest, even if my method of advertisement is not. I don't have an answer yet; I just feel a direction. One should not confuse my method of attack with my answer.

If you were to push me real hard on this "what-you-believe-reality-is" business, I might be inclined to say, "Read Schopenhauer's *The World as Will and Representation*." But since I haven't read it myself, I can hardly expect you to do that! Anyway, as a very *provisional* answer, I might say it's something like the "will" (the quotes around that word are very important) that Schopenhauer attributes to every piece of the world, animate and inanimate alike. For want of a better term, I call it zing.

Landahlism 18: *As for the mechanical details of the paper itself, I enjoyed your refreshingly casual writing style. I found one of your section titles to be either exceedingly clever or merely a typographical error. Either way, I'm the only one out of a dozen people who noticed it, even after I pointed it out. I'm hoping that you intended the convey the clever interpretation.*

Caves, Bilodeau, and Schumacher also asked me if it is a typo. It is not: you can be relieved.

Landahlism 19: *If so, I suggest you correct the grammar on the section title to "Wither Entanglement!" to make the homonym less subtle without sacrificing any wit.*

Too late. But in any case, I wanted all the section headings to be questions, except the beginning and end ones.

Landahlism 20: *The only other typo that jumped out at me was on page 13: "shear difficulty" should read "sheer difficulty."*

Thanks, I hadn't noticed the difference before.

Landahlism 21: *Once again, great paper. I'm psyched that it stirred up so much discussion in our group meeting.*

Me too!

Now, I said I would make some comments on Sumit's poll. But I'm too tired for that after all this writing. So I won't tell you what I think in any great detail at the present. I'll just cut and paste what Hans Primas thinks. It's below. I will say, however, that I don't see that there should be a qualitative distinction between my description of you (Andrew Landahl) and my description of the coffee maker sitting to my right. You are both physical systems embedded in this thing we call the world.

From: H. Primas, "Beyond Baconian Quantum Physics," in *Kohti uutta todellisuuskäsitystä. Juhlakirja professori Laurikaisen 75-vuotispäivänä* (Towards a New Conception of Reality. Anniversary Publication to Professor Laurikainen's 75th Birthday), edited by U. Ketvel (Yliopistopaino, Helsinki, 1990), pp. 100–112.

The methodology of experimental scientific research and engineering science is to a large extent characterized by the regulative principles emphasized by Francis Bacon. It is a tacit assumption of all engineering sciences that nature can be *manipulated* and that the initial conditions required by experiments can be brought about by interventions of the world external to the object under investigation. That is, *we assume that the experimenter has a certain freedom of action which is not accounted for by first principles of physics.* Without this freedom of choice, experiments would be impossible. Man's free will implies the ability to carry out actions, it constitutes his essence as an actor. We act under the idea of freedom, but the topic under discussion is neither man's sense of personal freedom as a subjective experience, nor the question whether this idea could be an illusion or not, nor any questions of moral philosophy, but that *the framework of experimental science requires the freedom of action as a constitutive though tacit presupposition.*

The metaphysics of Baconian science is based on the confidence that only the past is factual, that we are able to change the present state of nature, and that nothing can be known about nature except what can be proved by *experiments.* Francis Bacon's motto *dissecare naturam* led to a preferred way of dividing the world into object and observing systems. An experiment is an *intervention* in nature, it requires artificially produced and deliberately controlled, reproducible conditions. In *experiments* in contradistinction to *observations* – one *prepares* systems in initial states, *controls* some of the variables, and finally *measures* a particular variable. The regulative principles of Baconian science require *power to create initial conditions*, stress *the facticity of the past* and *the probabilistic predictability of the future*, and reject *teleological considerations.*

10-07-01 *Old McBleak's Ale House* (to N. D. Mermin)

Merminition 36: *I can't believe we're talking past each other on something this basic! [. . .]*

> [CAF wrote:] I hold firm in my opinion. It has *everything* to do with how you like to think about (quantum) probabilities. If you think the probabilities are subjective expectations for the local consequences of one's experimental interventions, then the question never arises.

To say that the question never arises is to say that probabilities can never have any bearing on frequencies of experimental outcomes.

Try it in the language you prefer: if Alice's subjective expectations for the local consequences of her experimental interventions differ, depending on what kind of an experimental intervention Bob chooses to make over in the next county — not, I stress, on what Bob learns from his intervention but just on how (or whether) he decides to intervene — then Alice will be wiped out by any competent Dutch bookie, unless unmediated action at a distance is an objective feature of the world.

We are talking past each other.

But, my wording was careful enough to cover your reply (modulo the confusing parenthesis I put around the word quantum, for which I apologize). If a physical action associated with a POVM—by definition—only affects the system associated with the POVM's Hilbert space, then by definition that is all it affects. Standard quantum mechanics has that feature.

The issue is whether we should question the reasonableness of that. Or, indeed, as you would like, turn the tables and check whether the physical requirement of no-signaling gives rise to the standard probability rule full stop. Your question is a well-posed question, I do not deny that. But, as I view it, its motivation is a throw-back to the days when entanglement was thought to have some connection to the spooky ghosts of nonlocality.

I am torn. 75% of the time, I think your question is a regressive turn to the Popescu-Rohrlich-Aharonov-Shimony-Gisin "passion-at-a-distance" mentality. It seems to me acknowledging that as an interesting paradigm (even one to be ultimately shot down) is a wrong turn. But 25% of the time, I think, "Why not? It is a valid question, so answer it if you can."

Still no sympathy for me? (Probably not.) But, am I at least coherent?

11-07-01 *Quantum Information / Evolutionary Universes* (to L. Smolin)

We've met before (when I was at Caltech), but you probably don't remember me. My name is Chris Fuchs; I'm on the research staff at Bell Labs, and my specialization is quantum information theory.

I'm writing you because lately I've taken a shine to evolutionary-universe ideas, because I've enquired with the Perimeter Institute about the opportunities they might hold for my quantum foundations program, and because I've heard that you will be joining them. (The first part of the sentence—the part about the shine—is the cause, not the effect!) Thus I would like to get to know you better.

For one thing, please allow me to share with you two of my writings on the subject:

- C. A. Fuchs, "Notes on a Paulian Idea: Foundational, Historical, Anecdotal & Forward-Looking Thoughts on the Quantum (Selected Correspondence)." 504 pages. Foreword by N. David Mermin. See `quant-ph/0105039`.

- C. A. Fuchs, "Quantum Foundations in the Light of Quantum Information," to appear in *Proceedings of the NATO Advanced Research Workshop on Decoherence and its Implications in Quantum Computation and Information Transfer*, edited by A. Gonis (Plenum Press, NY, 2001). (Until then, see `quant-ph/0106166`.)

In the case of the book (the samizdat), a good place to start within it is the chapter on Rolf Landauer. But also look up the references to John Wheeler and furthermore the discussion on Poincaré (and Boutroux) on page 195. Both manuscripts, by the way, are also posted at my website listed below. (At the website, you can find my CV in case you worry that I may not be legitimate.)

Of a more important nature, I wonder if you might help me with a project I am currently working on. It is in putting together a large compendium of quotes from and citations to materials concerned with the idea that the universe may be a "malleable" entity. It will eventually be submitted to *Studies in History and Philosophy of Modern Physics* (probably this Fall), and presently stands at 96 pages, with 422 citations. The working title is, "The Activating Observer: Resource Material for a Paulian–Wheelerish Conception of Nature."

If you wouldn't mind, I'd like you to look over it and point out any citations I missed. Especially as regards your own work, I know that I must have missed several things. But also, you may be able to help me with some obscure materials that I've never seen before. I'm shooting to make the document as complete as I can.

16-07-01 *Insults* (to S. J. van Enk)

> "The only gracious way to accept an insult is to ignore it; if you can't ignore it, top it; if you can't top it, laugh at it; if you can't laugh at it, it's probably deserved."
>
> — Russell Lynes (b. 1910), U.S. editor, critic. *Reader's Digest* (Brit. ed., Dec. 1961)

[The recording of this was prompted by my 04-07-01 note "Carts and Horses" to U. Mohrhoff. It hardly needs to be said, but on that day I was not laughing.]

18-07-01 *Horizons* (to J. Bub)

That is awful news about your visual problem and its possible causes. Please do keep me up-to-date on your health. For my own part I will cross my fingers and think of you often.

Don't worry at all about leaving me up in the air concerning a visit to Provence. Because of certain of our own medical issues, I've been lobbying my wife to postpone her European vacation until September or early October anyway. (So, you see, I would have to leave you up in the air right now too.) If it happens, it happens. The main thing is that it sounded like a good opportunity to pound out the similarities and distinctions between our points of view on quantum mechanics without being interrupted every three minutes.

I know I suggested I would write a longer letter soon, but I'm going to wimp out of it again for now. It would concern the main point of distinction I see between us (and also between myself and Pitowsky). Namely, A) that I view a large part of quantum mechanics as merely classical probability theory (which on my view may be an a priori "law of thought") PLUS an extra assumption narrowing down the characteristics of the phenomena to which we happen to be applying it to at the moment, while B) you are more tempted to view quantum mechanics as a *generalization* of classical probability theory (and with it information theory). I know that my view is not fully consistent yet, especially as I have always distrusted mathematical Platonism—which you pointed out to me I am getting oh so close to—but it still feels more right (to me, of course). Ben Schumacher, Rüdiger Schack, and I had a long discussion on this (on a long walk) the day after the round table, and I'd like to record that too. Ben took a stance quite similar to yours, and maybe even Rüdiger did too (despite his overwhelming Bayesianism). So, I may be the lonely guy out on this. And my view may be subject to change.

What I probably really need right now is more conversation than writing. So, I do hope I get to see you in an uninterrupted way soon. (By the way, would it be possible for me to get a copy of the talk you gave in Växjö? Could you copy that and mail it to me?) For now, let me post below parts of two notes I wrote Andrei Khrennikov. They touch on the discussion above, even if they are somewhat out of context here. The second note, in particular, struck me as a clean way of stating my position (in a way that I hadn't explored before). Maybe that'll help to zoom us in on the relevant issues.

There is some good news on the horizon. Gilles and I will be holding another foundations meeting in 2002. (Purely quantum info people, much like the original.) All the details aren't clear yet, but we think we may be able to have desk space for people, it may be for an extended period—maybe a month—with a revolving set of participants, etc., etc. I hope you'll be able to join us (once I get the details to you). The main difficulty is that it may have to be in the fall (after the school semester starts), which will cause participation trouble for those with a teaching load.

18-07-01 *Letters: the Long and the Short, 2* (to A. Plotnitsky)

I agree. We ought to get together (for lunch?) sometime while you're in NYC! I'll probably be tied up until at least July 25, though. Are you in email contact all the time? So that we can try to set something up more spur-of-the-moment if need be? I'd probably just take a train in and meet you somewhere convenient in Manhattan.

Do you know anything about Schopenhauer's "will"? Could you give me a small lecture on it when we meet. Would you say it's anything at all like you "efficacity"?

Arkady's Reply

> I can easily explain to you Schopenhauer's "will" and its relation to "efficacity." The short answer is no, they are not the same, but one could interestingly qualify why not and thus illuminate better what I mean by efficacity or how quantum objects should be seen according to informational, rather than ontological, view. If we do not manage to meet this time around, I could still explain this to you by email, or we might arrange for a phone date one day.

18-07-01 *Page 270!!* (to L. Smolin)

I'm excited to hear that you're reading some of my things. Especially since I've come across pages 270–272 of your book (paperback edition)! Indeed, there appears to be a significant overlap between some of our toy ideas. The one I'm speaking about is (in a technical way) the undercurrent of my paper "Quantum Foundations in the Light of Quantum Information." But, you can find broader-view statements of it on pages 156 and 190 of my samizdat. Also, you can see a trace of it in Mermin's foreword, page iii, last paragraph. Do you see the overlap that I do?

Anyway, I find this quite intriguing: Somehow, I had gotten the impression that you were a staunch many-worlder, and that our views of quantum mechanics might be diametrically opposite. I really apologize for my previous misreading (based on reading your book for an hour in a bookstore one day). I will read your book more carefully, and also look at the papers you recommended.

I also apologize for writing you back so late. Late last week I had to give a presentation to the president and vice-president of Bell Labs, and that really had me on edge until it was over with. (The VP, Bill Brinkman, by the way, will become the president of the APS in January.) After that, my wife and I took a long weekend in the country, and then I returned to find a hundred fires that needed putting out at the office.

I had contacted Perimeter (both Laflamme and Burton) previous to my contacting you, and I talked to Howard Burton for a long time on the phone Monday. So, they are aware of my existence. You may have been confused: I'm not looking for a postdoc position, but for (possibly) a long-term one. I already have a permanent research position at Bell Labs. The issue I'm toying with in my mind is in turning a more directed focus on the quantum foundations. (I've recently organized two large meetings with that theme, one in Montréal and one in Sweden—and am now working on a third bigger one in Montréal—and it's given me a taste for the hope that the quantum information community may be the key to this long-annoying puzzle.) If Perimeter can help me in making these dreams come true, then I may be all for it. What are your thoughts on Perimeter?

You asked me, "What is the Paulian idea?" I wish I knew! More seriously, the best summaries I can give you are 1) the *conjunction* of two Pauli quotes on page vii of the samizdat, and 2) the wispy little piece I wrote in the first paragraph of Section 4 of my paper "Quantum Foundations in the Light of Quantum Information". This is a very deep idea I think, and I don't know that I've ever seen it expressed anywhere except (very sketchily) in Pauli's writings. It is that, in a world where the experimental context cannot be deleted from the consequences it brings about, there must be a kind of randomness or impredictability. Else there would be no way to distinguish between wake and dream for any observer who makes use of such contexts. It is the ultimate impredictability of the consequences of our interactions with the world that gives us firm evidence that there is something beyond us. By this view, the world is not real because it can be mathematized completely, but because it cannot.

20-07-01 *The Matchmaker* (to A. J. Landahl & N. D. Mermin)

Please allow me to introduce you two to each other:

> David meet Andrew: Andrew Landahl is a promising young grad student in quantum information at Caltech, with a little bit of a taste for fundamental questions.
>
> Andrew meet David: David Mermin is a promising recent retiree from Cornell with a long history in fundamental questions, and a little bit of a taste for quantum information.

I woke up this morning and said to myself, "If you can't do good physics yourself, be a matchmaker!" So, I introduce you to each other because you've both recently written me about—I think—the same question.

Andrew said,

Landahlism 22: *I spent most of my time discussing the Correlations section. I went in detail over your proof of what I called "Gleason's theorem for Classically Semilocalizable Operations (CSOs)" in deference to the terminology introduced in a recent paper by Beckman et al. [i.e.,* `quant-ph/0102043`*]. Personally, I thought it was cool that the tensor product arose out of noncontextuality and the measurement model. John Preskill wasn't so impressed — he believes that the tensor product will arise out of any reasonable model of measurement which has the property of locality. (I.e., where neither Alice's nor Bob's local actions can meaningfully impact the other.) He may be right, but for me that isn't the point. The point for me is that the proper way to view Gleason's theorem is as a machine. The input to the machine is the measurement model and the output of the machine is the state space structure and the probability law. I suppose I should have realized this a long time ago (especially once the POVM Gleason's theorem was proven), but it took this proof to open my eyes.*

What especially excites me about this point-of-view is its potential impact on quantum field theory. The main point of the Beckman et al. paper is that causal measurements and localizable measurements are not one in the same. Wouldn't it be interesting to see what happens when we impose only causality on our measurement model and send it through the "Gleason machine?" What do you suppose the resultant structure of the state space would be?

David said,

Merminition 37: *The question you're evading is what it means for one and the same positive operator E to appear in many different POVMS. A POVM is defined by the the entire collection of E's that sum to the identity. What does it mean to associate a probability with a single one of them without reference to any of the others? Isn't this a question that simply has to be addressed, independent of whether you think a quantum state is a state of knowledge or a state of the world, or whether you think a probability is a degree of belief or an objective propensity? Different POVMs (with one E in common) are associated with entirely different interventions. But somehow you're thinking of that one E these utterly different procedures have in common as an independent outcome with a likelihood all its own. It sounds to me as if you're the one who's reifying things. [...]*

No! The signalling has nothing to do with quantum-state change. (We've been through this before.) If Bob and Alice share a large number of identically prepared pairs, then a very reasonable requirement is that the statistical distribution of outcomes Bob gets from his members of the pairs cannot depend on what Alice chooses to do to her members. (If it did Alice could send useable unmediated signals to Bob.) Again, this has nothing to do with how you like to think about probabilities or quantum states. I offered this to you as an example of a situation in which you can, in fact, justify the non-contextuality of certain probabilities by appealing to an independent physical requirement (no remote signalling).

1) Am I indeed on the right track that you two are thinking about the same things? 2) Am I to take it from Andrew's note that there is some evidence that no-signalling (in a Gleason-like theorem) may not be enough to specify the standard quantum probability rule?

If any sparks fly, I hope you'll let me be a voyeur.

21-07-01 *The Reality of Wives* (to A. J. Landahl & J. Preskill)

This morning one of the local hospitals had a fund-raising flea market, and I picked up a copy of Martin Gardner's *The Whys of a Philosophical Scrivener* for $0.50. I haven't been able to put the thing down all day; it's quite good, and the beginning parts are especially relevant to my recent discussion with you.

This evening while sitting outside enjoying the end of the day, I couldn't help but read Kiki a cute little story from it. Gardner writes:

> When I was an undergraduate philosophy student at the University of Chicago I attended a seminar given by Bertrand Russell. Carnap, then a professor at Chicago, went to these sessions and often engaged Russell in spirited debates which I only partly comprehended. On one occasion they got into a tangled argument over whether science should assert, as an ontological thesis, the reality of a world behind the phaneron. [Phaneron was Peirce's term for the world of our experience, the phenomenal world.] Carnap struggled to keep the argument technical, but Russell slyly turned it into a discussion of whether their respective wives (Russell's new wife was knitting and smiling in a back-row seat) existed in some ontologically real sense or should be regarded as mere logical fictions based on regularities in their husbands' phaneron.
>
> The next day I happened to be in the campus post office, where faculty members came to pick up mail. Professor Charles Hartshorne, a whimsical philosopher from whom I was then taking a stimulating course, walked in, recognized me, and stopped to chat.
>
> "Did you attend the Russell seminar yesterday?" he asked. "I was unable to go."
>
> "Yes," I said. "It was exciting. Russell tried to persuade Carnap that his wife existed, but Carnap wouldn't admit it."

> Hartshorne laughed. Then, by a quirk of fate, in walked Carnap to get his mail. Hartshorne introduced us (it was the first time I had met Carnap; years later we would collaborate on a book); then, to my profound embarrassment, Hartshorne said: "Mr. Gardner tells me that yesterday Russell tried to convince you your wife existed, but you wouldn't admit it."
>
> Carnap did not smile. He glowered down at me and said, "But that was not the point at all."

I followed that by saying, "You know some of my friends are afraid that I don't believe in reality. So there, you're just a figment of my imagination!" She reacted in shock. "Well, I know that can't be true," she said. "Clearly you'd make some changes!"

22-07-01 *Noncontextual Sundays* (to N. D. Mermin)

I know you're busy, but I'm going to try again. (Don't feel the need to write back until you get some time.) The issue is still noncontextuality in the Gleason-like theorems: Is it a natural assumption or not?

Here was the best answer I gave you before, but now I'm going to try to improve on it.

> **Merminition 38:** *The question you're evading is what it means for one and the same positive operator E to appear in many different POVMS.*
>
> No, I don't think I'm evading it. It means that those various interventions or ways of gathering data—those POVMs—physically diverse though they may be—all lead to at least one common possibility for what my knowledge can be updated to (modulo the unitary readjustment).

The point I'm going to try to make is that not only am I finding noncontextuality a natural assumption, but actually it may be the most *basic* assumption of the whole game. (I.e., it may even be prior to the notion that measurements correspond to POVMs.) The idea is captured above, but—I can see now—it is in too idiosyncratic of a language to convince you easily.

Here's the new shot at it (emphasizing a slightly different aspect than previously).

1) Here's the scenario. Forget about quantum mechanics for the moment. Let me take a system S and imagine acting on it with one of two machines, M and N. For the case of machine M, let us label the possible consequences of that action $\{m_1, m_2, \ldots\}$. For the case of machine N, let us label them $\{n_1, n_2, \ldots\}$.

2) If we are good Bayesians, nothing will stop us from using all the information available to us to ascribe probabilities to the consequences of these two potential actions. Thus we naturally have lying around two probability distributions, $p_M(m_k)$ and $p_N(n_k)$.

That's well and good, but it's hardly a physical theory yet. We need more. So, let us suppose the labels m_k and n_k are at least drawn from the same master set (possibly even a set with further structure, like a vector space or something). But then we must ask, under what conditions should we identify two particular labels m_i and n_j with the same element in the master set?

There's really only one thing lying around to do it with, and that's the probability assignments. If $p_M(m_i) \neq p_N(n_j)$, then surely we would not imagine identifying m_i with n_j. If, on the other hand, $p_M(m_i) = p_N(n_j)$ *regardless* of the initial state of knowledge about S, then we might think there's some warrant for it.

And that's the whole story of noncontextuality. It is nothing more than: The consequences (m_i and n_j) of our disparate actions (M and N) should be labeled the same when we would bet the same on them in all possible circumstances (i.e., regardless of our initial knowledge of S).

By this point of view, noncontextuality is a tautology—it is built in from the start. Asking why we have it is a waste of time. Where we do have a freedom is in asking why we make one particular choice of a master set over another. Why should the m_i's be drawn from the set of "effects" (i.e., the positive operators smaller than the identity on some Hilbert space)? Recall the problem on page 86 of the samizdat. Not all choices of the master set are equally interesting once we've settled on noncontextuality for the probability assignments.

You see, I really never do dismiss anything you say! Now I'm off to buy a new BBQ grill. (My family is tugging on me, and refused to let me try to hone this letter. But I really hope by this point it does make some sense.)

23-07-01 *Law without Law* (to J. Summhammer)

I very much enjoyed reading your letter to Carl Caves titled "promoting the Bayesian view." It was quite thoughtful, and makes me regret not having talked to you more while we were in Sweden.

Please allow me to ask a couple of questions based on what you wrote.

Summhammerism 1: *Here I think that, even if there is absolutely no order in the physical world, it will exhibit statistical order to a rational observer. The existence of rationality is to be taken as outside the physical world. It is a transcendental fact. (The term "law of thought" in your paper circles around the same thing.) Analysis of brain functions and molecules explains nothing, because that analysis is done by means of rationality.*

There have been times in my life when I have been very attracted to ideas like this. In particular, right now might be one of them (though I have a history of going up and going down). My first exposure to the idea came from John Wheeler's writings on what he termed "law without law." In fact presently, I'm putting together a large compendium of quotes and citations titled "The Activating Observer: Resource Material for a Paulian-Wheelerish Conception of Nature." At the moment, it consists of 423 annotated citations, taking up 96 pages of print. The manuscript is far from complete, but will eventually be submitted to *Studies in History and Philosophy of Modern Physics*.

I wonder if you have any suggestions for things I should include in it (based on your passage above). If so, please give me as complete of references as possible. If I'm not mistaken, I detect a Kantian tinge in your thought: that's an area I haven't explored too deeply in my compendium.

Summhammerism 2: *p.21: ... the Bayesian interpretation places actualization outside its provenance ...*

I agree. Defenders of interpretations which claim to handle actualization should read selected articles on the mind-body problem, written over the last three thousand years.

Would you mind expanding on this, and also what are some of those selected articles? Can you provide references?

Anyway, it was very nice meeting you for the first time.

Johann's Reply

Now I come to your mail.

As to references on what is to be accepted as transcendentally given I would first think of Kant, in the *Critique of Pure Reason*. Then Hume should have something on it, but I read only passages of Hume. Then there is C. F. von Weizsäcker's *Aufbau der Physik* (1985), (perhaps *Reconstruction of Physics*) and his more philosophical book *Zeit und Wissen* (1992), (*Time and Knowledge*), both of which, unfortunately, are not translated into English, as far as I know. But he has a number of articles in English. Lyre has put a number of papers onto the `quant-ph` server in recent years. He is expounding on von Weizsäcker's ideas. (There is one paper of Lyre which I like quite much. It dissects Bell's "Against Measurement". Perhaps it fits into your compendium. Exposing the naive parts of Bell's thinking might be wholesome to the community.)

I have scanned through *Aufbau der Physik* and a little through *Critique of Pure Reason* over the weekend to find something that would support the following passage of my mail that you wanted me to find references to:

Summhammerism 3: *Here I think that, even if there is absolutely no order in the physical world, it will exhibit statistical order to a rational observer. The existence of rationality is to be taken as outside the physical word. It is a transcendental fact. (The term "law of thought" in your paper circles around the same thing.) Analysis of brain functions and molecules explains nothing, because that analysis is done by means of rationality.*

I found a compact one (but certainly not the best one) in *Aufbau der Physik*, where v. Weizsäcker freely outlines Kant's thinking and then says in which way his way of thinking about QM has gone beyond Kant.

It is in a section on Geist und Form (Mind and Form, pages 580–587). First he says there is no reason why abstract quantum theory should not also be applicable to knowledge which consciousness can obtain about itself. Then he remarks that one might have objections against this, and, following Kant, one objection might go like this: [I translate a section from pages 582–583]

> "... Loosely leaning on Kant we could make the following injection: Science is knowledge, and therefore — insofar as we may use the notion of consciousness — it is the contents of consciousness. Matter is the object of knowledge. In scientific usage forms are notions. Therefore it appears meaningful to explain the matter of physics by means of forms, thus notions; as such physics is what we can know of matter. Consciousness is a precondition of knowledge; consequently it would be circular to explain it by the means with which knowledge operates, the forms. Following Kant, it is for this reason that the knowing subject cannot be described as substance; for substance is itself a category, a notion.
>
> This injection is based on the argument of circularity, thus on the hierarchical approach of traditional philosophy (also see *Zeit und Wissen* 5.2.3). [But] we are moving on the circular walk around and through nature. Physics describes that which is lawful in nature, which in classical physics was called matter. Abstract quantum theory can attempt with the same right to describe that which is lawful in consciousness. ... The claim to achieve a complete description of reality in this manner is presumably unattainable; but it is legitimate to expect a consistent description. ..."

So much the quotation from von Weizsäcker. An important idea of his is the "Kreisgang der Natur" (= walking through nature in a circle). This does not mean circularity in reasoning, but recognizing that no matter with which notions you start, you must start with some, and you can try to see how far they can be illuminated when applying this whole set of notions to analyze each of them. In this von Weizsäcker seems to have been influenced by Bohr (as he himself often admits, his other influences being Plato and Kant). For instance, you could start with what we know of molecules and see how much it explains of the workings of the brain and the formation of concepts the brain arrives at and why these should in turn lead to the idea of molecules. What I like about this is that the question of what exists primarily is tacitly shown as ill-conceived. (If I am not wrong Bohr liked to ask "what do you mean by this?", and this outraged so many people, because they could not accept that you can think penetratingly and live happily without believing that all is based on material points that interact with each other. Here, von Weizsäcker has a poignant statement: Druck und Stoss sind keine Grundbegriffe der Physik. (Hitting and tossing are not basic notions of physics.) You couldn't dismiss classical physics more thoroughly. Personally I have a less dignified view of classical physics: It is the ape's way of projecting his muscular self-experience onto the world.)

Perhaps you should get in contact with von Weizsäcker directly, before he dies. The man is 89, but from what I hear still very much active in seminars. I have met him only once at a conference. He was a close friend of Heisenberg. Lyre would be able to give you his coordinates. If I am not mistaken, there was a common effort of Wheeler, von Weizsacker, D. Finkelstein and others, in the late sixties, early seventies, of really getting on with quantum theory. von Weizsäcker's input was "Ur-theory" and that the distinction of past and future is fundamental (one is fact, the other is possibility, like data and wavefunction). In Ur-theory knowledge is built up from empirically decidable alternatives, but that these decisions must have a material embodiment. That's what struck me most, when I first encountered this. That the distinction of knowing, and that what you know about need not be considered so fundamental. Knowing constitutes the thing, but not in the sense of idealism. Very quantum mechanical. A nice idea that shows how this can permit you to at least try to break out of the old realism-idealism prison is that, also human consciousness, as something that can be talked about by means of decidable alternatives, must have a physical manifestation. I translate a passage from page 581 of *Aufbau der Physik*: "... When we do the step towards concrete quantum mechanics, we will build up the alternatives encountered in obtaining the knowledge consciousness can have of itself by means of ur-alternatives. From this we must conclude that it must be possible to describe human consciousness as a body in three-dimensional space. We might expect that this should be the human body. ..." It is perhaps necessary to say that for von Weizsäcker three-dimensional space follows almost trivially from yes-no alternatives. (To me it is not that trivial.)

I think the recent effort of Anton Zeilinger and Časlav Brukner, of deriving quantum theory by saying an elementary system carries one bit is a revisit to ur-theory. (But I don't think Anton would agree, and Časlav might be hesitant. They are reading it off from their EPR and teleportation experiments, where you can posit something and then ask yourself how many bits of information do you have about it, rather than saying, I know so many bits, what something does this constitute?)

As to actualization as essentially the mind-body problem, I touched on this with Kant and Schopenhauer. My occupation with the latter was 20 years ago, and with Kant 15 years ago. But from works of von Weizsäcker I learnt that already Aristotle and Plato were aware of the problem, and the modern distinction of mind and body as two substances stems from Descartes. That is why I said the problem of actualization has three thousand years of history. To me it boils down to why there is something rather than nothing. To say there is something implies two concepts: The sensor and the sensed, or The observer and the observed, or The contemplator and the contemplated (ordered with increasing levels of complexity). Anyway, the question has a long tradition. In `quant-ph/0107005` on p.8 Ulrich Mohrhoff has just cited it in the following form: "Accounting for the existence of facts is the same as explaining why there is anything at all, rather than nothing — an impossible task." Perhaps he knows who pondered this first.

Finally, a quote from Kant, which I happened to open accidentally just now. It deals with empirical information (*Critique of Pure Reason*, in the second analogy of transcendental analysis; A210, B255, my translation from the German edition):

> "... All increase of empirical knowledge, and every progress in perception is nothing than an extension of the determinations of the inner sense, that is, a progression in time, the objects may be what they please, appearances [to the senses], or pure intuition. ..."

(My addition in rectangular brackets.)

It must have been this or a similar statement that lead me to the idea of the robot observer whose information about the world can only increase, which I mentioned in the mail to Carl Caves.

In my next mail I hope to get down to asking you a few questions on your paper "Quantum Foundations in the Light of Quantum Information". And the prior probability distribution of probabilities in the classical de Finetti theorem is causing me some trouble. Also, I would appreciate a copy of your paper (PS, PDF, or address for downloading preferred) "How much information in a state vector?" Unfortunately I had not read any of your papers before Växjö. There would have been a number of interesting points to discuss.

23-07-01 *A Nonbayesian Bayesian?* (to C. M. Caves)

I enjoyed reading your dialogue with Summhammer.

I have one question of my own.

Cavesism 1: *I do believe that natural selection only works in a world with at least a statistical order, which leads to the quasi-determinism of the macroscopic world. That we and other creatures are exquisitely attuned to this order, to the point of often finding it where it's not really there, is not surprising. The costs of finding order where there is only chaos must be less than the cost of failing to notice and take advantage of order when it is there.*

What on earth do you mean by this? Similarly when you write, "statistical order is the first element of the Bayesian reality," in Section 7 of your *Resource Material*?

Your phrase "world with statistical order" seems to teeter awfully close to an objectivist notion of probability. And it frightens me, of course, having fully made a conversion now.

23-07-01 *The Principal PrincipleS* (to C. M. Caves)

It dawned on me that I should chide you on your discussion on page 21, starting with "Two further comments on Hamiltonians ...." You left out the all-important part about how to connect the two notions of Hamiltonian, the subjective—or effective, as you call it—with the objective. It must be a Cavesian version of the principal principle: When the objective determinant of the time evolution of one's subjective states of knowledge is known, then the subjective determinant of one's subjective states of knowledge should coincide with it.

Another typo btw (I think). Page 19: "If you have maximal information about a quantum system and you want to retain it, you must know the system is Hamiltonian." Don't you mean "system's Hamiltonian"?

24-07-01 *Feynman Quote* (to me)

> If, in some cataclysm, all of scientific knowledge were to be destroyed, and only one sentence passed on to the next generation of creatures, what statement would contain the most information in the fewest words? I believe it is the atomic hypothesis (or the atomic fact) that all things are made of atoms—little particles that move around in perpetual motion, attracting each other when they are a little distance apart, but repelling upon being squeezed into one another.
>
> Everything is made of atoms. That is the key hypothesis.

26-07-01 *BZZ* (to N. D. Mermin)

Renes and I are meeting Plotnitsky for lunch in NYC tomorrow. The agenda is Schopenhauer's "will" and Plotnitsky's "efficacity" (not to be confused with "effervescence").

26-07-01 *In the Middle* (to Y. J. Ng)

As you can tell from the note I just cc'd you, I'm finally taking to your paper(s) in a serious way. I'm not sure if you're familiar with all the terms I used in the letter (effects, operations, etc.), but my main worry is that your Eq. (1) numerically coincides with what has come to be known as the "standard quantum limit" (albeit in a different context), which we in the quantum measurement community know can be broken. Maybe I told you about some of those troubles during my visit to NC. Your Eq. (3) seems to be on firmer ground, but once again when we get into the quantum regime, it is not clear to me that troubles don't creep in.

Also I have some lesser—perhaps semantic—worries. Namely, identifying a single-component system with a computational device. That does not fall within the standard model of computing (either quantum or classical), the Turing machine. So, one might call the black hole a limit point of a sequence of computers, but I think I would be hard pressed to identify it with a computer itself.

Also I worry about the general nature of your "simple computers", and why these bounds should only apply to such things. This does strike me as a weak point. You really should build a stronger argument for it (i.e., one better than "this is the only case in which the derivation seems to work").

But I certainly like the general flow of the paper. It has the right feel about how to start to build up quantum considerations about spacetime—these are things that I have maybe pushed to the back of my mind for too long.

Anyway, once I hear from Ozawa, I will probably react again.

27-07-01 *In the Night* (to Y. J. Ng)

Ng-ism 1: *But the first thing that I am interested in is what replaces my Eq. (1) according to you.*

My fear is that there is simply no limit at all. (But it really is a fear, and I hope I'm wrong for your sake.) While we await Ozawa's reply, have a look at the article below. As I recall, it is written in a style that you would appreciate. It gives a nice physical motivation for the SQL that is very similar in flavor to the derivations in your article. Tell me whether you find its arguments believable. The problem is, they turned out to be wrong. You'll also note the significant overlap between that problem and yours. So, even if it is otherwise irrelevant—which I am afraid it's not—we're all bound to learn something from tabulating the distinctions. I really need to look up the old Wigner article, but I haven't had a chance to get to the library and I'm traveling this weekend.

> Phys. Rev. Lett. **54**, 2465–2468 (1985)
>
> Defense of the standard quantum limit for free-mass position
>
> Carlton M. Caves
> Theoretical Astrophysics 130-33, California Institute of Technology, Pasadena, California 91125
>
> Measurements of the position x of a free mass m are thought to be governed by the standard quantum limit (SQL): In two successive measurements of x spaced a time τ apart, the result of the second measurement cannot be predicted with uncertainty smaller than $(\hbar\tau/m)^{1/2}$. Yuen has suggested there might be ways to beat the SQL. Here I give an improved formulation of the SQL, and I argue for, but do not prove, its validity.

29-07-01 *Sunday Morning, Thinking of You* (to H. J. Bernstein)

Hey old philosophy friend,

I haven't heard from you in a while. And you never even replied to my last message. So, I wonder whether you got it.

Lately I've taken to trying to mix Arthur Schopenhauer, John Dewey and William James into a good quantum stew. I'm certainly getting the feeling that some of their ideas were before their time (and, indeed, a better fit to the quantum world than the classical world of their focus).

But do write me. I am lonely for your company.

30-07-01 *The Morning After* (to S. Henry)

Henryism 1: *I remember you dude! I guess the most vivid memory is being at a party at Marie Clark's house. If I remember correctly you called me Mr. Magician because I did a little trick with a quarter or something. Or maybe it was the way I could persuade Lori to do what I wanted while you had a harder time getting her to bend to your will! (hehe)*

It seems you've really excelled in science. And yes I'm totally interested in "quantum teleportation" and physics in general. I haven't read any of your writings yet but will do so. I've read several books on physics/science over the years. Some of my favorites are Hyperspace *by Michio Kaku, and* A Brief History of Time *by Stephen Hawking. And, of course, I did read* The Tao Of Physics *by Fritjof Capra that explores the parallels between physics and Eastern mysticism. It sounded so much like The Tao of Pooh I just had to read it. If you know of any other books/authors that you think I'd be interested in please let me know!*

I remember deciding I would devote most of my life to quantum mechanics my second week in college after reading Heinz Pagel's *The Cosmic Code*. It made a big splash in my mind at the time: I don't know what it'd do now, maybe the same. For my present mentality, a very good book for the layman is David Mermin's *Boojums All the Way Through*. (Most importantly, read the chapters on "quantum mysteries for anyone.") Both these books are out of print, I think. But you can find them easily enough in a library, or by going to the used book section at `BarnesAndNoble.com` (there's hardly a book one can't find there). Things getting closer to what I do in the field—quantum information theory and quantum computing—can be found in Tom Siegfried's *The Bit and the Pendulum*. I've heard it's pretty good, but I haven't read it myself. Also, tangentially, Simon Singh's *The Code Book*—in connection to quantum cryptography—but, again, I haven't read it either. I've just heard good things about it.

Henryism 2: *So how'd you find my webpage? Were you looking for the DJ Scott Henry and found my page instead?*

No, it was 4:00 AM, and I was going through the search engines looking for things on Arthur Schopenhauer and his ideas about "the world as will and representation." An advertisement for `classmates.com` kept flickering at me, and I finally had a weak moment. So, I went to have a look (like I did a few months earlier when I put my own name there). This time I saw your name and went to your website.

30-07-01 *Britannica* (to J. M. Renes)

This was the only passage in the *Encyclopedia Britannica* that I could find about Nietzsche that even remotely resembled quantum mechanics. In general, he looks like a lot to wade through for little return.

> Perspectivism is a concept which holds that knowledge is always perspectival, that there are no immaculate perceptions, and that knowledge from no point of view is as incoherent a notion as seeing from no particular vantage point. Perspectivism also denies the possibility of an all-inclusive perspective, which could contain all others and, hence, make reality available as it is in itself. The concept of such an all-inclusive perspective is as incoherent as the concept of seeing an object from every possible vantage point simultaneously.
>
> Nietzsche's perspectivism has sometimes been mistakenly identified with relativism and skepticism. Nonetheless, it raises the question of how one is to understand Nietzsche's own theses, for example, that the dominant values of the common heritage have been underwritten by an ascetic ideal. Is this thesis true absolutely or only from a certain perspective? It may also be asked whether perspectivism can be asserted consistently without self-contradiction, since perspectivism must presumably be true in an absolute, that is a nonperspectival sense. Concerns such as these have generated much fruitful Nietzsche commentary as well as useful work in the theory of knowledge.

31-07-01 *Parachutes* (to C. H. Bennett)

Bennettism 7: *I'd be glad to recommend you to the Perimeter Institute, and I think it a prudent preparation given what I've heard about Lucent. But before you place too much faith in a place called perimeter, I would remind you of a famous saying in general relativity (a field I understand hardly at all) to the effect that the boundary of a boundary is nothing.*

John Wheeler would say "the boundary of a boundary is zero," so you were pretty close. But, yes, you pinpoint a worry of mine.

Today, the bosses are gonna give another big general announcement. I'm sitting on needles and pins. I just want to do physics, and stop worrying about jobs!

01-08-01 *The Montréal Commune* (to W. K. Wootters)

Gilles and I are once again putting together plans for a quantum information/foundations party in Montréal, though this one may be a little more like a commune than a party. The Montréal Commune. (Probably more officially, "Workshop on the Impact of Quantum Information Theory on Quantum Foundations," or some such thing.) We hope you will join us as a communard. [...]

On another subject, the meeting in Sweden went quite well, but we did miss you. Maybe some of the most interesting discussions centered around Andy Steane's paper "Quantum Computation Only Needs One World" (which Richard Jozsa presented). Doug Bilodeau had the wonderful idea that perhaps some combination of it and your old Ph.D. thesis could give us a deeper insight into where quantum computing derives its power from: Quantum computers are not powerful because they perform so many calculations in parallel (as the many-worlds pundits imagine), but rather because they do so FEW calculations! I.e., Their power derives from not doing anything they don't have to do for the final result. (Much like in your thesis, the photon—which can only express its preparation through a probabilistic law—does better by explicitly NOT carrying around the baggage of a local hidden variable theory.) So, your input at these meetings really would be very valuable.

Let us hear from you as soon as you can.

01-08-01 *Missing Anyone?* (to L. Hardy)

Good to hear back from you so quickly. Let me ask your advice: would you mind looking over my list of potential attendees and telling me whether I missed anyone really interesting? The criteria for getting there are:

1. Have to be practicing quantum information or something sufficiently close,

2. Should have a healthy attitude that there are still some mysteries in QM. (By this criterion, Bennett, Deutsch, and Griffiths probably should be taken off the list.)

02-08-01 *Schopenhauer* (to U. Mohrhoff)

Schopenhauer-like, not Kant-like.

02-08-01 *Quantum Philosophy* (to C. H. Bennett)

That guy Mohrhoff. By his classification, you are indeed more Platonic and I more Kantian. (Even though I don't think I'm overly Kantian.) But more importantly, also according to him ... HAH! ... I am merely "unilluminating" whereas you are "inconsistent."

02-08-01 *The Montréal Commune – Ditto* (to B. W. Schumacher)

I've marked you down in my spreadsheet, and we'll let you know what's up in a couple of weeks.

Schumacherism 1: *An interesting result that I happened on, based on two propositions: (1) "Information" resides in the relation between systems, and (2) "classical" information is exactly that information which may be copied. So we have two systems, Q and R, in a joint state ρ_{RQ}. Think of R as a "record" of Q. Suppose we require that there exists an operation on R only such that, at the end of the day, there are two systems $R1$ and $R2$ so that $\rho_{R1Q} = \rho_{R2Q} = \rho_{RQ}$. (So both $R1$ and $R2$ can have just the same relation with Q that R had.) This is possible if and only if the state is of the form*

$$\rho_{RQ} = \sum_k p_k |k\rangle\langle k| \otimes \rho_k$$

where $|k\rangle$ is an orthonormal set of R-states. The result is a pleasant application of the no-broadcasting theorem.

I like your result (which can't be questioned)!

No subject without an object. No object without a subject. No information without both. I like that—it seems like a good track for ontologizing information, to the extent that it can be. The only thing that scares me is your secret desire to reify the quantum state—namely by translating (1) into a statement about bipartite quantum states (which seem to me to have no other good interpretation than information to begin with)! It takes information to get information off the ground?

03-08-01 *Making Quantum Look Like Bayes* (to M. C. Galavotti)

I was reading Brian Skyrms' book *Pragmatism and Empiricism* this morning, and I thought of you. Perhaps you remember me from the old note below? It dawned on me that I haven't told you about two of my latest papers (listed below). They can be found on the Los Alamos archive `http://xxx.lanl.gov/find/quant-ph` by doing a search on my name, or, if you wish, I can mail them to you (provide an address). I think you may enjoy them, as they go the greatest distance yet in my efforts to draw out the analogies between quantum mechanics and Bayesian probability theory.

I hope things are going well for you and that you are continuing your own Bayesian efforts.

- C. A. Fuchs, "Quantum Foundations in the Light of Quantum Information," to appear in *Proceedings of the NATO Advanced Research Workshop on Decoherence and its Implications in Quantum Computation and Information Transfer* edited by A. Gonis (Plenum Press, NY, 2001). (Until then, see `quant-ph/0106166`.)
- C. M. Caves, C. A. Fuchs and R. Schack, "Making Good Sense of Quantum Probabilities," submitted to *Physical Review A*. (See `quant-ph/0106133`.)

Letter to M. C. Galavotti dated 5 May 1998, "If It's Not Too Late ..."

> I have just read your paper "Probabilism and Beyond" and am now even more excited than I was several days ago! It looks as if there is much that I have missed out on by not having studied Ramsey and de Finetti before! Unfortunately, I am also finding that there is even more of your work that I am not able to get my hands on here at this small library. (Though Caltech has had literally 26 Nobel Prizes distributed to its faculty and alumni, it has a library about the size of a pea.) If it is not too late—if you have not already sent the last one—can you also send me your article "F. P. Ramsey and the Notion of Chance"? I am now hoping that something along the lines of Ramsey's "objective chance"—to the extent that I understand the notion from your last article—is just the sort of thing that I have been looking for.
>
> My collection of your papers presently consists of:

>
> If there is anything else that you've written that you think I should be aware of, please send that on also!

05-08-01 *Sunday Morning, Thinking of You, 2* (to H. J. Bernstein)

Bernsteinism 1: *ISIS's fall series is supposed to be about scientific and medical ethics: Can you connect your proposed talk and simplify its level to be appropriate?*

Does that mean there's an honorarium that comes with giving the talk?

I might be induced to give a William James kind of lecture ... with a title something like, "Ethics in an Ultimately Lawless World." Or, "Ethics in a Law-Without-Law World." Or, "Timeless Ethics in an Evolving Universe?" Use your imagination.

07-08-01 *Knowledge, Only Knowledge* (to T. A. Brun, J. Finkelstein & N. D. Mermin)

Below is a note I started composing last Friday—but then had to leave for a long weekend for my wife's birthday—and only finished up today. In the mean time, Todd and Jerry have skirted very close to the point I wanted to make. So, the note is not quite as relevant as it might have been, but maybe some of it is still worth contemplating.

Allow me to start off in a fanciful way (like usual) with a couple of quotes:

> The subjectivist, operationalist viewpoint has led us to the conclusion that, if we aspire to quantitative coherence, individual degrees of belief, expressed as probabilities, are inescapably the starting point for descriptions of uncertainty. There can be

no theories without theoreticians; no learning without learners; in general, no science without scientists. It follows that learning processes, whatever their particular concerns and fashions at any given point in time, are necessarily reasoning processes which take place in the minds of individuals. To be sure, the object of attention and interest may well be an assumed external, objective reality: but the actuality of the learning process consists in the evolution of individual, subjective beliefs about that reality. However, it is important to emphasize, as in our earlier discussion in Section 2.8, that the primitive and fundamental notions of *individual* preference and belief will typically provide the starting point for *interpersonal* communication and reporting processes. In what follows, both here, and more particularly in Chapter 5, we shall therefore often be concerned to identify and examine features of the individual learning process which relate to interpersonal issues, such as the conditions under which an approximate consensus of beliefs might occur in a population of individuals. — pp. 165–166, Bernardo and Smith, *Bayesian Theory*

What is the nature and scope of Bayesian Statistics within this spectrum of activity? Bayesian Statistics offers a rationalist theory of personalistic beliefs in contexts of uncertainty, with the central aim of characterising how an individual should act in order to avoid certain kinds of undesirable behavioural inconsistencies. The theory establishes that expected utility maximization provides the basis for rational decision making and that Bayes' theorem provides the key to the ways in which beliefs should fit together in the light of changing evidence. The goal, in effect, is to establish rules and procedures for individuals concerned with disciplined uncertainty accounting. The theory is not descriptive, in the sense of claiming to model actual behaviour. Rather, it is prescriptive, in the sense of saying "if you wish to avoid the possibility of these undesirable consequences you must act in the following way." — p. 4, Bernardo and Smith, *Bayesian Theory*

Thanks again to all of you for letting me look in on your interesting emails! I've learned a lot from this exchange. Last night I was up between 1:30 and 5:00 reading them all one more time (and David's original paper too), and thinking much harder than I had before on these issues. So, now I hope to say some things in that regard, but not inane things (as I had done a couple of days ago).

The main thing that started striking me more deeply last night is that now it is very obvious that you *have* an answer, but—much more than ever before—I don't really understand what the question ought to be. In a sense, I'm only coming across the same troubles (Samizdat, p. 236) I've had ever since David first wrote me on this issue, and it relates to the comment I made after his talk in Växjö (in case he remembers). Let me try to explain.

David, in his paper, quotes Peierls as saying,

Merminition 39: *In my view the most fundamental statement of quantum mechanics is that the wavefunction, or, more generally the density matrix, represents our knowledge of the system we are trying to describe. ... [Yet, density matrices] may differ, as the nature and amount of knowledge may differ. People may have observed the system by different methods, with more or less accuracy; they may have seen part of the results of another physicist. However, there are limitations to the extent to which their knowledge may differ.*

And David himself says,

Merminition 40: *I have the feeling that if quantum mechanics is really about knowledge and only knowledge, then there ought to be further elementary constraints on the possible density matrices describing one and the same physical system that are stronger than the very weak second condition of Peierls, but not as strong as his overly restrictive first condition.*

What is being called for here—perhaps unintentionally—is a way to think about quantum mechanics from the bottom up (as Caves, Schack, and I might like it, in a Bayesian way), rather than from the top down (as Everett, Deutsch, and Bennett might like it). That is, one should view quantum mechanics as a conduit for stitching our individual pictures/thoughts/beliefs into a pastiche we ultimately call "the world." This contrasts with imagining that we have miraculously grasped the ultimate reality (the universal wavefunction, say), and can somehow see our individual points of view as being derived back out of that.

But if this is the case, then I cannot understand Peierls' command, David's quest, or the *answer* all three of you ended up coming up with:

> Two density operators ρ_a and ρ_b can describe the same system if and only if the support of ρ_a has a nontrivial intersection with the support of ρ_b.

This theorem is certainly consistent with a top-down view of the Everett sort—that, to be explained below, is really is what it seems to me to demonstrate—but it is not consistent with the bottom-up view. For, from the bottom-up view, there should not—and more importantly, there cannot—be any constraints whatsoever on what an agent can believe. I have every right to be as wrong-headed as I want to be with respect to you: The density operator belongs to me, not to you, and not to the system. I have every right to say inane things and make inane predictions—I do it all the time. What I should not do, however, if I want to remain rational, is refuse to listen to you when you point out my inanities or refuse to listen to the detector clicks that contradict my previous predictions. From the Bayesian view, it is the process of updating and the general structure of beliefs that is constrained by rationality—i.e., by the physical world, or the Platonic ideal, depending upon your orientation. It is not the actual beliefs themselves.

This point, perhaps more than any other, is why I (and Caves and Schack) should adopt the word "belief"—rather than "knowledge" or "information"—for describing the operational significance of quantum states. (I will try to be more consistent in the future, but that is really an aside as far as this note is concerned.)

Of course, your theorem is a theorem—or at least I can see nothing wrong with it—the issue here is how I, with my little Bayesian mind, can put it into a context I am more happy with. At first, I was the most pleased with Jerry's way of motivating it: From that point of view, what the theorem seems to express is simply the conditions under which a third agent Carol can consistently incorporate Alice and Bob's disparate beliefs into her own belief system.

But from the Bayesian view, why should we care about a Carol at all? What if there's no Carol to be found? What if neither Alice nor Bob ever intend to share their thoughts about this poor physical system with anyone else? To say that there is always a Carol about, or that there ought to be one, is to come dangerously close to endorsing the Everettian (or, for that matter, Bishop Berkeleyian) program. This, of course, may not bother Jerry or Todd—I'm not completely sure about their foundational dispositions—but it does bother me, and I suspect it might bother David, with his newfound deconstructionist tendencies.

Thus, it now seems to me that Todd's original way of posing the issue may be the safer way after all. BUT that is not because it gives us *the* answer, but instead *an* answer. (I.e., there should *only* be sufficient conditions, rather than necessary ones.) Let me let Bernardo and Smith speak again (and again):

> [T]here is an interesting sense, even from our standpoint, in which the parametric model and the prior can be seen as having different roles. Instead of viewing these roles as corresponding to an objective/subjective dichotomy, we view them in terms of an intersubjective/subjective dichotomy. To this end, consider a *group* of Bayesians, all concerned with their belief distributions for the same sequence of observables. In the absence of any general agreement over assumptions of symmetry, invariance or sufficiency, the individuals are each simply left with their own subjective assessments. However, given some set of common assumptions, the results of this chapter imply that the entire group will structure their beliefs using some common form of mixture representation. Within the mixture, the parametric forms adopted will be the same (the *intersubjective* component), while the priors for the parameter will differ from individual to individual (the *subjective* component). Such intersubjective agreement clearly facilitates communication within the group and reduces areas of potential disagreement to just that of different prior judgements for the parameter. As we shall see in Chapter 5, judgements about the parameter will tend more towards a consensus as more data are acquired, so that such a group of Bayesians may eventually come to share very similar beliefs, even if their initial judgements about the parameter were markedly different. We emphasize again, however, that the key element here is intersubjective agreement or consensus. We can find no real role for the idea of objectivity except, perhaps, as a possibly convenient, but potentially misleading, "shorthand" for intersubjective communality of beliefs. — pp. 236–237, Bernardo and Smith, *Bayesian Theory*

> In the approach we have adopted, the fundamental notion of a model is that of a predictive probability specification of observables. However, the forms of representation theorems we have been discussing provide, in typical cases, a basis for separating out, if required, two components; the parametric model, and the belief model for the parameters. Indeed, we have drawn attention in Section 4.8.2 to the fact that shared structural belief assumptions among a group of individuals can imply the adoption of a common form of parametric model, while allowing the belief models for the parameters to vary from individual to individual. One might go further and argue that without some element of agreement of this kind there would be great difficulty in obtaining any meaningful form of scientific discussion or possible consensus. — p. 237, Bernardo and Smith, *Bayesian Theory*

You'll find something similar to this theme infused throughout my paper `quant-ph/0106166`, "Quantum Foundations in the Light of Quantum Information." In the present context the question is, under what conditions (on the density operators themselves), can Alice and Bob move toward consensus in their future density operator assignments for a system? You guys have answered this for the *case* when there are some extra systems beside the one of interest (all noninteracting) lying around for Alice and Bob to make measurements on. If there is no overlap between the initial supports, then no measurement-at-a-distance, which can only have the effect of refining a density operator, can get Alice and Bob any closer to agreement.

What about necessity? As I've tried to say, there can be no requirement of necessity from the Bayesian view I'd like to see prevail. Instead the question is *always* to identify those situations where agents (with disparate beliefs) can move toward consensus be it by indirect measurements, direct ones, or even by communication with further members of the community.

A good and indicative example comes from the quantum de Finetti theorem along with the points made by `quant-ph/0008113` (Schack, Brun, and Caves). From it, we have a natural case where two agents can start out with distinct density operator assignments on a large collection of systems, but through updating via some commonly viewed measurement outcomes, they can move toward complete agreement in their estimates of the outcomes of all future measurements. The only thing the agents need to walk into the room with is this much INITIAL AGREEMENT: (1) that the systems in the collection are exchangeable, and (2) that the parametric form given by the de Finetti theorem has full support (in the sense defined there). Without that initial agreement, the techniques of quantum-state tomography would lead to no final agreement at all. No one can require that two observers in Mike Raymer's lab must walk into it with such an initial agreement, but if they happen to, there will be a reward at the end of the day.

That's my spiel. How would I modify David's quest in light of all that I've just said? Here's my shot:

> I have the feeling that if quantum mechanics is really about knowledge and only knowledge—or better, belief convergence and *only* belief convergence—then FOR ANY GIVEN METHOD OF GATHERING INFORMATION, there *should* be a way to ferret out of quantum mechanics the necessary and sufficient conditions on two observers' initial state assignments, so that the gathered information leaves them in a better agreement than they started out with.

Let me give you an example of where such an exercise can go. This is a question I posed to Rüdiger while we were in Växjö, but also it is a generalization of Todd's considerations (now letting Alice and Bob's measurements being disturbing ones).

Let us agree on a distance measure on density operators. A convenient one (and my favorite) is

$$d(\rho, \sigma) = \mathrm{tr}|\rho - \sigma|,$$

but that's not so important for the considerations here. (Well, it may be in the long-run, but I don't want to let such a technicality detract from posing the question.)

Suppose Alice walks into a room and says to herself that a system is described by ρ, while Bob says to himself that it is described by σ. We can gauge their amount of initial consensus by $d(\rho, \sigma)$. Now, suppose Carol (or Alice or Bob for that matter) performs a measurement on the given system whose action—i.e., whose associated completely positive map—is to take any initial state τ to

$$\tau \longrightarrow \tau_b = \frac{1}{\mathrm{tr}(\tau A_b^\dagger A_b)} A_b \tau A_b^\dagger$$

depending upon the particular outcome b. Here, of course,

$$\sum_b A_b^\dagger A_b = I.$$

(This is nothing more than the general form of an "efficient" measurement as defined in my QFILQI paper cited above.) Let us allow Alice and Bob to be privy to this map, and indeed to the actual outcome b.

Thus, the final consensus of Alice and Bob will be gauged by $d(\rho_b, \sigma_b)$. The question is: When can Alice and Bob expect to be in better agreement after the measurement than before? That is, as far as Alice is concerned, she will *expect* their final distance to be

$$D_A = \sum \mathrm{tr}(\rho A_b^\dagger A_b) d(\rho_b, \sigma_b).$$

As far as Bob is concerned, he will *expect* their final distance to be

$$D_B = \sum \mathrm{tr}(\sigma A_b^\dagger A_b) d(\rho_b, \sigma_b).$$

For a given set of A_b's, what are the necessary and sufficient conditions on ρ and σ so that

$$D_A \le d(\rho, \sigma)$$

and

$$D_B \le d(\rho, \sigma) \text{ ?}$$

Suppose we can answer these questions. Then we will be able to identify the minimal fact Alice and Bob must reveal to each other (even without explicitly revealing their full beliefs captured by ρ and σ) so that they can expect to walk out of the room in better agreement ... even if they still can't say with certainty what each other now believes.

Beliefs, only beliefs. But sometimes we can say something about their convergence. And you guys have provided an example.

07-08-01 *Knowledge, Only Knowledge: Amendment* (to T. A. Brun, J. Finkelstein & N. D. Mermin)

I just reread the thing after sending it. Let me be more careful before one of you accuses me of being a flaming positivist again. (I suspect Todd, in particular, will be inclined to do so, and I want to fend that off before it happens.) In my closing sentence, I wrote:

> Beliefs, only beliefs. But sometimes we can say something about their convergence. And you guys have provided an example.

Let me temper that to:

> Beliefs, only beliefs. But sometimes we can say something about their convergence, as they are steered by our interactions with the world external to us. And you guys have provided an example.

Now, I can sleep safely ...
Good wishes to all!

07-08-01 *The First Amendment* (to J. Finkelstein)

Thanks for the note. But nothing changes for me (yet, at least). Sorry for my overemphasis on Carol.

Finkelsteinism 5: *If that can be agreed to, then the rest is essentially just algebra. $S[\rho_a]$ is the orthogonal complement of the zero-eigensubspace of ρ_a, which is the set of $|\phi\rangle$ such that Alice knows with certainty that a measurement of $|\phi\rangle\langle\phi|$ must yield the result zero. So the support of the updated version of ρ_a must be a subset of the support of the original ρ_a. Likewise, Alice can see that the support of the updated ρ must be a subset of the support of ρ_b. Etc.*

The issue for me is not whether Alice *might* be willing to incorporate Bob's beliefs/knowledge into her own knowledge base—that, I'll grant her, in which case I agree that everything you say is true. Instead it is whether she *must* be willing to do it. I think you are (tacitly) trying to get me to agree that she *must* be willing to accept Bob's quantum state as extra, valid information. That's something I can't do. I reserve the right for Alice to think that Bob's quantum state is complete nonsense, something that she would never want to incorporate into her own knowledge base. (It's part of being an American.)

To say that two observers *must* be willing to incorporate their separate states of knowledge into a single state is—I think—to tacitly (there's that word again) accept an Everettian kind of view. For it never allows that quantum states are states of belief in the normal sense. Instead it makes them more like "objective points of view" (relative states) that *must* be derivable from a larger, more encompassing picture. Why else would the states have to be "consistent" with each other (for instance, in your and Todd's sense)?

Is that helping any to get my wacky point of view across?

07-08-01 *Kiki, James, and Dewey* (to J. A. Waskan)

The last month or so, I've been logging quite a few hours in the philosophical world. I read about 100 pages from this little book: A. Schopenhauer, *The Philosophy of Schopenhauer*, edited, with an introduction by I. Edman, (Modern Library, New York, 1928).

It's a small collection of pieces from Schopenhauer's big masterwork. I read about 50 pages on the world as representation, and about 50 on the world as will. Even that little was not easy for me. It's fanciful stuff, but maybe I extracted an idea or two that I like. The main one is simply the idea of a dichotomy between what things look like from the inside of any phenomenon (when there is a view from that perspective)—Schopenhauer called it will—and what things look like from the outside of the phenomenon (when there is a view from that perspective)—Schopenhauer called it idea. Or, maybe I should have more safely said "is" rather than "look like." But, in any case, that distinction (and a strict separation between the concepts) strikes me as useful or at least worth contemplating. Just about all the rest, though, I probably wouldn't be able to accept: the strict Kantian categories, the principle of sufficient reason, etc., etc.

On the other hand, I have gotten *completely* carried away with William James and John Dewey. Here's how I put it to my friend Carl Caves the other day:

> Today I focused on rounding up some more William James, John Dewey, Percy Bridgman material. I think James is taking me over like a new lover. I had read a little bit of him before, but I think I was more impressed with his writing style than anything. But I was drawn back to him by accident, after reading Martin Gardner's *Whys of a Philosophical Scrivener*. Gardner devoted a lot of time knocking down James' theory of truth, because it is just so much easier to accept an underlying reality that signifies whether a proposition is true or false, rather than saying that the knowing agent is involved in eliciting the very proposition itself (along with its truth value). And something clicked! I could see that what James was talking about might as well have been a debate about quantum mechanics. He was saying everything in just the right way. (Let me translate that: he was saying things in a way similar to the way I did in my NATO "appassionato.") And things have only gotten better since.

And indeed, they have only gotten better since! Since coming to Munich, I have not been able to put James and Dewey down (when I'm not writing emails trying to translate their ideas into the quantum mechanical context, in particular for a technical problem Caves, Schack and I are disagreeing violently on). I read James' *Pragmatism, and four essays from the Meaning of Truth*, and now I'm about halfway through *John Dewey: The Essential Writings*. I'm moved by this stuff like nothing else I've ever read.

You can't tell me philosophers don't have the good life!

07-08-01 *Parachutes* (to J. Preskill)

Preskillism 2: *[T]hanks for teaching me the word "communard". . . . [I] guess I have a conflict in October 2002. I have agreed to go to Leiden for that month to be the "Lorentz chair," teaching a short course on quantum computing. It is an odd thing to do for someone who travels as little as I do, but they convinced me that it is too big an honor to turn down. The list of past recipients includes 10 Nobel Prize winners.*

Congratulations on the Lorentz chair thing. That is quite an honor. I looked at the list: Steam started rising from my computer screen! Here's my challenge: Use the fanaticism of Wheeler, the thoroughness of Wigner, the religion of Rosenfeld, the science fiction of Klein, the common sense of Peierls, the intuition of Yang, and the poetry of Mermin to tell your audience in a convincing way that quantum computing and information is just the beginning of quantum mechanics, not the end.

08-08-01 *Cross Entropy Min* (to J. Finkelstein)

Finkelsteinism 6: *Which brings up a slightly different question. Suppose, again, that Alice describes a system by ρ_a, but this time let's say for simplicity that she considers what would happen if Bob were to tell her that his ρ_b corresponded to a pure state $|\phi\rangle$; then, given her knowledge of the system (ie, given ρ_a) what could Alice say about what $|\phi\rangle$ might be?*

It follows from what we have been saying that Alice knows that for $|\phi\rangle$ to be possible, it must be in $S[\rho_a]$, and that (in finite dimensions, at least) she cannot, based on her own knowledge, rule out any $|\phi\rangle$ that is in $S[\rho_a]$. But can Alice say any more than that? Would it make sense for Alice to put a probability distribution on the possible $|\phi\rangle$ that Bob might announce to her? (It would have to be a probability density; eg, if ρ_a were a multiple of the identity, then Alice would surely judge all states to be equally-likely.) If that did make sense, it would mean that Alice would be constructing a particular (continuous) ensemble representation of ρ_a. What could that be?

As I recall, this is quite similar to the classical problem ("principle of minimum cross-entropy") explored in the two references below. But I'm not going to have a chance to refresh my memory for a while. If you've got the time, you might see if it's relevant.

1. John E. Shore and Rodney W. Johnson, "Axiomatic Derivation of the Principle of Maximum Entropy and the Principle of Minimum Cross-Entropy," IEEE Transactions on Information Theory **IT-26**(1), 26–37 (1980).

2. John E. Shore and Rodney W. Johnson, "Properties of Cross-Entropy Minimization," IEEE Transactions on Information Theory **IT-27**(4), 472–482 (1981).

08-08-01 *The First Eye* (to C. M. Caves)

I am just about to get down to some serious (political) scheming to do with our Bayesian program: I'll let you know what I'm talking about if it turns out to be successful. First though, I want to take a moment to tell you about a point of similarity between our (both far-from-completely worked out) flavors of quantum ontology. This one just struck me a few days ago.

Some time ago, I tried to explain to you what I was hoping for for [sic] an ontology behind quantum mechanics. (See Samizdat, pp. 127–129.) I said it would have something to do with the information-disturbance tradeoff in quantum eavesdropping. You replied that, try as you might, you could see no ontological content in such a statement. I think what was troubling you was that the information-disturbance relations (as I am thinking of them), by their very nature, require explicit reference to the *subjective* points-of-view/opinions/beliefs (i.e., quantum states) of various *agents*.

I, on the other hand, have no problem with that. For the way to think about it is that the world (independent of our existence) has latent within it a property that simply has no way of being properly expressed without inserting information-manipulating agents into the picture. (Or, at the very least, that this anthropocentric way of stating things may be our first firm handle for getting at a better, more objective-sounding, formulation of the latent property.) Taking this tack does not mean, of course, that there is no world independent of human existence, and that is my point. It just means that we may sometimes have to take into account our (presumably contingent) existence for expressing some of the world's properties.

Here is something, however, that you should think about in connection to your "world = Hamiltonian" hopes. Let me put the ball back into your court. Can you explain to me the role of Hamiltonians in your ontology in a way that does not make use—even tacitly—of the concept of a (subjective) quantum state? What is it that Hamiltonians do if their primary role is not in evolving (subjective, agent-required) quantum states? In the classical world, one could give an answer to this question by saying, "They evolve the positions of phase-space points." Such a statement makes no use of the concept of information-bearing agents for its formulation. (I view it as just nitpicking to argue whether the points or their trajectories (from which we can derive the Hamiltonian) are the more primary of the entities. Or whether they are equally primary.) But in the quantum case, I haven't yet seen what you can say if I take away the linguistic tool of "the quantum state" from your explanatory repertoire. What can you say?

I'll put a few passages of Schopenhauer below to inspire you. [From: A. Schopenhauer, *The Philosophy of Schopenhauer*, edited, with an introduction by I. Edman, (Modern Library, New York, 1928).]

> "No object without a subject," is the principle which renders all materialism for ever impossible. Suns and planets without an eye that sees them, and an understanding that knows them, may indeed be spoken of in words, but for the idea, these words are absolutely meaningless. On the other hand, the law of causality and the treatment and investigation of nature which is based upon it, lead us necessarily to the conclusion that, in time, each more highly organised state of matter has succeeded a cruder state: so that the lower animals existed before men, fishes before land animals, plants before fishes, and the unorganised before all that is organised; that, consequently, the original mass had to pass through a long series of changes before the first eye could be opened. And yet, the existence of this whole world remains ever dependent upon the first eye that opened, even if it were that of an insect. For such an eye is necessary condition of the possibility of knowledge, and the whole world exists only in and for knowledge,

and without it is not even thinkable. The world is entirely idea, and as such demands the knowing subject as the supporter of its existence. This long course of time itself, filled with innumerable changes, through which matter rose from form to form till at last the first percipient creature appeared—this whole time itself is only thinkable in the identity of a consciousness whose succession of ideas, whose form of knowing it is, and apart from which, it loses all meaning and is nothing at all. Thus we see, on the one hand, the existence of the whole world necessarily dependent upon the first conscious being, however undeveloped it may be; on the other hand, this conscious being just as necessarily entirely dependent upon a long chain of causes and effects which have preceded it, and in which it itself appears as a small link. These two contradictory points of view, to each of which we are led with the same necessity, we might again call an *antinomy* in our faculty of knowledge, and set it up as the counterpart of that which we found in the first extreme of natural science. The objective world, the world as idea, is not the only side of the world, but merely its outward side; and it has an entirely different side—the side of its inmost nature—its kernel—the thing-in-itself. This we shall consider in the second book, calling it after the most immediate of its objective manifestations—will. But the world as idea, with which alone we are here concerned, only appears with the opening of the first eye. Without this medium of knowledge it cannot be, and therefore it was not before it. But without that eye, that is to say, outside of knowledge, there was also no before, no time. Thus time has no beginning, but all beginning is in time. Since, however, it is the most universal form of the knowable, in which all phenomena are united together through causality, time, with its infinity of past and future, is present in the beginning of knowledge. The phenomenon which fills the first present must at once be known as causally bound up with and dependent upon a sequence of phenomena which stretches infinitely into the past, and this past itself is just as truly conditioned by this first present, as conversely the present is by the past. Accordingly the past out of which the first present arises, is, like it, dependent upon the knowing subject, without which it is nothing. It necessarily happens, however, that this first present does not manifest itself as the first, that is, as having no past for its parent, but as being the beginning of time. It manifests itself rather as the consequence of the past, according to the principle of existence in time. In the same way, the phenomena which fill this first present appear as the effects of earlier phenomena which filled the past, in accordance with the law of causality. Those who like mythological interpretations may take the birth of Kronos ($\chi\varrho o\nu o\varsigma$), the youngest of the Titans, as a symbol of the moment here referred to at which time appears, though indeed it has no beginning; for with him, since he ate his father, the crude productions of heaven and earth cease, and the races of gods and men appear upon the scene.

09-08-01 *Lock Box Reference* (to J. A. Smolin)

Page 101 in:

C. A. Fuchs, *Notes on a Paulian Idea: Foundational, Historical, Anecdotal & Forward-Looking Thoughts on the Quantum (Selected Correspondence).* 504 pages. Foreword by N. David Mermin. See `quant-ph/0105039`.

10-08-01 *The Fifth Amendment* (to T. A. Brun)

Thanks for the note, which I thoroughly enjoyed. You hit a lot of nails on the head with it. Let me try to expand on some of the points that—I believe—show that at least you and I are coming to a little consensus. (As for Jerry and David, I will put them in a superposition for the time being, and see how this this interaction shakes things up.)

Brunism 1 : *That doesn't mean that I completely disagree with you, Chris, but I think you are making a point which is pretty far from the spirit of this problem.*

This is the point. What I am trying to get straight is: *What* is the spirit of this problem?

You write,

Brunism 2 : *We have been describing a consistency criterion.* If *one wishes to combine two state descriptions of a single system into a* single *state description, the criterion tells one* when *it is consistent to do so (i.e., when the two descriptions are not actually contradictory).*

I agree that nobody is holding a gun to Alice's head and forcing her to incorporate Bob's information.

Putting it like that, I can certainly accept the proposition. I want to emphasize that. The attractive feature for me is that it is built on a conditional at the outset.

But you speak of *the* spirit of *this* problem. How is your statement to be reconciled with the tone of David's `quant-ph`? In particular, say, David's quote of Peierls (which he takes as his guiding light):

Merminition 41 : *In my view the most fundamental statement of quantum mechanics is that the wavefunction, or, more generally the density matrix, represents our knowledge of the system we are trying to describe. ... [Yet, density matrices] may differ, as the nature and amount of knowledge may differ. People may have observed the system by different methods, with more or less accuracy; they may have seen part of the results of another physicist. However, there are limitations to the extent to which their knowledge may differ.*

Peierls does not use the qualification that you did—nor do any of you three in many of the emails I have seen—and that is what bothers me.

What I see in Peierls's version of the spirit is that two quantum states cannot co-exist (even in a Platonic sense) unless they are consistent (in one manner or another, yet to be fleshed out). It is as if the universe has these little properties floating about, called quantum states, that MUST be consistent in the BFM sense (or some other sense). I will agree that that might be fine from an Everett-kind of point of view. But if one insists on consistency (as one should with ontological, physical properties), then—it seems to me—one breaks away from the desire to give the quantum state a *purely* epistemological role ... which, as I understood it, was the goal of Peierls and Mermin (though I am willing to accept that it may not be the goal for you and Jerry).

Brunism 3 : *The point of consistency is to determine* if *two points of view can be combined into a single description, not to require that they must be.*

This I also agree with: It was meant to be the whole point of my note "Knowledge, Only Knowledge." My only point of disagreement, was that it was seeming to me that the tendency in David (and Jerry?) was the assumption that the "if" must be satisfied—in some sense—in the "real" physical world.

I just don't know how to say this more clearly. I think it is a valid worry about the intent, the very definition of what the problem is about. I don't think I'm being subtle: that is certainly the last thing I want to be.

Brunism 4 : *I will make one additional comment. I think that in science there is usually a* tacit *(to use your word) assumption that the separate states of knowledge of different observers can be combined, provided that they make no errors and reason logically. This then implies that there* is *a kind of "global state," in the limited sense of a state including all available knowledge. If two observers' beliefs are so inconsistent that they cannot be combined together with any amount of communication and experimental data, they might as well be living in different worlds. This is why we say that insane people are "out of touch with reality."*

I can see why one would say that, especially if one believes that the process of science has an end, and that there is a sense in which the universe is pre-formed. (So maybe I will admit to *some* postmodernist tendencies.) But then . . .

Brunism 5 : *Also for this reason, a rational person may very well never assign a perfectly pure state to a system, but always a mixed state of the form*

$$\rho = (1-\epsilon)|\psi\rangle\langle\psi| + \epsilon\rho'$$

where ϵ contains the unspoken acknowledgement "But I might be wrong."

giving an agent the right to set his own density operator seems to me to be a concession to the quantum state's (purely?) epistemological content.

A note on the "The Second Amendment" to be sent to David soon after lunch.

12-08-01 *A Silver Lining in the Deutsch Cloud* (to R. Pike)

I like to think that there are silver linings to the clouds of my many diatribes! (E.g. the note I just sent Patrick.) Anyway, thinking more about Deutsch this morning (and his silliness that quantum computing only makes sense from a many-worlds view), see the two papers below.

Brooding on the Raussendorf-Briegel one especially (since David DiVincenzo brought it to Steven's and my attention Thursday), I think these are really important ones. And they may give us a much easier, nicer, more insightful way to describe what quantum computing is about.

`quant-ph/0010033`
Title: Quantum computing via measurements only
Authors: Robert Raussendorf, Hans J. Briegel

`quant-ph/0108020`
Title: Universal quantum computation using only projective measurement, quantum memory, and preparation of the 0 state
Authors: Michael A. Nielsen

13-08-01 *Out of the Frying Pan . . .* (to R. Garisto)

My thoughts are with you, and thanks for including me in the list of updatees.

I don't know if it'll work for you, but in times when I'm hanging on the edge, listening to John Coltrane and contemplating quantum mechanics seem to help more than anything. The two activities are not unrelated.

13-08-01 *Reference You Wanted* (to D. P. DiVincenzo)

The formula can be found on pages 26 and 27 of:

> C. A. Fuchs, "Quantum Foundations in the Light of Quantum Information," to appear in *Proceedings of the NATO Advanced Research Workshop on Decoherence and its Implications in Quantum Computation and Information Transfer*, edited by A. Gonis (Plenum Press, NY, 2001). (Until then, see `quant-ph/0106166`.)

See you tomorrow probably.

13-08-01 *A Silver Lining in the Deutsch Cloud, 2* (to N. D. Mermin)

By the way, you might enjoy these too if you haven't already run across them. I think there is some parallel here to thinking of quantum teleportation in the two ways: i.e., the original 1993 way, and the quantum circuit way (like you wrote about recently). The dichotomy goes much deeper and may pervade all of quantum computation, or least that's what is starting to strike me.

"Pinging the sensitive substrate, that's what quantum computing is about." Or, at least, that's what I think would build a pretty picture. The two papers below may give us the right language to view it that way.

14-08-01 *Law without Law, 2* (to J. Summhammer)

Thanks for your note. Give me a few days to digest it. In the meantime,

Summhammerism 4: *In my next mail I hope to get down to asking you a few questions on your paper "Quantum Foundations in the Light of Quantum Information". And the prior probability distribution of probabilities in the classical de Finetti theorem is causing me some trouble. Also, I would appreciate a copy of your paper (PS, PDF, or address for downloading preferred) "How much information in a state vector?"*

let me give you the reference you requested. It can be found on the Los Alamos archive (as can about 75% of my publications). Here's the abstract:

> `quant-ph/9601025`
> Date: Wed, 24 Jan 96 21:21:01 MST (31kb)
>
> Quantum information: How much information in a state vector?
> Authors: Carlton M. Caves, Christopher A. Fuchs
> Comments: 32 pages in plain TEX, to appear in *Sixty Years of EPR*, edited by A. Mann and M. Revzen, Ann. Phys. Soc., Israel, 1996
>
> Quantum information refers to the distinctive information-processing properties of quantum systems, which arise when information is stored in or retrieved from nonorthogonal quantum states. More information is required to prepare an ensemble of nonorthogonal quantum states than can be recovered from the ensemble by measurements. Nonorthogonal quantum states cannot be distinguished reliably, cannot be copied or cloned, and do not lead to exact predictions for the results of measurements. These properties contrast sharply with those of information stored in the microstates of a classical system.

15-08-01 *Knowledge, Only Knowledge – Reprise* (to T. A. Brun)

Brunism 6: *Frankly, I find your negativity about this problem puzzling.*

On the contrary, I'm quite taken with it: otherwise, I wouldn't have given it the time of day. Reading the collective emails has been a great learning experience for me.

15-08-01 *Compatible States* (to R. Schack)

Schackcosm 2: *I got a number of rather incoherent messages on compatible states from you. Is there anything more recent on this?*

Yes. About three thousand more notes. The issue refers to David Mermin's recent `quant-ph` paper "Whose Knowledge?"

Where it stands right now is with Brun, Finkelstein, and Mermin all ganged up against me (as being the unreasonable one). The conclusion they've come to is something like this:

> Two density operators ρ_a and ρ_b can describe the same system iff the support of ρ_a has a non-trivial intersection with the support of ρ_b.

I, on the other hand, think such a statement is far too dictatorial for a Bayesian's taste. Try as I might, they just don't think my points are relevant.

I'll paste (what I deem to be) my most lucid notes below. You can judge for yourself. I'm soon going to drop out of the debate, I believe: it's now at a point of diminishing returns. But, I would like to hear your thoughts!

16-08-01 *Subject-Object* (to P. Grangier)

Thanks for your note! I'm always amazed when anyone reads or skims my papers: You have a friend for life!

Last night I read your paper `quant-ph/0012122`, which I had never seen before. Thanks for bringing it to my attention.

Grangierisme 1: *You are probably aware that statements such as : "The quantum state is information. Subjective, incomplete information." ... "Quantum states are states of knowledge, not states of nature. That statement is the cornerstone of this paper." are unwarranted, since just opposite statements can be made without changing any physical predictions or even any technical development. My personal view is that these statements are even wrong, as soon as "quantum state" is understood as "pure quantum state" (see eg* `quant-ph/0012122`*, missing in your list on p.1).*

In your words,

> [C]ontrary to the copenhagian dogma, a central point in our approach will be to give an "objective reality" to the quantum state of a physical system, in a sense which is developed below. ... The quantum state of a physical system is defined by the values of a set of physical quantities, which can be predicted with certainty and measured repeatedly without perturbing in any way the system.

Here is a problem I have with this conception. (It is a problem I am quite sure you are aware of, but for some reason you did not address it directly in your paper.) Consider two electrons originally prepared in a spin-singlet state—one electron in the possession of Alice, one in the possession of Bob. Let us imagine now two alternative scenarios. In one, Alice measures σ_x on her particle; in the other scenario, she measures σ_z. By your criterion, Bob's particle does not start out with a quantum state (since the two electrons are in an entangled state)—which is fair enough (I have no qualm with that)—but *immediately upon* the measurement it will go into a definite quantum state, either an eigenstate of σ_x or an eigenstate of σ_z, depending upon the scenario. We know this because if Bob were to thereafter repeatedly send his particle through a Stern-Gerlach device with the proper orientation (for the given of the two scenarios), Alice would be able predict with complete certainty which way Bob's particle would go. Moreover, if Bob is careful enough, these further measurements on his part will not perturb his system (in the sense of changing the spin quantum state of the electron). So, we have just what you had wanted: complete certainty and no necessary perturbation.

But if the quantum state is an objective feature of the electron, then we see that it can be toggled one way or the other instantaneously from a distance. (Alice's measurements causes Bob's electron to go into one or another quantum state instantaneously.) Thus, if you accept the objectivity of the quantum state, then you must also accept the objectivity of instantaneous action at a distance (that in no way diminishes with distance or the particulars of the medium filling the space between Alice and Bob).

This is something I'm not willing to do. Not out of dogma, but because it strikes me that the world would have to be horribly contrived to have this property: a little private (instantaneous) telephone line between each and every physical system that will not accept outside calls. I.e., I can never make use of this instantaneous action for real, live communication even though it really, really, really is there. It stretches my imagination too far.

You, of course, may accept it as you wish; but the reasons above are mine for not doing so. Let me address your other point that I quoted above:

> [Your statements] are unwarranted, since just opposite statements can be made without changing any physical predictions or even any technical development.

I certainly disagree with the latter part of this sentence: that was the whole point of my paper (i.e., that it can change the technical development of the theory). Taking one or another point of view about the objectivity of the quantum state motivates different directions of theoretical exploration. In my case, it motivated trying to find the four theorems I presented in that paper. One who believed in the objectivity of the quantum state—I am quite sure—would not have sought those theorems in the first place.

Grangierisme 2: *By the way I also disagree with your point of view that "Quantum Theory Needs No 'Interpretation'," Phys. Today* **53***(3), 70 (2000). The fact that a physical theory ALWAYS needs an interpretation is in my opinion a central difference between physics and mathematics.*

You won't find a disagreement with me here. The title and closing sentence of that paper were meant to be tongue-in-cheek plays on something Rudolf Peierls once said: "The Copenhagen interpretation *is* quantum mechanics." The whole paper is very definitely about an interpretation, and why one does not need to go any further than it to make sense of quantum mechanics as it stands. My paper `quant-ph/0106166` and the large (more personal) collection `quant-ph/0105039` is about going the next step, i.e., what to do once we have established the belief that quantum states are states of knowledge.

When we do finally dig up an ontology underneath quantum mechanics, I'm quite sure it will be an interesting one!

17-08-01 *Your Computational Model* (to H. J. Briegel)

A couple of weeks ago, David DiVincenzo brought my attention to your paper with Raussendorf on models of quantum computation that make use of measurement only (once the initial state is set). I must say, this model has me absolutely enamored! (Besides being intrinsically interesting for our field, it seems to mesh well with the quantum foundational direction I have been trying to develop.)

I wonder if you (or Raussendorf) might have some time to let me hear the word from the horse's mouth, so to speak? I tried reading the first small paper the other night, but it was a bit tough going for me. So, I'd really like more to be eased into the subject with a presentation or two. I will be in Munich (Zorneding actually) visiting my parents-in-law from August 30 through September 9. If you've got some free time in the middle of that, I'd surely like to drop by your university for a discussion.

17-08-01 *Unloading Bayes* (to C. M. Caves & R. Schack)

Let me unload a couple more Bayesian thoughts on you—i.e., some things we will probably want to address in the RMP article.

1) Attached below is a note I wrote to Mermin giving what I think is the cleanest justification for noncontextuality in any Gleason theorem. In fact, it shows that noncontextuality is more basic in the hierarchy of theories than anything else we've dealt with yet. I.e., it comes far before the particular details of quantum mechanics. (Maybe this is what Carl has been saying all along, but I had to work through it for myself before it stuck.)

2) Let me bring your attention to a cluster of papers that I think are really important.

> `quant-ph/0010033`:
> Title: Quantum computing via measurements only
> Authors: Robert Raussendorf, Hans J. Briegel (LMU Munich)
>
> `quant-ph/0108020`:
> Title: Universal quantum computation using only projective measurement, quantum memory, and preparation of the 0 state
> Authors: Michael A. Nielsen
>
> `quant-ph/0108067`:
> Title: Computational model underlying the one-way quantum computer
> Authors: Robert Raussendorf, Hans Briegel

I am especially taken with the Raussendorf-Briegel development. On one level, I think it might be the simplest avenue for addressing quantum computation from a Bayesian point of view: One just builds up the proper initial (universally valid) entangled state, and then does a measurement site by site, doing proper (Bayesian) updating of the quantum state of the remaining sites at each step. At the end of the day, one's knowledge is updated to the sought after answer. On another level (not for RMP), I think it starts to capture what I have been hoping for as an explanation of the power of quantum computation: it is not quantum parallelism that is doing the trick, but the "zing" of quantum systems that makes them sensitive to our interventions.

3) Let me put further below my replies to Khrennikov on his "contextual probabilities" business. I've already shared this with Carl, but not Rüdiger yet. What I like about my statement there is that it starts to put Gleason's theorem in a more Dutch-book kind of light. Just as in classical theory, the setting of initial probabilities is completely free (and therefore subjective). What is set by coherence/rationality is the transformation rules. To that extent, this is the objective content of probability theory. Similarly with quantum mechanics in the light of Gleason's theorem: The objective content of quantum mechanics (or at least part of it) is that if we subjectively set our probabilities for the outcomes of any informationally complete POVM, we are no longer free to set them arbitrarily for any other observable. The probabilities are now fixed and can be calculated uniquely from our previous subjective judgment. (I hate the American way of spelling "judgement.")

That's about it for now. I've certainly written loads more (Bayesian oriented stuff) since we've last seen each other. But nothing else that might have been striking is coming to mind right now. I'll probably unload more as I think of it.

As I'm hearing about more and more of you arriving in Santa Barbara, I'm starting to get a little envious that I'm missing all the fun. At least Kiki and Emma will be off to Munich Monday evening. I won't be joining them until the following Wednesday. I have this great dream of idling away my hours in the mean time with Arthur Schopenhauer, William James, and the Reverend Bayes. But I'm sure some reality will set in to knock me off my course of purity.

20-08-01 *Unloading Bayes, 2* (to C. M. Caves)

Cavesism 2: *I'm not sure anyone is going to be convinced by the above, but I think it is a start. So here's the scenario. There is a big set of things that can be true or false. The big set is determined by the (physical) theory you are dealing with. There are further rules that say how the elements in this big set can be gathered into subsets that correspond to questions whose outcomes are exclusive and exhaustive. Now, if you make noncontextual probability assignments to the questions, you have just ignored the structure that led to your original set. That being the input from your basic theory, if you make noncontextual assignments, you are deciding not to pay attention to your own theory. Not too bright. So you should make noncontextual assignments.*

I know this won't come as a surprise to you, but (really) I found my (operational) explanation much more convincing. So, I guess I really didn't take my cue from you after all. Probably more from Pitowsky/Renes/Hardy.

Can you pinpoint what you didn't find convincing about my argument?

My trouble with your argument is that I still don't find the statement, "if you make noncontextual probability assignments to the questions, you have just ignored the structure that led to your original set," all that compelling. I guess I still don't quite understand what you are saying.

21-08-01 *Contextual Reality = Information??* (to P. Grangier)

Thanks for the longer explanation. It has indeed clarified things for me.

What I think is funny though, is that for precisely everything you say below (which I quote), I would call the quantum state "information" rather than an "objective reality."

Let me ask you this: Would you reread Section 3, "Why Information?" in my `quant-ph/0106166` and comment why and how you would use a different language in rewriting that? It seems to me that to say "a (pure) quantum state is objective, but it is contextual, i.e., defined relatively to a particular set of measurements results" (as you do), can only be to teeter very close to admitting that the state is information (and only information). If the state is only defined relative to Alice's measurement results, why not call those measurement results the actual reality and be done with it? What does having the quantum state being objectively real add to the story?

Philippe's Preply

Alice may obviously choose between several measurements, but she must eventually decide for one and perform it. My definition of the "objective quantum state of a system" *requires* that Alice's measurement is completed, which does not "toggle" the state, but simply define it (at Alice's location).

Once Alice's measurement is completed, and given her measurement result, she will be able to make predictions about Bob's state. But obviously the corresponding information (orientation of Alice's polarizer and measurement result) will have to travel (non-instantaneously) from Alice to Bob. Thus there is nothing here like "objective instantaneous action at a distance", that I dislike as much as you do. On the other hand, there is an objective quantum state, in the sense that once Alice's results have reached Bob (and not before !), Alice and Bob will know "the values of a set of physical quantities, which can be predicted with certainty and measured repeatedly without perturbing in any way the system". In this view BI are violated as a consequence of the lack of "separate reality" of the two particles, rather than as a consequence of non-locality.

To put it another way: a (pure) quantum state is objective, but it is contextual, i.e., defined relatively to a particular set of measurements results. If new measurements are done that are not in the initial set, the definition of the new physical state *must* include the results of the new measurements. In some sense, this is simply a restatement of Bohr's 1935 answer to the EPR article (and maybe this can be related to your "Bayesian" approach?).

21-08-01 *Noncontextuality* (to C. M. Caves)

Cavesism 3: *This is a weird notion of operational, since you rightly note immediately afterward that it is really tautological. How does it justify assigning the same probability to an element in the big set, no matter what the context, to note that you have a rule that assigns the same probability to an element in the big set, no matter what the context? It seems to me the real point is why you would ever identify two elements from different contexts, and the reason is that that they are the SAME element in the underlying set, which is handed to you by your underlying theory. Moreover, you only have one thing to go on, and that is the fact that the theory tells you that two elements are actually the same element in the underlying set. This means that the theory wants them to have the same probability in all contexts.*

I think what is creeping in here (anew) is a fundamental philosophical difference that is starting to come between us. Maybe I can characterize it in the following way. You want the theory to come first, and then to (somehow) recover our activity as scientific agents back out of that grander picture. I, on the other hand, am becoming more and more content to start with the scientific agents and thereafter pluck out those terms in their discourse with various common features to call a theory.

Cavesism 4: *How does it justify assigning the same probability to an element in the big set, no matter what the context, to note that you have a rule that assigns the same probability to an element in the big set, no matter what the context?*

It doesn't justify assigning the same probability. Assigning the same probability is the very reason for assigning a common element in our theoretical descriptions of two very distinct devices.

22-08-01 *Contextual and Absolute Realities* (to P. Grangier)

Grangierisme 3: *This may sound like rhetoric, but if a theory explains nothing less than the stability of matter, is able to calculate $g = 2$ (and many other things) with an incredible accuracy, and nevertheless does not speak about "physical reality", what is physics? I thus consider much more useful to put forward a reasonable definition of reality, that allows me to say to a journalist : "QM speaks about the reality of micro-objects. It is a weird reality, ... but it is REAL."*

You ought to know that I could not agree more with this (the part that I quoted, not the part that I did not quote). The issue on my mind is whether it is productive to view the quantum state in particular as THE term in the theory that corresponds to the objectively real. The way I view the issue is this: Quantum theory is a mixture of objective and subjective elements and we will only make progress in quantum foundations when we have had the intellectual strength to cleanly separate those two ingredients. With this point of view, I can answer the journalist just as soberly as you (i.e., without carrying him off to a postmodern fuzz fest).

There are certainly elements in quantum theory that I am immediately willing to identify as objectively real. A good example comes from our Alice and Bob example, generalized ever so slightly. Suppose Alice's system has a Hilbert space of dimension E and Bob's has a Hilbert space of dimension D, and that again Alice and Bob start off with an entangled state for the bipartite system. I say that the quantum state must be (freely) subjective information because, depending upon what measurement Alice chooses to perform on her side, she will ascribe one or another quantum state to the system in Bob's possession. However, there is one obvious thing that Alice cannot change by the free choices she makes on her side of the world: It is the dimensionality of Bob's system's Hilbert space. Thus, I would say the number D is the objective reality in this situation. The number D remains constant regardless of what Alice does.

I could put this in language more to your liking, saying something like:

> The quantum state that arises for Bob's system after Alice's measurement is a "contextual reality," whereas the Hilbert-space dimension of Bob's system is an "absolute reality."

but I personally don't see that as a road to further progress. I.e., it distracts from what I view as the main point of our task in clearing up the foundations: namely, working hard to separate the subjective from the objective.

What I want to know in the most physical of terms is what does that number D signify? I want to find a way of describing its meaning that never once refers to a quantum state. When I can do that, then I will say that some progress has been made in identifying the objective part of quantum theory. But that is just an example.

Grangierisme 4: *Remember my quotation about the 2 electrons in He: in their singlet state is "subjective information", how do the electrons know it?*

It seems to me, this is just a varied form of the Penrose argument I wrote at the end of my Section 3. I dismiss it in the same way that I did there. From my point of view, to say that the electrons are in a singlet state is to give nothing more than a compendium of things we can say about how they will react to our experimental interventions into their nonhuman bliss. It is not they who can predict the consequences of my invasions into their territory, it is me.

22-08-01 *Identity Crisis* (to C. M. Caves & R. Schack)

I enter this note with trepidation, because I know that what I am about to say will not be taken lightly by either of you, and chances are you will just view me as a troublemaker (again). I don't want to be a troublemaker, but I do have some concerns that are starting to eat more and more at me.

The problem is, I am starting to have serious misgivings about our Sections II and IV of "Making Good Sense" (PRA Version). Most of this new thinking has come about through my taking David Mermin's quest in his paper "Whose Knowledge?" to task, and my ensuing debate with Todd Brun, Jerry Finkelstein, and David himself. But some of it, I think, flows directly from the spirit of Bruno de Finetti, which I now believe I had shut my eyes to for too long.

The issue is no less than whether we really believe probabilities are subjective or not. I think a failure on our part to take their subjective character completely seriously is causing us to go down a path I'd rather not take.

Let me try to explain as best I can. The trouble is localized in our claim:

> ... if two scientists have maximal information about a quantum system, Dutch-book consistency forces them to assign the same pure state.

In the mildest version of my troubles, I am starting to think this statement is contentless. In the stronger versions, however, I find it misleading, and I almost want to say "wrong" (though maybe I won't go that far).

To make sense of what I mean by this, let me start by taking a cue from Bernardo and Smith:

> Bayesian Statistics offers a rationalist theory of personalistic beliefs in contexts of uncertainty, with the central aim of characterising how an individual should act in order to avoid certain kinds of undesirable behavioural inconsistencies. ... The goal, in effect, is to establish rules and procedures for individuals concerned with disciplined uncertainty accounting. The theory is not descriptive, in the sense of claiming to model actual behaviour. Rather, it is prescriptive, in the sense of saying "if you wish to avoid the possibility of these undesirable consequences you must act in the following way." — p. 4, Bernardo and Smith, *Bayesian Theory*

If we accept this, then I think there is a much better way to word our "$p = 1$ when certainty" addition to the Dutch book argument in Section II. It seems to me it should more properly be viewed as a normalization condition, subordinate *only* to internal consistency/rationality as all the rest of the Dutch-book argument is. I say the latter to contrast it with how we presently have the argument worded in our paper—namely, by making the $p = 1$ condition subordinate to some objective feature of the world. We write:

> The only case in which consistency alone leads to a particular numerical probability is the case of certainty, or *maximal information*. If the outcome E is certain to occur, the probability assignment $p < 1$ means the bettor is willing to take the side of the bookie in

> a bet on E, receiving an amount px up front and paying out x if E occurs, leading to a certain loss of $x(1-p) > 0$. Consistency thus requires that the bettor assign probability $p = 1$. More generally, consistency requires a particular probability assignment only in the case of maximal information, which classically always means $p = 1$ or 0.

What does it mean for an outcome E to be "certain to occur"? I think that phrase is much more loaded than we have previously treated it. In the Dutch book argument there are three players, two of them animate and conscious (the bettor and the bookie) and one of them presumably inanimate and unconscious (the world). To which player does the certainty get attached? I don't think we make this clear in the way we ought to.

If the certainty is to be attached to the world, then what business does it have to do with my subjective judgments (which by definition cannot be in a bijective correspondence with the world's states)? Instead, I would say the "certainty" can only be a subjective judgment in and of itself. The Dutch-book argument for requiring $p = 1$ in the case of certainty should then be more accurately advertised as a call to be "true to our hearts." I.e., the argument is really that, *when* we believe an event will happen with certainty (a nonnumerical judgment), then we should ascribe $p = 1$ (a numerical judgment) for booking purposes. That is, Dutch-book coherence gives us a way to translate a nonnumeric belief into a numeric one.

The thing that is really at issue here is that I think we should remind ourselves always that "certainty" itself is nothing more than a belief. It may be a belief that can ultimately be tested against the world in a single shot, but nonetheless it is a belief. I believe with all my heart that my mother loves me; Schopenhauer believes with all his heart that she hates me. The only thing Dutch-book consistency can give us is that "if we wish to avoid the possibility of undesirable consequences" (Bernardo/Smith), then I should ascribe $p = 1$ and Schopenhauer should ascribe $p = 0$ to the proposition "love." The Dutch-book argument prescribes that we each should be true to our hearts—that we should both act in accordance with our beliefs. But it does not have within it the power to make us believe the same thing ... EVEN in the case of "certainty."

Now, we whitewash all that by introducing the phrase "maximal information," which somehow makes "certainty" seem more objective, but now I'm starting to think that that phrase is pretty impotent in this context. What role does it really play in our argument? I can't find any, other than that it is a euphemism for declaring that we *believe* we have nothing left to learn (in the sense that we *believe* there is nothing left to learn from the remainder of the world that will help us refine our predictions for the system at hand). That belief may be wrong in the sense that rationality AND the world will not allow us to perpetuate the belief AFTER the experimental trial, but until the trial, "certainty"—from the Bayesian view—can mean nothing more than a metered belief.

You should be able to tell where I'm going with this by now. In Section IV, we write:

> Maximal information in quantum theory instead corresponds to knowing the answer to questions that share one particular projector.

I suppose what I am saying is that I just cannot accept this anymore. At least not in its present form. Instead, if I were to modify it to bring it into alignment with everything I said above, I would have to write something like this:

> Maximal information in quantum theory instead corresponds to believing adamantly that one knows the answer to all the questions that share one particular projector.

You might think this is nitpicking, but it completely takes all the steam out of Section IV. For it gives Dutch-book consistency no grounds for enforcing that two agents "with certainty" should believe the same thing. And consequently it gives no grounds for enforcing that two agents with "maximal information" should make the same quantum-state assignment.

The only way I see to reinstate our original role for maximal information is to say that two observers can only have maximal information *when* they are both right (in the sense that the world MUST CONFORM to their probability one predictions). But then, using our argument for Gleason's theorem, we would have DERIVED that quantum probabilities are objective probabilities! (This will be my only exclamation point in the whole note, so you should take it in seriousness.) That is, we would be saying that we have maximal information only when we *know* an objective reality, and by our derivation, that objective reality would then be equivalent to a compendium of probabilities.

Instead I think the best we can say is: If Alice and Bob both believe adamantly that they know the answer to some potential measurement AND that measurement happens to be the same for both of them, then Dutch-book consistency and Gleason's theorem will enforce that they make the same probability assignments for all other measurements (i.e., that they assign the same quantum state). But said that way, I don't think any non-Bayesian will be particularly impressed: For they would say that all we have shown is "if two people know the same things, then they will know the same things." Woop-ti-do.

The Bayesians among us will still have some room to be impressed: For it will not be a priori obvious to them that beliefs about one observable should have anything to do with beliefs about another. In particular, it might even surprise them that a common belief in certainty (for two observers) for any fixed observable should lead to equal probability assignments for all other observables. But even then, I think our the shock-value of our paper will be diminished. For I think in no way have we shown that when two observers make two pure-state assignments for a system, those pure states MUST be identical.

For me, this is a liberating thing to understand, i.e., that there are no dictatorial constraints on quantum state assignments. But I suspect you will feel otherwise, at least on the first reading of this note. So, let me beg your forgiveness in advance.

As I alluded to in the beginning, these thoughts of mine don't live in a vacuum. They have been spurred by my debates with Brun, Finkelstein, and Mermin. Thus let me give you some more material to chew upon: I'll attach it below, in the form of a composite note that I've already sent to Rüdiger. Perhaps it will help clarify the things that have brought me to this position. Some of it, of course, will require that you try to imagine the context, but I think the notes are self-contained enough that you will be able to fall into the line of thought and see its relevance.

Best wishes (in spite of my predictable trouble),

23-08-01 *My Own Version of a Short Note* (to C. M. Caves)

I'm just back from a very long day in NY City (bookshopping), and a very long night before that (reading). So I won't reply to your notes until I'm a little more refreshed. But one quick comment:

Cavesism 5: *I get the feeling, strengthened by your own confession that it is true, that my e-mail doesn't make much of a dent, so why bother with it.*

That's absolutely not true. I read everything you send me many, many times over. When they are reasoned well, I accept your arguments. And you know I much prefer this method of communication, just so I can have the opportunity to fully understand what my correspondent hopes me to absorb—I've never been a quick thinker, and this helps me fill in for that inadequacy.

Today I focused on rounding up some more William James, John Dewey, Percy Bridgman material. I think James is taking me over like a new lover. I had read a little bit of him before, but I think I was more impressed with his writing style than anything. But I was drawn back to him by accident, after reading Martin Gardner's *Whys of a Philosophical Scrivener*. Gardner devoted a lot of time knocking down James' theory of truth, because it is just so much easier to accept an underlying reality that signifies whether a proposition is true or false, rather than saying that the knowing agent is involved in eliciting the very proposition itself (along with its truth value). And something clicked! I could see that what James was talking about might as well have been a debate about quantum mechanics. He was saying everything in just the right way. (Let me translate that: he was saying things in a way similar to the way I did in my NATO "appassionata.") And things have only gotten better since.

Have safe trips to everywhere you need to go. Kiki is due December 23, but I'll see what can be done about ITP in November.

26-08-01 *Quantum Commune* (to the invitees)

As many of you know, Gilles Brassard and I have become enamored with the idea that the field of quantum information and computing stands to tell us something deep about quantum mechanics itself. To that end, we organized a small party in May of 2000 to flesh out the issue; we titled it "Quantum Foundations in the Light of Quantum Information." This coming year we will do it again, but on a grander scale—something more like a commune than a party. We hope you will join us as a communard.

Quantum Foundations in the Light of Quantum Information II
Montréal, Canada
October 13, 2002 – November 2, 2002

The purpose of the meeting is to gather a group from the quantum information circle who think there are some aspects of quantum foundations that are more mysterious than they ought to be and, importantly, are intrigued by the idea of applying quantum information to the task of cleaning things up. The atmosphere of the meeting should be quite relaxed with plenty of time for discussion and/or private brooding. The autumn leaves in Montréal will likely be quite beautiful. Keeping with the tradition of the last meeting, we only ask that all attendees compile and share a list of concrete problems whose solution, they believe, will tell us something novel about quantum foundations.

We can accommodate up to 15 attendees at any one time, with all attendees having a desk and a computer in an office of one or two mates. (Of course, the longer you can stay, the better, subject only to our head-count constraint.) At this time, we can promise to cover all local and living expenses. There may also be some money for travel costs.

What we would like to know from you for the present are three things:

1) Would you like to attend?

2) If so, will your ability to attend be contingent upon travel reimbursement?

3) What is your desired length of stay?

It is fairly important that we get this information before September 1, so that we can put the attendees' names on a poster the Centre de Recherche Mathématiques (our sponsors) will use to advertise their theme year.

We look forward to hearing from you. (Since Gilles and I will both be traveling this week, please carbon copy your reply to both of us.)

With warm wishes,

Chris (and Gilles)

PS. If you can attend, your companions may be any of the colleagues listed below. (A * beside a name denotes attendance at the first QFILQI meeting.)

26-08-01 *Lock Box* (to R. W. Spekkens)

Spekkensism 7: *Onto my question. It seems to be implied in the above quote that the statements "none of us can ever completely hide the effects of our interactions with the world" and "There are no lock boxes for information" are roughly synonymous. So it seems that your conception of a lock box refers only to the property of concealment. As far as I can tell, in the sense you use the term here, a lock box need not be binding. Later you state "Item (1) sounds a lot like the nonexistence of bit commitment." However, it doesn't sound that way to me because being able to "hide the effects of my interactions with the world" requires only a BC protocol that is concealing. Indeed, it seems to me that item (1), as I am understanding it, is in fact false for QM. QM* does *allow me to hide the effects of my interactions with the world. Simply use a BC protocol that is perfectly concealing but not at all binding. Indeed, I would argue that if one only seeks lock boxes that are concealing, then one need only look as far as Wiesner's proposal for quantum money to see that such lock boxes* are *provided by QM (note that Wiesner's scheme can easily be modified so as not to rely upon the ability to prepare 'absolutely' pure states, so the finite strength of preparatory measurements is not an issue). So my question, in a nutshell, is where does bindingness enter the picture?*

You are certainly right about this; I was not being careful enough in my formulation. Thinking back on it, I guess I was tacitly wanting to reject concealingness and while retaining bindingness, but the thoughts were still pretty vague at the time ... and *are* still pretty vague today.

Let me record a few random thoughts:

1. I certainly have no problem with an information-writing agent being able to reverse his symbol, so long as the physical system on which he writes it can be thought of as an extension of his body. But there should come a time when the agent becomes detached from the system, and at that point he should lose such privileges.

2. In the quantum mechanical case, when Alice makes it so that the system is perfectly concealing, then it has zero binding power. In that case, one might say that she has not "really" recorded any symbol at all.

3. What is the meaning of the existence of intermediate cases? Do they have anything to do with the motif I was trying to imagine? Or do they lean on a completely different motif?

I'll be sending you an invitation to a quantum foundations workshop Gilles and I are organizing in Montréal for next October, in a very short while. I hope you can come.

27-08-01 *Bayesian Pill Taking* (to N. D. Mermin)

I am finally writing to reply to your long note on "knowledge." I apologize for keeping you waiting so long, but even now—since Rüdiger is still in the woods—I feel a little like I am writing you prematurely. Nonetheless, I have this overpowering desire to get this issue out of my mailbox and be done with it. So here, I am. I would ask you, however, to please keep these thoughts private, at least until Rüdiger finally emerges. For, what I am about to say involves him (and Caves) directly.

I know that you think your note is ultimately conciliatory, writing:

Merminition 42: *It seems to me that these are all valid statements about the formal structure of quantum mechanics, independent of what interpretation you favor.*

But after much soul-searching, I still cannot agree with your language. The soul-searching was required because this position of mine flies in the face of some of my very own published words (`quant-ph/0106133`).

The difficulty hinges on your Proposition 1:

Merminition 43: *1. A system that is known (by somebody) to be in a state psi cannot be found (by anybody) to be in a state orthogonal to psi.*

In my new view, to say this is to throw away all that we have been striving so hard for in establishing that quantum states are subjective entities (and purely subjective entities). You admit so much yourself at the end of your Comment (c). [You can take this to mean that I also disagree with the beginning part of Comment (c).]

In 1880, I suspect there was not a single educated physicist who doubted one iota that the speed of light was set with respect to the stationary ether. Regardless of that, in 1881 the first evidence came out against the common belief. The *spirit* of your Proposition 1 would outlaw the very happening of that wonderful historical event.

I see no way (nor even want to anymore) to get around this. If the quantum state is a subjective entity, without rigid connection to the world in itself,—as I think Einstein's original argument for its subjectivity indisputably shows us—then this is something we simply have to live with. We must allow that experimental data can speak against our predictions, no matter how set we are to believe that they will not. Yet, on top of this, we must also accept that there is no objective sense in which a (pure) quantum state is simply "wrong" before the experiment is performed.

I put all my heart and soul into presenting this point of view in the note below to my coauthors, and I will share it with you. It took me a whole day to write the thing; I would like to think it is worth reading. (Also I have slight evidence that it makes sense in that Caves ultimately concurred himself.) I believe the note is just as relevant to you and your note on "knowledge" as it is to Caves and Schack. I will also send you the PRA version of `quant-ph/0106133`, so you can track the sections.

There. Now I will clean out my mailbox.

27-08-01 *A Little Contextuality on Noncontextuality* (to C. M. Caves)

I've finally got enough time to write a small reply to your old note.

Cavesism 6: *There are two distinct approaches here, and I don't know which is to be preferred.*

1. The first point of view, which I have been pushing (as a way to justify noncontextuality), is that there is an underlying theory that sets up the structure of questions. This theory is primary. Noncontextuality emerges as the natural assumption that probability assignments should recognize the structure provided by the underlying theory.

2. The second point of view, which you have been pushing, starts with the role of scientific agents, as you put it, and uses the fact that probabilities are the same in different contexts to say that the elements with the same probabilities in all contexts explains why they are actually the same element in different contexts.

I do want you to understand my position, which is that I appreciate both these points of view. I'm not sure which will be the most fruitful in the long run. But they are trying to do quite different things. Here are two points:

1. The second point of view doesn't provide a justification for assuming noncontextuality, as you understand. Coming at things from the back door, as it were, it uses the fact of noncontextual quantum probability assignments to conclude that apparently different things are, in fact, the same.

I would not use language quite like that. I would say it IS a justification for noncontextuality. And it relies on quantum mechanics not one iota. Noncontextuality should be a property of any instrumentalistic theory (where Bayesian probability has been grafted onto to the world as the best way for us to steer our actions within it). By an instrumentalistic theory, I mean one where we explicitly have to talk about our various possibilities for experimental intervention into nature—a theory where we cannot detach the experiment from the phenomenon.

Cavesism 7: *2. The first point of view appeals to me presently because it manages to make a long straight run to the state-space structure and the quantum probability rule given only the Hilbert-space structure of questions and probabilities faithful to that structure (i.e., noncontextuality). I think the second point of view needs to address the following question: given a set of elements to which noncontextual probabilities are assigned, what structure is forced onto the set by the existence of these noncontextual probabilities? This question seems hopelessly underconstrained to me, but Howard described to Joe and me some math research on this sort of question.*

What you say "needs" to be done, seems hopelessly underconstrained to me too. But I think you shouldn't view the problem that way. The point is, one simply has a way of clearing the air of the noncontextuality issue BEFORE getting down to the nitty-gritty of quantum mechanics. Noncontextuality is the base assumption upon which one plays a new game: What *physical* assumption makes it so that our instruments should correspond to POVMs and not some other mathematical structure?

By the way, you know I really dislike your phrase "given only the Hilbert-space structure of questions." I've probably said this to you before, but let me try to articulate why in more detail so that maybe you'll remember it a little better. In your own words, the phrase is "hopelessly unconstrained." What does it mean? It seems to me there are all kinds of possibilities one could imagine if one didn't know quantum mechanics beforehand. Here's a simple example: An even more basic feature of Hilbert-space before orthogonality is linear independence. When God came down and said, "You will use Hilbert-space structure for the questions you can ask of nature," why did he not mean that any set of linearly-independent vectors corresponds to a valid question? Presumably there are good reasons. But those good reasons need to be spelled out, and are not at all implied by the simple phrase "Hilbert-space structure."

Let me send you to pages 86–88 and pages 361–362 of the samizdat. There it is shown that linear independence does not mesh so well noncontextuality. It is a dumb exercise, I know, but it does indicate that ones need to be careful with one's phraseology.

Oh, let me tell you another thing, of historical note. I talked to Howard Friday, and he tells me that this kind of justification for noncontextuality goes all the way back to Mackey (but then he settles on the setting of ODOPs thereafter).

Cavesism 8: *I'm also quite interested in another question: How general are the theories where maximal information does not lead [to] certainty, yet does lead to unique noncontextual probability assignments? In other words, for what classes of theories is there a Gleason theorem?*

I think this is a really good question. I was talking to Eric Rains the other day and he thinks that the appropriate generalized setting might be the Jordan algebras. This is because this is the largest structure he knows where there is a notion of positive operator. (I had shown him the trivial POVM way of proving Gleason.)

If Gleason can be proved in such a wildly general setting, I think it would be quite interesting. For it would tell us that the quantum probability rule is not very closely connected to physics at all. Dreaming of the process of deriving quantum mechanics as successively tucking up the more general structure of Bayesian probability theory, one might say that the real physical assumptions don't come until much later in the game. That would be worthy knowledge!

Waiting for a stupid doctor's appointment,

28-08-01 *Introduction* (to A. Wilce)

Please allow me to introduce myself: We have a mutual friend in Howard Barnum. Howard brought my attention to some of your work, and he has also told me that you are reading my paper "Quantum Foundations in the Light of Quantum Information."

As you surely know by now, my section "Whither Entanglement?" is just plain wrong. Positivity alone on local measurements does not narrow down the bi-linear map to one derived from a density operator. I am so ashamed of this mistake. And I am already planning how I can make amends for my insult to nature.

I think what I would like to do rather than amend the original paper, is instead write a short comment and post it on `quant-ph`, with a title something like "Wither 'Wither Entanglement?'?" I could use this as another opportunity to inspire people to this issue, but also (importantly) to draw attention and advertise your and your colleagues' work to an audience not previously aware of it.

I can see at least two routes by which to stitch up my failed attempt of a theorem. The first is to simply say that local measurements (with one-way classical communication) alone are enough to get us that "states of knowledge" must correspond to linear operators on the tensor product of the Hilbert spaces. But then to completely nail down the state-space structure we contemplate putting the systems back together and imagine performing completely general measurements subject to this weaker property we have just derived. Positivity *then* forces us to the density operators on the tensor product space. Another way to say this is that local measurements alone tell us how to derive a dimensionality for the composite system—they just don't get us to positive semi-definiteness.

In a way, though, that is a dull way to patch the problem. Another way that comes to mind is to ask what further conditions should we add upon the local-measurement statistics so that we nail down the density operators solely. What I mean by this is that, since local measurements will get us to a *unique* linear map, it must be the case that some of can be ruled out by the local-measurement statistics they give rise to.

So, let me ask you these questions:

1. Can you give me pointers to all the relevant literature to do with deriving the tensor product structure along our kinds of lines?

2. Do you know of any conditions like the ones I'm contemplating in the second strategy above that will do the trick? Where are they published?

I hope you will be patient with me in that I am not so familiar with the language quantum logicians use.

I'm glad to get to know you.

28-08-01 *Some Questions Regarding Your Comments* (to N. D. Mermin)

Merminition 44: *The trouble with our exchanges is that I'm always trying to zoom in on the issues under dispute and you're always trying to zoom out.*

Thanks for the note. Your point is a good one. (It's just that I've had to write so much email lately, and always, that it does take a toll. For instance, the present debate has been particularly taxing in that regard. Yet the issues have been important enough to not give up. So certainly I was hoping to recycle some material.)

I will try to write you a (focused) reply tomorrow, after recovering from today. Tomorrow evening, I fly out to Munich for a week and a half. Then I go to the quantum foundations meeting in Ireland to tote the wares.

Still tonight I've got to work on packing, etc.

31-08-01 *Tina* (to A. S. Holevo)

Thanks for the good wishes for my travel. They worked! The flights went without a hitch, and I got a significant amount of reading done. (I've been focusing on the writings of William James, John Dewey, and the other American pragmatists lately. I now believe they had a set of thoughts significantly in sync with the quantum foundational program I sketched in my paper.)

31-08-01 *MSRI Q. Info Workshop Dates?* (to R. Jozsa)

I hope Umesh can easily changes his dates: that certainly would be the easiest option for the Montreal thing. I will keep my fingers crossed. If I hear anything from Umesh I'll let you know as soon as I do. Likewise, if you hear anything before I do, please let me know. It'll give me a sigh of relief.

I'm in dreary Munich for the week. But I like dreary weather like that: I find it especially conducive to philosophical thought. I'm going to visit Hans Briegel next week, by the way. I'm quite enamored by this "measurement-only" computational model of his and coworkers'.

01-09-01 *Left Wing, Right Wing, Not a Wing to Fly With* (to N. D. Mermin)

I was going to use my day today to write you a long, thoughtful (but focused) note on all the recent issues you raised with me on "Whose Knowledge?", but now you've gone and angered me. I mean that.

Merminition 45: *I took my left-right terminology from the Science Wars. It seems to me that in arguing against anything objective other than knowledge Chris is taking a decidedly post-modernist position and therefore allying himself with the "Academic Left" attacked by Gross and Levitt.*

Is my point of view so very subtle that even my most sympathetic patrons cannot decipher it? Or have I finally caught on that you're really not listening to me after all?

You can't stand this, but you deserve it: I will excerpt part of a note I recently wrote to Andrew Landahl. What set me off in his case was when he wrote me the following after having read my paper "Quantum Foundations in the Light of Quantum Information" and given a Caltech journal club talk on it.

> On the whole I portrayed your "party platform" as the statement that "Quantum states are states of knowledge about the consequences of future interventions." In particular, those consequences aren't consequences to reality, but rather consequences to

states of knowledge about even further future interventions. In this worldview Bayesian agents don't work to align their predictions with an underlying reality. Instead they work to align their predictions with *each other*. It is as if reality in this picture is solely the agreement of predictions!

I'd be interested to hear if you believe that this is a fair characterization of your party's platform. After reading this paper, I came to the conclusion that you didn't believe in reality at all. (Or at best I thought you believed reality = knowledge.) John Preskill tells me you believe otherwise, namely that there *is* a reality, which surprised me. I'm curious to hear what you believe reality is.

The scheme below is that everything marked with a ">" is a direct quote from Andrew Landahl's letter. Everything else is either me, or a quote from my paper. I will put only the very most relevant part of my reply.

Please do read it before you—*yes*, you, the most trusted of my academic friends—slander me again. It is nothing if not *exactly* relevant to what you wrote about me above.

With surprisingly kind regards,

02-09-01 *Left and Right* (to N. D. Mermin)

Merminition 46: *I thought you were safely away in Ireland or pre-Ireland.*

Yes, I am in pre-Ireland mode (in Munich), but keep in mind that I am never safely away.

Merminition 47: *I'll read what you sent in a little while. But note that I would not have made such a remark (even in jest) before I got your comments on my summary (and the cc of your letter to your own coauthors) which struck me (and I thought you too) as going beyond your earlier position.*

I will take this remark into account for the longer reply I am presently constructing for your earlier query. (It is sitting at 6K in length now, and will likely be finished tomorrow. Right now, I'm having my first beer of the evening.) But preliminarily, let me say that the only thing that letter to my coauthors did was clarify my position on the subjective character of the state vector. In that I went further than before, having gotten weak in the knees briefly about my position on two agents sharing differing quantum states. But, I do believe that I have long held fast in my opinion that there is something in the universe beyond human ken: It has always been a problem of finding the right language and right ideas for expressing what that something is, AND how it is PARTIALLY reflected in the structure of quantum mechanics.

If this does not make sense yet, I hope it will make more sense after my long note to you tomorrow.

02-09-01 *Intersubjective Agreement* (to N. D. Mermin)

Let me finally throw myself into the ring of intersubjective-agreement to see if I can wrestle you down a little. I will try to be every bit as focused for you as the issue will let me be.

Merminition 48: *Well maybe you're more radical than I thought. It was to avoid correlations floating in the void, unattached to anything whatever, that I've been interested in trying to follow you down the path of knowledge. If all it led to were knowledge, floating in the void, unattached* *to anything whatever — even to other knowledge — then I'd be no better off [than] when I started down the trail.*

I think you misunderstand something very deeply here. The point of separating the categories "knowledge" and "reality" (or "subject" and "object" for that matter) is not to make knowledge an objective reality in its own right or, even worse, to make it the sole reality. Rather it is to say that there is a distinction and that that distinction should be recognized. I see nothing wrong with allowing a physical theory (such as quantum mechanics) to contain formal elements that correspond to *both* categories. The issue in my mind is which elements should be thrown into which category? The answer is not completely clear to me, but I am fairly convinced of one thing: The state vector should not be thrown into the reality side of the line.

What I have ultimately NOT been able to stomach about your wording of the whose-knowledge "answer", and Jerry's wording of the whose-knowledge "answer"—some of Todd's versions would actually survive—is that you say, under certain circumstances, two scientific agents (observers, or what have you) MUST assign "consistent" quantum states to a given system. In the case of pure states, the two agents MUST assign the *same* pure state to the system.

Let me get that through your head: What I object to is the word MUST. Todd once wrote it this way,

Brunism 7: *We have been describing a consistency criterion.* If *one wishes to combine two state descriptions of a single system into a* single *state description, the criterion tells one* when *it is consistent to do so (i.e., when the two descriptions are not actually contradictory).*

I agree that nobody is holding a gun to Alice's head and forcing her to incorporate Bob's information.

and to this way of speaking I can agree. But if you take away Todd's "*If*", then everything collapses in my mind. Enforcing that two agents MUST make the same state assignment if they are going to be "right" at all reinstates the very objectivity, the very agent-independence of the quantum state that the Mechanica-Quantica-Lex-Cogitationis-Est program has been working so hard to exorcise. [As you know, we made a serious misstep in our `quant-ph/0106133`, but that will be rectified in the next edition.]

It is much like the old debate. Is materialism right? Or is it Berkeley's idealism that is right? Who cares, I say. Both philosophies are just simple samples of realism: They only disagree on the precise concept which ought to be taken as real, mundane matter or sublime consciousness. The way you characterize it above, one would think that the only fruit of the Mechanica Quantica program would be the RENAMING of a material reality into an ideal one—a shift more of emphasis, rather than anything of grit.

Merminition 49: *Are you also unable to agree with the statement that a photon that is known (by somebody) to have just passed through a horizontal polaroid cannot immediately thereafter be found (by anybody) to pass through a vertical polaroid.*

I'm asking you about this concrete example of the general proposition because I can't tell whether you're objecting to the language in which I generalized it or whether you object to the statement about photon polarizations too. If it's only the former I'm happy to use less provocative phrasing. All I meant by "be in a state psi" was "has been found to be" in the sense I specified prior to making the objectionable statement. But I worry that you object to both statements. In that case you are walking a dangerous path, denying that one of the most elementary applications of quantum mechanics has a legitimate meaning.

Here is what you are losing sight of. In the Bayesian world, two agents must agree a little before they can agree a lot. Agreeing a lot is the currency they are seeking, but agreeing a little to begin with is not the limitation of their existence. I'll come back to this from a more positive angle in a minute, but let me tackle your particular question before that.

What does it mean for "a photon that is known (by somebody) to have just passed through a horizontal polaroid?" Presumably it means that a particular quantum mechanical test, a POVM, $\{E_b\}$ has been performed and one of the outcomes of that test has obtained—in this case, the label b is "photon passed through horizontal polaroid." Now, you ask, "immediately thereafter [can it] be found (by anybody) to pass through a vertical polaroid?" Implicit in that, you are thinking that the state transformation, subject to the measurement outcome, is

$$\rho \longrightarrow E_b^{1/2} \rho E_b^{1/2}$$

up to normalization.

Suppose you are the somebody spoken of above; and let me be part of the anybody. Now, let us say that I stubbornly insist that the state transformation is

$$\rho \longrightarrow U_b E_b^{1/2} \rho E_b^{1/2} U_b^\dagger,$$

where the U_b are some unitary operators, and in particular, when

$$b = \text{photon passed through horizontal polaroid}$$

we have

$$U_b = \text{horizontal} \rightarrow \text{vertical}.$$

There is nothing in quantum mechanics (as a theory) that can keep me from believing that, so long as the ONLY thing specified is the "measurement" $\{E_b\}$. The point is, let us suppose we disagree on how our beliefs should get updated upon the incorporation of a measurement outcome into our knowledge bank. [As an aside, notice the distinction here: b is given the lofty title of knowledge, whereas ρ is subjected to being a belief. I allowed myself to do that because I am assuming we agree on the $\{E_b\}$, even if not the state-change rule. You might say we need at least this much to get the problem off the ground.]

So, it boils down to this in more common language,

Merminition 50: *Are you also unable to agree with the statement that a photon that is known (by somebody) to have just passed through a horizontal polaroid cannot immediately thereafter be found (by anybody) to pass through a vertical polaroid?*

And I say no, I cannot agree: I saw Hideo Mabuchi in his lab yesterday, and I saw that he inserted a really fancy polarizer into his lab bench, one with an intriguing optical coating that allows horizontal photons in, but has them come out as vertical ones. I insist that I saw him do that: There's not a doubt in my mind. You insist that he is an honest upright boy, and he would never do such a thing to confuse us. With equal tenacity, there is not a doubt in your mind. We disagree, and in the strongest of ways.

How do we put our disagreement to test in the context of photo-detector clicks? WE insert a vertical polaroid—this one, I assume, we both do agree on—behind the "horizontal" one and see what happens. Aha! You were right after all! Mabuchi really did use an honest-to-god von Neumann polaroid; the input photon never made it to the final detector. It wasn't the fancy-coated polaroid after all, but I could swear I saw him put it in.

By now, I know that you are thinking I have gone through a ridiculously long-winded and pedantic way of describing a triviality: that one of us made a FALSE assumption. Implicit in your question was the reasonable starting point—indeed, the one we use in all common discourse—that all the agents involved start from a TRUE state of affairs.

But what can TRUE and FALSE mean in a world where our only handle for getting at things are SUBJECTIVE quantum states? We get at the world through our beliefs and belief updates—that's the fundamental tenet for me. And in that light, the only thing a FALSE belief can mean—as I put it to Caves and Schack in the infamous email—is that rationality (i.e., the Bayesian laws of thought) PLUS the world (i.e., the detector clicks, whose meanings in the end are also set by subjective considerations) will not allow the believer to perpetuate any remnant of his initial belief after the experimental trial. Let me say that sentence again for extra emphasis:

> The only thing a FALSE belief can mean is that rationality (i.e., the Bayesian laws of thought) PLUS the world (i.e., the detector clicks, whose meanings in the end are also set by subjective considerations) will not allow the believer to perpetuate any remnant of his initial belief after the experimental trial.

But if that is the case, what is so overpoweringly evil about having a "false" belief? Why must two valid quantum scientists necessarily be aligned in their beliefs, even in the case of "true" and "false"? I remain hardened: I see no compelling reason for asserting that necessity. Indeed, such an assertion is antithetical to the idea that a quantum state is a compendium of subjective degrees of belief.

If you think TRUE and FALSE mean something more substantial than I just described, then you tell me what role they play in my life other than as a kind of shorthand for some characteristics of my belief updates.

In pointing out these deficiencies, I am not "denying that one of the most elementary applications of quantum mechanics has a legitimate meaning." I am coming nowhere near that. I am merely asserting each scientific agent's constitutional right to believe what he will—i.e., to carry about whatever quantum state he wishes—SO LONG AS those beliefs do not contradict the constitution itself.

It is the latter that, from my view, is the most essential point you have been missing. So, let me get to that directly. With this I can finally start to define a positive program.

Merminition 51: *I don't see that limiting "objectivity" to mean "complete and necessary intersubjective agreement" is abandoning your quest. Indeed, your Bayesian authorities say as much,*

> We can find no real role for the idea of objectivity except, perhaps, as a possibly convenient, but potentially misleading, "shorthand" for intersubjective communality of beliefs.

It must be the "necessary" that raises your hackles [...]

If anyone cannot see by now that it is almost solely the word "necessary" that raises my hackles, then they are not listening. You wrote at the beginning of your note that:

Merminition 52: *If all it led to were knowledge, floating in the void, unattached to anything whatever — even to other knowledge — then I'd be no better off [than] when I started down the trail.*

But that is just not true. We have gained a serious amount of positive knowledge from this exercise. It has allowed us to see much more clearly what is firm and what is squishy in quantum mechanics. The state assignments I would say are always squishy; the rules for updating them are not. To the extent that these rules fulfill an edict in the spirit of Bernardo and Smith,

> Bayesian Statistics offers a rationalist theory of personalistic beliefs in contexts of uncertainty, with the central aim of characterising how an individual should act in order to avoid certain kinds of undesirable behavioural inconsistencies. ... The goal, in effect, is to establish rules and procedures for individuals concerned with disciplined uncertainty accounting. The theory is not descriptive, in the sense of claiming to model actual behaviour. Rather, it is prescriptive, in the sense of saying "if you wish to avoid the possibility of these undesirable consequences you must act in the following way."

I would say we have identified an objective piece of quantum mechanics.

It is not that "physics as intersubjective agreement" requires that agents always agree, or, at least, that they must agree in certain limiting circumstances. Instead it is that there is a procedure in any given case for deciding whether two agents will move closer to agreement than not after looking at the world. Quantum mechanics gives us such a framework. It might have been otherwise: One can imagine a world so chaotic that any percipient beings which happen to arise in it would forever be in their own individual dreamlike states, never realizing that it is even possible to come to agreement with their fellow quixoticoids.

Maybe a good (but limited) analogy is this. Think of an electric potential function from which, by taking a gradient, we can derive the electric field. The potential itself cannot be the real stuff because of its ridiculous freedom that can be set freely from observer to observer. Instead it is the way the potential changes spatially that is what is of interest. That spatial change which is the common denominator of all the disparate potential assignments is the real, real stuff. Now think of the quantum state in the role of the potential, and the quantum structures of POVMs, the Gleason theorem, and the state-change rule in the role of the potential's gradient.

As long as you and I play according to the quantum rules for updating our beliefs in your example—you with your

$$\rho \longrightarrow E_b^{1/2} \rho E_b^{1/2},$$

me with my

$$\rho \longrightarrow U_b E_b^{1/2} \rho E_b^{1/2} U_b^\dagger$$

—who is to fault one of us for being irrational? We just have different beliefs about how a state ought to get updated in the particular situation. Neither one of us is taking the constitution to task; neither one of us are using a state-updating method that does not fall into the quantum mold.

The analogy of this with classical probability theory is that we both might agree on the probability for some hypothesis $p(h)$, but disagree on the joint distribution $p(h, d)$ for hypothesis and data. Learning the data and using Bayes' rule, we will generally then come to two distinct posterior assignments $p(h|d)$. That nevertheless gives us no warrant for backtracking our opinion that $p(h, d)$ is just a subjective belief (as are all probability assignments). Instead it helps us see that the objectivity working in the background is Bayes' rule; it is our common denominator.

Quantum states—or through Gleason's theorem, nothing more than compendia of quantum probabilities—do not float in a void. They are tied together more tightly than any other probabilities hitherto ever found. I cannot assign probabilities for σ_x outcomes, σ_y outcomes, and σ_z outcomes at the same time as *independently* assigning them to the outcomes of any more exotic POVMs. In changing my probabilities for the outcomes of some potential new measurements (just after a previous measurement), I had better tie all those probabilities together along the lines of the general form of the quantum state-change rule.

In this, we see something like a much greater deepening of the Dutch book argument. In the classical case, we find that we will bring havoc upon ourselves if we allow ourselves to freely assign $P(A)$, $P(B)$, $P(A \wedge B)$, and $P(A \vee B)$ all independently. All compendia of quantum probability assignments must be tied to the particular structure of quantum states and the quantum state change rules. You should be thinking of the firmament rather than the void.

I think that's all the really general remarks I had wanted to say. Let me now *briefly* address the remaining specific points in your notes.

Merminition 53: *If you do indeed object to both, then the only reason I can see for it (and I agree that this does raises non-trivial issues) is that probability 1 and probability 0 statements are idealizations — that nothing in the actual world we inhabit can be said to be certain or impossible. In that case, of course, the support of any acceptable density matrix is the whole Hilbert space and there is no content left to the criterion. But since the theory does allow you to talk about certain or impossible measurement outcomes, I'm reluctant to declare that its illegitimate to consider them in trying to develop a better understanding of the theory.*

I hope that you can see by now that "probability 1 and 0 statements being idealizations" (i.e., states of belief that we none of us, even Job, are really ever in possession of) has nothing to do with my considerations. A belief is a belief. Rationality itself cannot infringe on what numerical value a belief ought to be. It is therefore perfectly legitimate to think about these idealized situations.

Merminition 54:

> CAF Said: on top of this, we must also accept that there is no objective sense in which a (pure) quantum state is simply "wrong" before the experiment is performed.

[Do] you also require me to accept there is no objective sense in which a pure quantum state is simply correct, after the experiment is performed?

Yes. The ghost of Bruno de Finetti haunts us:

QUANTUM STATES DO NOT EXIST

And I understand that oh so much better now than I did two months ago.

Merminition 55: *P.S. I also asked for clarification of your views on objectivity as nothing more than intersubjective agreement, which on the one hand you seemed to reject in accusing me of going objective in comment (c) but on the other hand you seemed to endorse in quoting approvingly your Bayesian gurus.*

Bernardo and Smith would have never held fast to a "necessity clause" like you seem to be doing. That puts a gulf of distance between your two separate uses of the phrase "intersubjective agreement."

Merminition 56: *P.P.S. Just got a blast from the Eastern Front (Mohrhoff — cc'd to you, I believe). I have the funny feeling that you two, who are so far apart in opposite directions (knowledge-without-facts vs facts-without-knowledge), may yet turn out to be strangely similar in some respects.*

To the extent that I understand him, I myself don't believe this is likely. The direction I see for physics, and quantum mechanics in particular, was perhaps no better put than by William James:

> Metaphysics has usually followed a very primitive kind of quest. You know how men have always hankered after unlawful magic, and you know what a great part in magic *words* have always played. If you have his name, or the formula of incantation that binds him, you can control the spirit, genie, afrite, or whatever the power may be. Solomon knew the names of all the spirits, and having their names, he held them subject to his will. So the universe has always appeared to the natural mind as a kind of enigma, of which the key must be sought in the shape of some illuminating or power-bringing word or name. That word names the universe's *principle*, and to possess it is after a fashion to possess the universe itself. 'God,' 'Matter,' 'Reason,' 'the Absolute,' 'Energy,' are so many solving names. You can rest when you have them. You are at the end of your metaphysical quest.
>
> But if you follow the pragmatic method, you cannot look on any such word as closing your quest. You must bring out of each word its practical cash-value, set it at work within the stream of your experience. It appears less as a solution, then, than as a program for more work, and more particularly as an indication of the ways in which existing realities may be *changed*.
>
> *Theories thus become instruments, not answers to enigmas, in which we can rest.* We don't lie back upon them, we move forward, and, on occasion, make nature over again by their aid.

Mohrhoff, from what I can tell, sees a "block universe" (to use another piece of Jamesian terminology). It is a completed thought in the cosmic consciousness.

Good wishes, and I hope this document answers more questions for you than it raises. Now I've got to run to the biergarten again for a little oompah-pah.

02-09-01 *Truth and Beauty* (to N. D. Mermin)

Here's another passage from William James's *Pragmatism* that may help reveal a little more of my mindset.

> The truth of an idea is not a stagnant property inherent in it. Truth *happens* to an idea. It *becomes* true, is *made* true by events. Its verity *is* in fact an event, a process: the process namely of its verifying itself, its veri-*fication*. Its validity is the process of its valid-*ation*.

03-09-01 *Subject/Object* (to M. A. Nielsen)

Nielsenism 1: *You may also be interested to hear that I'm engaged to be married :-)*

Excellent! This is only a joke partially, but lately I've been so taken with the idea that unions can give rise to things greater than those contained in the parts—thinking of quantum measurement, in particular, from this angle—I've thought about calling my view on QM "the sexual interpretation of quantum mechanics."

Many congratulations!

04-09-01 *Note on Terminology* (to C. M. Caves & R. Schack)

Thinking about it more, I would like to emphasize a point that was buried away as an "aside" in my recent note to Mermin titled "Intersubjective Agreement."

I am becoming more and more dissatisfied with the slogan "A quantum state is a state of knowledge, not a state of nature." The reason for this is that people tend to view the word "knowledge" as something that can be right or wrong, depending upon whether it is in direct correspondence or not with something in the external world. For this reason—as brought out clearly in my debate with Mermin, Brun, and Finkelstein—I think we should get more into the habit of calling a quantum state a state of BELIEF. This is more in line with the language both de Finetti and Bernardo and Smith use for probabilities anyway, and therefore gets us into a quicker connection with the personalistic Bayesians.

I now think it is much better to reserve the word KNOWLEDGE solely for the outcomes of quantum measurements once they become part of the mental makeup of an agent interested in them. I walk into Mabuchi's lab, and to the extent that he and I agree that he is performing some POVM (denoted by a set of positive operators $\{E_b\}$), it seems to me valid to call the outcome b we both witness to be an addition to our knowledge. Now, what either of us may do with that knowledge is a different story. One thing is for sure, it ought to cause both of us to update our beliefs.

Thus knowledge (and information) bear on how we change our beliefs, and in that way—in a sense—become incorporated into our beliefs, but there is no rigid connection between the two concepts. Knowledge/information, as it is encoded in measurement outcomes, is a bridge to the external world that the quantum state has no right to be.

You may also recall another strange phrase I used in my note to Mermin: "the world (i.e., the detector clicks, whose meanings in the end are also set by subjective considerations)." This oddity is reflected in my definition of knowledge above: that is, I make a distinction between the raw stuff of the world that the measurement intervention brings about and the registration b in our noggins (as a flag for further actions in our role as agents). What I am thinking here is something roughly like the following. Take the famous white-on-black or black-on-white visual illusion that can be viewed either as a vase or as two faces facing each other. The raw stuff of the world may be compared to the ink and the paper giving the image. In order to say, however, that Mabuchi and I gain the same knowledge in viewing this we need the deeper cultural agreement that we will *both* call it a face or instead a vase when we see it.

Below I will put a glossary that tries to summarize where I have come so far in my attempts to make sense of quantum mechanics. Essentially, I'm expecting only the two terms above to be relevant to the fights we'll be having in writing our RMP article. But maybe it is nevertheless useful for me to lay my full set of language oddities on the table.

Lately, I've been jokingly calling my view (as it stands) the "sexual interpretation of quantum mechanics." (Most people turn red and become uncomfortable when I do that and explain why. I suspect the same will be true even in your reading of this note. So, brace yourselves.) The essential idea is that something new really does come into the world when two of its pieces are united. We capture the idea that something new really arises by saying that physical law cannot go there—that the individual outcome of a quantum measurement is random and lawless. The very fact that the consequence of the union is random signifies that there is more to the sum than is contained in the parts. But I promise you I won't reflect the licentious details of this view in the glossary below. I'll leave the missing terms to your imagination.

- ACT – The actual carrying out of a quantum measurement/INTERVENTION, after a DE-

CISION has been made by an AGENT to do so.

- AGENT – Any participant in the construction of a scientific theory. In older language, the observer.
- BELIEF – In the context of quantum discussions, a quantum state. Or one might say the quantum state is a compendium of BELIEFS.
- CONDITIONALIZING BELIEF – The rule one uses to update one's BELIEF consequent to the completion of a measurement INTERVENTION. In the language of Kraus and Preskill this would be called the "quantum operation" or "superoperator", respectively.
- CONSEQUENCE – Whatever it is that a measurement INTERVENTION elicits out of the world.
- DECISION – An AGENT, within his power can decide to perform one ACT or another upon the world. Just as physical law cannot impinge on what determines the random outcome of a quantum measurement, neither can it impinge on the mechanism behind an AGENT's decision.
- FACT – This is a word I do not like. One might have said that the outcomes of quantum measurement could be called facts just as well as CONSEQUENCES: But the word fact, to me, contains the connotation of a kind of permanence that I do not see in the quantum world. Facts are irreversible additions to the furniture of the world. But measurement INTERVENTIONS (and their CONSEQUENCES) can be reversed through the agency of a further outside intervener.
- INTERVENTION – The physical act that we call in older language the measurement of a POVM.
- KNOWLEDGE – One's mental representation of the obtained CONSEQUENCE of a given INTERVENTION into the world. Implicit in the use of this word, is that all communicating parties agree to the meaning of the given INTERVENTION, i.e., that it is this POVM rather than another.
- PROPERTY – A property is something possessed by a FACT. I don't like the word FACT.

04-09-01 *Brilliance* (to N. D. Mermin)

Merminition 57:

> CAF Said: I am becoming more and more dissatisfied with the slogan "A quantum state is a state of knowledge, not a state of nature." ... I think we should get more into the habit of calling a quantum state a state of BELIEF.

Brilliant! All kinds of trouble would have been avoided.

You know, I'm not one to turn down a "Brilliant!" But your second sentence does clash a little with what you wrote on August 8:

Merminition 58: *It seems to me Chris is getting much too subtle about this. I would talk about knowledge, not belief.*

All kinds of trouble WOULD HAVE BEEN avoided?

Speaking of brilliant—real brilliance this time—today I'm going into Munich to talk to Hans Briegel about his papers with Raussendorf. (I told you I would be in Munich, but I'm actually in the little village of Zorneding outside of Munich.) I think there's something very deep in them, if they hold up. You may recall I recommended them to you once.

I've got more things of a philosophic nature to write you, but I've just got to find some time to do it. I'll try to be back to the waves tomorrow.

04-09-01 *Objective Probability* (to C. M. Caves & R. Schack)

Cavesism 9: *I expect you to have a really hard time with this—please skip the lectures on my not being sufficiently Bayesian—but it is, in my present view, a necessary feature that expresses the tension that exists in the notion that maximal information is not complete. The state assignment can't be verified by examining the system, but it can be verified by examining the trail of evidence from which I acquired maximal information. If someone else finding that trail of evidence could say that he didn't have maximal information or that he had different maximal information, the notion that the information is maximal would be untenable, since apparently something further would be required to make it so. This seems like a natural for someone who takes seriously those quotes about the process of intersubjective coming to agreement. It grants to maximal information in quantum mechanics some, but not all of the properties of maximal information in a realistic world.*

It is hard for me to understand what that "trail of evidence" is a stand-in for if it is not a compendium of OBJECTIVE probabilities. You follow that trail, and you have NO CHOICE but to assign all the probabilities that the Gleason theorem gives (presumably if you are rational). So, pure quantum states give rise to "propensities" ... when those pure states are "right"? Is that what you are saying? (I said all of this, of course, in my original longer note, but it seems good to isolate it here.) Can you give me an operational definition of this notion of "propensity"?

And why can we toggle these propensities from a distance? Are you giving up on spacetime after all? Or is this a new way of applying the principal principle?

Now I really do have to join the family.

04-09-01 *Fourth and Fifth Reading* (to C. M. Caves & R. Schack)

Cavesism 10: *The point of our conclusion is that the Dutch-book argument leads to a unique probability or density-operator assignment in the case and only in the case of maximal information. This is just an entirely different thing from using frequency data—or something else—to specify every component of a density operator.*

I still don't get it (though I've had a lot of wine by now). By hook or crook, I use the information available to me to assign a probability distribution over the outcomes of some informationally complete measurement. That assignment gives rise to a unique density operator.

I'm still having trouble seeing what is special about a "maximal information" assignment. I'm not lying; I'm not trying to cause trouble; I'm just not seeing it. (Think of me as the second referee of the paper. Would that be ethical?)

Good night!

05-09-01 *Noncontextuality Again (and Again)* (to C. M. Caves)

Cavesism 11 : *The underlying structure is a specification of alternatives that can be grouped in various ways—these are the contexts—to make exhaustive sets. We are required to make noncontextual assignments; otherwise we are ignoring the fact that this specification doesn't distinguish an alternative in two different contexts. If it did, we would be dealing with a different specification. This is the perspective of my first point of view, which justifies noncontextual probability assignments in quantum mechanics from the Hilbert-space specification of alternatives.*

I still don't entirely get this. You say we are required to make noncontextual assignments, otherwise we would be ignoring the fact that the original groupings do not distinguish an alternative in two different contexts. But why could we not ignore it? Perhaps the underlying structure is there for an entirely different reason than something to do with probabilities? For some reason, this point of view is just not clicking for me.

Cavesism 12 : *Your perspective is different. As I understood it, you think of an alternative in different contexts as a single alternative because it has the same probability in all contexts. But where did you get this equal probabilities? Surely they're not measured or determined or anything like that, since they are states of knowledge. In quantum mechanics you get that they're the same because the standard quantum rule says so, but this is using noncontextuality, not justifying it.*

I don't know what more to say on this. It means that identifying this consequence of this intervention with that consequence of that intervention is a SUBJECTIVE judgment. (I.e., that identifying this outcome of this measurement with that outcome of that measurement is a subjective judgment.)

Cavesism 13 :

> CAF Said: What you say "needs" to be done, seems hopelessly underconstrained to me too. But I think you shouldn't view the problem that way. The point is, one simply has a way of clearing the air of the noncontextuality issue BEFORE getting down to the nitty-gritty of quantum mechanics. Noncontextuality is the base assumption upon which one plays a new game: What *physical* assumption makes it so that our instruments should correspond to POVMs and not some other mathematical structure?

I'm going to adopt your strategy, and just flatly say I don't get this.

Let me try again. Here is the game we should be playing. In the most general terms, a measurement is defined to be a group of elements (satisfying some given property) drawn from a set with a given structure. The individual elements correspond to the outcomes of the measurement. The question is, what should that structure be? What should that property be? What are the reasons for those choices? This much we will safely assume (for the reasons given above): The probabilities of the outcomes should depend only upon the individual elements, not the group.

That's all I'm saying. Here is an example of dumb theory.

> UNDERLYING STRUCTURE = one-d projectors onto a complex vector space.
> GROUPING PROPERTY = choose any set of projectors that project onto a complete set of linearly independent vectors.

Then the only probability assignment that can be given to the outcomes of such a notion of "measurement" is the uniform distribution.

So, we start over and say, "Maybe the grouping property ought to be that the projectors add up to the identity." Aha, that gives us quantum mechanics. But you see, there are any number of other combinations of structures and properties one might have played with. The question is, what is essential about the structure and grouping properties that we do use? By saying that we have cleared the air of noncontextuality, I simply mean that the existence of noncontextuality in the probability assignments should not be a question. It was settled before we ever started the game.

Cavesism 14: *Well, when I say "Hilbert-space structure of questions," I clearly don't mean only that there is a Hilbert space, but that the questions correspond to one-d projectors. That's why I add "of questions" to the phrase.*

No, what you mean precisely is: A "question" corresponds to a set of one-d projectors that sum up to the identity. So why don't you just say it in a precise way rather than a vague way? If I were uninitiated to quantum mechanics, I might have thought that you meant the dumb theory above. I'm serious about this.

05-09-01 *Unique Assignment* (to C. M. Caves & R. Schack)

Cavesism 15: *The point of our conclusion is that the Dutch-book argument leads to a unique probability or density-operator assignment in the case and only in the case of maximal information. This is just an entirely different thing from using frequency data—or something else—to specify every component of a density operator.*

I guess my trouble stems from one of the things I said in the long note announcing my worries about "Making Good Sense." There I said:

> I think the best we can say is: If Alice and Bob both believe adamantly that they know the answer to some potential measurement AND that measurement happens to be the same for both of them, then Dutch-book consistency and Gleason's theorem will enforce that they make the same probability assignments for all other measurements (i.e., that they assign the same quantum state). But said that way, I don't think any non-Bayesian will be particularly impressed: For they would say that all we have shown is "if two people know the same things, then they will know the same things." Woop-ti-do.
>
> The Bayesians among us will still have some room to be impressed: For it will not be a priori obvious to them that beliefs about one observable should have anything to do with beliefs about another. In particular, it might even surprise them that a common belief in certainty (for two observers) for any fixed observable should lead to equal probability assignments for all other observables.

What I am wondering is: What would impress a devout Bayesian (who is just learning quantum mechanics) about our argument? Thus, given what I said above, I wonder whether he would not be equally impressed by the following. By hook or crook, Alice and Bob individually come to their own subjective probability assignments for the various outcomes of a single informationally complete POVM. Then, because of Gleason, they will have to match in their subjective beliefs about the outcomes of all other measurements they might perform. That matching made no use of the concept of maximal information. What does the maximal information case give us in shock value?

I think what you're going to say is that in the case of nonmaximal information, Alice and Bob may have come to different probability assignments for that informationally complete observable. And that they couldn't have done that if they had had "maximal information" in the first place. But as all this debate has already shown, I think I reject that position.

As my glossary from yesterday attests, I think what is going on with me is that I am becoming ever more uncomfortable with identifying quantum states with information, maximal or otherwise. Thus, instead of calling a pure state maximal information, I am becoming more inclined to something like:

$$\text{pure state} \;=\; \text{maximally tight belief (or judgment)}$$

or

$$\text{pure state} \;=\; \text{a nonrefinable belief (or judgment)}$$

or anything else more along those lines.

Leave the word information for what we gain when we see the outcomes of measurements. This entity we know two disparate observers should agree upon—by definition—if they are in free communication with each other. But the quantum state, on the inside of one's head, is a more personal state of affairs.

I'm going into Munich for much of the day (to visit with Briegel), so you may not hear from me again until tomorrow.

05-09-01 *Identity Crisis, 2* (to C. M. Caves & R. Schack)

I've now given your long note the fourth and fifth readings it deserves. (I'm holed away in an office near Briegel's.) And I'm not sure how to respond yet. I think I will await your responses to my other notes first. I think it is clear in the time that has elapsed since our first communication that we have moved further away from each other's position. Or I should say I've moved further away, from our original position.

Briegel just came; I'll be back.

05-09-01 *Malleable World* (to G. L. Comer)

Just a little quote I liked.

> Once you bring life into the world, you must protect it. We must protect it by changing the world.

From: Elie Wiesel (b. 1928), Rumanian-born U.S. writer. Interview in Writers at Work (Eighth Series, ed. by George Plimpton, 1988).

06-09-01 *The Underappreciated Point* (to C. M. Caves & R. Schack)

My fit of insomnia is running out, so I'm going to have to go back to bed soon.

Schackcosm 3: *Please give me some feedback on these thoughts. I know that you wrote A LOT more, but I find it easier to go through your emails paragraph by paragraph.*

You know, of that LOT, most of it was written very carefully and very purposefully, so I do hope you will try to read it all with that in mind before trying to get me to readdress too much. (You can ignore the stuff on noncontextuality for now; that's not important for present issues.) Next week I won't have the leisure of writing too many notes, as I'll be out on the election trail trying to stump this Bayesian point of view … and trying to make it LOOK consistent. (I.e., I'll be at the quantum foundations meeting in Ireland.)

But, before crawling back into bed, let me address your greatest FEAR:

Schackcosm 4: *The most important thing to remember is the limited scope of the paper. It tries to show that Bayesian probabilities do have a place in qm, not more. Remember that most physicists would reject this. We show that, contrary to conventional wisdom, subjective quantum probabilities are not arbitrary. Let me remind you that you agreed to a paper of this limited scope last year in Montréal. I do not want a paper that is significantly expanded.*

This must be addressing my single remark of September 3,

> Of course, as you know, I view this as a good opportunity (with page limitations no longer of great concern) to expand some points and give some more references. I think we can read the referee as agreeing with that.

because, in all my voluminous letters, I don't think I ever mentioned modifying the paper otherwise. Of course I think it is unhealthy that your first trip-up would be that point … but we are all moved by different things. (I don't fathom your pressures, and you don't fathom mine.) In any case, let me say this for the record to try to clear the air:

> If given free reign—which I do not actually want—I think I could modify the paper to my own tolerance without changing its length at all, or, at most by a paragraph. I would be more than happy if you and Carl would just find a language I could agree to, and modify the paper accordingly. The phrase *more references* was a euphemism for citing more of Chris's papers.

Deep in my heart, I believe you guys fool yourselves in thinking that this paper will be more widely read simply by being short, but that is not the issue (and it has never been the issue). My passion is to get quantum mechanics straight: So, let's get it straight.

On the whole, in reading your two notes, I found your method of expression better fit to my present mentality than Carl's. Maybe I'll give more specific examples tomorrow. For the present, let me just mention two things.

Schackcosm 5: *It does indeed not follow from our Dutch book argument alone that two agents must agree on the maximal info they have. But suppose agent A has maximal information and agent B insists on assigning a pure state that is not consistent with A's information. A can then extract money from B. I don't think the symmetry of the situation is a problem here. From A's perspective, B is wrong, in the same sense of wrong as if A had a piece of classical knowledge that B chooses to ignore in a bet.*

Perhaps the greatest life change I have had is that I no longer like the phrase "maximal information" in this context. That little phrase carries with it an entire philosophy, and it is one that, to me, does not seem consistent with its roots and, more importantly, does not seem right.

The most one can say on Bayesian principles is that:

> From A's perspective, B is wrong. And from B's perspective, A is wrong.

If A and B can have two pure-state assignments, and the most one can say is the item above, then pure states should not be called "maximal information." They are maximal "something else", but it is not information. (In another note, I have outlined what I think that "something else" is.)

Carl thinks he can fix this by invoking a "trail of evidence" that uniquely fixes which of two pure states is actually the case. But let me juxtapose two of his paragraphs and then try to reemphasize the underappreciated point.

> Paragraph 1:
> In quantum theory maximal information also constitutes a belief, but we resist the notion that it corresponds to some objective reality out there. Why this resistance? Ultimately it's because the maximal information leads to a pure-state assignment that gives probabilities whose only reasonable interpretation is subjective. It is very important to remember that this is the primary motivation for much of what we do. Probabilities are the subjective language used to deal with situations of uncertainty, so wherever we find them, they must be subjective. The subjective view of pure quantum states gains additional support from the fact that a pure-state assignment can't be verified by consulting the system—the same can be said for a probability assignment—and the fact that a state assignment for a distant system changes when we obtain information about it without ever getting close to it—this also holds for correlated probability assignments.

and

> Paragraph 2:
> The state assignment can't be verified by examining the system, but it can be verified by examining the trail of evidence from which I acquired maximal information. If someone else finding that trail of evidence could say that he didn't have maximal information or that he had different maximal information, the notion that the information is maximal would be untenable, since apparently something further would be required to make it so. This seems like a natural for someone who takes seriously those quotes about the process of intersubjective coming to agreement. It grants to maximal information in quantum mechanics some, but not all of the properties of maximal information in a realistic world.

If you hold fast to the view that that trail of evidence must *exist*, then you hold fast to the view that quantum probabilities (in some cases) must be objective after all ... *independently* of the issue of intersubjective agreement. And that negates Paragraph 1.

I am now of the opinion that if we can just clear the air [I'm fond of that phrase] of this nonBayesian trapping from bygone times, we will finally be in a position for real progress. It is in Dutch-bookian type coherence (as a general principle) that one finds an objective statement in quantum mechanics; it is never in the quantum state itself, even when that state is pure. The OBJECTIVE statement is: All of you, each and every one of you, should manipulate your compendia of beliefs according to the rules of quantum mechanics if you wish to maximally avoid undesirable consequences in your gambles. The particular quantum states at any one time are just thin films of subjectivity floating on that wider sea of objectivity.

But, please, please do read the other notes carefully. I can only write a finite amount. I'll comment more particularly on your present notes tomorrow (i.e., today, after I get back up).

06-09-01 *Another Way* (to C. M. Caves & R. Schack)

> If you hold fast to the view that that trail of evidence must *exist*, then you hold fast to the view that quantum probabilities (in some cases) must be objective after all … *independently* of the issue of intersubjective agreement. And that negates Paragraph 1.

Let me put it another way. By Carl's view, if trails of evidence MUST exist, then quantum states MUST exist, and the ghost of Bruno de Finetti should have stayed in the netherworld. For the probabilities derived from the quantum state will exist after all.

06-09-01 *Some Comments* (to C. M. Caves & R. Schack)

Now I return from an unrestful morning in bed.

Schackcosm 6: *I guess you are right that we should be more explicit about "whose certainty". It is the bettor's certainty.*

The deeper issue is not that we *should* be more explicit about "whose certainty," but *why* we should.

Schackcosm 7: *You should leave Schopenhauer and your mother out of this discussion. The distinction between the cases of certainty (classical logic) and reasoning in the face of uncertainty (probability theory) is useful.*

I didn't understand this comment.

Schackcosm 8: *As I said in my previous message, two agents having conflicting certainties is a completely classical situation. If you accept classically that in this case, one of them must misread or ignore some of the available information, then the point of the paper is that the same classical argument gives you unique state assignment, even though states are Bayesian. This is a forceful conclusion.*

It is safer to have the wrong metaphysics in the classical case. This is because certainty (i.e., overpowering belief in the outcome) for one question means certainty for all questions. And that certainty can be verified or falsified in a single shot. So, one gets in the habit of thinking that the proposition (or its material counterpart, as instantiated in the world) was already there before the verification. One can accept that metaphysics or leave it, but it is usually more convenient to accept it. In the quantum case, however, if you assert that the proposition was already there (say, as uniquely specified by Carl's "trail of evidence") then you have to assert that all the rest of the quantum probabilities were already there too. That sounds an awful lot like objective, agent independent probabilities to me.

You can retreat to objective probabilities if you wish. But I say it is better to be creative with our metaphysics. JAW said it like this, "No question, no answer." And that distinction is rearing its head in this very problem.

Schackcosm 9: *Making a pure-state assignment is an extreme statement. It entails the conviction that assigning a different state is equivalent to handing over money. It entails the conviction that the agent assigning the different state is wrong in this sense, in the sense of irrational behavior, not in the sense of not conforming to reality.*

It "entails the conviction." That is language I can accept. It is language I like. Trying to instate that way of saying things has been the whole point of my writing such detailed notes, especially the point about "not in the sense of not conforming to reality." But though you use it so nonchalantly now, it had no representation in our previous discussion, and it has no representation in our paper. At least looking at myself personally, I feel as if I have come through a phase transition.

Schackcosm 10 :

> CAF Said: But said that way, I don't think any non-Bayesian will be particularly impressed: For they would say that all we have shown is "if two people know the same things, then they will know the same things." Woop-ti-do.

Still quite impressive. A and B know the same certain thing. Hence they must assign the same subjective probabilities to all questions. Even subjective probabilities $0 < p < 1$ *are prescribed by this knowledge. The non-bayesian should be quite surprised and impressed by this.*

I said non-Bayesian. Non-Bayesians do not accept subjective probabilities.

Schackcosm 11 :

> CAF Said: For I think in no way have we shown that when two observers make two pure-state assignments for a system, those pure states MUST be identical.

If they are not identical, each agent has perfect reason to assume that the other one is unreasonable.

I accept that. But the point has been, and remains, that that is the ONLY conclusion we can draw.

Schackcosm 12 : *There are dictatorial constraints only in the limiting case of maximal information.*

Unless all of this email has been a grave mistake on my part, I continue to not be able to accept this. The only argument we have at our beck and call is that Dutch Book + Gleason dictates what *I* must do in my head and what you must do in your head. It tells us each how to translate a *nonnumeric* belief (certainty) about the outcomes of a single question, to a *numeric* belief about the outcomes of all possible questions. Indeed, I will lighten up: For a raw BAYESIAN that must be quite an impressive conclusion. There must a good way to say that in the paper. [For the non-Bayesian however—one with no qualms about objective probabilities, one with no qualms about the objectivity of quantum states—I remain in my belief: it will strike him as little more than a tautology.]

But all of this does not lessen my debate with Brun, Finkelstein, and Mermin which started this whole affair. There is no a priori principle in the universe that will tell us that two quantum states OUGHT to have overlapping supports. The best one can say is that IF Alice and Bob have overlapping support, then (if they wish) they may be able to communicate the reasons for their beliefs and come to a more refined consensus. If they do not have overlap in their supports, then the only they can do to lessen their strife is consult the world.

The objectivity is not in the states, but in the state-space STRUCTURE and in the answers the world gives us upon our consultations. When one has gained the latter, one has gained information. But the quantum state before and after remains belief, pure state or not.

06-09-01 *Weak Point* (to C. M. Caves & R. Schack)

Cavesism 16: *I think we all agree that if states are Bayesian , then anyone can assign any state he pleases, including any pure state. He can be misled or tricked, or he can just be crazy, but this sort of freedom to assign any state is not of much interest for our paper. An objectivist will have no trouble agreeing that someone who is misled or irrational will use the "wrong" quantum state.*

Let me try to say it again. The main point is, in the quantum mechanical world, these "trails of evidence" you are thinking of in the back of your mind are NEVER enough to uniquely specify a quantum state. It has NOTHING to do with being misled or being irrational. Even the purest of states is thoroughly infused with belief from the get-go. That is what my note titled "Fw: Intersubjective Agreement" from September 3 is essentially about. So, this is not a case of measure zero, where the players are irrational or dumb to begin with ... so long as we take our own arguments about subjectivity seriously.

Cavesism 17: *What he wants to know is whether scientists acting like scientists, sharing all information in a spirit of genuine co-operation, mutual respect, and dedication to truth, can assign different pure states. And we show that scientists acting like scientists can't: sharing maximal information, they must make a unique quantum state assignment.*

If that is what he wants to know, then he is not going to find it from anyone's Dutch-book argument: our last one, or our slightly modified new one. Your point is a weak one. The Dutch-book game is an adversarial game. Anyone whose intention is to make his opponent go bankrupt is NOT going to share everything he knows with him. He will be silent and bet his money.

Cavesism 18: *What rescues this conclusion from trivia? First, it answers the question of why science doesn't go down the drain: subjective state assignments are constrained in the case of common maximal information.*

I don't believe the conclusion is trivial; I said this to Rüdiger yesterday. But I also don't believe it has anything to do with rescuing science. Playing by the quantum rules ought to be enough.

Cavesism 19: *Second, it answers the question without referring to real, verifiable properties of the system in question. In a realistic world one might justify the agreement in the case of maximal information by saying that any disagreement can be resolved simply by looking at the system and seeing who's wrong.*

Disagreements in the quantum world are resolved also simply by looking at the system. Suppose you and I agree to everything in the world *except* the quantum state for a given system. How do we resolve our dispute? We perform a maximally refined quantum measurement (a POVM with rank-one elements). We agree on the system's state thereafter. That is all that has ever been important in science anyway—that the world provides us with a way to *come into* agreement for all *future* predictions. For god's sake, Albert Michelson did not believe that the speed of light could be a constant. But his tenure was not stripped away when he found a negative result. He revised his "impossible" belief and got over it.

All that one need to demand from a theory is that it provide a way for two agents to come to agreement for all FUTURE predictions. Quantum mechanics (surely) satisfies that. It has nothing to do with re-objectifying quantum probabilities, and I can't see that it has anything to do with this stuff we got in the habit of calling "maximal information."

06-09-01 *The Well Appreciated Point* (to C. M. Caves & R. Schack)

Your notes are well-appreciated themselves; I am finding reading them productive. Unfortunately, I cannot reply in detail tonight, but I hope more will be waiting for me tomorrow morning.

Let me do say though that I think I addressed some of your points in the note I just sent to Carl (and CC'd to you). The main thing was this:

Schackcosm 13: *What the Bayesian can say is: If A assigns a pure state, he knows with certainty that any other pure-state assignment is foolish (handing over lots of money).*

It is not a situation that can be resolved within science, by discussion or experiment or comparison of notes. Both A and B are certain there is nothing that could change their belief. For A, B could just as well reject all of quantum mechanics.

It is not a sin for A and B to disagree about the present. What would be a sin is if they could not come to agreement in the future. And quantum mechanics provides just such a mechanism. It is not true that experiment cannot change (absolutely firm) beliefs in the quantum world: quantum measurements are invasive, and thankfully so. Each measurement gives us the opportunity to throw away the past and start afresh.

07-09-01 *Email Not Received* (to C. M. Caves & R. Schack)

Schackcosm 14: *But, as I argued in my last email, I think that a modified betting argument, now having A and B as adversaries (Carl thinks that this modified argument should not be called a Dutch book argument), shows that starting from two different pure states to come to a later agreement is not what science is about. A must dismiss B as a crackpot. This argument would be useful in the Peierls debate. But maybe not for our paper.*

I didn't receive such an email; can either of you send it again?

Indeed I would bet that science cannot be made in a (purely) adversarial environment. Science is about cooperation, trying our best to come to a consensus. (That is why I have not lost heart in writing all these ridiculous emails!) But, nevertheless, from time to time I do talk and try to come to consensus with people I deem crackpots. The point is, though someone may be adamantly wrong about ONE thing (say, a pure-state assignment from my perspective), it does not mean that he is adamantly wrong about ALL things. And therein lies a backdoor for a discussion with such a person.

The only thing that one has to trust in the making of science is that one's colleague is internally consistent. It is OK if he got SOME of the *facts* (*The Well Appreciated Point*) wrong (from my perspective), and that I got SOME of the "facts" wrong (from his perspective). It is enough that he is willing to join in with me in letting the world pull us together. I.e., that each of us is willing to participate in trying to convince the other that he is wrong by consulting the ultimate arbiter.

But, I'll write more later (in the context of your last two notes).

07-09-01 *(Backbreaking) Analysis* (to C. M. Caves & R. Schack)

Schackcosm 15: *We need to find some common ground.*

Yes, that is true. And I think we already have some, maybe even a lot.

But, as I see it, there still remains a significant amount of trouble in the language we chose to use in the past ... and that is what is putting stoppers on our progress in the present.

Of course, I feel like I am repeating myself over and over, but let me go to your explicit "common ground" paragraph and try to lay out what I like and what I don't like about it. The thing that keeps me going is the hope that maybe this whole debate is a lot like beer: On their very first taste of it, most kids think it is a foul stuff. But after more and more of their friends offer it to them over time, it starts to become a pleasant diversion.

Schackcosm 16: *Assume A has information of the kind we call maximal, i.e., A knows that a measurement of a POVM containing the 1D projector P will give the outcome corresponding to P. Then assigning any state but P will be Dutch-book inconsistent. This will be A's inconsistency with her own belief. The beliefs of the bookie or of Nature do not matter. A knows that assigning any other state would make her accept a bet in which she (not Nature or the bookie) knows that she will lose for any outcome she believes is possible.*

Now assume B has access to the same piece of maximal information. B then knows that a measurement of a POVM containing the 1D projector P will give the outcome corresponding to P. Then assigning any state but P will be Dutch-book inconsistent. This will be B's inconsistency with his own belief.

Hence: Two agents having access to the same maximal information MUST assign the same state.

Here is how I would reword it to suit my present tastes.

> Assume A is absolutely sure that a measurement of a POVM containing the 1D projector P will give the outcome corresponding to P. Then assigning any state but P will be Dutch-book inconsistent. This will be A's inconsistency with her own belief. The beliefs of the bookie or of Nature do not matter. A knows that assigning any other state would make her accept a bet in which she (not Nature or the bookie) is absolutely sure she will lose for any outcome.
>
> Now assume that B is absolutely sure of the same thing, i.e., that a measurement of a POVM containing the 1D projector P will give the outcome corresponding to P. Then assigning any state but P will be Dutch-book inconsistent. This will be B's inconsistency with his own belief.
>
> Hence:
>
>> Two agents having the same absolutistic belief about the outcome of a measurement containing the projector P *MUST* assign the same quantum state.
>
> Or equivalently (but, to me, more forcefully):
>
>> Two agents having the same absolutistic belief about the outcome of a measurement contain the projector P *MUST* assign the same (subjective) probabilities to the outcomes of all measurements that can be contemplated.

What were the main substitutions? Essentially, they were simply:

$$\text{"maximal information"} \longrightarrow \text{"absolutely sure"}$$
$$\text{and}$$
$$\text{"maximal information"} \longrightarrow \text{"absolutistic belief"}$$

And the same substitutions count for the word "know."

To me, those simple substitutions completely change the metaphysical complexion of the statement. The statement goes no further than it has to go to make the quantum Dutch-book theorem stand its ground. Why go further?

Carl gave his reasons: To save science. But I do not see that is necessary in any way, and I do not personally believe that that method is on the right track.

What is wrong with the word "know"? To my Western-trained mind, it conveys the idea that there is something in the external world (the world outside of my head and beyond my control) and that my mind contains a mirror image of it. It conveys the idea that the outcome to the contemplated measurement already exists "out there" in some deterministic or fatalistic sense. It conveys the idea that I really need never have a look to see if the outcome is produced by my measurement: It's already there, and I know it; why waste time on a measurement? Notice that I let the word "knows" stand when it came to describing the very logic of the Dutch-book argument.

What is right about "absolutely sure" and "absolutistic belief" for me? They convey the feeling that what I have in hand is a belief, an extreme belief to be sure, but nonetheless a belief. That phrase never reaches out to the external world for its justification—or, at least it seems so to me.

What is wrong with "maximal information"? I think it screams out no more clearly than in your concluding statement above. In words that Gary Herling might use: The very phrase "SAME maximal information" is an abomination of the English language. In my mind, information is much like the word "know" (though a little looser in constitution). It too conveys the idea of a mind or a newspaper mirroring aspects of a preexisting reality. Besides that, the very fact that we have to go to the trouble to use the word "same" in conjunction with "maximal" conveys the feeling that the word "maximal information" was never appropriate in the first place. If information is some stuff we have gathered from the world AND it is maximal—the very most one can get—AND two agents really should be gathering up the same stuff, else one of them is wrong, THEN why do we have to go to the trouble of using the word "same"?

Well, we use it (i.e., "same") to keep ourselves from contradicting the belief that probabilities are subjective after all. Fine, so that is a good reason to keep the word "same". BUT, it is a bad reason to keep the phrase "maximal information" to merely convey the concept that one is "absolutely sure" of the consequence of some action that one might take (i.e., the measurement being contemplated here).

Schackcosm 17:

> CAF Said: Suppose you and I agree to everything in the world *except* the quantum state for a given system.

It follows from what I just wrote that this situation cannot arise in the case of maximal information.

To me, that statement is a *non sequitur*. I cannot find any *logic* to bring it about. And I say that especially if you can agree to the validity of my attempt at expressing a "common ground" for us in the highlighted paragraphs above ... no matter how pedantic you think my actual phrasing is.

If the quantum state is not uniquely declared by some reality, then there is nothing to stop us from agreeing on some aspects of the world and disagreeing on others.

Please read the note I wrote Mermin titled "Intersubjective Agreement" again. If you and I (in the presence of each other) perform a given POVM consisting of rank-one projectors on a system, then you might say that we will agree on the system's state thereafter. But that requires the assumption that we BELIEVE the same quantum operation (for updating our states) will be associated with that measurement. If we don't agree on that at the outset, then we will come to conclusion of two different pure states for the system after the measurement is completed.

You say, well a quantum operation is surely an element of reality: It is either right or it is wrong. (Carl would say that in any case; I wouldn't.) But suppose it is so—I will relax my debate with Carl for the moment. How would we know which quantum operation we had? We would have to have prepared a load of quantum states beforehand to map which quantum operation is "really" there. But then we would have had to agree on our cache of exploratory quantum states in the first place. How did we get to that stage of agreement, I ask you? And, on I will do the same, ad infinitum.

The point is, in a world where our only exploratory tools are quantum states and quantum measurement outcomes, we can never terminate the chain. This is one aspect of what I meant yesterday when I said that quantum states are infused with beliefs from the get-go.

Quantum measurement outcomes alone will never, ever be enough to uniquely determine a quantum state. One has to have some further a priori information or beliefs to do that. You can play the game—as Carl wants to—that that a priori information is the world's Hamiltonian. But then you will be about as stuck as Kant was with his transcendental idealism: you will still have to start off with agents of some initial common belief before they will ever be able to come to agreement about the Hamiltonian's form. And how are we poor finite beings to ever get to such a starting stage?

I say simply: throw out any trappings that a quantum state can ever be objective.

Schackcosm 18 : *Is there ever maximal information? Yes. You give us an example where C and F both obtain the same maximal information about the system:*

> CAF Said: We perform a maximally refined quantum measurement (a POVM with rank-one elements). We agree on the system's state thereafter.

In the sense that you want maximal information, i.e., something beyond absolutistic belief, I would therefore say that there is never any. My example required that the two agents share an almost strangulating amount of common belief. See discussion in previous section.

Schackcosm 19 : *As Carl writes, if C and F have the same maximal information, they must assign the same state. This is an important situation, as scientists share the information they have.*

If we can get past the language, I will (clearly) agree that this is an important situation. Scientists share the data AND the beliefs (interpretations, machine designs, etc.) they have.

Schackcosm 20 :

> CAF Said: The Dutch-book game is an adversarial game. Anyone whose intention is to make his opponent go bankrupt is NOT going to share everything he knows with him. He will be silent and bet his money.

No. The Dutch book game is about ONE agent's consistency.

Yes, you are absolutely right. And I apologize for throwing in extra junk that is not relevant. But the only point I really meant was that there is nothing in the Dutch-book set-up that forces the bettor and the bookie to share their information. That is an extra requirement if you want it. But it is a requirement that seems to me almost to give up the whole spirit of the Dutch-book situation: it involves no communication beyond the numbers p and x.

Schackcosm 21 : *That agents having access to the same maximal information must assign the same state is all we need for our paper.*

It seems to me, the only thing we need for our paper is the "common ground" statement I made above. I would not think that I need to say it again, but I'm getting pretty fearful of the phrase "maximal information." At the very least, I would like to start using it in a more limited sense or in a more limited way. Or perhaps in a vague enough way (for the present project) that I can worm out of it when I want to write future papers of my own without you two. (But this issue is likely to haunt us all the way through to the end of the RMP deal.)

All this email is starting to exhaust me, and it has certainly kept me from making this trip to Munich even resemble a vacation. I would like to draw it to a reasonable end soon. (But I do understand that that will require flexibility on all our parts, even me.) This may help my samizdat production, but it no longer feels like it is helping the rest of my life. I feel like I have hold of some important points that we were just too much in the "classical" tradition to recognize before. If we ultimately disagree, then we'll just have to do that, but I would rather not end up in that state of affairs.

If you have to make choices on what to do with your own time, please comment on my note titled "Note on Terminology" sooner rather than later. I fly out for Ireland Sunday morning.

08-09-01 *Negotiation and Compromise* (to C. M. Caves & R. Schack)

Let me tell you a little story I dreamed up while driving through the Austrian countryside today. It is based on one of the most annoying realities of my life: there are times when Kiki and I just cannot come to agreement. If I can use Rüdiger's words, there are times when I just think:

Schackcosm 22: *A is a physicist who would bet his career on his state assignment. If he says B is wrong he means this in an absolute, very strong sense. He has examined all the evidence, and there is no doubt left. He is certain that B is missing some evidence. The Dutch book argument shows that A is certain that B's position is equivalent to handing over B's entire fortune. Wrong implies foolish, deluded. For A, B is a crackpot, and the circumstance that B is certain that A is wrong reinforces this position.*

But there are realities: Kiki and I are married; we share a bank account. And here and there, Kiki consorts with the Dutch.

What I am leading up to is that I think there is a place for Ben Schumacher's observation about a three-person Dutch book in our ongoing debate.

You two want to believe that there are god-given constraints on how much two people can disagree. I say there aren't. It'll be a miracle if we ever come to some consensus on this. But I have never said that there ought not to be reasons that two people might want to come to agreement ... EVEN when they have differing but, nevertheless, "maximal information." (I use the phrase "maximal information" despite my dislike for it in order to be sarcastic and to underline a further difficulty with the term in a moment.)

I am internally consistent; there's no Dutch bookie who can take me to the cleaners. And despite my feelings for Kiki's complete foolishness, I feel that she is internally consistent; there's no Dutch bookie who can take her to the cleaners (as far as she is concerned). But we will be in deep trouble if that Dutch bookie approaches us separately. (Being married, we report all our beliefs to each other.)

I can see two outs to this problem. The first one—which is less interesting—is that we make an effort to come to agreement by consulting the world. We make a measurement, and thereby, through its invasiveness, force the quantum system into a state we can agree upon. (Assuming, as

I keep harping on, we can agree on the quantum operation associated with our measuring device.) But what if we have no access to the system of interest? What are we to do then?

I think we would have no choice but to, each of us, back off in the firmness of our beliefs. That is, we should agree upon a density operator that contains in its support both of our earlier ascriptions. We both give up some of our certainty is this process, but the upshot is that we no longer have probability one of becoming bankrupt.

So think about this: Two agents start out saying that they are absolute in their convictions about a some quantum measurement. But then the reality of their partner's stubbornness hits them, and the only thing they can do is back off.

You continue to want to call a quantum state information. But for the present case, again, it seems the term "information" is stretched beyond common usage by the factors people must sometimes take into account in coming to their assignments. From my point of view, Kiki's foolish quantum state assignment is not information about the physical world at all. It is completely wrong, with no reflection in the world as far as I am concerned. Nevertheless, I had better take it into account in making my bets if I don't want to lose our whole joint bank account.

The point I take home is that is sometimes better to negotiate and compromise even when one has "maximal information."

10-09-01 *Short Reply* (to C. M. Caves & R. Schack)

Just a very short reply to your latest posting. But first let me say something about this:

Schackcosm 23: *I hope this email establishes a little more common ground. I would like to start, next week, on revising the paper in the view of this discussion and the referee's comments.*

Yes, do it. With the draft in hand, I'll be better able to see which statements make me feel like a liar and which do not. (Hopefully most of them won't.) And then we can be done with this, and then you can finally stop saying to me, "But not for this paper."

Schackcosm 24:

> CAF Said: What is wrong with the word "know"? To my Western-trained mind, it conveys the idea that there is something in the external world (the world outside of my head and beyond my control) and that my mind contains a mirror image of it. It conveys the idea that the outcome to the contemplated measurement already exists "out there" in some deterministic or fatalistic sense. It conveys the idea that I really need never have a look to see if the outcome is produced by my measurement: It's already there, and I know it; why waste time on a measurement? Notice that I let the word "knows" stand when it came to describing the very logic of the Dutch-book argument.

I do not think any of this is clear. I "know" something means I have a firm belief in it. I don't think more is implied. The question of whether something corresponding to the knowledge (or the belief) exists out there is entirely separate from these wording issues.

Mermin once wrote me this:

> It seems to me Chris is getting much too subtle about this. I would talk about knowledge, not belief. I take "knowledge" to mean simply "true belief", a definition that as I remember goes all the way back to Plato and can be made unproblematic even in the quantum context. [Only a postmodernist would sneer at my saying this.]

And then this:

> C'mon, don't drag your heels. QM is sometimes capable of assigning probability 0 to certain outcomes. For those one doesn't have to argue about whether probability has to do with ensembles or degrees of belief or anything else. "True belief" seemed a good term to describe such outcomes, and then I remembered that Plato (I think) had used the same term (in contrast, as I remember, to "opinion".)

William James writes it like this:

> The popular notion is that a true idea must copy its reality.

The *Encyclopedia Britannica* says this (mainly the last sentences are relevant):

> In general, the philosophical tradition from the Greeks to the present has focused on the kind of knowledge expressed when it is said that someone knows that such and such is the case, e.g., that A knows that snow is white. This sort of knowledge, called propositional knowledge, raises the classical epistemological questions about the truth or falsity of the asserted claim, the evidence for it, and a host of other problems. Among them is the much debated issue of what kind of thing is known when one knows that p, i.e., what counts as a substitution instance of p. The list of such candidates includes beliefs, propositions, statements, sentences, and utterances of sentences. Each has or has had its proponents, and the arguments pro and con are too subtle to be explored here. Two things should, however, be noted in this connection: first, that the issue is closely related to the problem of universals (i.e., whether what is known to be true is an abstract entity, such as a proposition, or whether it is a linguistic expression, such as a sentence or a sentence-token) and, *second, that it is agreed by all sides that one cannot have knowledge, in this sense of "knowledge," of that which is not true. One of the necessary conditions for saying that A knows that p is that p must be true, and this condition can therefore be regarded as one of the main elements in any accurate characterization of knowledge.*

I put stars beside the hot stuff. [It is italicized in this samizdat version.] And I'd send you more quotes if I could, but I'm a gazillion miles away from home in a piss-poor dormitory room (with no library).

Schackcosm 25: *There must be a misunderstanding. If you and I agree about everything in the world, we also agree on the certainty of a particular measurement outcome. We can not then disagree on the state to assign, because at least one of us would be internally inconsistent.*

You must mean that we agree on everything except the state AND the measurement.

Yes.

Schackcosm 26:

> CAF Said: I now think it is much better to reserve the word KNOWLEDGE solely for the outcomes of quantum measurements once they become part of the mental makeup of an agent interested in them. I walk into Mabuchi's lab, and to the extent that he and I agree that he is performing some POVM (denoted by a set of positive operators $\{E_b\}$), it seems to me valid to call the outcome b we both witness to be an addition to our knowledge. Now, what either of us may do with that knowledge is a different story. One thing is for sure, it ought to cause both of us to update our beliefs.

This is a very difficult debate. I am not sure I understand why you draw the line between knowledge and belief exactly where you do. Why give belief in b a special role? I need to think much longer about this.

Because I had assumed that Mabuchi and I had agreed to a fixed "random variable." With respect to that prior assumption the thing we gain is "information" in the standard Shannon sense. I'm willing to call that knowledge that we did not have before. There is nothing personalistic about it; we both have gained the same thing.

I went to dinner with Jon Barrett, Harvey Brown, Matthew Donald, and David Wallace. Getting Bayesian ideas across to them is going to be a hard sell. But the most amazing thing is that each and every one of them was familiar with the Dutch book argument! (Now, how could anyone know it, and yet it not change their life?)

12-09-01 *Ireland* (to S. L. Braunstein)

Thanks for the offer. If it looks like I'm stuck here, I'll surely take you up on it. (Mostly I want to get home, safe and sound, and then *not* get on a plane again for some time.)

It's amazing here, at this meeting: It has practically stopped. People just can't get the news off their minds.[15]

13-09-01 *Re: Hope You Are Fine* (to H. J. Briegel)

Thanks for the concern. They have indeed been horrible events. But my family and I are both safe: Kiki and Emma are in the States, and I am still in Ireland (I may be here for a while, depending upon the airlines).

I certainly enjoyed getting the little private lecture. The word will be spread: You've had a great set of papers.

I'll write you with information about Montréal as soon as Gilles and I get our heads together (maybe next week or the week after).

15-09-01 *Question on the Manuscript* (to R. Schack)

Just send me the draft when you're pleased with it. And I'll tell you then what I can tolerate.

Schackcosm 27: *But as your (ugly) term "absolutistic belief" shows, they should be extremely careful before making pure-state assignments.*

I am not committed to that term, like you guys are to the (inaccurate) term "maximal information." It was just the best I could come with at the time. Change it if you wish. The most important thing is that whatever you substitute for it should carry no flavor of a "reflection theory" of knowledge.

---

[15]The conference in question was the "10th UK Conference on Foundations of Physics" in Belfast, Northern Ireland, September 10–14, 2001. It is the meeting where I met Marcus Appleby for the first time, at a dinner with Matthew Donald. Matthew said, "Would you mind if Marcus Appleby comes along? He's done some interesting work on Bohmian mechanics."

You won't buy it, and you'll think I'm just saying this out of less than pure reasons, but you would be surprised at how many people have now encouraged me to call the quantum state a "belief" rather than "knowledge." (Four.)

I'd like to come to SB, but we'll have to see how things play out with Kiki.

15-09-01 *Melancholy Molly* (to N. D. Mermin)

I'm sorry to be writing you back so late: this week has taken a big toll on me.

Merminition 59: *Well for better or for worse Todd, Jerry, and I came up with something we could all agree on.*

I suspect for the worse (if Renes's report to me on it is accurate). I haven't been able to download the paper myself yet, and won't until I get back into the states. My personal opinion is that it is likely to muddy the already troubled waters even more.

Merminition 60: *Am still enchanted by the knowledge-belief breakthrough. How do your coauthors like it?*

The world has become a little lonely for me lately. I'll show you the lengths I've had to go to with all of you below. You are a troublemaker, getting me started down this route! (The document is in the format of the samizdat.)

Merminition 61: *Are you now in Ireland? What part? Be careful.*

To think, I was once scared to be in Ireland. I'll instead take "be careful" to mean "get back into the US safely." I am in London as I'm writing this to you. My original return flight was cancelled; now I'm on the backlog with a million other people.

> Blow up your TV,
> Throw away your paper.
> Move to the country,
> Build you a home.
> Plant a little garden,
> Eat a lot of peaches,
> Try to find Jesus on your own.

16-09-01 *For Worse* (to N. D. Mermin)

Merminition 62: *Well for better or for worse Todd, Jerry, and I came up with something we could all agree on.*

Well, I managed to download your paper this morning after all. I ended up in the airport for over four hours. Now, I'm somewhere over the Atlantic.

I hate it, of course. It's built around the same stubborn disregard for the issues involved in trying to give the quantum state a NONontological status that all the BFM emails were.

To use a term I picked up from a philosopher this week in Ireland, the proposed outcome of a single quantum measurement simply cannot be a "candidate for knowledge." Its source must be considered ineffable, else the wrath of Gleason's theorem would strip away the nonontological status that was being sought for the quantum state in the first place.

I can guess from the format of the paper that it is being submitted to PRL. If I were being mean, I might say, "Good. That'll give it a higher chance of being rejected." But I'm not mean. If I were the referee I might even accept it. But, ONLY if the authors use the extra column at their disposal to explain why their statement of the problem is not a deep endorsement of the Everettista manifesto. (Or, if it is, then just come out and say it.) What else is Zeno but a baroque name for the quantum state of the universe (mixed or not) or a candidate for the one that really gets it "right"?

On a personal note: If you're going to cite a personal communication that appears in the samizdat, why don't you cite the samizdat? (I'm always looking for further ways to draw people into it.)

Best regards (in continuing disagreement),

16-09-01 *Persnickety Business* (to N. D. Mermin)

Since my last note, I've looked over your paper again. I must say I found the sentence,

> It is surely a significant feature of the theory that consideration of impossible outcomes and very little else leads, without any invocation of "the uncertainty principle" or "maximal information", to the fact that pure state assignments must be unique, as well as the more general constraint on mixed-state assignments.

a bit snobbish. Especially since you gave zero devotion to the issue of whether a quantum state could be "true" or not. If they can be "true," then why don't you just take them to be a bit of material reality and forget all this crap about knowledge? If they can't be, then what do you mean by the word "impossible"?

I still hate the paper, probably more so now.

A little further over the Atlantic (and wishing I were closer to Greenland),

16-09-01 *Arlo and Arlo* (to D. B. L. Baker)

As I just wrote another David—i.e., Mermin instead of Baker—right now I'm somewhere over the Atlantic, wishing I were a little closer to Greenland. I'm on my way back home from Northern Ireland. What a week it has been. I've never been so homesick for America before.

> Good mornin' America, how are you?
> Don't you know me, I'm your native son.

I think I might just kiss the ground if I really do land at JFK.

Once upon a time, we could actually see the twin towers from Morristown on a clear day. They pierced the horizon like nothing else in Manhattan. Hearing Emma's voice on the phone the other night was one of the toughest things. She said, "Hi Daddy-o," and then told me all about her first day in playschool. It's not easy to juxtapose that with the death of 5000 people and the many more deaths that may come in the near future.

Life is an essence in this universe. Creative, productive, reproductive life: I'm not one of those scientists who think it is just an illusion, an epiphenomena rolling on top of a clockwork or a dice-rolling world. It is something in itself. It was latent there all along, long before the trilobites had found their place, and it is our task to see that it does not return back to that latency.

Very sad times.

16-09-01 *Registered Complaints* (to J. M. Renes)

Good to hear from you; thanks for the note. I'm flying back from Ireland as I write this to you. I think the conference was successful in many ways. While there, I got to know Marcus Appleby, and he is a really good guy. He's very Jamesian in his perspective, very clear in thought, and a real seeker of the truth. I think I'm going to work to get him to Montréal next year (even though he does not practice quantum information).

I agree with your assessment of the BFM paper. I've already registered my complaint with Mermin. But you know, it's not like there are no pansies even in the midst of our own little group: Carl and Rüdiger have had no great fortitude when it came to this issue, no courage of their convictions.

I'll place my small samizdat on the subject below in case you're curious.

I hope your transition back to New Mexico has gone well. We'll miss you at Bell Labs.

16-09-01 *Nerve Therapy* (to R. Schack)

I'm in the last 1.75 hours of my flight to New York, and I'm doing everything I can to keep from getting too nervous. Let me finally turn my sights to your note from a week ago.

Schackcosm 28 : *I was referring to the argument that, from A's perspective, if B assigned a different pure state, that would force B to accept a bet offered by A that amounts to handing over money to A. Therefore B is a crackpot from A's perspective (but not from his own, of course). This is interesting because it is the very fact that B has maximal information that forces him to accept A's bet: B "knows" A cannot know anything that would give her an unfair advantage in the bet. I still think this is a strong argument. Scientists would try to overcome this critical situation by questioning the world, i.e., by making measurements, but NOT on the system in question, but on everything else, e.g., Hideo's optical table. After all they both are convinced that the world is disentangled from the system in question.*

Personally, I only find this restriction to not touching the system of interest (by you and BFM) ad hoc. Since when in science do we restrict the experimentalists to never touch the objects of their interest? Besides, I think you may be missing one of the deepest facts of the quantum world: it has the power to cause agents to agree *henceforth*, no matter how adamant their previous beliefs ... AND EVEN without the underlying reality of preexisting measurement outcomes that the classical world had. With each quantum measurement, a part of the world starts afresh.

Schackcosm 29 :

> CAF Said: But there are realities: Kiki and I are married; we share a bank account. And here and there, Kiki consorts with the Dutch.
>
> What I am leading up to is that I think there is a place for Ben Schumacher's observation about a three-person Dutch book in our ongoing debate.

I cannot quite see where this situation offers any specifically quantum insight. In any case, it is completely different from the "adversarial game" I am talking about.

I'm not sure that it does lead to any specific quantum insight. But then again, I had never seen you and Carl be so adamant about taking probabilities to be objective features of nature before. (Don't do it! I know you're going to say "NO, NO, NO, we have never wanted objective probabilities!" But all the pieces of evidence—to me—point to the contrary.)

What it does show—and that is maybe where quantum theory comes in a little bit—is that there are times when no matter how adamantly I believe something, I should bet according to odds different from my belief. I.e., there are internal beliefs, and external "beliefs."

To that extent, I am starting to wonder if "belief" is even an appropriate word for capturing the essence of a quantum state. Instead it is starting to seem to me that it may more appropriately be described as a negotiated signifier to external action. I.e., in some cases, it signifies the betting strategies that a community of scientists can agree upon, even in the case of more refined and divergent beliefs.

Whose knowledge, Mermin asked? Sometimes, mine. Sometimes, yours. Sometimes it's more a matter of the policy we have been able to negotiate.

I do get a little worried in saying all of the above, in that, maybe I have not taken Savage's and Bernardo and Smith's views of probability into adequate account: namely, that probabilities and utilities spring into existence at the same time, and are a little inseparable. But presently I don't see how that fits this problem. Nor does it extinguish the problem that sometimes it really is in people's best interest to lie about what they believe.

Schackcosm 30:

> CAF Said: I am internally consistent; there's no Dutch bookie who can take me to the cleaners. And despite my feelings for Kiki's complete foolishness, I feel that she is internally consistent; there's no Dutch bookie who can take her to the cleaners (as far as she is concerned).

I strongly believe that here marriage is fundamentally different from science.

Perhaps. But the point is, sometimes we bet according to situations that have nothing to do with our beliefs. We bet so as to obtain the best common good. And with that we do return to some aspects of science (and politics).

Schackcosm 31:

> CAF Said: But we will be in deep trouble if that Dutch bookie approaches us separately. (Being married, we report all our beliefs to each other.)

This deep trouble arises even if both you and Kiki assign mixed states with the same support, I believe (but I need to think more about this). I am trying to make the point that pure-state assignments are different.

That is true. I chose the particular example of pure states to be as dramatic as possible ... in an attempt to hit you and Carl in a point where you were being the most hardheaded.

Schackcosm 32:

> CAF Said: I can see two outs to this problem. The first one—which is less interesting—is that we make an effort to come to agreement by consulting the world. We make a measurement, and thereby, through its invasiveness, force the quantum system into a state we can agree upon. (Assuming, as I keep harping on, we can agree on the quantum operation associated with our measuring device.) But what if we have no access to the system of interest? What are we to do then?

Well, I gave my answer above. We question everything in the world BUT the system of interest. Using quantum measurements, of course.

Ad hoc.

Schackcosm 33 :

> CAF Said: I think we would have no choice but to, each of us, back off in the firmness of our beliefs. That is, we should agree upon a density operator that contains in its support both of our earlier ascriptions.

Yes, the same is true for two reasonable scientists. But as your (ugly) term "absolutistic belief" shows, they should be extremely careful before making pure-state assignments. Your way out is similar to having second thoughts after placing the bet.

No. My way out is to point out that there is, after all, a distinction between an (internal) belief and its manifestation as an outward bet. The belief comes before the bet.

OK, I've just passed Boston, and in the mean time, got another meal in my stomach. For the obvious reason, getting past Boston carries some symbolic significance. Let us believe in symbols.

18-09-01 *Hi Back* (to A. Peres)

Good to hear from. Yes, I am home. I was delayed by a day, spent a night in London, had to return to JFK rather than Newark, and had the most tense flight of my life, but I am home. I held and held and held on to Emma when I saw her waiting for me.

I have been in a huge email debate with David Mermin about his two latest papers. Consequently, I also got into a huge debate with Caves and Schack, though they are (slightly) more sensible. (The whole thing has been quite taxing.) John Wheeler once told us a story of a condemned man who, while waiting for the firing squad, calmed his nerves by contemplating Hamilton's beautiful equations. I learned a lesson from this: When I was worried about the safety of my flight, I calmed my nerves by continuing my email debate with Mermin, Caves, and Schack!

I hope you and Aviva are able to get home on schedule. I suspect your grandchildren are waiting for your return with excited eyes.

18-09-01 *Goodbye* (to N. D. Mermin)

I just don't know what more to say. Clearly there is something that is keeping us from communicating. I write more and more, and you just don't get my points. It's probably better if I just write less and less.

I'll record the way Caves put the best part of your paper the other day and just leave it at that. I've never said anything different, but maybe if you hear it from another voice something will click.

> It seems to me that there are various kinds of coming to agreement or inability to do so. Much of this is a recapitulation of what we have already discussed. It is phrased in a way that is supposed to avoid the notion that beliefs incorporated in a state assignment require the world to do things. [. . .]
>
> 1. BFM consistency (a multi-party condition): If the parties share their information, it is not ruled out that they can come to agreement on a common state assignment.

If they share information, they must rule out all vectors in the subspace generated by the union of their null subspaces, and they must assign nonzero probability to all vectors in the intersection of their supports. They have the possibility of making a joint state assignment if and only if the intersection of their supports is of dimension 1 or more.

Notice that we don't have to say here, as BFM do, that an outcome assigned probability zero by any party definitely cannot occur.

But let me say one last thing before I give up on this conversation. In your last note you wrote:

Merminition 63: *We've sent the hateful paper to Phys Rev A as an ordinary low-grade submission. My concern is that a referee will condemn it as trivial or well-known, not outrageous or Everettistan.*

You have probably summed up the referee's response correctly, but it doesn't make it so. Nor does it make you paper non-Everettistan after all. The whole point can be summed up with the following part of your paper.

A necessary condition for compatibility

Suppose Alice, Bob, Carol, … describe a system with density matrices $\rho_a, \rho_b, \rho_c, \ldots$. Each of their different density matrix assignments incorporates some subset of a valid body of currently relevant information about the system, all of which could, in principle, be known by a particularly well-informed Zeno.

This is an edict you are placing ON TOP OF quantum mechanics. It is a construction of your own doing. I find it in no axiom system I have ever looked at. It IS a good half of the Everettista starting point.

You might say the other half of Everett is that he takes the quantum state explicitly to be an ontological entity. But you've got that too. By imagining that facts of the world (measurement outcomes) uniquely determine a quantum state, what else could a quantum state be but a stand-in for those real things, those FACTS (the stuff that one absorbs into one's mind and calls information)? You simply cannot say that quantum states MUST be consistent, if you want them to retain a nonontological status. The second you say they MUST be, then you have given up the game: states are then properties of the world, and this question of consistency was a waste of time from the beginning.

With this, I end the conversation: I give up.

19-09-01 *Morning Coffee* (to C. M. Caves & R. Schack)

Schackcosm 34: *Yes, and this is great progress!*

Well, the note really is some progress. Let me just accept the gifts the Lord has given me.

I have two questions.

1) What does Peierls' consistency have to do with coming to agreement? I don't see it yet. It seems to me to be more a technical definition for the word "wrong" than anything else. Using it, I can say when you are "wrong" with respect to my beliefs, but that seems about it.

2) This thing you call fuchsian consistency. You bring to the surface, a point I've always been a little worried about. Why refuse to consider outcomes lying in the null subspace of a density operator? Let me give an example:

Chris: I say the state is spin-up in the z-direction.
Carl: I say it is spin-down.
Chris: Spin-up!
Carl: Spin-down!!
Chris: OK, let's test it. Here is an ideal z-spin-measuring device. Its Kraus operation is just a von Neumann collapse. Do you agree?
Carl: Yes, I agree.
Chris: Are you sure you agree? We need some agreement or this won't be a meaningful game.
Carl: Yes, I agree and am growing impatient.
Hideo: Spin measurement done. It's spin-down.
Chris: Damn, I honestly believed with all my heart that it'd be spin-up!
Carl: Well, I wouldn't have said it if I didn't know it.
Chris: OK, from here out, I say the spin is spin-down. I was a fool before, but at least we agree now.

Your worry seems to be that the formal apparatus of quantum mechanics will not allow me to propagate my belief. According to the Kraus rules, my new state should be the zero operator renormalized by a probability zero: i.e., it is an undefined object. Nevertheless, life goes on, just as the story above indicates. This, at least, does have a formal counterpart in that, if I back off in my belief even the slightest amount to any mixed state (not on the boundary), then the Kraus operation will take us both to the same place, to the same one-d projector. Consequently, the limit exists even if the actual point is undefined.

So, in saying this, I don't think one has to do anything fancy with a measurement to get this thing you call fuchsian consistency off the ground. No intricate constructions of states seem to be needed. Choose ANY (mutually agreed upon) von Neumann measurement you like, and Carl and Chris will have to agree at the end of the day. One of them will feel foolish for having been so wrong, but as long as he is rational, agreement can still be had. As Rüdiger said, the idea is that this is a property of quantum mechanics (in its capacity as a law of thought), not of the initial states.

Alternatively, one can turn the problem around, as I tried to do in my August 7 note to BFM: suppose Carl and Chris agree to a *particular* Krausian state change rule (one not even closely resembling a von Neumann collapse). Now one can ask, under what conditions on the initial states will C and C be left with more agreement at the end of the day than they started with? But that is a different problem than this f-consistency condition you speak of.

19-09-01 *2001 Japanese-American Frontiers – Background Information Needed* **(to E. R. Patte)**

Title: Quantum Information, Quantum Channels

Abstract: Most physics students, with their first lesson on the Heisenberg uncertainty principle, are given a subliminal message: quantum mechanics is a limitation. The attitude is, "Quantum mechanics is something we deal with because we have to, but wouldn't the world have been so much better if we could just measure a particle's position and momentum simultaneously?" This talk is about the counterpoint to that attitude. Recent advances in the fields of quantum computation, quantum cryptography, and quantum information theory show that the physical resources supplied by the quantum world are anything but a limitation. With these new resources we can do things almost undreamt of before, from the secure distribution of one-time pads for use in cryptography to the factoring of large numbers with a polynomial number of steps. The magic ingredient in all this is something called quantum information. I will illustrate the subtle strangeness of this new kind of information and the nice effects it buys with several concrete examples drawn from my own work in quantum cryptography and quantum channel-capacity theory.

19-09-01 *Tentative Hello* (to N. D. Mermin)

Merminition 64: *I may take a shot at rewriting our argument, since I'd like to produce something for the Växjö proceedings. At that point I may try it out on you, but if you think it's likely to induce nausea, you don't have to respond.*

I owe you many things. If you want me to look at it, I will look at it, and I will try to respond (i.e., give you constructive criticism) in a civil tone.

19-09-01 *Practical Art* (to C. M. Caves, N. D. Mermin & R. Schack)

I suspect all of you have seen, in one form or another, the optical illusion where, looking at the drawing in one way, it appears to be a beautiful young woman. But looking at it in another way, it looks to be an old hag. Here's a true story about that. The first time I ever saw such a thing was in Roger Penrose's book *The Emperor's New Mind* in 1989 or so. Below the picture was a caption, explaining just exactly what I ought to see: alternatively, a beautiful woman and a old hag. But the oddity was, I could only see the beautiful woman. As much as I tried to find a hag in the picture, I couldn't do it. That fascinated me—so much so that, from time to time throughout the next year, I would pull the book off the shelf and try to find the old hag. I never did see her until one day I was searching through the book for something completely different and happened to come across the page. In fact, that may have even been two years after my initial encounter with the picture.

I think it is safe to assume from this that if Penrose had never pointed out to me that there ought to be an old hag there, I simply may have never seen her.

Let me apply this piece of art to a question on my mind. Let us imagine that some perpetrator has committed a dastardly deed to my family and left a note promising that before the end of her life she would do it again. Beyond this I have no clue of the identity of the perpetrator (or of her cause) except a sketch made of her by an eyewitness, who has now also disappeared from the scene.

For intentional completeness, let us suppose there is simply no further evidence that I can lay my hands on—there is no more "currently relevant information," no deeper "trail of evidence." The carbon atoms laid out on the two pieces of paper—the note and the drawing—are the only links I have to the cause of the crime. The trouble is, in the case of the drawing, the carbon atoms sketch out the shape of Penrose's beauty-hag.

Now suppose an insurance salesman appears on the scene and is willing to sell me insurance against a recurrence of the crime precisely 30 years hence at such and such a premium. Do I buy it? That, of course, will depend upon the probability I ascribe to the crime's recurrence in precisely 30 years. What probability do I ascribe?

It will depend upon what I see in the picture. If I "see" the old hag, it will be one thing. If I "see" the beautiful woman it will be another. If I "see" there is an ambiguity, it will be still a third. But one thing is sure from this example, what I "see" is not completely dependent upon the pattern laid out by the carbon atoms. Part of what I "see" is dependent upon psychological factors that I *myself* may simply never have access to—things deep within my head, things determined when I was first toilet trained, things to do with the self-referential nature of consciousness, things that physics just ought to (and maybe even has to) leave alone. My beliefs (my probability assignments) after seeing the sketch are determined in part by something objective in the world external to me, but also in part by my previous, purely subjective beliefs. This example ought to make it clear that I cannot put all the weight of my posterior beliefs on the external world.

Here's my question: Where do you draw the line? More importantly, how do you draw the line? What is it in your view that gives the clicks of a quantum mechanical measurement a status that goes deeper than the example above? What makes the phrase "currently relevant information" more decisive in the quantum mechanical case? How does that "trail of evidence" have more power to eradicate my subjective pre-beliefs than any other? So much so, in fact, that one gets the feeling that we might even view the quantum state as determined solely by such a trail? You say, "Well, there the information conforms to a physical theory." But in what way does that change things? Can you pinpoint it? Can you make that declaration meaningful? Indeed, can you pinpoint what about the example above is not quantum mechanical? It had atoms, it had systems, it had probabilities.

I said I would not talk to David anymore, and here I am talking to him. I guess that just goes to show that that Mermin can steal your heart ... as can all of you.

20-09-01 *The Stopgap* (to C. M. Caves & R. Schack)

Attached is the latest draft. You will find two (and only two) changes.

1. I added the word "the" in front of "records."

2. I added two citations to myself. One at the beginning, one at the end. If you don't like where I put them, that's fine—feel free to change their positions—but I would like to have them somewhere in the paper.

Of course I am still troubled by the use of the phrases "maximal information" and "with certainty". I continue to think that they convey an image that is better left unconveyed, but I'm the odd man out here so I'll shut up. The main thing is that you left me enough wiggle room that I can defend my view of the quantum state when I need to. E.g., "Oh, I'm sorry, that was just a bad choice of language. The thing to keep in mind is ..." Rather than my having to say, for instance, "Yes, I believe we were wrong about that, but I couldn't convince my coauthors."

Another thing I guess I really didn't like—and this is only a new one for me, it's not something that had eaten away at me before—is the slogan "Gleason's theorem can be regarded as the greatest triumph of Bayesian reasoning." To say that is to imply that Bayesian reasoning IMPLIES Gleason's theorem. I don't think you mean that. I think what you mean is that it is one of the most valuable additions to Bayesian reasoning ever. But I won't cause trouble here: I know you both like the saying.

I think I read the paper very carefully again—more carefully than ever actually. I will live with its consequences, and I apologize for dragging my feet for three or four years.

Now, I just wish we three could come to agreement in our views of quantum mechanics!!!!!! So that I could look back on that day and say, "We few, we lucky few, we band of brothers ..."

20-09-01 *Praise, Folly, Enthusiasm* (to W. K. Wootters)

A million thanks for your encouraging letter of August 30! But also, please accept my apologies for not writing you back for more than 20 days. I had wanted to write you a rather long, contemplative note in response, and I kept waiting for the right mood. Somehow it just never came—first with my travels to Munich and Belfast getting in the way, and then with all the horrible events in the world in the last 10 days.

I certainly like aspects of this speculation of yours. Indeed, I wish you would write it down so we could all have a chance to think about it a more deeply. (Would you be willing to do that? You do have tenure now, and our individual lives are finite: we should never lose sight of that.) But of what little bit I understand of your ideas presently, they don't seem to have as much reciprocality or as much dynamism as I would like to think the world has. What I mean by this is that your ideas seem to carry a significant flavor of the Cartesian cut: the graphs take the place of res extensa, and the identifications take the place of res cogitans. The two realms—as I understood your explanation—don't really interact: The graphs are timeless and independent of the identifications we might make between them.

But, as you say, we are both speculating. And we both realize that. Here's the way William James put it:

> The history of philosophy is to a great extent that of a certain clash of human temperaments. Undignified as such a treatment may seem to some of my colleagues, I shall have to take account of this clash and explain a good many of the divergencies of philosophies by it. Of whatever temperament a professional philosopher is, he tries, when philosophizing, to sink the fact of his temperament. Temperament is no conventionally recognized reason, so he urges impersonal reasons only for his conclusions. Yet his temperament really gives him a stronger bias than any of his more strictly objective premises. It loads the evidence for him one way or the other, making a more sentimental or more hard-hearted view of the universe, just as this fact or that principle would. He *trusts* his temperament. Wanting a universe that suits it, he believes in any representation of the universe that does suit it. He feels men of opposite temper to be out of key with the world's character, and in his heart considers them incompetent and 'not in it,' in the philosophic business, even though they may far excel him in dialectical ability.
>
> Yet in the forum he can make no claim, on the bare ground of his temperament, to superior discernment or authority. There arises thus a certain insincerity in our philosophic discussions: the potentest of all our premises is never mentioned. I am sure it would contribute to clearness if in these lectures we should break this rule and mention it, and I accordingly feel free to do so.

Since reading this a month ago, I've been wondering what my temperament really is. What is the "potentest of all my premises"? I haven't completely tied it down yet, but I think it has to do with the idea that the world can be moved (from within), that it is malleable, that it is still under construction. That the future, for better or for worse, is not yet determined. And that this malleability—like the turtles—goes all the way down: there is no ultimate level that grounds it.

This, if it is, my "potentest of premises" has so far taken manifestation in the speculation that the components of the world are "sensitive" or "irritable." But I suppose that is part of the "impersonal reasons" that James speaks of—i.e., that they form not quite the whole truth of my motivation. The better truth is perhaps that the components of the world—the things that come out of the ways we carve the world up—are movable in a deep sense. They reach out and affect us in ways that we cannot foresee, and we reach out and affect them in ways that they cannot. And through that intercourse, birth arises in the world in a sense every bit as real as biological birth.

But I don't know how to make any of that more precise. It stands at just a program and a direction, but one I take seriously.

Your letter gave me courage, and with such speculations, believe me, one needs courage! How I wish we could get together more often to hash these things out, letting our disparate speculations refine each other. I feel deep in my heart that there is progress to be made—technical progress—it's just a question of building a community with a critical mass of ideas, constructive opinions and techniques.

What are your plans for your sabbatical this year? In which direction do you plan to use your time? Will you be visiting IBM often? If I could get a chance to talk to you more often about the sublime side of physics, I'd surely take it.

By the way, let me draw your attention to a mistake I made in the paper you read. Howard Barnum brought it to my attention last week, and next week I plan to write a short comment on it and post it on `quant-ph` (before someone else does). It is in the derivation of the tensor product rule. For the most part the derivation holds, but I got sloppy in the very last step. I.e., by requiring the existence of a noncontextual probability assignment to the outcomes of local measurements (with one-way classical communication), one does indeed get that the probabilities are controlled by a linear operator on the tensor product of the two spaces. But, these assumptions alone don't get you that the linear operator ought to be a positive semidefinite operator. That requires more assumptions. In principle, one should be able to state those assumptions as a restriction on the correlations one can obtain by local measurements, but I don't quite see how to do it yet. (An easy way out would be to require that the linear operator give rise to positive probabilities for all measurements, local and nonlocal. But, that's kind of a dull answer after relying on locality for so much. I'm sure one can find a more interesting answer.) For instance, I'm not quite sure how to tackle the question of ping-ponging measurements in this framework. Or even whether that's the sort of thing that should be looked at for a natural restriction.

There's so much work to be done! But, it's our place to do it . . .

20-09-01 *Pots, Kettles, and Frying Pans* (to N. D. Mermin)

More seriously. I think the line you are talking about is not the line I was talking about.

Caves has been writing me things like this:

Cavesism 20: *I do want to conclude with my obligatory diatribe against wholly e-mail exchanges. You think all your messages were perfectly clear, I think all mine were perfectly clear, Rüdiger probably thinks the same, but the evidence is that they were not. It's just not possible to come to agreement by e-mail, the reasons among others being that, first, questions arise in reading something* *after which further comments get devalued and, second, peripheral and main points often have their roles exchanged when a message is read.*

And ever more I am having to come over to his view on this subject. But, it is just so hard to give up my old email habits, especially since I've seen them become so ineffective of late. It's like a captain who just can't tear himself away from a sinking ship.

So let me say a few words in response to you. You should know I've got too much invested in the phrase "knowledge about the consequences of our interventions" to back out: it's part of my whole being. If you think that is what is going on with me, you are mistaken.

I do not deny: (1) that trails of evidence exist, and (2) that trails of evidence are created in part by our interventions into the world. What I deny is that those trails of evidence can ever uniquely determine a quantum state, even a pure one. That is what is at issue (with me at least), and that is what yesterday's note was referring to. (Somehow I get the impression that you saw something completely different in the note.)

A detector goes click. You write down that it went click; I write down that it went click. To that extent, the click is part of the objective world independent of us; it is part of the trail of evidence that you and Caves speak of. (Now, maybe the measurement apparatus itself isn't completely part of the agent-independent world—somebody built it to begin with—but that is a different story.) The formal structure of quantum mechanics says that we must identify the click with an element in some POVM. Fine. I agree with that. (Presumably you do too.)

The issue is, which POVM? And which state-change rule associated with that POVM? Show me a place in quantum mechanics where you are told how to do that. I say it is a subjective judgment, just like the quantum state is. Or, more precisely, it is exactly *that* subjectivity that keeps our view of the quantum state as being subjective from being an inconsistent notion. In any given experiment, if there is a single POVM (and state-change rule) that is correct and objective, then so must be the quantum state.

Do you just not see the mapping problem here? If a POVM (and state-change rule) is an objective property of the interaction of two systems, then so will be the post-measurement quantum state ascribed to one of those systems. Now, if the quantum state is an objective state of affairs, why quibble about calling it "knowledge" or "information"? That would be just using two words for it that never needed to be invoked in the first place. If the quantum state is objective, then call it "quantum state" and be done with it.

If you can stomach it, try to read my note "Practical Art" again. It was meant to be a call to do some soul-searching. It was meant to try to persuade you that the subjective element can never be eliminated in a theory that makes fundamental use of probabilities. It was not meant to convey the idea that one cannot draw a line between systems and apparatuses. It was not meant to be a call to join the ranks of the Everettista.

Chris (on a rainy day—it always happens on a rainy day)

20-09-01 *Comment on Practical Art* (to C. M. Caves)

You still don't recognize that the difficulty is a logical one, do you? There is nothing squishy, postmodern, deconstructionist, or new age about the issue: if POVMs (von Neumann ones in particular) are nonsubjective, then so are quantum states. Period. You can't get around that. If you want to claim that quantum states are subjective judgments, then you have to accept that POVMs (and their associated state-change rules) are subjective judgments too. Else the post-measurement states that they give rise to would be objective.

I say this slightly better in my reply to Mermin. It is not that I am leaving the realm of science: it is the strict practice of the art that put me here. Assumptions $\longrightarrow$ conclusions.

Don't worry though: I'm not offended by your note. I'm just (continuingly) surprised by your immense rigidity.

25-09-01 *Further Comment on Practical Art* (to C. M. Caves)

Cavesism 21: *I was initially mightily annoyed by the tone and content of your message. My comment said nothing about and intended nothing about being "squishy, postmodern, deconstructionist, or new age." Moreover, your reply didn't address any of the points I raised, apparently because they were all just further examples of "rigidity."*

Let me reply to your last point first. Here's what happened: I thought I'd reply with a short and to-the-point comment first (about what I saw as the overriding issue), and then follow that up with a detailed reply to your particular points. But then time ran out before having to leave for a weekend trip to the beach. I certainly did not mean to ignore your points, and I certainly won't (as time permits this week). It was just that I was banned from email for the weekend: I'm sorry I didn't warn you of that.

Now, as far as the postmodern business, I apologize for being oversensitive on that point. It had to do with this remark:

Cavesism 22: *It suggests to me that agonizing over the sorts of questions in your hag-beauty-insurance story is not going to help us understand what we're doing as scientists and, moreover, that it will lead our program into a place where no other scientists wants to go.*

This is (what I recall to be) the third time you have made such an allusion, i.e., that I am going places where no scientist ought to want to go. The only conclusion I could draw from this was that you were implying that the subject of this whole discussion is nonscientific. I hope you will at least understand that I might find that insulting. And my reply was an attempt to put a quick end to that train of thought. Over and over, I feel that I have been trying to make a simple point, and most importantly, a logical point—it just happened to be an unpalatable point. So, in the end I guess it seemed to boil down to both of us accusing the other of being unscientific.

I will write a (calm) set of emails replying to all the new issues you and Rüdiger have brought up in the next day or two.

26-09-01 *Form 1* (to R. Pike)

Below is what I wrote up this afternoon. You'll probably find it too long, but you can tell me what you'd like to see trimmed out.

My First Year at Bell Labs

> If I had to pinpoint the thing I discovered liking most at Bell Labs, it would be the incredible freedom it afforded me to pursue pure research, unchained from the bureaucratic duties of my previous institutions. This year has been a good one for science. My focus (as promised last year) has been in mapping out the very foundations of quantum information. The idea is a simple one: Where the foundations are strongest, the tallest,

most sweeping structures will be built. The best example of this in my own work came from trying to make sense of the concept of an "unknown quantum state" from the point of view of Bayesian probability theory. The solution to the conundrum required the proof of a representation theorem for the most general form a density operator can take for sequences of quantum systems with permutation symmetry. As abstract as this problem sounds, the same representation theorem allowed Steven van Enk and I to give a (surprisingly) never-explored analysis of the quantum state of a propagating laser field. This analysis assured the validity of all recent and future quantum-information experiments to do with laser light, from Caltech's quantum teleportation experiments to Richart Slusher's squeezed-light experiments here at Bell Labs—both of which had come under recent attack in the literature.

Along the same foundational lines, I deem my deepest physical insight of the year to be in a reexpression of the content of quantum entanglement, long considered the main ingredient of all quantum information processing. Carried along by the same current of thought that led to the representation theorem above, I was able to show that quantum entanglement is a secondary effect within quantum mechanics: Entanglement, it turns out, is subordinate to the structure of quantum mechanical measurements. This lays open a whole new point of view on quantum information processing: Its power may actually come from the invasiveness of quantum measurements, not from the smooth flow of unitary evolution. Indeed, a concrete expression of this can be found in the new quantum computational model of Raussendorf and Briegel that makes use solely of quantum measurement as its computational primitive. This is now a field of research that is wide open for rapid progress.

In all, I submitted six papers for publication in professional journals, and one very large paper as an invited contribution to a NATO Advanced Research Workshop. In step with this activity, and in perceiving one of my main roles in the physics community as an enthusiastic promoter of the view that the power of quantum information arises from something deep in the quantum measurement process, I also posted a 504 page (edited) collection of correspondence on this subject on the Los Alamos archive. I believe—and joking only slightly—this work has received more attention than all of my more technical publications combined. Also in the same role, I accepted 10 invitations to present my work at international meetings and colloquia around the world, including Hungary, Northern Ireland, Japan, Poland, and Sweden. I turned down three other ones because of time constraints. Furthermore, I co-organized two meetings of my own, and am in the process of co-organizing two major meetings for next year: "Workshop on Quantum Foundations in the Light of Quantum Information" to be held in Montréal, and "DIMACS-CCR Tutorial and Workshop on Capacities and Coding for Quantum Channels" to be held in Princeton. As far as media relations are concerned, I garnered a little attention for Bell Labs in two small appearances: (1) in an episode of *History's Mysteries* on the History Channel, and (2) the September 2001 issue of *Discover Magazine*. Finally, in the capacity of general service to the physics community, I served as an Associate Editor for the new journal *Quantum Information and Computation* and accepted a position on the Advisory Board of the International Center for Mathematical Modeling, Växjö University, Sweden.

As concerns internal service for Bell Labs, here are some items I recall. (1) I gave a presentation to Arun Netravali and Bill Brinkman in a private session on "The Future of Quantum Information Processing." With Brinkman mentioning quantum cryptography and computing as long-term research areas for Bell Labs in his July 31 address, I like to think the presentation was somewhat effective. (2) I played an active part in the recruitment of Alexander Holevo to our group. (Holevo is to quantum channel capacities, what Peter Shor is to quantum computing.) (3) I gave six tutorial lectures to the Mathematical Sciences Research Center on quantum information theory. (4) I mentored an undergraduate student for the SRP program. (5) I presented a talk in Arnold Auditorium for the Lucent Global Science Scholars Program. And (6) I have spent a lot of time in general trying to get people throughout the company practicing research in quantum information. Indicative examples can be found in the recent work of Lorenz Huelsbergen, Gerhard Kramer, and Serap Savari, but also in my role in co-organizing the Wednesday quantum talks.

26-09-01 *How Close Is He?* (to G. Brassard)

Not as close as I want him to be, but there are a couple of good theorems in the paper. Charlie Bennett once asked me, "How will you know when you've got a clean, crisp, PHYSICAL statement of the content of quantum theory? Is it like pornography: you'll know it when you see it?" I replied, "Yeah, actually." Hardy's porn is good for a starter, but it's not as hot as I want it to be.

01-10-01 *Difficulties* (to A. Furusawa)

I wonder if you might consider allowing me to lay a huge burden upon you?

I am an invited speaker at the 4th Annual Japanese-American Frontiers of Science Symposium, sponsored by the Japan Society for the Promotion of Science and the U. S. National Academy of Sciences, Wednesday, October 10 through Friday, October 12 in Tokyo at the Tokyo International Exchange Center. I think it is a fairly prestigious talk. However, because of the recent terrorist threats to Americans, and because our "state department" issued an announcement Friday warning particularly of potential trouble in Korea and Japan, I have decided that I will not come to it. My wife and I will be having a new baby in December and this would have been my fifth trip overseas this year: In all, it seemed like a good time to curtail my travels, before my "number" came up. Tomorrow I will announce this to the conference organizers.

But, all that said, I am plagued by a great sense of guilt in turning down my invitation on such short notice: This is why I am writing you. Would you consider giving a talk in my place? The format of the conference is to have two talks in each of eight subjects: one speaker in each subject is Japanese, one speaker is American. In my session, the Japanese organizer is Hiroshi Imai (from your university), and the other speaker is Tetsuro Nishino. My plan had been to give an introductory talk on quantum cryptography and quantum teleportation. Because the audience is mixed, from all areas of science, the talk should be a very introductory one.

I fully realize that you are not an American; however, your quantum teleportation experiment was performed in America, and I am hoping to use that as a bargaining chip. I think it would be a good talk for you to give, to get you and quantum information recognized by a wider audience.

If you are willing to do this, then I will send your name to the organizers tomorrow and write a strong letter of recommendation. Thanks for any help you can give.

03-10-01 *Kid Sheleen* (to N. D. Mermin)

What a busy couple of weeks it's been for me! I am sorry it has taken me so long to reply to you. But cars needed buying, lots of newspapers needed reading, lots of soul-searching needed doing (before canceling what would have been my fifth trip abroad this year), and Bell Labs needed some tolerance (with the transition from Brinkman to Jaffe as our Research VP).

Merminition 65 : *Sorry. Didn't mean to go on for so long. Caves is right; this is a rotten way to have a conversation. No need to reply.*

Yeah, Caves is right in many ways. I've never had more frustration in an email run before. But then, I don't think I've ever made such a headlong transition in open view before either. Regardless, however, I have certainly benefited from this: I've never had to strive so hard to make a simple point clear, and I think that gave me a load more perspective on the issue than I would have come to by myself. Strangely, in a way, the whole affair has hardened me and made me confident in this new direction of thought.

Merminition 66 : *so I'm sympathetic to what you're saying, but I worry that you're giving up "objectivity" on too many fronts.*

You think you worry! That reminds me of a dialogue in the old movie *Cat Ballou* (with Jane Fonda and Lee Marvin):

> Jackson Two-Bears: Kid, Kid, what a time to fall off the wagon. Look at your eyes.
> Kid Sheleen: What's wrong with my eyes?
> Jackson Two-Bears: Well they're red, bloodshot.
> Kid Sheleen: You ought to see 'em from my side.

But I don't think I've given up objectivity on too many fronts: If there's one thing for sure, it's that I don't want to go too far. The tenet I hold fast to is that there is something happening in the world, something was happening before scientists appeared on the scene, and something will continue to happen (in one form or another) should we wipe ourselves off the planet next year.

The issue is, how does that something interface with us, to what extent can we grasp it, and how do we modify it by our very attempt to grasp it?

Let me try to reply to some of the points in your letter.

Merminition 67 : *On the other hand you did seem to be undermining the impact of the trails of evidence when you gave a central role to the question of whether your Lucent colleague really had the polaroid oriented the way you had been led to believe it was oriented.*

Hideo Mabuchi is a young professor at Caltech (probably the youngest); he won a MacArthur Fellow (i.e., $500K) last year too. He started grad school at Caltech at about the same time that I started up with Caves. You can see he's the smart one. We've been friends ever since we first met at the Torino meeting of 1994. He keeps the napkin where I first explained the Holevo bound to him; I mention him whenever I can (like in the NATO paper) because of all the pearls of wisdom he gave me.

Merminition 68 : *I'll grant you that that's something to worry about, but it seems to me on a different level from the characteristic quantum ambiguities,*

Three months ago, I would have thought it was on a different level too. But now it is clear to me that the two NECESSARILY feed in to each other. (Though the whole issue has been building in me for two years: See Samizdat, page 127, in a note to Caves titled "The Dangers of Probabilismo." I'll talk about that more in a minute.)

Merminition 69 : *unless you want to deal with your colleague and his polaroid on the same footing as the photons, whence my joke about your closet Everretism. (Please read on before concluding that I still haven't got the point.)*

I did read on—many times—and I think you've got some of the point, but not the whole thing. In particular, I still contend that Everettism is the antithesis to my point of view.

There is a sense in which Hideo and his polaroid are on the same footing as the photons (and I have always thought this). It is that in reasoning about them—i.e., in reasoning about what kinds of traces they will leave from my interactions with them—I am obliged to use the formal structure of quantum mechanics if I want to do the best job I can in that reasoning. But I don't think your remark in particular has anything to do with this.

Your remark seems to be more of the flavor: Chris says POVMs (even simple von Neumann measurements) are "subjective judgments," so he must mean that their outcomes are every bit as dreamlike and subjective too. Measurements that have no concrete outcomes? What else could this be but Everettism in disguise?

But there is a non sequitur there (if indeed that is the flavor of your reasoning). It is that you (or my caricature of you) think I am identifying—in a supremely steadfast way—the "click" that makes its way to our senses when we perform a measurement and the very being of a POVM.

Instead, the idea is that the "click" is REAL, as real as you could want anything to be (for those concerned, for those who know of it). But, the index b (from some POVM $\{E_b\}$ that we associate with it) is not the thing-in-itself. It just gives the "click" a NAME and a *context* through which we can draw inferences and through which we can start to contemplate further reasoning. It is that identification which is an ultimately subjective element; it is not the "click" itself.

I had hoped to draw your attention to this distinction with the Penrose beauty-hag example, but I see I completely failed on that count (not only with you, but also with Caves and Schack). There is the stuff of the world—the "click" (in part). And then there is our description of it. The two things are not the same things; one lives in my head, and one lives partially outside it. To accept quantum mechanics, is to accept a template for that description and to accept a method of manipulating one's judgments thereafter.

Does any of this make sense? I think it is the main point I have been wanting to make to you, but as far as I can tell, you've ignored it.

Merminition 70 : *I agree that figuring out what measurements are associated with what operators (even at the von Neumann level) is something you have to bring in from the outside. So is knowing what the Hamiltonian is. I'm not so sure these are the same kinds of subjective judgments as a state assignment, as you maintain next. . . .*

The new thing I've been saying since August is that the identification of a particular POVM (and one element therein) with a measurement "click" is a subjective judgment. I had not clearly appreciated that before. However your mention of the Hamiltonian is apropos, because that one, at least, I had caught before. (That is what Samizdat, p. 127 is about.) There are several ways to see that "the Hamiltonian" must be on the same subjective footing as the quantum state. Here's one; I'll just quote you:

Merminition 71 : *I worry that "objective" is taking on too many different meanings here. For example, EPR makes it clear (at least to sensible people) that the polarization state of a photon is not an objective property of that photon.*

Will you accept that the existence of quantum teleportation carries as much force as the EPR argument that the quantum state is not an objective property of a photon? If you will, then can you tell me what the import of all the recent papers on "teleporting a unitary operator" is? (See for example `quant-ph/0005061`, but there are a plethora more.) But even if you don't, the argument is simple: Hamiltonians can be toggled from afar by our measurements on entangled states. (Carl gets himself out of this by saying that the only thing being toggled is the "effective" Hamiltonian, not the underlying quantum circuit, but I say where there is a tear in the fabric there is a rip.)

Merminition 72 : *I think you're saying that if the vertical alignment of the polaroid is an objective fact, then the state — "vertically polarized" — of the emerging photon is also an objective fact. But that's not the same as saying it's an objective property of that photon.*

That is right, there is a difference. And you have gathered what I was saying (almost) correctly. (I wrote "almost" to help remind you of the points above about identifying "clicks" with POVM elements.) The point is, the quantum state had better not be an objective fact, or the point of view that Caves and Schack and I have been trying to build up will be in deep trouble. What is wrong with taking a quantum state to be an objective fact, as long as one drops the insistence that that fact be localized with the photon? (I.e., as long as one does not make it a property of the photon where it stands.) At first sight, maybe nothing: I think that is probably the point of view you are trying to build; it is also the point of view Philippe Grangier has been trying to build in his recent `quant-ph`'s. But, on second sight, one cannot forget that the quantum state uniquely specifies a set of probabilities. If the quantum state is an objective fact, then so are those probabilities. And now it is on your shoulders to tell me what objective probability can possibly be. I won't stand for anything short of an operational definition.

Merminition 73 : *I worry that "objective" is taking on too many different meanings here. For example, EPR makes it clear (at least to sensible people) that the polarization state of a photon is not an objective property of that photon. It appears from the above that you believe you can only consistently take this position if you deny objective status to the outcome of the actual polarization measurement which enables you to predict the outcome of the measurement that has not yet been made.*

No. See the point above, where I used a little TeX notation. I accede to the objective status of something happening in a measurement intervention. I just don't accede to an objective status for what we decide to call it, i.e., for which POVM we decide to associate it with.

Merminition 74 : *(Forgive me, but this smells like a many-worlds strategy again. Your answer to the EPR paradox would seem to be to deny that the first measurement had an objective outcome. Recall Henry Stapp who has been saying for decades that only for the Everretista is nonlocality not a consequence of EPR.)*

I forgive you. But I hope you'll tell me that, with your newfound enlightenment, it doesn't smell so much like Everett anymore. (Your imagery conjures up my own imagery of walking on a warm day near a trash can full of lobster parts behind some coastal New England restaurant.)

Merminition 75 : *I'd prefer a middle ground which allows me to talk about objective facts but not objective properties. (It just now strikes me that one might call this correlations without correlata.) I've never been sure I can do this coherently, so I'm sympathetic to what you're saying, but I worry that you're giving up "objectivity" on too many fronts.*

I am in partial agreement with your first sentence, and I would like to think I have hit a sweet spot for that part. I'll give you objective "clicks" (though I might not call them "facts" ... but that's a story I probably shouldn't get into right now); I just stand fast against the objectivity of the quantum state. What is more middle ground than that? However, I do not share your aversion for objective properties.

It seems to me, quantum systems do have some properties that we can get our hands on. I usually preach the bundle of information-disturbance curves associated with a system, but let me try from a different angle to convince you of at least one property. I say that the quantum state cannot be an objective property because we can toggle it from a distance. I say that the Hamiltonian cannot be an objective property because we can toggle it from a distance. But what about a quantum system's Hilbert-space dimension d? Can you think of a way to toggle that number from a distance? I can't. And so, to that extent, I'm willing to call the raw number d an objective property of a part of the world. Now, what is the physical meaning of d? Well, that's why I struggle with all this information-disturbance stuff, but that's not the issue at hand. The issue is that one need not give up on all objective properties.

There are things in the world beyond our control: One them is the outcome of a quantum measurement, and one of them may be the dimensionality of a Hilbert space. Objectivity means nothing to me if it doesn't mean that some things are beyond my control, are beyond my whim and fancy. To the extent that I'm willing to say this, I don't think I'm giving up on objectivity on too many fronts.

Does this strike any chords in you?

PS. By now you should have received our modified version of "Making Good Sense." I won some good battles there: We no longer claim that two observers must be compelled to the same unique state via a Dutch-book argument. But I lost some too. I continue to think the paper is misleading as hell, always talking about a "unique" state assignment and using the word "certainty" in a way that still troubles me. We were able to compromise only in that I thought things were now worded in a sufficiently vague way that I could worm out of them in my future talks and publications. I don't think we say anything factually against my beliefs, but the reader will have to be on his toes to not get fooled about where I really stand.

PPS. Here's another thing I ought to tell you. PRA made the mistake of asking me to referee the BFM paper. Despite what I wrote you earlier about probably accepting the challenge if it came up, I decided to decline the opportunity. I like the math of the paper, but I just could not agree with what you make of it. It seemed more appropriate to let some less tainted souls than mine tell you what they think of it.

03-10-01 *Replies on Practical Art* (to C. M. Caves & R. Schack)

Cavesism 23: *The philosophers tend to proceed by telling a story—reasoning by analogy, they call it. The actual problem is too hard for them to formulate, so they immediately introduce a simple analogy, reach a conclusion they like within the analogy, and then transfer the conclusion back to the actual problem, without ever justifying why the analogy has anything to do with the actual problem.*

Except for omitting the final justification—which is more than important—is this so different from what you teach in your physics classes? I.e., That one ought to try one's ideas out on a simple example first? One that may already contain the essence of the problem, before embellishing it with too many details?

Cavesism 24 : *I enjoy reading your stories, but perhaps you're falling into the same sort of trap in a less obvious way. The difficult and very personalistic questions about assigning probabilities in your hag-beauty-insurance story are important in thinking about Bayesian probabilities. These personalistic factors are well known to be present in a subjective interpretation of probabilities, but do we really have to worry so much about them in the context of interpreting quantum probabilities?*

My point was to remind you guys and Mermin that these personalistic factors always must exist, else we would have no need to take such pains to talk about a "subjective interpretation of probabilities." If they are well known (as you say), then they should not be forgotten and replaced with purely objective "trails of evidence."

The point is, yes we must worry about them in the context of interpreting quantum probabilities. We must recognize that that is part of the very problem. Once we have recognized it, then we can move on and almost forget that the issue was ever there—just as one can do in whole textbooks on orthodox probability theory—but that first step is a supremely important step.

Cavesism 25 : *You and others write papers every day where this party assigns this state and that party assigns that state, and I don't see any of these papers agonizing over difficult, personalistic questions of what state to assign. You're right to keep badgering us to pinpoint why this is true, but the fact that it is true—we don't worry about this kind of stuff when making quantum state assignments—leads me to believe that there is an answer.*

Nor do you see any sophomore-level textbooks on probability theory agonize over these personalistic questions when posing its exercises at the end of each chapter. On the one hand, you completely missed the point I was trying to make, but on the other you also completely answered it.

The point is one does not have to worry about these personalistic questions to get quantum mechanics as a *calculational* tool off the ground. In that regard, the present issue is no different than with classical probability theory. Indeed, this is probably why in both theories a large sect of the practitioners have turned to "objective" interpretations of their main terms (alternatively, probabilities and quantum states) in such a misguided way. It is in the very recognition that personalistic questions exist, that one is compelled to finally get the foundations of the two theories straight.

In practice, what almost always happens? In the case of classical probabilities, when given a specific problem, one reduces and reduces the problem until one has transformed it into an equivalent problem for which one feels confident in making the uniform probability assignment. Thereafter one *derives* the probabilities for the problem of real interest by transforming and grouping, etc., until one rearrives back at the starting point. (This is a point I probably first learned from Rüdiger.) Think for instance, if I were to ask you what is the probability of obtaining a 7 or an 11 in a roll of two dice. Your mind would probably first jump to the judgment that all six sides of each die are equally likely, and then let the calculations flow.

Now of course, being a Bayesian, you would leave open the possibility for something else than a uniform assignment in that step above. But in practice, there are some things that most of us can usually agree upon . . . and those are usually the starting points for textbook problems.

The issue is little different in quantum mechanics. When presented with a problem of calculating a quantum state for a given physical system, what do we usually do but reduce and reduce (or expand and expand) the problem until we come across an equivalent one for which we are confident we can predict the outcome of some measurement with certainty? Thereafter we work our way back just as before. Just think of Scully and Lamb's derivation of "the" quantum state of a laser.

Alternatively, think about Mølmer's justification of the same state. [Indeed one might say that this is what the whole (worthless) decoherence program amounts to: deriving one subjective state from another and then thinking there is something deep about it. But that's an aside.]

Now just as before, being a Bayesian, one ought to leave open the possibility for something else than the particular pure state in the basic step of this derivation. But in practice, there are some things that most of us can usually agree upon ... and these are usually the starting points for textbook problems.

I think the similarity is overpowering. It is enough in both cases to recognize that ultimate personalistic issues exist, but then the homework assignment goes on—the student reduces the problem to a judgment few people would dissent on.

Cavesism 26 : *It suggests to me that agonizing over the sorts of questions in your hag-beauty-insurance story is not going to help us understand what we're doing as scientists and, moreover, that it will lead our program into a place where no other scientists wants to go.*

Looking back over this note again, your language really was very scolding throughout—"trap," "badgering," "agonizing," "a place where no other scientists wants to go"—in spite of the fact that you warned me it would be "a constructive and gentle criticism." I understand that I am guilty of no less: There is no doubt that I can be arrogant and abrupt (and paranoid) at times. But in all this massive email, I feel that I have been providing a service, sharing ideas that I might not have if I didn't feel we should be brothers in arms. It became a little hard to gulp that all these notes might be viewed as little more than a nuisance.

Cavesism 27 : *The answer might be as simple as this: we can only do science in situations where we scientists have agreed that such personalistic factors can be essentially eliminated, and quantum mechanics is the very pinnacle of this kind of situation. I think that's the content of our statement that "Gleason's theorem is the greatest triumph of Bayesian reasoning" and of our "principle of quantum indeterminism."*

I think the answer might just be as simple as that, but at a level higher than the one you are contemplating. The agreement we need is in accepting quantum mechanics as a method and a restriction for shuffling about our more mundane, everyday beliefs. What that entails is accepting POVMs as the structure of the questions we can ask a system and the Kraus state-change rule as our method for updating our beliefs.

Everyone keeps asking, what is the objective piece of quantum mechanics? I answered some of my beliefs on that issue in the letter I just sent off to Mermin (and then forwarded to you). But I think there is also quite a bit to be learned on the issue by first turning the question toward Bayesian probability theory. What is the objective piece of Bayesian probability theory? I think all three of us are in agreement that it is not in the particular probability assignments that one might make. But is there *any* objective piece at all? I think there is. Take Bayes' rule as an example. I would say that it is something objective in the theory: it is the ideal of behavior. If one doesn't use it, one can be taken advantage of. You agree that Bayes' rule is the ideal of behavior, and I agree that Bayes' rule is the ideal of behavior: it would remain the ideal of behavior if all of us were wiped off the planet.

Likewise, it seems to me, Gleason's theorem plays a similar role. There must be a sense in which accepting that the structure of our questions to the world (or, alternatively, our interventions upon it) conforms to the structure of the POVMs must be the ideal of behavior—something not so far removed from Bayes' rule itself. It is the ideal of behavior in the light of some crisp, physical fact.

I don't know what that fact is yet (in any precise sense), but that does not stop me from seeing the outline of how the various structures in quantum theory should be classified:

measurements = POVMs	objective feature (physical fact)
Born RULE (via Gleason)	objective feature (an ideal of behavior)
Kraus state-change RULE	objective feature (an ideal of behavior)
quantum state	subjective judgment (always)
time-evolution map	subjective judgment (always)
Hilbert-space dimension	objective feature (physical fact)
particular POVM assignment	subjective judgment (always)
particular Krausian assignment	subjective judgment (always)

The list is not exhaustive; but I think these are the ones I see clearly at the moment.

The point is: Agreement required for science? Yes. Compelling interpersonal agreement as a (potential) statement about the agent-independent world? Yes. Agreement necessary at the level of quantum states? No.

Cavesism 28: *I'm not sending this to Rüdiger and Mermin, but you can send it to them if you think it's worthwhile to do so.*

Well, clearly I thought it was worthwhile to share my answers ... but there's that arrogance again. ;-)

With a smile and a conciliatory tone,

03-10-01 *Further Replies on Practical Art* (to C. M. Caves & R. Schack)

Cavesism 29: *I think we agree that there are things that are effectively facts in the effective reality of ordinary experience.*

In the words of Bennett's father (in such a context), "These are very deep waters." Since becoming enamored with James, Dewey, and Schiller—and having read copious (by my standards) amounts of them—I'm not completely sure how I should answer you. The issue is, I'm not completely sure in which sense you are using the word "fact." I have a feeling it is a more loaded sense than you would guess. But I don't want to get into that now: You suggested some simmer time, so I will leave you some until it becomes absolutely necessary.

There is, however, one thing I dislike about this sentence, and that is the phrase "the effective reality of ordinary experience." But you touched upon that very point in your note "More on Pots and Kettles"; so I'll say more to the issue in detail when I reply to that note. The main thing, though, is that I would say our ordinary experience is the rawest stuff around: It's the very stuff from which we build these super-smooth pictures by way of which we derive our further expectations. There is nothing effective about it: It is the stuff, it is the starting point. To use the word "effective" makes it feel secondary and derived (which is what you have been striving to get at, not me).

Cavesism 30 : *The questions arise in what those facts tell us or, perhaps, in whether and what they compel us to believe. The argument is about pure-state assignments, not about mixed-state assignments. You believe that the subjectivity of pure states requires that it be possible for different agents to assign different pure states.*

Yes.

Cavesism 31 : *To say something is subjective is to say that it exists only because of us and does not have an independent existence out there in the world. It also implies that different agents can disagree, the degree of possible disagreement being just the flip side of the degree of intersubjective agreement.*

Yes.

Cavesism 32 : *Suppose we had the idea that facts in the effective reality force one to a particular pure-state assignment. The resulting pure state is then based on a trail of evidence in the effective reality and is embedded in each agent's mind. Is the pure state then out there in the world, independent of us?*

I would say, yes it is. The agent's state of belief is then an unneeded complication in everything under discussion. The fact is that there is a one-to-one correspondence between (sets of) facts and quantum states. You can say the agent's mind is nevertheless needed to "house" that state, but then, to me that looks to be nothing deeper than invoking the luminiferous ether to support the electromagnetic field.

Cavesism 33 : *Do I have it right that this is the issue, or at least an issue?*

Yes. I have always perceived this to be the main issue. To the extent that I have said words all around this, it has been—I believe—to attempt to give different angles for viewing the same thing. Every time I saw you, Rüdiger, Mermin, Brun, etc., be reluctant to accept the point, I tried to present it from a different angle so as to be more convincing. I take it now that everyone only found that to be confusing. But what else could I do? And I can't complain too much, because I think the whole process has sharpened my presentation of the point (which I maybe only dimly perceived at the beginning).

Cavesism 34 : *I don't necessarily see where the pure state is if it's thought to be out there in the world. The trail of evidence is not a pure state; we construct the pure state from the trail of evidence, but dogs don't and dinosaurs didn't.*

A one-to-one mapping is a one-to-one mapping. I do not see how YOU cannot see that making these statements is not a tacit acceptance that the quantum state is an objective entity after all. Maybe you have thought this all along. Namely, that when you said a quantum state is not a state of nature, what you really meant was that it was simply not localized on the physical system it is meant to describe. It is a state of nature, i.e., it is a collection of facts within nature, it is just not living on the system it's intended for. From this point of view, it's clear why dogs don't use them: Dogs aren't clever enough or advanced enough technologically to discover the true states of nature.

But I surely never thought this when I used the slogan, "a quantum state is a state of knowledge, not a state of nature." If facts can uniquely determine a quantum state, and facts live in nature, then a quantum state is a state of nature after all.

Cavesism 35 : *The pure state is not out there in the system for the reasons we have long discussed: the system can't report its pure state, and a system's state can be changed to any pure state drawn from incompatible sets without ever getting close to the system. It looks to me like the pure state is purely in our minds.*

I'm not sure how this remark fits in. You might be making a call for me to consider putting the "trails of evidence" into the mind, but I'm not sure.

Cavesism 36 : *You are insisting, I believe, that in order for a pure state to be subjective, it must be possible for different agents to disagree on a pure-state assignment. You say, I believe, that if we are forced to a particular pure-state assignment by the facts in the effective reality, then the pure state becomes objective.*

Yes.

Cavesism 37 : *I don't know where to come down on this. It is one aspect of the question I always ask of which aspects of maximal belief get translated from realism to quantum mechanics. It also has to do with the nature of the "facts" in the effective reality and thus how the effective reality arises out of quantum mechanics (this is the content of Mermin's Pots and Kettles). My own take at present is that the effective reality is a form of intersubjective agreement.*

Fair enough that you don't know where to come down on this: I will try not to lose my patience any more.

Cavesism 38 : *You are right in principle that nothing compels us to a particular pure-state assignment, but clearly wrong in practice. All our experience with quantum mechanics suggests that we have no trouble agreeing about pure-state assignments, so no matter how the facts in the effective reality arise, there is nearly total intersubjective agreement on what they imply for pure-state assignments (this is the content of my Comment on Practical Art and further comments on Pots and Kettles).*

I hope my previous note addressed this adequately. In contrast to what you say, I believe that I am right in principle and right in practice. You might have said the "all our experience" sentence about classical probability theory if your name were Richard von Mises. He would have said that all our experience with dice shows that we have no trouble agreeing that its outcomes are all equally probable. But you're not von Mises, and you've had the advantage of having had 75 years of good Bayesians clear the air for you. The issue you bring up has little to do with the structure of the physical world, and little to do with the structure of the Hamiltonians we feel compelled to describe it with.

Cavesism 39 : *Let me know if I have got your position straight.*

I think you did.

Cavesism 40 : *If I have, then it seems to me that we are not far apart, the only gap being how much we are willing to ascribe to the apparent agreement that exists in assigning pure states. You prefer to emphasize that nobody can be coerced into this agreement, and I prefer to emphasize that in practice nobody has to be coerced into it.*

A point of emphasis can make a huge difference in a philosophy. And a difference in a philosophy can make a huge difference in the practical and applied questions one might ask of quantum mechanics.

And I'm off to Lupé's for the best Mexican food in New Jersey. (You know that's not saying much.)

More tomorrow!

03-10-01 *Next Week* (to J. N. Butterfield)

Thank you for reminding me that you'll be in town soon! It was a hard decision, but I decided not to go to Japan after all. (It would have been my fifth trip overseas this year, in any case, which is maybe too much.)

I would love to meet with you. Probably the most fun thing for me would be to meet you in the city somewhere, if you're game to that. I could spend the morning book shopping, meet you for lunch and afternoon discussions somewhere in the Village or East Village, and then return to book shopping. How does that sound? Monday would probably be best for me; but Wednesday (second most favorite) and Tuesday (least preferred) would be doable too.

I would especially like to hear more about the deeper desires that underlie the program you outlined in your talk in Belfast.

I'll put all my phone numbers (work and home) below. Let me hear from you before your departure and we can start to work on a more precise plan.

04-10-01 *Champagne and Roses* (to J. N. Butterfield)

Butterfieldism 1: *Thanks for yours. Im very Glad theres a chance well meet; but I don't want you to come to NY unlesss (i.e. and only unless! A Halmos-ism) youd like to come for book-shopping etc anyway.*

Please realize, you are the imperfection on the smooth surface of my champagne flute. You are the catalyst in my converter. No, I wouldn't normally go to NY City on a Wednesday, no matter the strength of my constant obsession to hoard books. But all it ever takes to seed the bubble is the promise of a good conversation! Let's meet in NY City.

I know of a good Afghani restaurant ("Khyber Pass") in the East Village. Would you like to meet there if it's still open?

04-10-01 *Finicky Sins* (to C. M. Caves)

By the way, in saying this yesterday,

> There is, however, one thing I dislike about this sentence, and that is the phrase "the effective reality of ordinary experience." But you touched upon that very point in your note "More on Pots and Kettles"; so I'll say more to the issue in detail when I reply to that note. The main thing, though, is that I would say our ordinary experience is the rawest stuff around: It's the very stuff from which we build these super-smooth pictures by way of which we derive our further expectations. There is nothing effective about it: It is the stuff, it is the starting point. To use the word "effective" makes it feel secondary and derived (which is what you have been striving to get at, not me).

it dawned on me afterward (on my drive home) that I was committing a sin: There was a time when I liked the phrase. As you know, I commandeered it when writing my *Physics Today* articles with Asher.

So, maybe I was being overharsh, or maybe just finicky. In any case, even when I used it unreservedly, I know that I had a distinct flavor of the phrase in mind from the way you had been using is. [See our discussion starting on page 133 of the Samizdat.]

Maybe I'll say more about this later today.

04-10-01 *Replies on Pots and Kettles* (to C. M. Caves & R. Schack)

This letter is going to be a hard one to reply to, because I don't quite see how much of what I have said in the past led to the points you make here. So, let me just plunge into the thing and see what comes out.

Cavesism 41: *I thought you were in the camp that holds that the our experiences—our actions or interventions and our perceptions of the world's response—are primary*

I thought I was too.

Cavesism 42: *and that the function of science is to account for them.*

It's this part of the sentence that I'm not so sure of (though it's not clear to me exactly what you have in mind). If our experiences are primary, then it does not seem to me to be within science's purview to account for them. I believe, instead, the view I have had for quantum mechanics for some time is best mimicked by these words I picked up from William James last month:

> Metaphysics has usually followed a very primitive kind of quest. You know how men have always hankered after unlawful magic, and you know what a great part in magic *words* have always played. If you have his name, or the formula of incantation that binds him, you can control the spirit, genie, afrite, or whatever the power may be. Solomon knew the names of all the spirits, and having their names, he held them subject to his will. So the universe has always appeared to the natural mind as a kind of enigma, of which the key must be sought in the shape of some illuminating or power-bringing word or name. That word names the universe's *principle*, and to possess it is after a fashion to possess the universe itself. 'God,' 'Matter,' 'Reason,' 'the Absolute,' 'Energy,' are so many solving names. You can rest when you have them. You are at the end of your metaphysical quest.
>
> But if you follow the pragmatic method, you cannot look on any such word as closing your quest. You must bring out of each word its practical cash-value, set it at work within the stream of your experience. It appears less as a solution, then, than as a program for more work, and more particularly as an indication of the ways in which existing realities may be *changed*.
>
> *Theories thus become instruments, not answers to enigmas, in which we can rest.* We don't lie back upon them, we move forward, and, on occasion, make nature over again by their aid.

Science does not account for our experiences. Science builds on them and gives us a structure by which to imagine pushing them to a new extreme. This is why I have laid such emphasis on calling the world "malleable" (for instance in my "Activating Observer" document that I shared with Rüdiger … and maybe you too, I can't remember). It seems to me, science does not say so much about what is, but what can be (subject to the limitations to our actions captured in the very structure of the given theory).

Cavesism 43: *Trouble is that when our interventions proceed to too fine a level, the world's response is not deterministic and, furthermore, cannot be described within the realistic language of ordinary experience. Surprisingly we find that we can use the strange, unrealistic formalism of quantum mechanics to describe the intrinsic indeterminism that intervenes between our actions and our perception of the world's response.*

What do you mean by "too fine a level?"

Cavesism 44: *I thought you were ascribing some sort of objective or intersubjective reality to our primary experiences.*

Pretty much. Or, at least that's what I thought too.

Cavesism 45: *I thought the difference between you and me was that I think that we must somehow derive from quantum mechanics—or, at least, make consistent with quantum mechanics—the apparently realistic features of the emergent "effective reality" of ordinary experience, whereas you think this is unimportant, thus accounting for our different reactions to the decoherence program. But you now seem to be demanding much more than I do,*

I've always thought that I've demanded much less than you, and I don't think I've changed my tune on this account for several years. For the view I dream of constructing, what is the classical world? It is a world for which the agents describing it are full of ignorance and the best to which they can muster is a lot of imprecise control.

I look out at one of the trees outside my window, and I ask how I might capture everything I'm willing to say about it into a single density operator. I can't say much about that, but I'm willing to bet that if I would carry the project through, what I would end up with will be so mixed, so thermal, that it'll be just about commuting with anything else I might have come up with, even if I had stared at the tree a little longer. This little fact—it seems to me—has nothing to do with the Hamiltonians of the world (as if they were objective things). It is a function of my pure ignorance and my unwillingness to tear the tree apart and refine my beliefs.

The idea toyed with here is that it is just ignorance, no matter how we each walk into the room with it, that leads to the classical world. If I am so ignorant as to use an almost commuting set of density operators for a given object, then any (gentle) attempt you—as another scientist—may make to refine those beliefs will not cause my beliefs to be any less valid: Your information gathering, will not cause a disturbance to my description. And therein—the speculation goes—lies the essence of classical mechanics.

Cavesism 46: *that before we even start, we be able to explain exactly how the effective reality works and at what point it emerges. As David points out, this is exactly what the Everettistas demand.*

As best I can tell, this remark can only come from viewing my program (more accurately, my dream) from your philosophical predispositions. I would never demand that we "explain exactly how the effective reality works and at what point it emerges." The classical world comes first.

Quantum mechanics (as a theory of inference) extends beyond it, by taking into account new phenomena that simply can only be seen when working in a regime of less ignorance.

A relevant ditty to read might be my essay "Always One Theory Behind" on page 464 of the Samizdat.

Cavesism 47: *Of course, after making the demand and finding present responses unsatisfactory, you and the Everettistas go in quite different directions. They, out of an anal need for naive realism, simply concoct a naive realism to go with the state vector. You certainly aren't going in that direction, but being risk averse and already burned, I'm not going to risk a description of your direction here.*

I loved the phrase "anal need."

Cavesism 48: *To your credit I think you won't claim to have gotten your ideas worked out entirely (perhaps the rest of us can be allowed some access to that defense). Still you might want to think about the road you're traveling on and how it relates to this question of taking as given the apparently objective experiences of our daily lives.*

Thanks for the credit. It's refreshing to be complemented for not acting like a guru with all the answers. People at foundations meetings will have none of that. It's been my experience that they demand you tell them exactly what reality *is* ... before they quickly tell you you're wrong. (Matthew Donald told me he couldn't take me seriously as a foundations researcher because I keep evading the question of what reality *is*.)

Anyway, in conclusion, give me some feedback: Did I answer anything that you wanted answered? (I sure hope I did: I'm trying.)

04-10-01 *Replies to Morning Coffee* (to C. M. Caves & R. Schack)

Schackcosm 35: *Oh no, I thought we had reached some agreement. One problem is that Kraus operations (unless they are 1D projectors) will not bring you to a unique place. Which means that qm does NOT provide a universal rule of coming to agreement. You need some ad hoc assignment.*

Yes, I had always understood that. I am sorry if I was sloppy about expressing it, but I thought I had always emphasized that there are two things that one can contemplate: 1) if Alice and Bob have complete freedom to choose what measurement they might perform, and 2) if instead they have at their disposal some fixed measurement (perhaps not of their choosing). In the later case, only certain initial states for Alice and Bob will lead to further agreement after the measurement. (See, for instance, my note to Mermin and company dated August 7.)

Schackcosm 36: *The other problem is that your conversation is far too playful. State assignments are compilations of betting odds. They are COMMITMENTS. Chris in your dialogue should have been deeply shaken. He would have betted his house in New Jersey on this outcome to be impossible.*

Yes, perhaps. But, on the other hand, there is a counter trend in you that troubles me. And that is the basic philosophy that comes across as the message, "Once a quack, always a quack." What I mean by this is, suppose I ascribe a pure state $|\phi\rangle$ to some system, whereas you ascribe $|\psi\rangle$. As we have laboriously teased out of this correspondence, from your perspective, I am simply wrong. My judgment is not to be trusted (from your perspective). This much we agree upon. But I sense that you want to conclude more: Not only am I not to be trusted in my conclusions about the given system, but that I am not to be trusted about anything. You conclude that I am truly insane just because I adamantly disagree with you about one thing (as captured by our differing pure states). I say that goes too far.

I tell too many stories, but here is a true story. In discussing the cardinality of the natural numbers versus the even numbers, Kiki will accede that there is a one-to-one and onto mapping between the two sets. Nevertheless she contends that there are more natural numbers than even numbers. I have never had more annoying conversations than the one we revisit about once a year on this subject. I simply cannot convince her that she is not being logical on this issue. But still I do find that I trust her judgments on other issues.

A "misstep" on a quantum state (even a pure state), it seems to me, is not the end of the world precisely because of this.

Granted, I am a bit confused on what I think the ascription of a pure state actually does capture, but I think making it carry the weight of an agent's rationality or irrationality goes too far.

Schackcosm 37: *Yet another comment: You have said nothing in all your notes (to my best knowledge...) that tells me why this situation is different from Chris being certain that there are two chairs in this room, and Carl with Hideo's help convinces him that he was wrong. I'd say either Chris was tricked, or he had hallucinations. Todd said: "This is why we say that insane people 'out of touch with reality'". I said the same thing in a different way.*

Since you ask this question more pointedly in another note, I'll wait on answering it until I get there.

Schackcosm 38:

> CAF Said: So, in saying this, I don't think one has to do anything fancy with a measurement to get this thing you call fuchsian consistency off the ground. No intricate constructions of states seem to be needed. Choose ANY (mutually agreed upon) von Neumann measurement you like, and Carl and Chris will have to agree at the end of the day. One of them will feel foolish for having been so wrong, but as long as he is rational, agreement can still be had. As Rüdiger said, the idea is that this is a property of quantum mechanics (in its capacity as a law of thought), not of the initial states.

I found the idea quite attractive that in a quantum world, differences can be resolved (using a well-chosen measurement) that would be impossible to resolve classically. I thought that this was what you had in mind.

As far as I can tell, no physical statement (no ascription of a phase space point) is impossible to resolve classically. What is different is that quantum mechanics can do that even without the preexistence of a phase-space point ... and that surely is a property of quantum theory. But I said I'd come back to this in another note.

04-10-01 *Replies to a Conglomeration* (to C. M. Caves & R. Schack)

Now let me reply to a conglomeration of notes from you two.

First to Rüdiger:

Schackcosm 39 : *I remember you writing something to the effect that the click in a measurement is the closest thing to a fact one could come up with (sorry for not looking it up, but you write TOO MUCH).*

Did the reply I wrote to Mermin yesterday make any sense to you? I am now in the habit of drawing a distinction between a "fact" and a "proposition." The difference was not so important classically, but I now think it is paramount quantum mechanically. The fact (or consequence of our intervention) is the raw, uninterpreted, unclassified stuff of the world. It is the real stuff that makes its way to our senses and then to our brain to be pondered. The proposition, on the other hand, by its very nature attaches a meaning to the fact and, as such, is a subjective judgment. What this means in the quantum case is that to say there is a "click" is one thing: Presumably that is not a subjective judgment if I say it, and Steven says it, and everyone else we talk to says it. However, to say that that means the particular outcome E_b occurred in the POVM $\{E_b\}$ is to lay down a proposition, a subjective judgment.

The reason we could get confused in the classical case, and think that a proposition was more than a subjective judgment is because in the classical case, propositions don't entail probability assignments.

This distinction I'm drawing is not so different than the one Marcus Appleby draws in criticizing the Meyer-Kent-Clifton "nullification of the Kochen-Specker theorem." See his paper, `quant-ph/0109034`.

Schackcosm 40 : *I am afraid that I still don't know precisely where you stand, despite of your effort at explaining.*

Let's start from the classical notion of certainty. Let's consider the case where a physicist is certain that some outcome will not occur. Dutch book consistency implies that the outcome will be in his nullspace. That's the quantum part.

Do you agree?

Yes.

Schackcosm 41 : *1.) Carl is certain that up will occur and Chris is certain that down will occur.*

2.) Carl is certain that there are three chairs in the room, and Chris is certain that there are two chairs in the room.

In both cases their beliefs are contradictory in the same, classical sense.

Do you agree?

No, I do not think the statements have the same meaning. In the first case, in order to find out which of us is "right" and which of us is "wrong" we must elicit the world to produce something that it didn't contain beforehand—namely, the result of the measurement. In the second case, we can go blissfully along thinking that one of us is "right" and one of us is "wrong" simply because the world has something in it that one of the two of our brains is mirroring correctly.

There is a difference. In the classical world, reality is the ultimate arbiter of truth. In the quantum world, where we are fairly convinced that "unperformed measurements have no outcomes," we are actually lucky in a way that there is still an arbiter of agreement—we just can't identify it with a preexisting reality. It seems to me this is a feature of quantum mechanics: The theory can still bring us to agreement even without a preexisting truth value for our propositions. One might have imagined a more malicious world where we would not have even been able to rely upon that.

Schackcosm 42 : *If we make claims, we are COMMITTED to those claims (e.g., via betting behavior implied by the claims). I believe that starting from the notion that different scientists (different agents in the same linguistic community) should not have contradictory beliefs is eminently reasonable. To throw this notion over board, one needs excellent reasons. I enjoy playing with the idea, but I am far from converted.*

This hits upon what I wrote to Carl yesterday. The gulf that separates us seems only to be in where we think this agreement must be applied to get the engine running. I say both of us accepting QUANTUM MECHANICS as a structure is good enough. (I.e., accepting the theory is our common agreement.)

Now to Carl:

Cavesism 49 : *Your point, as we see, is that we can think about life going on after finding a result deemed to be impossible. As you point out, there is a limit (add on the null subspace with epsilon eigenvectors, get a result in the epsilon subspace, update, and then take the epsilon goes to zero limit) in which we can think of updating a state assignment based on outcomes in the null subspace. But I think this misses the point. This isn't updating a prior belief. It's realizing that your prior belief is full of it and abandoning it in favor of life going on, as you put it.*

Moreover, the really nice distinction between classical and quantum Fuchs consistency is lost if we adopt your point of view. If we adopt your way of formulating Fuchs consistency, then it has no content either classically or quantum mechanically.

I'm just repeating myself now, I but I don't see that as contentless at all. In fact, though the effect is the same in both theories, the content is quite different across the two of them. In the classical case, we can always "pick up the pieces" as you say, by realizing that there is something really there and just checking what it is. In the quantum case, we can always bend the world into something we *will* agree upon, even if we violently disagree upon the meaning of some subset of our previous interventions.

Here's the way, Josiah Royce put it in a letter in 1888:

> Thus called upon to explain amid the trade-winds, and under the softly flapping canvas, the mysteries of [quantum mechanics], I put the thing thus: "There was once a countryman," I say, "from Cape Cod, who went to Boston to hear Mark Twain lecture, and to delight his soul with the most mirth-compelling of our humorists. But, as I have heard, when he was in Boston, he was misdirected, so that he heard not Mark Twain, but one of Joseph Cook's Monday Lectures. But he steadfastly believed that he was hearing Mark. So when he went home to Cape Cod, they asked him of Mark Twain's lecture. 'Was it *very* funny?' 'Oh, it was *funny*, yes,—it was *funny*,' replies the countryman cautiously, 'but then, you see, it wasn't so *damned* funny.' Even so, Captain," say I, "I teach at Harvard that the world and the heavens, and the stars are all *real*, but not so *damned* real, you see."

Cavesism 50 : *The parties can always come to agreement, no matter what their state assignments, simply by getting amnesia regarding their prior beliefs and then picking up the pieces in the only way they know how.*

But there's really more to the story. They can always come to agreement, indeed—regardless of how disparate their initial opinions—if they are willing to make an essentially infinite expenditure toward laboratory technique. That is to say, the only thing that will give assured agreement in all cases is a set of Kraus operators all of rank-one. Jacobs and I called those infinite strength measurements: the idea being that they are hard to actually do. In more real-world measurements, where the operators are never really rank-one, coming to final agreement will generally require some initial agreement. Whence the point in my August 7 letter to Mermin.

Cavesism 51: *I believe that Fuchs consistency is about coming to agreement in the light of the outcome of an agreed-upon measurement where no party has to abandon his prior beliefs (certainly one has to agree that this is a legitimate case to consider). It could be that all parties are dumbfounded by the result, but let's put that case aside. For all other outcomes, the point is that all the parties be able to come to agreement by updating their prior beliefs. This imposes a strong constraint classically—all parties must have the same support—but appears to be no constraint quantum mechanically. That's an important distinction, it seems to me.*

I do agree that that is a legitimate case to consider. What I am not seeing presently is that its study will shed some foundational light. But I think I'm open-minded on this one: I might be convinced yet; I just don't see it now.

06-10-01 *Your Spelling Conscience* (to J. Bub)

I was committing one of your notes to my computer archive, and I caught such an intriguing spelling variation in it that I had to write. In describing Steane's article below, you write "inciteful." Wonderful! How apropos for the context. Did you do that on purpose?

Jeff's Preply, 08-08-01

> [**Chris said:**] Maybe some of the most interesting discussions centered around Andy Steane's paper "Quantum Computation Only Needs One World" (which Richard Jozsa presented). Doug Bilodeau had the wonderful idea that perhaps some combination of it and [Wootters'] old Ph.D. thesis could give us a deeper insight into where quantum computing derives its power from: Quantum computers are not powerful because they perform so many calculations in parallel (as the many-worlds pundits imagine), but rather because they do so *few* calculations! I.e., Their power derives from not doing anything they don't have to do for the final result.

I think this is exactly right. I've been thinking along these lines myself. I just wrote an article on 'Quantum Entanglement and Information' for the *Stanford Encyclopedia of Philosophy* (an online encyclopedia at `http://plato.stanford.edu`). It's not posted yet because I have to make a few minor changes. The concluding section says:

> The favoured explanation among Deutsch and others of how a quantum system processes information is the so-called 'many worlds' interpretation. The idea, roughly, is that an entangled state of the sort that arises in the quantum computation of a function, which represents a linear superposition over all possible arguments and corresponding values of the function, should be understood as a manifestation of parallel computations in different worlds.

The quantum circuit is designed to enable the computation of a global property of the function by achieving some sort of 'interference' between these different worlds. (For an insightful critique of this idea of 'quantum parallelism' as explanatory, see Steane.)

An alternative view, not much discussed in the literature in this connection, is the quantum logical interpretation, which emphasizes the non-Booleanity of the structure of properties of quantum systems. (The properties of a classical system form a Boolean algebra, essentially the abstract characterization of a set-theoretic structure. This is reflected in the Boolean character of classical logic, and the Boolean gates in a classical computer.) A crucial difference between quantum and classical information is the possibility of computing the truth value of an exclusive disjunction – for example, the 'constant' disjunction asserting that the value of the function (for both arguments) is either 0 or 1, or the 'balanced' disjunction asserting that the value of the function (for both arguments) is either the same as the argument or different from the argument – without computing the truth values of the disjuncts. Classically, an exclusive disjunction is true if and only if one of the disjuncts is true. In effect, Deutsch's quantum circuit achieves its speed-up by exploiting the non-Booleanity of quantum properties to compute the truth value of a disjunctive property, without computing the truth values of the disjuncts (representing the association of individual arguments with corresponding function values.)

08-10-01 *Larger, Smaller* (to J. Summhammer)

Thank you for your wonderful, thoughtful, long letter! I have now read it several times, and each time I think I've gotten a little more from it. Thank you also for your concern over my family and associates in light of the September 11 attack: As far as I know, all my friends, and my friends' friends were left unscathed physically. But it is all a very frightening affair, and it is certainly weighing on everyone's life on this continent and the world.

Concerning the content of your letter, let me especially thank you for the large number of YES's you wrote into the margin of my paper! Let me make a couple of small comments on your one NO.

Summhammerism 5: *It appears to me that quantum theory is the correct way of reasoning, and classical probability theory is a certain limit of it. But both spring from the SAME way of reasoning. So far, physics has stood in the way of clarifying this. The perennial talk of systems and properties of systems one is forced to carry along when dealing with quantum theory is a real hindrance to clear thought. Remnants of mass points, forces, fields, etc. always sneak in, and with it the need to allude to an objective world out there. As if repeatably detectable structures in the statistics of probabilistic events and their efficient description weren't objective and "out there" enough (to me mathematical truths and the Himalayas are equally "out there"; the former are mastered by acts of mental climbing, the latter by acts of physical climbing, but both require willful action to be conquered. You call it free-standing reality.)*

This issue has now come up in my email a couple of times since the Sweden meeting. Here's the way I put it to Jeff Bub on the last round:

> The main thing is that it sounded like a good opportunity to pound out the similarities and distinctions between our points of view on quantum mechanics without being interrupted every three minutes.
>
> I know I suggested I would write a longer letter soon, but I'm going to wimp out of it again for now. It would concern the main point of distinction I see between us (and also between myself and Pitowsky). Namely, A) that I view a large part of quantum mechanics as merely classical probability theory (which on my view may be an a priori "law of thought") PLUS an extra assumption narrowing down the characteristics of the phenomena to which we happen to be applying it to at the moment, while B) you are more tempted to view quantum mechanics as a *generalization* of classical probability theory (and with it information theory). I know that my view is not fully consistent yet, especially as I have always distrusted mathematical Platonism—which you pointed out to me I am getting oh so close to—but it still feels more right (to me, of course). Ben Schumacher, Rüdiger Schack, and I had a long discussion on this (on a long walk) the day after the round table, and I'd like to record that too. Ben took a stance quite similar to yours, and maybe even Rüdiger did too (despite his overwhelming Bayesianism). So, I may be the lonely guy out on this. And my view may be subject to change.

To some extent, I can understand both motivations, i.e., to see quantum theory as the larger of the two structures, and alternatively to see it as the smaller of the two. My thoughts are not completely set yet about which direction is the best direction, but let me try to explain a little about what I mean by probability theory possibly being a larger structure than quantum mechanics. (As evidenced in my paper, this is certainly the direction I lean most toward presently.)

Consider some physical system, say my house. And consider some set of questions you might ask about it. For instance, what color is it? (The answers being R, O, Y, G, B, I, V.) Or, what kind of flooring does it have? (The answers being wood, tile, vinyl, or carpet.) On so on: Consider every question you might ask about it. If you were a Bayesian, you would not hesitate taking all the information you know about me and applying it to the construction of a probability function for the outcomes of each such question that could be asked. For instance, if you had gained the impression in Växjö that I am a sentimentalist, you might place a higher probability on my floors being wooden than otherwise.

However it is also part of the Bayesian creed that there is no such thing as an invalid probability assignment. If there are no logical connections between a set of questions, then there are no constraints on the probability assignments I might give for their potential answers. So, for instance, though you might put a peaked distribution on the answer to the question about my floors, you might put a flat distribution on the colors. And so forth, for every elementary question that might be asked about my house.

However, when we come to quantum mechanics something changes about this. Now, the elementary questions correspond to POVMs. But, using Gleason's theorem, we are no longer free to assign probabilities to their outcomes willy-nilly. All but a very few probabilities assignments are tied together via the existence of a density operator. For instance, viewing quantum probabilities as Bayesian probabilities, one is completely free to assign any probabilities one deems relevant to the outcomes of a σ_x, σ_y, and σ_z measurement. However, once that is done, one is no longer free to specify an arbitrary assignment for spin in the n direction, for any other n.

From this point of view then, quantum mechanics allows only a subset of the vastly larger set of probability assignments one might make to the answers of the physical questions one might ask. And one might think that restriction is accounted for by some physical fact—the yet-to-be-discovered fact that is the essence of quantum mechanics.

Summhammerism 6: *Still, it is in this connection that I wrote a NO into your paper. On p. 28 you say "Probability theory alone is too general of a structure.", and at some other place you say there must be an input from nature. Based on my own games with these questions I doubt this. I think quantum theory is already contained in the basic notions that lead to probability theory. The sum rule of probability is no obstacle, if you ponder what "mutually exclusive" means from an operational point of view. For this reason I see a valuable contribution in Lucien Hardy's attempt of starting from a few axioms, although an axiomatic approach is unsatisfactory as long as the axioms aren't simple truths instead of formal assumptions.*

So, indeed, what I said above is what I meant as an input from nature: It is whatever binds us to Gleason's theorem. (Gleason's theorem being the string that ties all the various distributions for a physical system together.)

You'll note actually that Hardy is almost an antithesis to this idea. He starts with structures that are larger than both classical probability theory AND quantum mechanics. By adding an extra postulate he can narrow it down to either one or the other (or any of a number of other structures). What I want is start with classical probability and then narrow it down to quantum mechanics.

It could be the wrong direction, but it is the one that feels predominantly right to me (and the one that seems to me to have the highest probability of leading to some interesting physics). It is a subjective judgment of course, but that's all that each of us has.

By the way, Caves and Schack and I have been thinking about applying for a visit to the Erwin Schrödinger Institute next spring or early next summer. The plan would be to write (the bulk of) an RMP article on all this Bayesian business while we're there. It'd be great to have your ear to test it out on, if we do follow through with the plan.

Johann's Preply, "Quantum Foundations in the Light of QI"

> Now I come to your paper "Quantum Foundations in the Light of Quantum Information". I had gone through it in summer, then practical problems intervened, and now I scanned through it again. I liked it very much, although I tended to skip the formal parts, due to a dislike of density matrices. (The unspoken opinion of the experimentalist is this: If you can't produce a pure state, you are not in control of the experimental conditions. And while it is true that a pure state can never be produced accurately, it can be approached arbitrarily well.)
>
> Let me write down a few of the qualitative statements which captured my interest because I agree with them:
>
> - p.6 Information about what? ... nothing more than the consequences of our experimental interventions into nature ...
> - p.7 The whole structure of quantum mechanics — it is speculated — may be nothing more than the optimal method of reasoning and processing information (in the light of the world's sensitivity to our touch)
> - p.9 The quantum state is subjective incomplete information. (Meanwhile I understand in what sense you, Carl Caves and Rüdiger Schack use 'incomplete' in this context. A kind of respectful bow towards Einsteinian expectations from physics.)
> - p.19 Quantum states are states of knowledge, not states of nature
> - p.22 The uncertainty that decreases in quantum measurement is the uncertainty one expects for the results of any possible future measurements.

- p.26 on maximal state of knowledge. I like the clarification that 'nothing new' is learnt when already having maximal state of knowledge, but that 'mental readjustment' happens. It is in line with the everyday truth that *each* observation tells you something, in other words, that by additional observation your overall information about the world can only increase, never just remain the same. A fundamental theory must reflect this. (I had remarked on this in my letter to Carl Caves.)
- p.28 ... perhaps the better part of QM is just a law of thought
- p.28 ... $|\psi\rangle$ must be information about the potential consequences of our interventions into the world.

From the paper I also got an appreciation of POVMs, which I had always looked at as an unnecessary extension. The hint of getting more information from a two-level system if measured via a three-level ancilla was important.

I did not delve much into what you wrote about Gleason's theorem, although it is probably important for the paper. It appears that contextuality and counterfactuality are surprises only, if one is rooted in classical thought.

I also appreciated the part on why the tensor product of Hilbert spaces (p.29 ff).

The application of Bayesian theory to quantum theory. It appears to me that quantum theory is the correct way of reasoning, and classical probability theory is a certain limit of it. But both spring from the *same* way of reasoning. So far, physics has stood in the way of clarifying this. The perennial talk of systems and properties of systems one is forced to carry along when dealing with quantum theory is a real hindrance to clear thought. Remnants of mass points, forces, fields, etc., always sneak in, and with it the need to allude to an objective world out there. As if repeatably detectable structures in the statistics of probabilistic events and their efficient description weren't objective and "out there" enough. (To me mathematical truths and the Himalayas are equally "out there"; the former are mastered by acts of mental climbing, the latter by acts of physical climbing, but both require willful action to be conquered. You call it free-standing reality.)

Still, it is in this connection that I wrote a NO into your paper. On p.28 you say "Probability theory alone is too general of a structure.", and at some other place you say there must be an input from nature. Based on my own games with these questions I doubt this. I think quantum theory is already contained in the basic notions that lead to probability theory. The sum rule of probability is no obstacle, if you ponder what "mutually exclusive" means from an operational point of view. For this reason I see a valuable contribution in Lucien Hardy's attempt of starting from a few axioms, although an axiomatic approach is unsatisfactory as long as the axioms aren't simple truths instead of formal assumptions.

Quite generally, you seek an understanding of QM on the basis of two or three statements of a crisp physical nature. And these should be about information. In line with what I just said, I share this wish wholeheartedly. Having grown up collecting clicks of individual neutrons I would start with "clicks" as the only point of contact between observer and observed. ("clicks" = outcomes of trials of probabilistic experiments). On the other hand, you want to distill out certain features of the established theory, take them as nature's core message, and attempt an understanding of the whole theory from these.

Here, I hesitate a little. Quantum theory itself is already too remote from the experience from which it was distilled. We may continue marveling at our extracts from nature, and perhaps overlook that they are trivial consequences of the scientific method applied to data which we have decided to view as intrinsically probabilistic. In other words, the theory may indeed just be a law of thought, but straightforwardly so, and not in the sense that we first have to accept its results (nonlocality, interference, etc.) and from these be pointed to laws of thought which make these results self-evident.

In clear moments I wonder why we still have to discuss quantum theory, just as you did in the beginning of the paper, but from a slightly different vantage point. All we have is probabilistic events. Simple events, and coincidence events of arbitrarily high level. And all we can do is calculate random variables from them. What should be difficult about finding the random variables with the highest degree of invariance and the possible, statistically testable relations between such random variables? That will be our structure, and quantum theory will be contained in it. And nature will fit in, or the idea that probability is basic is wrong.

So much for today. The priors-question in Bayesian theory and "How Much Information in the State Vector" I must postpone to another time. Perhaps I will think of a practical question in interferometry.

P.S.: I hope that neither you, nor anybody close to you, have been affected by the recent terrorist attacks.

09-10-01 *Writing Physics* (to N. D. Mermin)

I'll place the new supplement to the Samizdat in the next email as plain text. Please let me know whether you're able to TeX it up fine; if that doesn't work out, I can post it on my web page (as a PostScript file) as I did before.

Collecting it up, it's hard to believe I've written this much in the little time since Växjö. I guess it's been an active time for me. I think there's no doubt that I've gone through a phase transition. For all my Bayesian rhetoric in the last few years, I simply had not realized the immense implications of holding fast to the view that "probabilities are subjective degrees of belief." Of course, one way to look at this revelation is that it is a *reductio ad absurdum* for the whole point of view—and that will certainly be the first thing the critics pick up on. But—you wouldn't have guessed less—I'm starting to view it as a godsend. For with this simple train of logic, one can immediately stamp out the potential reality/objectivity of any of a number of terms that might have clouded our vision.

You'll find the most useful stuff in here starting at my last note to you, i.e., page 78 onward. In particular you might enjoy the chart on page 84. It shows, I think, that when this exercise of epistemologizing so much is over and done with, there's still a fair amount left that one might be willing to call concrete reality.

I do hope you get something out of this. Two of your questions were the sources for the vast majority of the pages in the document. If you hadn't pushed me, I may have never seen that so much was waiting in the wings to be made sense of.

10-10-01 *Lunch Thanks* (to J. N. Butterfield)

Reviewing the day, it dawned on my that I hadn't thanked you for lunch! Thanks so much. I very much enjoyed our conversation, and I have to commend you for giving me a lead: you helped me realize that I really should read the principal principle paper again, and come up with a firm opinion.

I hope you will have a gander at my QFILQI paper: the more criticism you can heap on it the better. I know that I'll certainly come out the stronger for it.

It was wonderful seeing you again. Don't forget to remind me about your particular dates for Princeton: by the then I should know something for real about pragmatism, pro or con. (But knowing me, I'll probably lie somewhere in the middle.)

11-10-01 *Returning Home and Future Plans* (to A. Peres)

Asherism 13 : *Can you imagine Swissair bankrupt? I remember flying Braniff in one of their last flights, but Swissair???*

Computers get exponentially faster at the same time that world change gets exponentially faster. The two phenomena are probably not so untethered to each other!

Asherism 14 : *I sent you my preliminary draft "Imprecise quantum measurements", which nullifies the Meyer-Kent nullification of the KS theorem. I got a few comments, from Appleby, Cabello and Mermin.*

I apologize, but I didn't have a chance to look at your manuscript. (I'll also apologize for the format I'm using to reply to your present letter! When time slips away, so does my good composition sometimes!) Also, I figured with your large distribution list, you would get some good comments in any case. How were Appleby's comments? I met him for the first time in Ireland, and he struck me as a very clear thinker there. But I have not read any of his papers.

Asherism 15 : *Soon there will be the deadline that Khrennikov gave for his book about the Växjö conference. I talked there about my work with Petra, and this is well documented in two PRL and a forthcoming JMO. No need of repeating that. So I thought that an extended version of my "Imprecise quantum measurements" could be a nice chapter in such a book. What is your opinion?*

I think that's an excellent idea.

16-10-01 *Craters on the Moon* (to J. A. Waskan)

In a way you stole me away from the family tonight; the little ride home was full of thoughts about craters on the moon. You said something like, "That there are a thousand craters on the dark side of the moon, is a true statement regardless of whether it's useful or not."

Below is a passage I took from David Darling. It once made a good impression on me (long before my James days), and I can't help but feel that it is relevant to tonight's conversation too. If all the world is but atom and void—or substitute your favorite metaphysic, for that matter—then, it seems to me, there is no strict sense in which there are "craters" on the moon at all. To interpret the coarse information I have about some aspect of my experience as a map of the craters of the moon, seems to me an ultimately subjective judgment—one that I make because it is more or less useful.

Of course, I'm not wedded to these ideas: the game I play is to pick and choose anything from any philosophy that will help me make sense of the physics I'm doing and to promote it to a new level. Sometimes, after a sufficient amount of play, I change my philosophical mind. But I think the observation below is not a completely idiotic one, and it sends me some way toward the pragmatic conception of truth. No proposition I use in my daily life can be strictly true or false in the sense of reflecting the world as it is independently of me. And if not the case in my daily life, then why should it be the case at some more "ultimate" level (i.e., fundamental physics) that—after all is said and done—was intellectually derived from that daily experience in the first place?

> The interface between mathematics and everyday reality appears sharp and immediate at this point: one sheep, one finger, one token; another sheep, another finger, another token, and you can take away tokens or add them, as you can with your fingers. The tokens—the numbers—are just abstracted fingers; the operations for dealing with the tokens are just the abstracted raising or lowering of the fingers. You make a one-to-one correspondence between the tokens and whatever it is you want to reckon, and then forget about the fingers.
>
> At first, it seems clear from this that mathematics must be somehow already "out there," waiting to be discovered, like the grain of the stone. One sheep add one sheep makes two sheep. Two sheep add two sheep makes four sheep. That is certainly the practical end of the matter as far as the shepherd and the merchant are concerned. But already, even in this most simple mathematical maneuver, something strange has happened. In saying "one sheep add one sheep" we seem to be implying that any two sheep will always be identical. But that is never the case. Physically, the first sheep is never exactly equal to the second: it may be a different size, have different markings. It takes only one molecule to be out of place between the two, and they are not identical. Indeed, because they are in different places they are inevitably not the same on that basis alone. We have extracted a perceived quality to do with the sheep—namely, their "oneness," their apartness—and then merged this quality by means of another abstraction—the process of addition. What does it mean, physically, to "add" things? To put them together? But then what is "putting together" two sheep? Placing side by side, in the same field—what?
>
> All this may seem like nit-picking. But on the contrary, it brings us back to the central mystery—the relationship between the inner and the outer, the world of the rational mind and the world "out there." In the physical world, no two sheep are alike. But, more fundamentally, *there are no "sheep."* There are only some signals reaching the senses, which the left brain combines and then projects as the illusion of a solid, relatively permanent thing we call a sheep.
>
> Like all objects, sheep are fictions: chimeras of the mind. It is our left hemispheres, having through natural selection evolved this skill for extracting survival-related pieces of the pattern, that trick us into seeing sheep, trees, human beings, and all the rest of our neatly compartmentalized world. We seek out stability with our reasoning consciousness, and ignore flux. We shut our eyes to the continuous succession of events if those events seem not to substantially affect the integrity of what we see. So, through this classifying and simplifying approach we make sections through the stream of change, and we call these sections "things." And yet a sheep is not a sheep. It is a temporary aggregation of subatomic particles in constant motion—particles which were once scattered across an interstellar cloud, and each of which remains within the process that is the sheep for only a brief period of time. That is the actual, irrefutable case.

17-10-01 *Quick Single Point* (to J. A. Waskan)

Thanks for the note: I'm still digesting it. But let me quickly reply to the one thing that I can reply to.

Waskanism 1 : *Also, it seems strange for the fellow you quote to concede that there is light, eyes, the left half of one's brain, a process known as natural selection, and at the same time to deny the existence of sheep.*

Indeed, it seems strange to me too: He's pretty clearly not being consistent. But the role of the quote for me was as a motivating piece. (I read Darling a few years ago, and the main reason I used the quote last night was because it was already in my computer and I could, thus, send off a quick note to you.) My sentences above the quote were meant to show that I toy with the idea of going a further (more consistent) step:

> And if not the case in my daily life, then why should it be the case at some more "ultimate" level (i.e., fundamental physics) that—after all is said and done—was intellectually derived from that daily experience in the first place?

It is going that extra step that seems to me to be heading down the track to Jamesianism. Let me read your note again ...

17-10-01 *Quick Second Point* (to J. A. Waskan)

Sorry, I can't wait for the beer.

Waskanism 2 : *Here's a daily affirmation for you. Look in the mirror (not Rorty's mirror of nature, the one in your house), and say the following:*

I am pretty darned sure that I exist. I think there is other stuff in the universe too. I'm pretty darned sure that I have beliefs about (i.e., representations of) the other stuff that might be out there. My beliefs are true insofar as the world is how I represent it to be. If the world outside of my mind is in no way how I represent it as being (e.g., IF THERE ARE NO SHEEP, etc.), then all of my beliefs are false. Even if all of my beliefs about the things outside of my mind are false, this should have no bearing on the nature of truth itself (i.e., correspondence).

If you want to use true and false that way, then—in my present state of mind—yes, I would say that, strictly speaking, most all my beliefs are false. Beliefs play the role of coordinating our actions, and, in that way, can be more or less useful. But (in the too small of thought I've given this) I can't find a role for the concept of belief outside its use.

Like you, I am pretty darned sure of the existence of a world outside myself. But I would say that that surety comes NOT from some (transcendental?) knowledge that my beliefs mirror that world as it is. It is just the opposite. I believe in a real world outside myself because, throughout my life, things continue to take me by surprise. Significant numbers of my beliefs are systematically INvalidated with each new day. There's my evidence of the real world. Below is the way I put this point in a recent paper.

The point of view is not completely worked out yet—and it may never be—but my experience in quantum mechanics makes it feel more right than the other options I've seen so far.

Knowing me, I'll probably give your note another read, and be back again tomorrow. I hope you don't lose patience with me.

17-10-01 *Quick Third Point* (to J. A. Waskan)

OK, one more for the day.

Waskanism 3: *Also, sure no two sheep are exactly alike. Neither are any two bachelors. That doesn't entail that there are no bachelors. X is a bachelor if X is unmarried, and X is male, and X is eligible (e.g., not a priest).*

Granted. But what I thought was at issue is whether there are "bachelors" without the agents who make up (and use) all these judgmental categories. If all the world is BUT atom and void—to use an allegory I like but which should not be taken literally as my view—then where do all these extra distinctions come from if not the judgmental agent?

I say I thought this was the issue because my reading of the pragmatic conception of truth is more to the following point: Without agents, there are no "propositions." Therefore "propositions" cannot be true or false in any absolute sense. Without the agent, there is the world, and it is just whatever it is. A proposition adds something to the world that it itself did not possess before the agent's attention was drawn to it (via the act of dreaming it up, writing it down, acting upon it, etc.).

There's probably nothing worse than to have an armchair philosopher in your presence ...

17-10-01 *Final Point* (to J. A. Waskan)

I just read my last note over again and, to my great fear, I discovered you might read my closing two ways!!

> There's probably nothing worse than to have an armchair philosopher in your presence ...

I hope you understood that I was calling myself the armchair philosopher and not being a complete jerk.

18-10-01 *No Doobies Here?* (to J. A. Waskan)

Waskanism 4: *Lots of folks want to say that there are joints in the natural order (though, admittedly, bachelorhood probably isn't one of those joints).*

I'm not sure what you mean by the term "joints." Can you define it precisely? (Not knowing what you mean, it leaves me unable to reply to most of your message.)

Waskanism 5: *If, however, you take a step back and look at the big picture, ... I suspect that the same can be said for the relationship between atoms and tables.*

You know what my worry is (fueled by the 75 year debate on the interpretation of quantum mechanics). It's that we just can't step far enough back. We are immersed in this thing called existence, and there's just no way to get a view from outside it. We do the best we can from the inside, and that's called science. (For me, the phrase "best we can" means to eliminate impredictability—i.e., (only half jokingly) to delete reality as much as possible. Cf. yesterday's note about Emma.)

Tell me what a joint is, so I can think a little more about what you said.

21-10-01 *Danny, Dewey, David, Delight, and Dilemmas* (to A. Peres)

Thanks for the note; I'm glad to hear about Danny's opportunities.

I suppose because of the war and a couple of other details closer to home, I've gone into a bit of an email slump for the last couple of weeks. I am so far behind with all my correspondents. At least in my spare time I have been motivated to read more philosophy. And indeed I have come across a very good strain of that for once: I've been absolutely taken away by the writings of William James and John Dewey.

I have written David Mermin about our scheme for the ITP, but I have heard no reply yet. But he is enjoying the beauties of Vienna, so in a way, I expected no less.

22-10-01 *Sad and Happy* (to R. Cleve)

Of course, I'm sad to hear that we couldn't entice you to New Jersey ... but, really, I expected as much. Please do keep us in mind though in case anything ever changes.

On the other hand, I was really happy to hear that you liked the little sound bite in *Discover Mag.* I expanded those vague thoughts into a (slightly less vague) paper: `quant-ph/0106166`, "Quantum Foundations in the Light of Quantum Information". There is a small technical mistake in there—that I'm presently writing a comment on—but on the whole, I think the paper is relatively sound, and maybe entertaining. I'd enjoy hearing any reaction you might have, and more importantly, any ideas you might have about how to proceed on the program posed there.

22-10-01 *The Dilemmas of Subjectivism* (to R. Schack & C. M. Caves)

I apologize for holding off so long in a reply to Rüdiger's letter concerning the RMP article. The difficulty has come in that I didn't know how to reply. (I guess I still don't.)

The point of some potential consternation is this:

Schackcosm 43: *What I think we should be doing is a paper on "Interpretations of probability in quantum mechanics (with special emphasis on the Bayesian viewpoint)". The paper would NOT be on the interpretation of quantum mechanics.*

The problem is, I don't see how to separate the two issues. Where does the interpretation of probability fall off and the interpretation of quantum mechanics kick in? How can one have an interpretation of quantum mechanics wherein the wavefunction is objective, but still think of probabilities as being strictly subjective? Similarly, vice versa?

Let me do this: Let me ship to you both the mini-samizdat of my thoughts that came out of my post-Växjö broodings. You tell me which *sentiments* will be banned and which won't if we end up skinny-dipping together. I can foresee some being excluded—like the stuff in my letter to Wootters—and I can accept that; but for the greater majority of the writings, I can't see myself drawing a line, and I'm wondering where you will draw it.

Looking back on the BFM debate, I think the most important thing to come out of it for us three in particular is that it makes it absolutely clear that we need to get our thoughts straight on the "principal principle" before we can embark on a consistent statement of our position. For I see no way to erase the dilemma: Either we accept that the ascription of one Kraus rule over another in a measurement intervention is a subjective judgment, or we accept a quantumatized version of

Lewis's principal principle. Why did we all reject the principle before if we find ourselves accepting it now? This is something we ought to reflect upon more deeply.

23-10-01 *Increased Surveillance* (to N. D. Mermin)

My spies tell me you gave a talk on "Whose Knowledge?" yesterday. How did it go? Did anyone in the audience (unintentionally) lobby any shells on my behalf? If so, hand over their names, and I'll put out a recruiting effort for them.

23-10-01 *United We Stand Airlines* (to R. Schack)

Schackcosm 44: *Do you think you could give me a lift at such an early time?*

I do whatever it takes for the greater good of quantum mechanics. Of course I can give you a lift! (If you can stand to listen to me babble that early in the morning.)

26-10-01 *The Feynman Cult* (to J. N. Butterfield)

I don't remember railing against the Feynman cult in your presence, but your letter gives some evidence that I must have. (Doing such things was a common pastime for me at Caltech, but I've mellowed a little in my efforts since leaving, i.e., since the cult hasn't been in my face on a daily basis.)

But, anyway, yes I told Brandt that I would come. (I hope you will come too.) I've even thought about how I will open my talk: with the Feynman quote below. Lord knows I'm no materialist, so you can rest assured that I'll do my best to "zing" it up afterward. (See my Samizdat, page 237.)

> If, in some cataclysm, all of scientific knowledge were to be destroyed, and only one sentence passed on to the next generation of creatures, what statement would contain the most information in the fewest words? I believe it is the atomic hypothesis (or the atomic fact) that all things are made of atoms—little particles that move around in perpetual motion, attracting each other when they are a little distance apart, but repelling upon being squeezed into one another.
>
> Everything is made of atoms. That is the key hypothesis.

27-10-01 *Coming to Agreement* (to C. M. Caves & R. Schack)

Schackcosm 45: *In any case, do you know a reference for strong Dutch-book consistency?*

Nothing comes to mind: I think I first learned of it from you (was it in Cambridge?). Might it have been in either of those papers we looked up in a trip to the university library one day? This was one of them (though I don't have it anymore):

> J. G. Kemeny, "Fair Bets and Inductive Probabilities," J. Symb. Logic **20**, 263–273 (1955).

Ahh, here was the other one:

> R. S. Lehman, "On Confirmation and Rational Betting," J. Symb. Logic **20**, 251–262 (1955).

It might be a good idea to dig those up again.

I'll try to answer your other questions next week, after I get a chance to get a better grasp on the paper.

27-10-01 *Literature* (to R. Schack)

Schackcosm 46: *A question to you: How much literature is there on interpretations of probability in q.m.? Would it be feasible to review it all?*

Attached is everything I had collected up previous to the Cerro Grande fire. A skim of that document might answer your question in the most direct way.

By the way, I've asked Maria Carla Galavotti for her criticisms (and any others that she knows) of the principal principle. But I haven't gotten a reply from her yet.

Thinking back on it, I can't remember if we ever had any NONquantum reasons that were substantially different than J. S. Mill's argument against a "substance" underlying the phenomenal world:

> If there be such a *substratum*, suppose it at this instant miraculously annihilated, and let the sensations continue to occur in the same order, and how would the *substratum* be missed? By what signs should we be able to discover that its existence had terminated? Should we not have as much reason to believe that it still existed as we now have? And if we should not then be warranted in believing it, how can we be so now?

Similarly one could say of objective probability: Bayesian coming-to-agreement would work precisely the same whether the objective probability is there or not. But did we have any other arguments than that (that did not depend on upon quantum mechanics, for instance in the nonuniqueness of the density operator decomposition)? Did we have any examples where believing in objective probability in Lewis's sense would be downright misleading in how it might suggest tackling a practical problem?

I so wish I had my old file cabinet back again; writing you this morning has made that feeling more acute.

01-11-01 *Your Limerick* (to I. Duck)

A couple of days ago I opened up a package of old mail that Los Alamos had finally forwarded to me. To my great delight, I found your letter and your limerick from February!!! Thank you so much; this is a very great honor. After reading your limerick I think I smiled all day.

I wish so that I had gotten your mail before May. I would have then been able to include (with your permission) your limerick in my large samizdat posted on the web at:

`http://xxx.lanl.gov/abs/quant-ph/0105039`

It would have been a great addition. And I think you are right: "the best we can ever surmise" catches the situation quite precisely.

Thank you again.

01-11-01 *Delayed Reactions* (to A. Peres)

Two days ago, I received a package of old mail that was finally forwarded from Los Alamos. Some of it was very old indeed, going back to November 2000. In any case, two pieces were relevant for our *Physics Today* articles. One was from someone named Fritz Froehner, and it looks like he sent an identical copy to you. But the far more interesting one was from a professor at Rice University (where, incidentally, Carl Caves got his undergraduate degree).

I scanned the letter into my computer this morning, and will put the whole thing below. I have just written him thanking him for the warm feelings he gave me.

> Dear Dr Fuchs:
>
> I am sending you a copy of a limerick which was prompted by your OPINION article with Asher Peres in MARCH 2000 PHYSICS TODAY. I hope it amuses you, and that it catches the gist of your 'No Interpretation' thesis. It is a fascinating subject which I believe to be completely rationalized by your point of view. I'm sure you have thought about this much more deeply than I. For instance, I just now realized that one does not have to invoke anything more miraculous than uninterrupted Hamiltonian evolution for the system. I had been thinking that it was a mystery that we should have gone from the mechanics of an inanimate object to a theory of knowing; but that is not what is happening. I think 'the best we can ever surmise' catches the situation quite precisely.
>
> I tried to interest Alan Alda in *Scientific American* with this, but I missed the deadline for his limerick contest and I don't think they ever forwarded it to him.
>
> With best regards,
>
> Ian Duck, Professor of Physics
>
> LIMERICK on the INTERPRETATION OF QUANTUM MECHANICS
>
> ON SCHROEDINGER'S CAT
>
> It comes as a total surprise
> That what we learn from the ψ's
>   Not the fate of the cat
>   But related to that:
> The best we can ever surmise.
>
> IAN DUCK, FEB 2001

02-11-01 *Positive Operators and Measurement* (to K. Jacobs)

Thanks for including me in the correspondence with Keiji Matsumoto. Did his question arise from having read our paper? (That would mean we might have 3 or 4 readers!!) I was supposed to visit his institute in Japan last month, but I wimped out of leaving the country. (In any case, I had already flown overseas four times this year ... and five seemed a bit too much.)

Let me make one comment on your points about the "identity" (as the unitary in the polar decomposition) giving a natural analog to Bayes' rule. Have a look at Section 5 in my paper: `http://xxx.lanl.gov/abs/quant-ph/0106166`. What I show there is that by appropriately adjusting the various U_i (but not to the identity), one can make a precise analog to Bayes' rule even in the noncommuting case. Of course, it's a trivial point that we probably both understood while

I was at LANL. What's new though, is that I've now come to think it is an important conceptual point.

04-11-01 *Dreams of an Ever-Evolving Theory* (to A. Peres)

Asherism 16: *I am reading a wonderful book "Dreams of a Final Theory" by Steve Weinberg. Chapter 7 is "Against Philosophy" and I highly recommend it. I got that book for $7.00+tax in a used books shop in Santa Barbara, where Aviva was looking for something else.*

Thank you for the tip; I did read Weinberg's chapter 7. He writes in a very crisp and no nonsense way, and I like that. (You know I constantly fight tendencies in the opposite direction in my own writing.) His points are well taken, especially the ones about how a preset philosophy can create immense blinders for the scientist:

> "... in rejecting it the [PHILOSOPHY-X]ists were making the worst sort of mistake a scientist can make: not recognizing success when it happens." — page 177, paperback version.

But, I think a deeper point is the one he makes near the beginning of the essay:

> "I do not want to draw the lesson here that physics is best done without preconceptions. At any one moment there are so many things that might be done, so many accepted principles that might be challenged, that without some guidance from our preconceptions one could do nothing at all." — page 167

And I agree with the numerical tally of the next sentence:

> "It is just that philosophical principles have not generally provided us with the right preconceptions." — page 167

However, I part company with him in thinking that that is a strong argument against pursuing philosophy as a sideline to science. That is, I don't know what the preconceptions can be if they're not philosophies.

When it comes to philosophies and, not unrelated to that, scientific research directions, I tend to take a lot of stock in a Darwinian kind of conception. That is, we each should do precisely what we feel compelled to do; we each should research precisely what we feel compelled to research. There's probably nothing we can do about it anyway. Indeed ninety-nine percent of the time we will be on the wrong track: The world supplies a selection pressure for our thoughts, just as it does for the lifespan of the drosophila. And just as it is not possible for the drosophila to change its genetic makeup before it meets its demise, I think the only thing we can do as scientists is cultivate to the best of our ability the philosophical preconceptions that led us down our own paths. Ninety-nine percent of us will be forgotten from the history books, but the ones of us that remain will do so because the world is such that it is less likely that we should fall.

For myself, I have DISCOVERED that I have chosen a direction of thought that is very closely aligned with the philosophical movement of pragmatism from the early part of the 20th century—a movement the details of which have been nearly forgotten in modern times. Interestingly, the thing that set me on to this realization was Martin Gardner's essay "Why I Am Not a Pragmatist" in his book *The Whys of a Philosophical Scrivener*. (You probably remember Gardner from his column in *Scientific American*.) This happened about three months ago. I really recommend you read the article if you get a chance. Maybe your library has a copy of the book. I think in reading it, you will discover that the essay might just as well have been titled, "Why I Am Not in Agreement with Fuchs and Peres's Physics Today Article." For, with each reason Gardner used to explain why he was *not* a pragmatist, I found myself thinking of quantum mechanics and saying to myself, "ahh, I guess that means I *am* a pragmatist." Really, the analogy is *that* close even though the article has nothing to do with quantum mechanics per se.

The issue is no less than whether "unperformed measurements have no outcomes." The pragmatists, for various reasons, thought it was *safer* to assume that they didn't. The movement then spent the greater part of its time developing the (liberating) consequences of this supposition. Gardner (and Bertrand Russell and G. E. Moore and gazillions of others) thought "how silly" and "how contrived" when it is so much easier to use standard realist language to describe the outcomes of experiments—to assume the outcomes are there before one has a look. But you and I know better, of course. And, I think it is quite useful to know that there was a set of people carrying through the detailed consequences of this line of thought for their broader worldview long before you and I were on the scene. The way I view it, these old thoughts can be a resource to our explorations of quantum mechanics just as much as any other: However, their use is in setting the directions for potentially fruitful lines of thought ... but that should always be the use of any philosophy for any scientist.

Below I'll attach a letter I wrote Bill Wootters a while ago on a similar subject. [See 20-09-01 note "Praise, Folly, Enthusiasm" to W. K. Wootters.] What I write just after the quote of William James better explains why I chose the title that I did for this note.

14-11-01 *Samizdat II* (to N. D. Mermin)

Merminition 76: *Expanding slightly on my reaction to Samizdat II: (Please don't conclude that I've missed the point yet again until we meet):*

It seems to me that all interpretations of QM have to come up against what is loosely called the "measurement problem" in one form or another, which I would describe as how we can reconcile a world empty of "facts" to the "facts" of our own experience. (I would not describe it as having to do with how wave-functions "collapse" or "decohere".)

Various people (at least those who don't want to decree that there is a "cut" between two domains) deal with the problem by extending the facts of our experience to everything else (Bohmians, GRW collapsists). Others deal with it by extending the indefiniteness of QM to our apparently definite experience (many worlders). It seems to me you're following the second strategy (which is all I meant by my irritating jokes about your Everettism — your version of the second strategy is obviously different from theirs) by insisting that the subjective character of quantum probabilities requires us to take the same subjective approach to classical "facts" — i.e. to insist that they too are beliefs that can also be dealt with only through a (subjective) probabilistic treatment.

This is intriguing and well worth exploring. I do worry (with Carl, I think) that it's getting rather far from how physicists do physics – or at least from how they think they do physics. But I wouldn't say it means the end of science. Whatever that means.

Thanks for the extended comments. I won't say you've missed the point: I think you've got it. But I don't quite understand the Everett analogy yet. I would say their world—Deutsch's world—abounds with facts. Facts far, far in excess of what any of us ever see. (I.e., all their worlds.) But I'll think much harder about your note. There's no need to reply yet again.

16-11-01 *Great Quote* (to J. W. Nicholson)

Now this is one I love! Which supersedes which? Christianity or humanity? I didn't realize the two notions could be considered so opposed.

> "It was very dramatic, right until the end," Taubmann said at a news conference Thursday night. He was wearing a new pair of pants that still sported the store tags, and he had sheared the scraggly beard and long hair he had when he had arrived in Islamabad.
>
> "I am a Christian — I have forgiven them [the Taliban] for what they have done," he said. "But as a human being, I hate what they did to us."

19-11-01 *A Lot of the Same* (to C. M. Caves & R. Schack)

Schackcosm 47: *Before you have me burned alive, please tell me why I am wrong!*

Come on, you know it's the Thanksgiving season. I would never burn you, only roast you. (Though my brother-in-law once fried his turkey in hot oil.)

Sorry for the hiatus, but I just got inundated with email last week, and I didn't have the proper mentality for replying to any of it. So I shut down for a while. Now I'm stuck with trying to clean out an even bigger pile of old mail. But let me compliment you by letting you know that I'm tackling your letter first! (It's the only interesting one in the lot.)

Schackcosm 48: *I started writing up a summary of our discussions, and hit upon a difficulty when I tried to formulate exchangeability for models. Here is the problem.*

In the traditional formulation of exchangeability, we say that we have N identical systems (same Hilbert space). At this stage, it is thinkable to assign a different state to each system. We then make the judgement that the state of the N systems is exchangeable.

For models, we say that we have N identical apparatuses. Alternatively, we say that we use the same apparatus to perform N measurements, let's say on different, independently prepared systems. At this stage, I can't think of a good reason to even consider assigning different models to the apparatuses. It seems to me that one is forced to say that each apparatus performs the same operation, so should be described by the same model. That leads immediately to a heresy: there exists a true model. If we don't know it, we assign probabilities to models. What we wrote down on your whiteboard is consistent with this viewpoint. The difficulty we encountered formulating exchangeability could mean that it is an unnatural concept in this case. Writing down a mixture of N-fold products of models is completely natural however.

Let me try to allay your fears. I think the issues here are almost precisely the SAME as they are in our old de Finetti considerations. To say it in a way that maybe Carl would endorse, "It's really all about learning." Or in a way that I'm more tempted to these days, it's all about demonstrating a willingness to update one's beliefs—one's commitments, one's pragmatic strategies for action, one's betting behavior—in the light of factual data.

Let me start with an example that's essentially already well-worn for us by now. Suppose we have a rather complicated quantum measurement device whose manufacturer purports it to be the best σ_z measurement device ever built. Furthermore, suppose we have a fresh supply of 10^8 calcium atoms, all meticulously prepared to have spin-up in the x-direction. What do we expect to happen if we individually dump all the atoms into the measuring device? We expect about 50% of them to get registered as spin down and about 50% of them to get registered as spin-up. But what happens if one after another, all the registrations are of the spin-up variety? Well, that outcome sequence would be no less likely or no more likely than any other outcome sequence if we walked into the laboratory with such a radically adamant prior belief. In a real-life situation, however, we would be shocked; we would update our beliefs accordingly—for we would have allowed for the possibility of "learning."

But in this situation, notice that there are at least two extreme cases to which we could attach the possibility of learning. The learning could be about the device or it could be about the preparations. Who's to say that the learning is about something more objective in the one case than the other? Prosaically, it takes both ingredients (the preparations and the device) to certify the device, and you can't get away from that.

Let me try to tighten this up by sketching how we ought to start thinking about a de Finetti theorem for unknown quantum models. I run a measurement device on N independently and identically prepared quantum systems. Suppose I am absolutely confident of these preparations—i.e., with respect to them, there is nothing left to learn in the technical sense of i.i.d. statistics for any repeated and KNOWN measurement. Then, what can it mean—from a Bayesian point of view—that the measurement device works according to an unknown model? It means that after all the outcomes are gathered, there's still something left to be learned from the posteriori quantum state for the systems that were measured.

That is, more simply, the best judgment we can make about the systems that passed through the measurement device is that they are exchangeable CONDITIONED on the registered measurement outcomes. For instance, suppose the device spits out an index i at each round. The issue is, what pragmatic meaning should we give to each such i? Quantum mechanically, the predictive meaning of an index i is specified by the Kraus operator A_i we associate with that outcome. (Its retrodictive meaning is given by the positive part of A_i—the POVM.)

If we think we don't exactly know what the device is doing to each individual system, then we shouldn't yet dare to make an association $i \to A_i$. (To make an extreme point of it, for all we know, the device might be entangling all our test systems.) We should just rest confident that no matter what order we send the systems through the device, we will end up with the same subjective beliefs in the end. Thus, if we gather up all the systems for which an outcome i occurred (as opposed to some other outcome j), then the subjective density operator we assign should be exchangeable. Using the standard quantum de Finetti theorem, we then get that that density operator must be of de Finetti form. Writing each of the final density operators as a linear map acting on the initial density operator, we (should) get something like the desired theorem for unknown quantum models. If we believe that we can learn something about the model, then the probability distribution that appears in the de Finetti form is restricted to being something other than a δ-function.

In summary, our belief that the best we can say of the outputs is that they ought to be exchangeable (conditioned on the factual outcomes), leads directly to a notion of mixture of models—i.e., that the output density operator is controlled either by a Kraus operator A_i, or a Kraus operator B_i, etc., etc., about which we capture our ignorance through some subjective probability distribution.

Now, just as the regular de Finetti theorem cannot put an end to the principal principle, we cannot use this (proposed) theorem to put a stake through the heart of the true believer of objective quantum models. That is, David Lewis might say of the regular de Finetti theorem, "That is a very nice theorem, but it doesn't change the fact that there really is always a 'man in the box.' His name is God." And so he would probably also say of our quantum models (if he knew quantum mechanics). Instead, all the (proposed) theorem can do is show that it is *possible* to get by without a man in the box. We don't need him; all we need is something like the judgment of exchangeability for the outputs (conditioned on the outcomes) along with i.i.d. on the inputs.

So that's the sketch. Now, how to dot the i's and cross the t's? I can foresee at least one difficulty that I'm not clear-headed about right now. That is, using the description above, for each index i, we will generate a probability distribution over models. But by what regularity condition can we assure that $p_i(\mathcal{A}) = p_j(\mathcal{A})$? What I mean by this notation is that $\mathcal{A}$ stands for the model in total (i.e., all the Kraus operators in it) and $p_i(\mathcal{A})$ stands for the probability distribution in the de Finetti theorem derived for each index i. It is probably so simple as this: If we were to imagine doing tomography on the posterior states for each index, then the states derived from that should always average up to a valid density operator. But I'm not exactly sure how to put that idea into action.

Oh, and here's another intriguing point that ought to be explored. Suppose we focus our attention on a given exchangeable density operator. There are many ways that operator could arise, but suppose that it came about as the posterior state arising from many identical measurements (in the sense above). The question I have in mind is how much freedom do we have for trading off between an unknown preparation and an unknown model for getting to the final state? Can one always find a fixed initial preparation and a mixture of models that will give rise to the final exchangeable state? Can one always find a mixed model and a mixture of initial preparations? Probably yes and yes, but I'm not completely sure.

I'm so glad to hear that you may have reversed your opinion on William James (at least a little). By the way, I hope you notice how these de Finetti considerations are drawing out a lot of the considerations I was trying to express to you in Samizdat-II and our subsequent discussions. For it helps draw the distinction between the amorphous index i that arises in a quantum measurement and the meaning A_i that I ascribe to that event. The symbol A_i plays the role of a proposition that I write about i: It carries the information about how I will react after having seen it, how I will place my bets.

I'm willing to believe this whole debate about "truth" might be a red herring—i.e., that we might easily be able to get away with never uttering the word. But I think the realization of the last paragraph had a primitive expression in James's worries about "truth" nevertheless, and to that extent maybe he and his movement of pragmatism are worth contemplating (though of course not subscribed to in toto).

19-11-01 *William James* (to R. Schack)

Schackcosm 49: *You will be pleased to learn that I bought a copy of "Pragmatism" and enjoy reading it a lot! His rhetoric is the best I have ever seen from a philosopher. He is definitely not tender minded.*

It's a curious mix, though. Sometimes he seems to be very close to Kantian ideas on truth, then he seems to subscribe to a naive correspondence theory of truth, at least for simple facts such as "this detector has clicked."

Yes, I'm more attuned to that now, and I'm trying to get it straight through extended readings (such as A. J. Ayer's book *The Origins of Pragmatism* that I picked up in New York City with you).

Schackcosm 50: *I am also a little disturbed by his praise for Ostwald.*

I don't remember his praise for Ostwald. Who was Ostwald? And what does James praise him about?

Schackcosm 51: *I am half way through writing a much improved draft of our paper.*

Sounds great.

20-11-01 *A Bathtub Moment* (to C. M. Caves & R. Schack)

I'm sure I've already told you both the story of the time I happened to end up at a British pub with Caroline Thompson, the famous Bell-inequality conspiracy theorist, but let me repeat it for the purpose of having it in this box. Somebody at the table was speaking of the great importance of intuition, of being able to "see beauty in a theory." I, with my usual example, piped up that I thought that was hogwash: I always thought Mary Ann was the prettiest girl on Gilligan's Island; my best friend thought it was Ginger. Anyway, I followed that comment with, "I never use any intuition in my calculations; I don't even know what intuition can be in that context." Caroline Thompson harrumphed, "Well we could see that from your talk!"

OK, so it won't be an intuition, but here's a hunch that hit me while I was taking a shower this morning. It's connected to the long note on de Finetti I sent you yesterday.

Among the thirty other reasons I have been thinking that trace-preserving quantum operations (and now measurement models explicitly) are subjective entities is because one can make a one-to-one correspondence between them and the density operators on a larger Hilbert space. That is, they have the same structure as the states of belief that we've already toyed with.[16] This has suggested to me that there ought to be a Gleason-like theorem for quantum operations (which I pursued a little bit but never could quite make things connect). But now this idea is rearing its head again in the context of a de Finetti theorem for models.

Yesterday, I blithely said something to the following effect. To get at a concept of an unknown model, what you do is 1) to 4) :

1. Start with many copies of a quantum system, for which you believe 1) that they are exchangeable and 2) that there is nothing left to learn. The standard quantum de Finetti theorem then gives us that the density operator we ascribe to the collective system will be a tensor product of identical quantum states.

2. Now drop each of those systems into a measurement device and note the outcomes i. Separate the post-measurement systems into bins according to those outcomes.

3. Finally suppose we believe that the quantum state we ascribe to each bin ought to be an exchangeable state for which we *can* learn something. The standard de Finetti theorem gives that this state must be of de Finetti form (with a nontrivial support).

4. The hunch was that the conjunction of 1), 2), and 3)—or them along with some minor additional regularity condition—would specify the content of the phrase "an *unknown* quantum measurement model." The unknown model is simply given by making explicit the form of the linear maps connecting 1) to 3) for all possible inputs into A.

Notice that nowhere in there did I say anything about these maps being completely positive. I just chose the word "linear" for some reason. But surely the assumption of complete positivity must come into this too. So now my question: UNDER THE ASSUMPTION that a measurement model is a state of belief, can one adequately explain the notion of an unknown measurement model by de Finetti techniques WITHOUT the technical assumption that these linear maps are completely positive? Or, instead, is complete positivity absolutely crucial to the program?

[16]By the way, Carl, as I recall, was never happy with thinking this point had any significance for our program. I think he saw it as little more than a coincidence.

It strikes me that Carl's superoperator calculus has got to be the way to go for exploring this question.

20-11-01 *James's Loose Lips* (to R. Schack)

Schackcosm 52: *In lecture 2, James says "I found a few years ago that Ostwald, the illustrious Leipzig chemist, had been making perfectly distinct use of the principle of pragmatism [...]"*

In my own words, Ostwald rejected as meaningless any statement that did not have observable consequences. A very pragmatic attitude indeed. The trouble was that Boltzmann's ideas about atoms fell into this category, at least that was the public opinion, led by Ostwald, at the time. No cash value in the "atom hypothesis". I imagine somebody like Ignacio (I pick him only because of his obvious scepticism at my talk in Benasque) to ask: where is the cash value in the Bayesian approach to quantum mechanics?

I agree with you now that that is a troubling praise coming from James. I noticed similarly somewhere else in the book that he also classified Mach in the ranks of the pragmatists.

But there is a grave distinction between positivism (Mach, Ostwald, etc.) and pragmatism (James, Dewey, etc.) as I see it. The positivists eschewed all metaphysical assumptions—thus the egg on their faces for not coming up to speed on the statistical mechanics an atomic hypothesis can afford. The pragmatists, on the other hand, are willing to glorify any metaphysics with a cash value. This relates to the passage by James on Mill that I read you while you were visiting. With metaphysics, the cash value is not in its explanation of any previously discovered facts, but in the concrete actions its BELIEF will give rise to in the agent believing it. Thus James's argument, for instance, for everyone's right to believe in a God, even if that God will never have the opportunity of being confirmed or falsified in an objective fashion. A God's validity in an agent is in his cash value for the agent's ethics, morals, and mode of action for his daily life.

To put this in concrete terms for Carl versus me: I would say that the ontological hypothesis I'm shooting for will show some cash value in the amount of interesting physics it leads to, to the opening up of new quantum computing and quantum control and quantum cryptography methods. And I think (or, more accurately, BELIEVE) it will help us make the leap to the next stage of physics. Whereas I would say—but it's just a gut feeling—that the ontology Carl has been shooting for (i.e., the Hamiltonian) has no such cash value. Only the money flow in the banks will ultimately tell. (And unfortunately, that can only be done with hindsight.)

James—I think in his essay "The Sentiment of Rationality"—has a beautifully worded passage on these considerations that I'll try to get scanned in tonight and sent to you. But I think James himself is either not consistent in his writings, or he's pretty sloppy in reading the other writers he wants to praise. (What I know of him now, I think it's probably mostly the latter.)

Sorry for writing all this. I got carried away. I hope to get your new draft printed out today, and studied partially tonight.

By the way, I think Ignacio is a good benchmark with all this. If we can't find a way to impact him in five or seven years, say, then maybe indeed all this is for naught.

20-11-01 *One Horse's Mouth* (to J. M. Renes)

I finally get to the last note I owe you.

Renesism 2: *You make this point in the nato paper explicitly (that the unitary taking the quantum Bayes rule post measurement state to the orthodox post measurement state is a "mental readjust-*

ment" and does depend on the input state). There's a lot here, though, especially since Carl initially balked pretty hard at the idea since "we're physicists so I don't know what he's (you) talking about."

I'm intrigued by your phrase "there's a lot here, though." I don't quite understand what you're trying to get at—that you agree that it's a difficulty, or that it's a good thing? Or that if Carl balked, that might be an unintentional mark in its favor? Can you explain a little better?

Renesism 3: *Some days I don't feel like a physicist (happily coinciding much of the time with the days I don't want to) so I'm not initially troubled by this. However, as I said, there's a lot of "stones unturned" here. Are you saying that there is no physical picture of what's going on, there must be some subjective element "uncaptureable" by a physical picture? This seems to fit with your rep as being an "extreme subjectivist" but I'd rather hear it from the horse's mouth.*

I'm not sure exactly how I should reply to this. You probably know my thoughts at this point better than I know them myself. Maybe I should say it like this: My pet idea at the moment is that there was a world here before humankind ever appeared on the scene; there'll be a world here after we disappear. But I would say the world is still under construction; there is no sense and no ultimate level at which it is already complete. To that extent, I believe our beliefs, our passions, our actions, our inventions, and our dreams modify the world and form part of its construction in a nonnegligible way.

And I think our greatest hint of that comes from quantum mechanics. I would say that what we're learning in a precise way from it is that there is something about the stuff of the world that makes it uncaptureable with a purely physical picture. We find that we cannot even draw a picture of the world without including our beliefs and belief changes as a crucial background in the sketch. (How could we if the world's not completed yet?)

Does that make me an extreme subjectivist? I don't know. Whatever it is though that I should be called, I think this willingness to accept a substantial part of quantum mechanics as simply "law of thought" will keep me from going down a misguided path. I.e., the path of trying to ascribe all the easiest terms in the theory a kind of physical reality independent of our presence as active agents.

One horse's mouth.

21-11-01 *Pragmatism versus Positivism* (to R. Schack)

Both quotes are taken from William James's essay "The Sentiment of Rationality."

Quote I:

> The necessity of faith as an ingredient in our mental attitude is strongly insisted on by the scientific philosophers of the present day; but by a singularly arbitrary caprice they say that it is only legitimate when used in the interests of one particular proposition—the proposition, namely, that the course of nature is uniform. That nature will follow tomorrow the same laws that she follows today is, they all admit, a truth which no man can *know*; but in the interests of cognition as well as of action we must postulate or assume it. As Helmholtz says: "*Hier gilt nur der eine Rat: vertraue und handle!*" And Professor Bain urges: "Our only error is in proposing to give any reason or justification of the postulate, or to treat it as otherwise than begged at the very outset."

With regard to all other possible truths, however, a number of our most influential contemporaries think that an attitude of faith is not only illogical but shameful. Faith in a religious dogma for which there is no outward proof, but which we are tempted to postulate for our emotional interests, just as we postulate the uniformity of nature for our intellectual interests, is branded by Professor Huxley as "the lowest depth of immorality." Citations of this kind from leaders of the modern *Aufklärung* might be multiplied almost indefinitely. Take Professor Clifford's article on the "Ethics of Belief." He calls it "guilt" and "sin" to believe even the truth without "scientific evidence." But what is the use of being a genius, unless *with the same scientific evidence* as other men, one can reach more truth than they? Why does Clifford fearlessly proclaim his belief in the conscious-automaton theory, although the "proofs" before him are the same which make Mr. Lewes reject it? Why does he believe in primordial units of "mind-stuff" on evidence which would seem quite worthless to Professor Bain? Simply because, like every human being of the slightest mental originality, he is peculiarly sensitive to evidence that bears in some one direction. It is utterly hopeless to try to exorcise such sensitiveness by calling it the disturbing subjective factor, and branding it as the root of all evil. "Subjective" be it called! and "disturbing" to those whom it foils! But if it helps those who, as Cicero says, "*vim naturae magis sentiunt*," it is good and not evil. Pretend what we may, the whole man within us is at work when we form our philosophical opinions. Intellect, will, taste, and passion co-operate just as they do in practical affairs; and lucky it is if the passion be not something as petty as a love of personal conquest over the philosopher across the way. The absurd abstraction of an intellect verbally formulating all its evidence and carefully estimating the probability thereof by a vulgar fraction by the size of whose denominator and numerator alone it is swayed, is ideally as inept as it is actually impossible. It is almost incredible that men who are themselves working philosophers should pretend that any philosophy can be, or ever has been, constructed without the help of personal preference, belief, or divination. How have they succeeded in so stultifying their sense for the living facts of human nature as not to perceive that every philosopher, or man of science either, whose initiative counts for anything in the evolution of thought, has taken his stand on a sort of dumb conviction that the truth must lie in one direction rather than another, and a sort of preliminary assurance that his notion can be made to work; and has borne his best fruit in trying to make it work? These mental instincts in different men are the spontaneous variations upon which the intellectual struggle for existence is based. The fittest conceptions survive, and with them the names of their champions shining to all futurity.

The coil is about us, struggle as we may. The only escape from faith is mental nullity. What we enjoy most in a Huxley or a Clifford is not the professor with his learning, but the human personality ready to go in for what it feels to be right, in spite of all appearances. The concrete man has but one interest—to be right. That for him is the art of all arts, and all means are fair which help him to it. Naked he is flung into the world, and between him and nature there are no rules of civilized warfare. The rules of the scientific game, burdens of proof, presumptions, *experimenta crucis*, complete inductions, and the like, are only binding on those who enter that game. As a matter of fact we all more or less do enter it, because it helps us to our end. But if the means presume to frustrate the end and call us cheats for being right in advance of their slow aid, by guesswork or by hook or crook, what shall we say of them? Were all of Clifford's works, except the *Ethics of Belief*, forgotten, he might well figure in future treatises on psychology in place of the somewhat threadbare instance of the miser who has been led by the association of ideas to prefer his gold to all the goods he might buy therewith.

In short, if I am born with such a superior general reaction to evidence that I can guess right and act accordingly, and gain all that comes of right action, while my less gifted neighbor (paralyzed by his scruples and waiting for more evidence which he dares not anticipate, much as he longs to) still stands shivering on the brink, by what law shall I be forbidden to reap the advantages of my superior native sensitiveness? Of course I yield to my belief in such a case as this or distrust it, alike at my peril, just as I do in any of the great practical decisions of life. If my inborn faculties are good, I am a prophet; if poor, I am a failure: nature spews me out of her mouth, and there is an end to me. In the total game of life we stake our persons all the while; and if in its theoretic part our persons will help us to a conclusion, surely we should also stake them here, however inarticulate they may be.

Quote II:

Now, I wish to show what to my knowledge has never been clearly pointed out, that belief (as measured by action) not only does and must continually outstrip scientific evidence, but that there is a certain class of truths of whose reality belief is a factor as well as a confessor; and that as regards this class of truths faith is not only licit and pertinent, but essential and indispensable. The truths cannot become true till our faith has made them so.

Suppose, for example, that I am climbing in the Alps, and have had the ill-luck to work myself into a position from which the only escape is by a terrible leap. Being without similar experience, I have no evidence of my ability to perform it successfully; but hope and confidence in myself make me sure I shall not miss my aim, and nerve my feet to execute what without those subjective emotions would perhaps have been impossible. But suppose that, on the contrary, the emotions of fear and mistrust preponderate; or suppose that, having just read the *Ethics of Belief*, I feel it would be sinful to act upon an assumption unverified by previous experience—why, then I shall hesitate so long that at last, exhausted and trembling, and launching myself in a moment of despair, I miss my foothold and roll into the abyss. In this case (and it is one of an immense class) the part of wisdom clearly is to believe what one desires; for the belief is one of the indispensable preliminary conditions of the realization of its object. *There are then cases where faith creates its own verification.* Believe, and you shall be right, for you shall save yourself; doubt, and you shall again be right, for you shall perish. The only difference is that to believe is greatly to your advantage.

The future movements of the stars or the facts of past history are determined now once for all, whether I like them or not. They are given irrespective of my wishes, and in all that concerns truths like these subjective preference should have no part; it can only obscure the judgment. But in every fact into which there enters an element of personal contribution on my part, as soon as this personal contribution demands a certain degree of subjective energy which, in its turn, calls for a certain amount of faith in the result—so that, after all, the future fact is conditioned by my present faith in it—how trebly asinine would it be for me to deny myself the use of the subjective method, the method of belief based on desire!

In every proposition whose bearing is universal (and such are all the propositions of philosophy), the acts of the subject and their consequences throughout eternity should

> be included in the formula. If M represent the entire world minus the reaction of the thinker upon it, and if $M + x$ represent the absolutely total matter of philosophic propositions (x standing for the thinker's reaction and its results)—what would be a universal truth if the term x were of one complexion, might become egregious error if x altered its character. Let it not be said that x is too infinitesimal a component to change the character of the immense whole in which it lies imbedded. Everything depends on the point of view of the philosophic proposition in question. If we have to define the universe from the point of view of sensibility, the critical material for our judgment lies in the animal kingdom, insignificant as that is, quantitatively considered. The moral definition of the world may depend on phenomena more restricted still in range. In short, many a long phrase may have its sense reversed by the addition of three letters, *n-o-t*; many a monstrous mass have its unstable equilibrium discharged one way or the other by a feather weight that falls.

23-11-01 *Bossa Nova* (to C. M. Caves)

Cavesism 52: *P.S. Jim [Hartle] also mentioned that the Perimeter Institute is currently still in its big-shot hiring mode as far as foundations is concerned.*

As far as I can tell the "big-shots" haven't done a useful thing in this area for 66 years.

25-11-01 *quant-ph/0106166* (to R. Cleve)

Thanks for the thoughtful comments! Let me fire back a couple of my own.

Cleve-ism 1: *What would the classical information theory version of the table on page 4 look like? Somehow the axioms of probability theory don't come out as crisply in English as those of relativity, do they?*

I think that's a superbly relevant point; it's one that Charlie Bennett keeps making to me too. Indeed, I do get a little worried about the axioms of information theory. But, I'm fairly optimistic on the axioms of probability at least. While you're at the ITP, you might take the opportunity to talk to Rüdiger Schack or Carl Caves about the "dutch book argument" for the classical probability axioms. They can sketch the argument for you, which I think you will find really intriguing. In essence, with respect to a fairly natural game, it does squeeze the structure of classical probability theory into a couple of English sentences.

This sort of thing gives me a lot of hope for both classical information theory and quantum theory too.

Cleve-ism 2: *Your comment on page 15 that starts on line 6 made me think of something I recently worked out. Consider the case of a one-qubit system in three possible states with an angle of 120 degrees between each pair and the goal being to determine which state as well as possible – is this the example you had in mind?*

If you're thinking 120 degrees in Bloch-sphere space, then yes that was the example I had in mind. On the other hand,

Cleve-ism 3: *I had thought this was a good simple example where one can illustrate how using a POVM is better than using von Neumann measurements (assuming one isn't willing to go into a larger Hilbert space). But it isn't. Instead of using the natural three-element POVM, one can first randomly pick one of three orthogonal bases (120 degrees rotated from each other) and then perform that von Neumann measurement. It turns out that the net result of this process will yield exactly the same information about which of the three states it was as doing the POVM would.*

Well, do you agree? My point here isn't against POVMs; I think there are other examples where one really can do more with a POVM (without enlarging the Hilbert space)

if you were thinking of what I said above, then I'm confident you made a mistake in your calculation. What is unique about the famous three-outcome POVM is that no matter what the outcome, one of the three possible preparations is eliminated, leaving the posterior probability of either of the other two preparations at 1/2. Thus the mutual information gained about the preparation is log(3/2). On the other hand consider the randomized measurement you speak of. First flip a (three-sided) coin, and then do one of the von Neumann measurements. If you get a "no" answer for that two-valued measurement, then you will have indeed eliminated one of the three possible preparations … giving log(3/2) bits. On the other hand, if you get a "yes" answer—which happens some fraction of the time—you will get less than that. For a "yes" does not eliminate any of the three possible preparations. It only makes one of them more likely than the other two.

Does that make sense? (It's a proof that goes back to one of Holevo's 1973 papers.) On the other hand, maybe I didn't really understand the example you had in mind.

Cleve-ism 4: *I am going to stop writing here (being halfway through the paper is a good point to pause) and hope to follow up with more comments (for what they're worth) soon.*

They're worth quite a lot, and I'm very grateful. More important than anything to me is that part of our community start thinking along these lines and make some progress (more than I can make with my feeble mind). If you've got the interest, I've got the enthusiasm!

Richard's Preply

I made it out to ITP where I'll be for the last three weeks. I've been meaning to read your paper for a while and on this quiet – and rainy! – day where I'm experiencing some frustration with a technical problem I decided this was as good a time as any to read and think about `0106166`. Of course, your engaging literary style gives a certain pleasure to the process. Here are some (admittedly brief) comments.

The NATO meeting sounded nice. I agree with you that decoherence doesn't occupy a sacred role in the foundations of quantum information. And – probably not surprisingly for someone with my background – the aspect of quantum mechanics that I also find the most interesting is its underlying information theory.

I recall the table on page 4 from one of your talks and I always find it compelling to see it, seeing the contrast between the two columns. I guess that special relativity is about geometry (more precisely a "generalization of geometry" that includes space and time). The fact that our brains and language are well equipped for spatial concepts, may be a reason why column one can be expressed so eloquently in words in column two.

An analogous table for quantum information would be nice. It is not really about geometry (in spite of geometric structure of Hilbert spaces) but about information theory. (Like many others, I think of quantum information as a "souped-up" version of classical information – i.e., a generalization of classical.) What would the classical information theory version of the table on page 4 look like? Somehow the axioms of probability theory don't come out as crisply in English as those of relativity, do they? On the other hand ... people don't seem to have that much trouble with probability theory. Card players, actuaries, casino managers all seem to do okay, in spite of numerous subtleties and the deep philosophical issues that arise when really thinks about what happens when one, say, flips a coin.

Your comment on page 15 that starts on line 6 made me think of something I recently worked out. Consider the case of a one-qubit system in three possible states with an angle of 120 degrees between each pair and the goal being to determine which state as well as possible – is this the example you had in mind? I had thought this was a good simple example where one can illustrate how using a POVM is better than using von Neumann measurements (assuming one isn't willing to go into a larger Hilbert space). But it isn't. Instead of using the natural three-element POVM, one can first randomly pick one of three orthogonal bases (120 degrees rotated from each other) and then perform that von Neumann measurement. It turns out that the net result of this process will yield exactly the same information about which of the three states it was as doing the POVM would. Well, do you agree? My point here isn't against POVMs; I think there are other examples where one really can do more with a POVM (without enlarging the Hilbert space).

I'm just reading the Bayesian stuff on page 21 and really like the idea – does the analogy really hold in some sort of sense? I am going to stop writing here (being halfway through the paper is a good point to pause) and hope to follow up with more comments (for what they're worth) soon.

26-11-01 *PRA Proofs* (to C. M. Caves & R. Schack)

I'm in the office again finally, and I've read over the PRA proofs. Of course, as always, I can't see that any of their changes were for the betterment of the paper ... but this time at least, none were overly annoying to me.

Here are my notes (which one of you two might want to incorporate into a reply).

1. page 2, "If one accepts this conclusion ... " : Note they take away the "a" in front of the kets. That grammatical change takes away the impression that the final state is unspecified within the set. I vote that we force them to reinstate the "a"s unless you can figure out a smoother way to express the proper idea.

2. page 2, "The physical basis of Einstein's ... " : They changed the end of the sentence to "amenable to experimental testing." That seems odd to me. Should we protest?

3. page 3, "We then use a version of the so-called Dutch-book ... " : They want us to explain "Dutch-book argument." That's pretty stupid, given that they didn't ask us to explain "Bayesian probability theory" or even "Gleason's theorem." We even used the warning sign "so-called." I don't know what more can be said without inserting Section II into the middle of this paragraph. Perhaps you guys have a nicer way to approach it than I would.

4. page 5, "The probability assignment is thus inconsistent ... " : You'll note in the proof that the equation at the end of the sentence is broken at the end of the line in an awful way. Can we ask them to keep it together? Or perhaps we can simply display the equation.

5. page 5, "For example, normalization of the probabilities . . . " : This is not a problem of theirs but a question of mine. We end the sentence with "so obvious that it needs no justification." Do we really need to insert that phrase? I find it a little distracting from the main point of the sentence.

6. page 6, "The keys to these results are . . . " : I would change the very last word to "paragraphs."

7. page 10, "The data gathered from the measurements are said . . . " : What is this, England? "The House of Commons have voted . . . " Horrible. I view "data" as a collective noun.

That's it really.

But let me take this opportunity to give one last ramble from the heart. It has nothing to do with changing the present paper: I just want to say it because it's on my mind again.

After reading the paper once more, I found myself feeling awful again. I don't think there is a reader out there besides Schack and Caves that will come away with the feeling that the Dutch-book argument is *purely* an internal consistency argument (or rationality check). The English in a sentence like,

> Given the assumptions of Gleason's theorem, if a scientist has maximal information, any state assignment that is different from the unique pure state derived in the last paragraph is inconsistent in the Dutch-book sense; i.e., it leads to a sure loss for a bet on the outcome of a measurement on a single system that includes the unique pure state among the outcomes.

is just loaded with imagery. Who out there will read "sure loss" as anything other than a factual state of affairs—something dictated by the world independent of the agent? Who out there will read the word "unique" as really meaning "unique with respect to the agent's belief of certainty"? Who out there will not interpret the phrase "maximal information" in an objectivistic way—i.e., that there is one and only one way to have maximal information? Or here's a better acid test: If a reader were to be confronted with our paper in its present form at the same time as the BFM paper, would he be able to see any philosophical differences in the approaches of the two papers? I can't imagine it. All that troubles me very deeply: A small change of language really could have made all the difference in the world.

29-11-01 *Observation* (to J. M. Renes)

Renesism 4: *Here's some stuff relating to what I wrote the other day from "The Taboo of Subjectivity" by B. Alan Wallace:*

> The disdain of scientific materialism for subjectivity has also shaped the very concept of scientific observation. While nonscientific kinds of observation also detect phenomena—such as our joys and sorrows, hopes and fears, ideas and inspirations—they are thought to be tainted by human subjectivity and are therefore suspect. From the perspective of scientific materialism, human sensory perception may be deemed not only unreliable but irrelevant. For a scientific observation to take place, all that is required is a detector, or receptor. The human eye is one type of receptor, which detects a certain range of electromagnetic frequencies, but other instruments also measure this and other types of information, and they are regarded as more reliable.

> In common parlance, for an observation to take place, the received information must be transformed into humanly accessible information that is, sooner or later, perceived and understood by a human being. But according to scientific materialism, *observation* is assimilated into the general category of *interactions*, thereby freeing it from the subjectivity of its normal associations. This interpretation is said to be central to grasping what is involved in scientific objectivity in the search for knowledge and the justification of belief.

[reference to Dudley Shapere "The Concept of Observation in Science and Philosophy," Philosophy of Science **49** *No. 4, 1982, pg 485.]*

Beautiful quotes! Do you have the whole Shapere article? Do you know whether he is for or against that conception of observation (i.e., as interaction)? If you do have the article, could you make a copy and send it to me? And what about the Wallace thing—is that a book or an article? How is it?

29-11-01 *Observation, 2* (to J. M. Renes)

Renesism 5: *As for Wallace, it's a book — pretty good so far. He's arguing that "scientific materialism" (i.e. the way someone like Feynman thinks of the world) is a bit like its own religion, with a major piece of dogma being the exclusion of subjectivity from consideration.*

Aha. Have a look at William James's essay "The Sentiment of Rationality" (in most any collection of his essays) if you get a chance. He also argues (for what amounts to) what you said above.

I'll try to see if I can find the Wallace book up here.

29-11-01 *Community* (to W. K. Wootters)

What a beautiful letter; thank you.

In a way, I've been going to my own seminar on science and religion lately—but with me, through my reading choices. I've gotten stuck on the "pragmatism" movement, predominantly William James's version. I had never realized before what a wealth of material was there (for the kinds of thoughts I'd like to think, about quantum mechanics in particular). Nor had I realized how Wheeleresque and Woottersesque James was in his outlook—hanging so much on the idea that the universe is (in part) a product of our collective experience.

In that regard, but with respect to religion, I have never been so impressed by the possibility—necessity even—of "faith" than when I read James's articles "The Sentiment of Rationality" and "The Dilemma of Determinism." They have made a huge effect on me. If you happen to read them and have any reaction, I would love to hear your thoughts. (For fun I just had a look at the Williams College library; you guys have a collection of 63 items penned by James! In contrast, not one hit in the Bell Labs library … but who would have guessed otherwise.)

I sympathize with your unease with telepathy. Here's how Stephen Brush put it:

> 'Wheeler's dilemma' is this: how can one maintain a strong version of the Copenhagen Interpretation, in which the observer is inextricably entangled with that which is observed, while at the same time denying that our consciousness affects that which we are conscious of—and thus accepting the possibility of telekinesis and other psychic

effects? For Wheeler himself there is no dilemma at all; one simply has to recognize 'the clear distinction between (1) the strange but well verified and repeatable features of quantum mechanics and (2) the pseudo-scientific, non-repeatable and non-verified so-called extra sensory perception.' But Wheeler's own views are likely to strike a non-physicist as being just as bizarre as those of the parapsychologists he deplores. Indeed, no one has yet formulated a consistent worldview that incorporates the Copenhagen Interpretation of Quantum Mechanics while excluding what most scientists would call pseudo-sciences—astrology, parapsychology, creationism, and thousands of other cults and doctrines.

The issue whether there is something besides unitarity—whether it can ever "breakdown" as you put it—is acute, but I think a lot of the problem hinges on how one views unitarity's status in a physical theory. I am inclined to believe that unitarity—or more generally "trace-preserving complete positivity"—does not breakdown either. But that is because I am inclined to view the time-evolution mapping one ascribes to a system as an epistemological entity (rather than an ontological one), much as I view the quantum state one assigns the same system. That is to say, I am struck that there is a deep reason one can make a bijective correspondence between the completely positive maps on one Hilbert space and the density operators in a larger space, a reason that has nothing to do with imagining ancillary systems: A CP map *is* a density operator, it is a state of knowledge in just the same way any other quantum state is.

There are other (peculiarly quantum) reasons for saying what I just did above, but it is also part of a larger program I have in mind (and one I think James had in mind too)—namely, to find a little slippage between the notion of a physical theory and the world itself. Below I'll quote a little piece I wrote to Carl Caves on the idea. It gets at the sentiment, even if not at the technical details! [See 04 October 2001 note to Caves-Schack, "Replies on Pots and Kettles".]

30-11-01 *Ramsey Theory* (to W. K. Wootters)

Just a small note. I want to bring up a reference that may or may not be relevant to thinking about your toy graph model—it's something I just learned about last week, called Ramsey Theory. Here's an example, "In any collection of six people either three of them mutually know each other or three of them mutually do not know each other." And more generally, "Every system of a certain class possesses a large subsystem with a higher degree of organization than the original." It's a subfield of graph theory, quite developed, with loads of examples like that.

Anyway, for what it's worth, I was told that the following is a good starter reference:

> Ronald L. Graham, Bruce L. Rothschild, and Joel H. Spence, *Ramsey Theory*, second edition (John Wiley and Sons, New York, 1990).

30-11-01 *Some Thoughts on Your Paper(s)* (to K. Svozil)

Svozilism 1: *I would kindly like to ask two questions:*

(i) are the Bayesian consistency requirement in any way related to Boole's "conditions of possible classical experience" (which have been interpreted by Pitowsky in terms of the faces of classical correlation polytopes)?

(ii) have you ever attempted to apply the methods to "exotic" but non-quantum event structures? It might at least be pedagogically helpful to consider such cases.

Thanks for your letter. You ask two good questions, and unfortunately I don't know the answer to either one! I will however have a good look at your papers and start thinking about them.

I think the Dutch-book argument for probabilities is not so strongly tied to the Boolean structure of propositions (as, say, Cox's argument for the probability axioms is). For instance, just look at Eqs. (1) and (2) in our paper. It seems to me that that part of the argument does not care one iota whether there is a distributive law for this event structure or not. If that's the case throughout the remainder of the Dutch-book mechanics, then maybe this is an important point.

30-11-01 *Later in the Book* (to J. M. Renes)

More great quotes! Keep 'em coming (as you like).

Joe's Preply

Wallace says

> James's philosophy of radical empiricism rejects the absolute duality of mind and matter in favor of a world of experience, in which consciousness *as an entity*, in and of itself, does not exist; nor is it a function of matter, for matter *as an entity* in and of itself, does not exist either. According to this view, the postulation of mental and physical substances is a conceptual construct, as is the metaphysical distinction between subject and object. Mind and matter are constructs, whereas pure experience, which is neutral between the two, is primordial. One implication of the hypothesis that we are directly acquainted with reality is that the contents of consciousness can no longer be regarded as being "in the mind" (let alone in the brain). Reality just *is* the flux of experience.

So my thoughts on this subject aren't very original! But to be in such company is far better. Wallace goes on to laud James some more, but does mention some work of Hilary Putnam:

> If all valid statements concerning the world of human experience have both a conventional and a factual element, it follows that the referents of language are also inseparable fusions of convention and reality. Thus, the existence of a concrete object like a tree is also a matter of convention, and our observation of a tree is possible only in dependence on a conceptual scheme. The reason for this, according to Putnam, is that 'elements of what we call "language" or "mind" penetrate so deeply into what we call "reality" that the very project of representing ourselves as being "mappers" of something "language-independent" is fatally compromised from the very start.' [from Putnam, *Realism with a Human Face* 1990]

This ending quote from Putnam reminds me a lot of the squabbles about the wavefunction and density matrix.

Okay, can't stop quoting.

> Once we have chosen a conceptual scheme, there are facts to be discovered and not legislated by our language or concepts. Our conceptual scheme restricts the range of descriptions available to us, but it does not predetermine the answers to our questions. As Putnam comments,

> "The stars are indeed independent of our minds in the sense of being causally independent; we did not make the stars ... The fact that there is no one metaphysically privileged description of the universe does not mean that the universe depends on our minds."
>
> On the other hand, if there were no language users, there would not be anything true or anything with sense or reference. Thus, the rich and ever-growing collection of truths about the world is the product of the experienced world, with language users playing a creative role in the process of production.

04-12-01 *The Power of Advertising* (to A. Peres & D. R. Terno)

Actually, reading over this again from your upcoming paper,

> The root of the difficulty we have to transform quantum expressions from one Lorentz frame to the other is that the process called "quantum measurement" is an intervention in the quantum dynamics by an "exosystem" [finkel], namely by an apparatus which is not completely described by the quantum formalism [interv].

I wonder if I can ask a favor of you? In my own paper,

- C. A. Fuchs, "Quantum Foundations in the Light of Quantum Information," to appear in *Proceedings of the NATO Advanced Research Workshop on Decoherence and its Implications in Quantum Computation and Information Transfer*, edited by A. Gonis (Plenum Press, NY, 2001 or 2002). (Until then, see `quant-ph/0106166`.)

I go to great lengths to try to explain why the term "intervention" is a better one than "measurement," and I try hard to promote its more frequent use in future dialogues on the subject. Of course, I cite Asher for the original introduction of the term in that. Nevertheless, might I ask you guys to cite this also? Certainly feel free to ignore this request as you wish: It just struck me that I might increase my readership if I happened to get a citation from you!

05-12-01 *Yep* (to R. Pike)

Regarding "Challenging Particle Physics as Path to Truth" by George Johnson in yesterday's *New York Times*:

`http://www.nytimes.com/2001/12/04/science/physical/04SQUA.html`.

Yep, you know the anti-unificationists have my sympathy.

05-12-01 *Dear Prudence* (to C. M. Caves & R. Schack)

Fellow Bayesians,

(Let's see if Carl's knowledge of 1960s music can help him guess the origin of this note's title.)

Anyway, to the real subject. Dutch-book coherence? Dutch-book consistency? Neither of them seem to be an accurate account of what's going on with the theorem. I know neither one of you will accept it, but I think "prudence" gets significantly closer to the mark.

- **Consistent** – 1. In agreement; compatible: "The testimony was consistent with the known facts." 2. Being in agreement with itself; coherent and uniform: "a consistent pattern of behavior." 3. Reliable; steady: "demonstrated a consistent ability to impress the critics." 4. In mathematics, having at least one common solution, as of two or more equations or inequalities.

- **Coherence** – 1. The quality or state of cohering, especially a logical, orderly, and aesthetically consistent relationship of parts. 2. In physics, the property of being coherent, as of waves.

- **Prudent** – 1. Wise in handling practical matters; exercising good judgment or common sense. 2. Careful in regard to one's own interests; provident. 3. Careful about one's conduct; circumspect.

- **Prudence** – 1. The state, quality, or fact of being prudent. 2. Careful management; economy.

How did Mermin's talk go? How did Rüdiger's talk go?

05-12-01 *Lucky Seven* (to B. W. Schumacher)

5) I was a little disappointed to learn from your prospectus that you'll be going to Caltech for your sabbatical, but on the other hand I can easily imagine several reason's why that's the best choice for you. Still, I'm going to miss having you around ... as will all the other guys in Bell Labs and the Bell Labs metro area, Charlie Bennett, David DiVincenzo, Steven van Enk, Danny Greenberger, Lov Grover, Mark Hillery, Alexander Holevo, Debbie Leung, Eric Rains, Terry Rudolph, Peter Shor, Dick Slusher, John Smolin, Barbara Terhal, Bill Wootters, and so forth. ☹

6) You know I'm always scheming, and this is one of the latest ones. Actually it's an older one, but revived with a new head of steam. Jeff Bub and I have decided to edit a special issue of *Studies in the History and Philosophy of Modern Physics* (SHPMP) on ... (you can guess) "Quantum Foundations in the Light of Quantum Information." But there are two things going on with this: 1) We pretty much want to get it done and published *before* the Montréal meeting, and 2) we really only want to go through with it if we can get commitments for some really good papers. Jeff wrote this in one of our emails:

Bubism 1: *We'd really have to think hard about how to ensure that the authors all deal with some conceptual or foundational question relevant to quantum information in a philosophically serious way. We want to avoid the issue just being 'intro to quantum information for non-specialists,' with some anecdotal interpretative comments as a nod to philosophy. And it also shouldn't just be a forum for one point of view.*

The difficulty, of course, is that very few philosophers have actually worked in this field. So we have to rely mostly or perhaps entirely on scientists for the papers. It will be hard getting papers from physicists and computer scientists for a philosophy journal. On the plus side, it does seem to be the case that some people working in quantum information have thought hard about the relevance of their research for foundational questions. Somehow, we have to motivate people to take it as a worthwhile and exciting challenge to write a paper that tackles a philosophical issue in an intellectually disciplined way — as intellectually disciplined as these authors invariably are when they write a technical scientific paper. Too often, all analytical controls seem to be switched off when scientists venture into philosophical terrain.

We've already gotten a commitment from Andrew Steane to beef up his "quantum computing needs only one universe" paper for it. Moreover, I know that you're also capable to the task, and already somewhat semi-committed to a paper on "doubting Everett." So I'm hoping I can get an official nod from you in the YES direction. If I can secure that, then I think I can make a weighty case to Charlie Bennett to record (more importantly defend) his thoughts on why he thinks Everett provides an adequate and conceptually simpler picture of quantum foundations than some other interpretive attempts.

Then beyond that I'm hoping to get some papers from *possibly* Jozsa, Caves & Schack, Mermin, Wootters, and maybe a couple of others (and Bub and myself of course). That's already more than enough.

Once I hear from you and Charlie, then Jeff and I will kick into "phase two" of our baiting, i.e., getting the other guys to say yes to getting a paper in before next summer.

7) I really loved the "How does it know?" story in your prospectus! Let me give you two stories from my Samizdat in connection to that below. Knowing and flying: the two questions might be a little bit of the same thing.

> **From a 17 December 1997 note to G. L. Comer, "It's a Wonderful Life"**
>
> Good holidays to you. This morning, as I was driving to work, it dawned on me that roughly this day 10 years ago, I was conferred my degrees at the University of Texas. Time does fly.
>
> It made me think of a little anecdote about John Wheeler that I heard from John Preskill a few days ago. In 1972 he had Wheeler for his freshman classical mechanics course at Princeton. One day Wheeler had each student write all the equations of physics s/he knew on a single sheet of paper. He gathered the papers up and placed them all side-by-side on the stage at the front of the classroom. Finally, he looked out at the students and said, "These pages likely contain all the fundamental equations we know of physics. They encapsulate all that's known of the world." Then he looked at the papers and said, "Now fly!" Nothing happened. He looked out at the audience, then at the papers, raised his hands high, and commanded, "Fly!" Everyone was silent, thinking this guy had gone off his rocker. Wheeler said, "You see, these equations can't fly. But our universe flies. We're still missing the single, simple ingredient that makes it all fly."
>
> Merry Christmas.
>
> **From a 02 December 1997 note to J. Preskill, "Flying Equations"**
>
> I couldn't help but think of the anecdote about John Wheeler's (non-)flying equations you told the other day when I came across the following little passage (presumably Biblical in origin):
>
>> "I forbade any simulacrum in the temples because the divinity that breathes life into nature cannot be represented."

06-12-01 *Baudrillard Maybe?* (to B. W. Schumacher)

Schumacherism 2: *I certainly loved the samizdat stories you included. Where did the second quotation, the one about "the divinity that breathes life into nature", come from? What a counterpoint to Wheeler's futile "Fly!"*

That's a good question; I really don't know anymore. Looking further through the Samizdat I see that I reported reading Jean Baudrillard on November 23. And I sort of faintly remember learning the word "simulacrum" from whatever book that was. So, I'd bet it was from there.

Schumacherism 3: *Well, yes, dammit. I owe you this paper. At this moment Mike W. and I are finishing off a paper on approximate error correction, but I will try to get something down afterwards. [...] We have also promised a paper to Mary Beth Ruskai for JMP. [...] But I owe you longer; I will put together a very rough draft over the vacation, and run it past you — I'd much value your comments.*

That's great!!! I'll inform Jeff Bub, and move to Phase 1.5 — i.e., coercing Bennett. Wish me some success there; it's gonna take a lot of work to loosen him up.

06-12-01 *Investigative Reporting* (to B. W. Schumacher)

It looks like Baudrillard was the right path. I just got on `altavista.com` and did a search on simulacrum, Baudrillard, and divinity. And I found the following:

> Baudrillard has interesting views on the nature of postmodern nihilism. In Simulacra and Simulation, he begins his discussion on the precession of simulacra by describing what he calls the "simulacra of divinity." He points out that "divinity that animates nature can never be represented" (p. 4). The idea of God embodied within religious icons and iconography is a complex system of human belief, in which the visible is supposed to evoke the religious all-being, the divine-referential. Yet when God's omnipotence and presence can only be felt through these icons, it is becomes probable that the existence of God is questioned, if the simulacra of divinity becomes the only visible image of God's presence.

Then I found an exact replica of the quote in someone's class notes about Baudrillard. So, I'm sure I got it from him.

So the question now is where did Baudrillard steal the quote from?

07-12-01 *A Sinking Ship?* (to C. M. Caves & R. Schack)

Fellow Bayesians,

Especially in light of what Carl wrote me yesterday, perhaps you should both have a serious look at Gavriel Segre's Ph.D. Thesis at `quant-ph/0110018`. Van Enk pointed it out to me this morning, and believe me it'll be worth your time! In particular, pay attention to Theorem 5.2.21 "Impossibility of a Subjectivistic Bayesian Foundation of Quantum Probability Theory" on page 193. Maybe we ought to get off this ship before it sinks?

Also, make sure you don't miss reading his acknowledgments on page 5. This is surely the best quote I've ever seen on `quant-ph`!

07-12-01 *A Sinking Ship?, 2* (to C. M. Caves & R. Schack)

Schackcosm 53: *Are you serious? Of course, the thought has crossed my mind.*

The sinking ship remark was a joke. The reference to the (unaccepted) thesis was a scoff (or at least a little). You did read the "acknowledgment" of the thesis, didn't you? Also look at the other contents of the "thesis."

I have never been more confident about anything scientifically than that we are on the right track in our quantum Bayesianism. No Bayesian that I've ever read called a probability assignment a "state of knowledge." What's different about quantum states? Why should they be above the "degree of belief" that every classical assignment is? Taking the "state of belief" appellation seriously is simply the cross we have to bear ... at least as I see it. (Sorry for the Christian motif, Carl.) But I'm also confident that it's not that bad anyway; it's just a question of packaging.

10-12-01 *Lost It* (to C. M. Caves)

I'll try to get in touch with you later today. Sorry we missed each other over the weekend.

Cavesism 53: *I managed to lose your last e-mail, where you expressed the view that no Bayesian views a probability as based on a state of knowledge. In the absence of your full statement, here's a thought on that point.*

I don't balk against "facts" having a say in determining probability assignments. I balk against "facts" *uniquely* determining them.

10-12-01 *The Spirit of Gandhi* (to N. D. Mermin)

Well, you took away some of my fun with the letter you just sent me! Over the weekend, I ran across your talk at the ITP and listened and watched the whole thing: In fact, I was going to send you some direct comments on it. Now some of my steam is taken away.

Still, let me gingerly point out some things I had wanted to point out earlier ... even if they may not be quite as relevant anymore.

Somewhere around 36 minutes into the talk—actually it was in your reply to a question (which sounded to come from Jeff Kimble)—you said:

Merminition 77: *Our presentation, at least in the paper we submitted on the web, can be read as being tinged with a view that quantum states are more than a reflection of knowledge ...*

the implication seeming to be that in the present talk you strove to get around that.

However, at 23 minutes into the talk you said this:

Merminition 78: *Of course there's the question of what it means for the combined knowledge of all observers to constitute a consistent body of knowledge about S, which is an interesting question. I'm taking a kind of dumb-physicist view, which is that there should be—at least in principle—there should be one observer who has a lot of data about various measurements and mutually commuting observables made on. The observer having access to all the data will realize that if ...*

I know I have said all this before, but let me "focus in" on these two passages and try to say it again (per your warning about me "focusing out" too often). I would say that what you said in the second passage has nothing to do with it being a "dumb-physicist view" of things. It is, however, the sine qua non of a view "tinged" with making the quantum state more than a simple epistemic entity. For it in essence says, there *should be* (your words) a "right" quantum state, or a range of "right" quantum states, and that has nothing to do with any *actually existent* observers.

Please do think about the similarities between your "dumb-physicist view" and the old limerick:

> There was a young man who said, "God
> Must think it exceedingly odd
> If he finds that this tree
> Continues to be
> When there's no one about in the Quad."
>
> REPLY
>
> Dear Sir:
>
> Your astonishment's odd:
> I am always about in the Quad.
> And that's why the tree
> Will continue to be,
> Since observed by
>
> Yours faithfully, God.

I would say that in supposing THERE SHOULD BE a superobserver, you are supposing that the quantum state should—in essence—already be there without any observer at all. When Bishop Berkeley ran into trouble with the question of where the trees go when there's no observer, he invoked the idea that God was there all along. Your superobserver is in essence a God, who—through his own objectivity—re-endows the quantum state with an objectivity I THOUGHT you were trying to get rid of in the first place.

But maybe that was never your goal.

Martin Gardner said something very clear in this regard in his essay "Why I Am Not a Solipsist," and so let me quote it:

> In this book I use the term "realism" in the broad sense of a belief in the reality of something (the nature of which we leave in limbo) that is behind the phaneron, and which generates the phaneron and its weird regularities. This something is independent of human minds in the sense that it existed before there were human minds, and would exist if the human race vanished. I am not here concerned with realism as a view opposed to idealism, or realism in the Platonic sense of a view opposed to nominalism or conceptualism. As I shall use the word it is clear that even Berkeley and Royce were realists. The term of contrast is not "idealism" but "subjectivism."

(The phaneron, by the way, was C. S. Peirce's term for "the world of our experience—the totality of all we see, hear, taste, touch, feel, and smell.")

If I were to give the BFM paper and your quest to make sense of Peierls (and Bohr and Heisenberg, as evidenced by your talk) a reading, I would say that what you are trying to do is give the quantum state an idealistic interpretation (via the word "knowledge") and thinking that that somehow contrasts with a realistic interpretation (and in doing so might fix everything up quantum interpretation-wise). But—in analogy to Gardner—for me, "realistic" and "idealistic" interpretations of the quantum state amount to the same thing. What I'm worried about is whether one can make any sense of the quantum state at all without simultaneously positing the active agent who makes use of it—I would claim you can't. And thus I'm left with the kind of "subjectivism" (for the quantum state) that frightens so many people.

PS. In case you're wondering why I titled this note "The Spirit of Gandhi," it is because I am hoping you will think of it as a form of nonviolent protest. Too many times in your talk you pointed out what a violent reaction I had to the BFM result, and I just can't think that that helped my reputation as a rational thinker or the seriousness with which a Bayesian-kind of quantum-foundation attempt should be viewed. (But I love you just as much as ever—maybe more with all the advertising you gave me—and there are no grudges.)

10-12-01 *Trumps and Triumphs* (to N. D. Mermin)

Also,

Merminition 79: *I did urge Carl and Rüdiger to do something about the phrase (in your other paper) "Gleason's theorem is the greatest triumph of Bayesian reasoning" which I read as a claim that Bayesian reasoning is the only way (or at least far and away the best way) to derive and understand Gleason's theorem. They explained that what you really meant was that Gleason's theorem, by providing stringent constraints on possible prior distributions, provided a powerful tool for Bayesian reasoning. But I think they did an inadequate job of removing the ambiguity, which is too bad, since I am rather sure it will put off most of the people you ought to be addressing.*

I'm glad you urged them. Here's what I had said to Carl and Rüdiger in a September 20 note:

> Another thing I guess I really didn't like—and this is only a new one for me, it's not something that had eaten away at me before—is the slogan "Gleason's theorem can be regarded as the greatest triumph of Bayesian reasoning." To say that is to imply that Bayesian reasoning IMPLIES Gleason's theorem. I don't think you mean that. I think what you mean is that it is one of the most valuable additions to Bayesian reasoning ever. But I won't cause trouble here: I know you both like the saying.

But they generally just view me as a trouble-maker.

10-12-01 *Reread (pronounced re-red)* (to N. D. Mermin)

I'm just reading through all my emails of the day again.

Merminition 80: *P.S. Spent a lot of time talking with Carl and Rüdiger in SB, which I enjoyed very much. I think the first half of your draft joint paper formulates the basis for the "necessary" condition of BFM much more coherently than we did: i.e. it is necessary if there is to be any density matrix that does not contradict anybody's strongly held beliefs. Much better than talking about "subsets of a body of data that anybody with access to all of which would agree constitutes nothing but valid results of measurements, none of which invalidate earlier measurement outcomes. . . ." It's hard even to put into a grammatical sentence. The other four cases strike me as interesting extensions of the case we (and Peierls) were addressing, which concerned existing knowledge prior to any subsequent interventions. My feeling was that there was no serious disagreement among the three of us, but maybe they will give you different reports.*

Thanks, that's a very nice compliment. Here's another way to put it, which might be my preferred way. Suppose two strongly consistent agents want to stand a chance of coming to agreement, just by talking to each other. Then BFM is the necessary condition. If it is not satisfied, then the only way they will ever get anywhere is by "consulting" the system with a (mutually agreed upon) measurement: With it, they can bend the world into something more congenial to both.

10-12-01 *Peace Pipe* (to T. Rudolph)

Thanks for the peace pipe.

I have seen the paper by Fivel before. We discussed it at a Maryland conference once. It somehow doesn't have the right flavor for what I've been seeking though: In the end, I want to find a kind of quantum ontology I can be happy with, not just something that feels more like a propositional calculus. But it's a little like the debate about art versus porn: You kind of only know porn when you see it. And I'm looking for porn.

Rudolphism 1: *But as I said its just an attempt to get something going, and I'm completely open to any suggestions you have – in particular I'd like to read any papers that you're thinking a lot about at the moment ...*

Are you kidding, I never read any papers any more! I'm becoming a bit solipsistic. But let me substitute this instead. Below I'll attach my notes on the big phase transition I've made from "knowledge" to "belief" for my view of the quantum state. If you need more of a context, first read the Brun-Finkelstein-Mermin paper on `quant-ph`. I start up with criticism on that at about page 19, and then it goes pretty thick into it thereafter. After October 9, Caves, Schack, and I started to work to turn a lot of that into a more technical argument: we're hoping to finish the paper by the end of the week and post it soon thereafter. (It stands at 14 pages at the moment.)

Anyway, the more radical stuff in those notes leads very quickly to some meaty technical questions. For instance, what does it mean to be an "unknown" quantum operation? It suggests a de Finetti theorem for completely positive maps, for instance, which Schack and I are working on in our spare time.

10-12-01 *Big Dreams* (to G. Brassard)

Brassardisme 3: *I've been talking around about our little dream of founding quantum mechanics on information theory. The more I talk about it to various people, the more I realize this is the only scientific topic that really excites me at this time. And the more I am sorry that I'm not doing anything about it.*

By the way, thank you for the very touching note. You are misplaced, however, in saying, "I am sorry that I'm not doing anything about it." At the very least, you are doing loads about it by organizing these meetings in Montréal!

The truth of the matter is, just like you, nothing excites me more. We're gonna prevail eventually. In fact, at the very moment, I'm writing another (pleading) paper titled "Quantum Mechanics as Quantum Information" (for the Växjö proceedings). For your private fun—but please do keep it private—I'll attach a new mini-samizdat I've recently put together with some of my latest musings. (It's probably hard to tell from it, but it has given rise to some new good theorems, that will be coming out soon in a paper with Caves and Schack.)

14-12-01 *Strong Consistency* (to C. M. Caves & R. Schack)

I know that I'm terribly slow to be coming up to speed on this project. But now I have another possibly frivolous question.

What was the origin of strong consistency? What motivated Rüdiger to invent the concept? And indeed, did either of you ever find it appearing in the literature otherwise? It, of course, has a very different flavor than normal Dutch-book—I know that's no surprise to you—but for me, for the moment anyway, it seems to me to be introduced more for mathematical nicety than anything else. (I.e., It seems more to be introduced just for the purpose of cleaning things up a bit axiom-wise.) It doesn't have the same operational/pragmatic flair that the rest of Dutch book has.

Indeed, it might be useful to lay this sort of issue on the line in the paper.

I can think of at least one case where one would never want to enforce strong consistency, namely for infinite event spaces. Consider an infinite number of draws from an i.i.d. distribution. One has that the probability of a typical sequence is one; however one should never then say that that implies the bettor believes a typical sequence will occur with certainty.

Reading ever so slowly (but I hope thoroughly),

15-12-01 *Bah, Humbug* (to C. M. Caves)

Humbug. Did I ever tell you I hate Christmas: It's the most intrusive holiday I know of, with people pushing me all over with obligations that they've invented for me. (Susie, Kiki's mom, arrived yesterday, by the way.) Now Thanksgiving, that's my favorite holiday: you cook, you eat, you watch a parade, and you end up rubbing your belly in a deep soporific ecstasy.

By the way, speaking of rubbing bellies, Kiki went into false labor last night. At first, when it was over, I thought, "Thank God it's false." But now, in the light of the morning, I'm thinking, "When are we ever going to get this over with?"

Cavesism 54: *There is evidence that it's out there in the literature (Sklar mentions it without any references), but we haven't dug up any references. In fact, Rüdiger and I had the impression that you might know where to find references.*

This is one of my biggest gripes about not being in a university. I don't have easy access to anything outside of the physics and mathematics journals. (In fact strangely, last night I dreamed that I was back at the University of Texas, surrounded by books, books, books on all subjects, and I was telling myself how glad I was to be back.)

Did you have a look at the Kemeny and Lehman references I recommended in an October 27 note? That at least would be my starting point. Also Bernardo and Smith, as I recall, had a lot of references on Dutch-book—in particular a lot of references dissatisfied with the argument (as Bernardo and Smith, in fact, are).

Cavesism 55: *I don't know about the flair point. I'll grant that strong consistency isn't as compelling as ordinary consistency, but it still registers on the flair scale: in a single trial, you never win, but definitely sometimes lose. Moreover—and this is the crucial point—strong consistency is absolutely essential so that probability assignments and density operators incorporate sufficient information about one's beliefs that one can use them as surrogates for the beliefs in our arguments.*

I wouldn't say that it's not "as compelling", it's just of a different flavor. To say that it's not as compelling, means it's directly comparable to the Dutch-book argument. But it's not clear to me that it is. Presently it seems to me much more like a Cox kind of thing. It says (at least in one case) my outward commitment *must* reflect my internal belief—not because I will be imprudent if I don't do so, but because I don't want my friends to see any discrepancy between my beliefs and my actions.

I believe I understand what you call the "crucial point." But I'm guessing—just a psychological point—you're more attracted to it, because it gives rise to (a better version of) the BFM statement.

Thus it gives the impression of giving something very solid. Whereas simple Dutch book lets everything fly in the wind—maybe that's the very thing I'm attracted to it.

In any case, I don't see anything wrong with exploring what strong consistency leads to. I'm just trying to get it straight in my head—and possibly also for the reader—what it's all about.

Cavesism 56: *Chris said, "Indeed, it might be useful to lay this sort of issue on the line in the paper."*

Perhaps you could be more specific. It seems to me that it is pretty well laid out in the paper, but you're looking at it with a fresh eye, so suggestions are welcome.

I'm sorry, I don't quite know how to be more specific right now. Maybe I would just like the reader to see more of the debate about it. And it should come across that it is (possibly) an invention of C and S, not de Finetti or Ramsey.

Cavesism 57: *You're absolutely right here: probability 1 cannot mean certainty and probability 0 cannot mean impossibility in the limit of an infinite number of draws from an i.i.d., but it's not clear to me that the problem is strong consistency. To apply probabilities to infinite sets, you need countable additivity for exclusive events, which doesn't follow from the finite additivity given by the Dutch book. To apply probabilities to continuous sets requires measure theory. These things are additional mathematical structure beyond what the Dutch book can provide. Perhaps the best philosophy is Rüdiger's: probabilities really apply only to finite sets of events; the generalization to infinite sets is an idealization, where additional mathematical structure is added to make things work nicely.*

Point well taken. But on the other hand, I'm still not convinced either. I think all three of us are aligned that the only thing really worth considering, conceptual-wise that is, are finite event spaces. However, it still strikes me as a chink in the armor that I can think of a limiting case where I would not want probability $1-\epsilon$ to have anything to do with internal certainty. That is to say, maybe there's a deep reason that Dutch-book consistency is NOT strong consistency ... and maybe we're missing something by plastering over its unsightliness so quickly.

Cavesism 58: *Let me know if you have specific recommendations. Rüdiger and I have agreed on a number of changes in presentation and a large number of additions on the POVM front. I will be attempting to incorporate these this weekend.*

I'm trying my best in the light of the present events. (But I'm sure you're not holding your breath for me.) The main thing I'm shooting for now, is to make sure I understand every aspect of the paper—in a defendable way, that is—before Mermin arrives Tuesday.

Did, by the way, you understand my issues with the *sufficiency* of the det $= 0$ conditions? Was I missing something?

15-12-01 *One So Far* (to C. M. Caves)

Just looking at the end of Section III, I was reminded that BFM posted their final version of the paper on `quant-ph` this week. So, they have made some changes. It might be worthwhile to check that they didn't sneak in too drastically different a formulation of the question.

Also, there you (or Rüdiger) write, "In contrast, our derivation is couched wholly in terms of the beliefs of the parties and does not appeal to a real state of affairs; it is therefore preferable in a Bayesian approach to quantum mechanics." I'm not sure—at least as hinted by the present structure of the manuscript—that any nonBayesian will have a clue why it's a preferable statement of the problem. "What's wrong with letting the quantum state reflect an objective fact, that what cannot happen cannot happen?," the reader might ask. "Aren't these CFS guys just paining over inconsequential points?"

Personally, I would like to see some discussion, perhaps in the introduction or in Section III, along the lines of those Bernardo and Smith quotes that I like so much. I'll place them below in case you forgot. I think they give the whole motivation for the work.

Finally, the present manuscript gives pretty short shrift to the Peierlsian ideas that got David's blood up in the first place. Nor do we say much about the apparent inconsistency between the goals and the "solution" of BFM in relation to the Peierls quest.

17-12-01 *Births and Mermins* (to R. Pike & S. J. van Enk)

Well, Kiki informed me a little while ago (it's 3:00 AM now) that she's been in labor since about 9:00 PM last night. So, I'm guessing—it's just a guess—I won't be in tomorrow. (That's a joke.)

I'm hoping you two can hold down the quantum fort while I'm away. In particular, David Mermin should be showing up Tuesday between 2:00 and 2:30. If by wild chance I'm not there—though really I have every plan to be—can one of you escort him around, make sure that he gets to his talk, and then make sure he gets to his room at the Turkey Hill Inn? (And criticize his paper a little bit while you're at it.)

But I think that'll be an utter emergency: this baby should certainly be born before today is out. In particular, I'm planning to be at Bell Labs by 1:00 on Mermin day (Tuesday).

Mermin will be coming to Bell Labs directly from a meeting at Rutgers in New Brunswick. For the heck of it, let me give you his contact number through Tuesday morning: New Brunswick Hyatt, 732-873-1234. But as I say, I should be at Bell Labs before his arrival.

Oh, and I'll cc this note to Caves and Schack so they'll understand why I might be silent on their latest draft.

19-12-01 *Katie Viola Fuchs* (to the world)

Dear Family, Friends, and Colleagues,

Katherine Viola Fuchs came to the world with Monday's sunrise, 17 December 2001. She was 8 pounds, 19.5 inches, and a delight to her parents' eyes—she is beautiful in every way. And like her big sister Emma, Katie has already made it clear that the future will not just unfold before her, but be made in crucial part by her presence and will.

With the greatest of expectations (and a modicum of pride), we send greetings to everyone on Katie's behalf.

Chris, Kiki, and Emma Fuchs

20-12-01 *Even Less Important* (to B. W. Schumacher)

Schumacherism 4: *Mike W. and I just posted the paper I mentioned to you about approximate error correction. (It ought to appear tomorrow at* `quant-ph/0112106`*.) This is not earth-shaking stuff, but it does mean that I can start working on the "Doubting Everett" paper next.*

That's great news, both about your paper with Mike and your "continuing doubt." Jeff Bub and I have just started to firm up the plans for the special issue. I'll let him know that we can count on you.

Schumacherism 5: *By the way, I did mention that we could bring you here to give a talk. [...] It turns out we have some open dates in late January and early February, too. Not that you should drop everything and come amuse undergraduates [...] but if you'd like to come, we'd be delighted to have you.*

Let's think of February as a possibility (but not too firm of one). What would be the latest date I can give you a firm decision? It would certainly be great to get a chance to talk a bit: I've recently made a further, more radical, Bayesian transition (and believe it or not, have had to drag Carl and Rüdiger kicking and screaming into it with me), and I'd like to test it out on as many moderately-sympathetic people as possible before opening my mouth to the general public.

23-12-01 *Princeton and the Bud of Bayesianism* (to J. N. Butterfield)

Thanks so much for the Italian lesson!

The last time we met, you mentioned something about a meeting in Princeton that you were organizing with Bas van Fraassen. Can you remind me of when it will be, so I can get it onto my calendar? Will it be a general philosophy of science meeting, or just something devoted to quantum mechanics? If it's the former, and you don't mind, I would like to bring a local friend-of-the-family with me while I attend. He has a Ph. D. in philosophy from Washington University in St. Louis and is a philosopher of mind and a cognitive scientist; he teaches at a small college nearby (can't remember the name). So, if the meeting is a general one, he'd fit right in, and I would certainly enjoy his company both there and on the drive over, etc.

I sure wish we could get together more often and talk. I very much enjoyed and appreciated your knowledge of *both* de Finetti's and Lewis's ideas. I believe I've made substantial progress in my Bayesianism in the last few months, and it would certainly great to have another test-ear to try it out on (and see it stand or fall) before I foolishly put it in print.

30-12-01 *The Two-Girl Rule* (to D. Petz)

Thanks for the happy note!

Petzism 1: *There is a saying in Hungarian, something like that "A clever man has daughters". I do not know if it is valid in the US but you may try further experimental checkings. (I have two daughters, too.)*

Here are the people (including myself) in quantum information that I can think of with two girls:

Herb Bernstein
Gilles Brassard
Ignacio Cirac
Claude Crepeau (adopted children)
Chris Fuchs

Jeff Kimble
Seth Lloyd
Asher Peres
Dénes Petz
John Preskill
Rüdiger Schack (2 girls, 1 boy)
Ben Schumacher

It is an interesting coincidence.

02-01-02 *Food for Thought* (to C. H. Bennett & J. A. Smolin)

The more I think about it today, the more I'm tickled about the idea of either Charlie or the two of you writing something on thermodynamics and quantum information (rather than Charlie writing a pro-many-worlds piece). I really hope you'll take the bait and view this as an opportunity to get some thoughts straight (including a response to Earman as Charlie suggested) and also to suck the philosophical audience into the excitement of quantum information ... and to let them see that quantum information is *actually* relevant to their subject matter.

Below I'll put a compendium of quotes from some of Jeff Bub's letters to give you a little more orientation on the goal of the project. As soon as I get off my lazy butt, we should be sending out a more formal set of invitations soon.

1. Rob Clifton has asked me whether I'd like to guest-edit a special issue of *Studies in the History and Philosophy of Modern Physics* (SHPMP) on quantum information. Apparently, he first made the suggestion to you some time ago, but since he hasn't heard back from you, he assumes that you are not too keen to take on the job. [...]

   The difficulty will be getting non-philosophers to write a paper that is not just informative for philosophers, but also philosophically convincing and articulate.

2. Well, Bub and Fuchs as editors would be fine with me. But we'd really have to think hard about how to ensure that the authors all deal with some conceptual or foundational question relevant to quantum information in a philosophically serious way. We want to avoid the issue just being 'intro to quantum information for non-specialists,' with some anecdotal interpretative comments as a nod to philosophy. And it also shouldn't just be a forum for one point of view.

   The difficulty, of course, is that very few philosophers have actually worked in this field. So we have to rely mostly or perhaps entirely on scientists for the papers. It will be hard getting papers from physicists and computer scientists for a philosophy journal. On the plus side, it does seem to be the case that some people working in quantum information have thought hard about the relevance of their research for foundational questions. Somehow, we have to motivate people to take it as a worthwhile and exciting challenge to write a paper that tackles a philosophical issue in an intellectually disciplined way – as intellectually disciplined as these authors invariably are when they write a technical scientific paper. Too often, all analytical controls seem to be switched off when scientists venture into philosophical terrain. [...]

I don't think we should tie this to the Montréal meeting. It would probably be better to go with people who have been thinking about a particular foundational issue for a while and whom we can persuade to write a paper on that issue, with the emphasis on philosophical relevance rather than the technical details.

3. This is probably not going to be easy, but I think it could be a very worthwhile project if we can get these people fired up about the idea of writing articles for a special issue that will clearly articulate the significance of the new work on quantum information and quantum computation for foundational and interpretational questions about quantum mechanics. SHPMP is right now the premier journal for foundational and philosophical issues in modern physics. So this is the right place to do this. As I said before, what we don't want is a bunch of articles on dumbed down quantum information for philosophers. Rather, we want a serious and analytically sophisticated attempt to explore foundational issues relevant to quantum information, and to show precisely how looking at quantum information sheds new light on the old questions that plagued Bohr and Einstein.

02-01-02 *Solipsism Story* (to C. H. Bennett & J. A. Smolin)

Here's the other story from Martin Gardner's "Why I Am Not a Solipsist."

> Russell once spoke on solipsism at a meeting chaired by Whitehead. As Russell tells it in his autobiography, he said he could not believe he had written those parts of Whitehead's books which he (Russell) could not understand, although he could find no way to prove he hadn't.

02-01-02 *Greedy Pragmatist* (to C. H. Bennett)

Kiki and I just got through looking through your photo-book. Here are probably the three that strike us the most (in that order):

1. Boat on Dam 1990
2. Surf, Bass Hocks 1967
3. Plant Saucers 1975

It'd be truly wonderful if we could hang any or all of these up in our new house. How about this: If you'd mat them, and label and sign the mats of course, we'd frame them and reimburse you for all the materials (except the love you put into them). Then, soon after that—after we get the house prim and proper—we would invite you and Theo up for the first showing.

Is that greedy of me? Anyway, despite what John says, I'm not a solipsist; I do believe in a reality external to me.

03-01-02 *Your Note* (to R. Balian)

Carl Caves recently shared a note with me that you had written concerning our paper `quant-ph/0106133`. Thank you so much for all the kind words! I am very flattered. Moreover, I will certainly read the papers you recommended to us: I wish we had known of them before sending off our final proofs to the publisher. In any case, I will not make the same oversight twice.

Let me address one of the points in your note:

Balianisme 1: *What I appreciated the most in your work is the use of Gleason's theorem. In my paper of 1989 I had assumed additivity of expectation values even for non-commuting observables, and it is an important progress, both conceptually and technically, to restrict to commuting ones. However, what do you do in the case of a 2-dimensional Hilbert space where Gleason's theorem fails?*

Yes, the two-dimensional case is interesting. There actually turns out to be a way to handle it that continues with the spirit of Gleason, though not by the exact letter of his original assumptions. The trick is to expand one's notion of measurement from the standard von Neumann type to the class of positive operator-valued measures (POVMs). If one does that while retaining the remainder of Gleason's assumptions, then the theorem works even for two-dimensional Hilbert spaces. Moreover the theorem also starts to work for Hilbert spaces over the rational number field—strangely, the original Gleason theorem seems to require the full power of the continuum to be valid—and beyond that, the proof of the theorem becomes essentially trivial (the sort of thing one can sketch on the back of an envelope).

I give what I believe is a fairly convincing argument for such a set of assumptions and a proof of the result in `quant-ph/0106166`. I think you will find the spirited discussion in that reference easy and enjoyable reading and also see that it promotes our common quantum-foundational position in spades.

03-01-02 *Prenuptial* (to R. Jozsa)

In a few days Jeff Bub and I will be sending out some more formal-looking invitations, but I wanted to discuss this with you a little privately first. The plan is to put together an issue of SHPMP (Studies in History and Philosophy of Modern Physics) on the impact of quantum information on quantum foundations and various related philosophical issues.

I know that you've been thinking hard for a long time about writing an article of this nature, and you pretty much (verbally) committed to me once that you'd do it if I could find a decent home for it. (OK, maybe it was during one of our late-night outings!) But, I really think this will be a decent home, and I hope you'll consider doing it.

So, far we have firm commitments from Andy Steane (he's going to put an extension of his "Quantum Computing Needs Only One Universe," which so far hadn't found a home) and Ben Schumacher (who has started to write up his "Doubting Everett" lecture). Beyond that, Charlie Bennett has pretty much said "yes" verbally and even seemed to relish the idea a bit. We'll also be going after Kent, Mermin, Pitowsky, Popescu, and a couple of others (yet to be decided), but we haven't contacted them yet. So I think I can promise you some "relatively established" company ... in case you're worried about reputation and such (since it is a philosophy journal).

As with Charlie Bennett yesterday, I'll place below some quotes from some of Jeff Bub's letters so you can get a better flavor for what the project is about.

I think whatever you wanted to write, it would be great, and we can give you about six months to do it. I hope you know that I honestly believe this stuff and this debate is important (and will be ever more so for the generation after us). Indeed, I'm guessing that a paper from you—it's just a guess, being tinged with mathematical Platonism and a fairly common-sense philosophical realism—would be a good counteragent to anything you might see Mermin and I spurt out ... and I hope you'll see all the more need for your own efforts because of that!!

So I'll leave it at that. I'll hope and pray you say "yes" and await your reply.

04-01-02 *New Breach of Faith* (to C. M. Caves)

Cavesism 59: *I agree wholly with your statement in the following:*

> *Also, there you (or Rüdiger) write, "In contrast, our derivation is couched wholly in terms of the beliefs of the parties and does not appeal to a real state of affairs; it is therefore preferable in a Bayesian approach to quantum mechanics." I'm not sure—at least as hinted by the present structure of the manuscript—that any nonBayesian [would] have a clue why it's a preferable statement of the problem. "What's wrong with letting the quantum state reflect an objective fact, that what cannot happen cannot happen?," the reader might ask. "Aren't these CFS guys just paining over inconsequential points?"*

But I don't quite know what to do about it. Your B& S quotes are nice, but they will just get in the way, in my view, of getting people even to grasp the setting for what we're doing.

Perhaps you misunderstood: I am not asking that the Bernardo and Smith quotes actually be used in the text. What I am asking is that we find a way to convey to the reader why any of this is important. One thing you've got to realize is that more than once, I've heard Mermin describe the reception of the BFM paper with words like these:

Merminition 81: *Sorry, I had the feeling that those few who understood anything at all thought it was pretty obvious, but they were polite anyway.*

What—it seems to me—is our task, is to convey to any readers who had such a reaction as above that they were actually snookered by BFM. The Bernardo and Smith report of what Bayesianism is about builds a context for our efforts—they make it clear why one should expect a hierarchy of conditions (like the ones we explore in the paper) rather than an *absolute* answer.

It is in saying terse, "only established clique"-interpretable (i.e., only preformed-radical-Bayesian interpretable) things like, "In contrast, our derivation is couched wholly in terms of the beliefs of the parties and does not appeal to a real state of affairs; it is therefore preferable in a Bayesian approach to quantum mechanics" ... and just kind of leaving it at that, without any further buffer ... that is going to get us in trouble. Or at least, that is one of my continuing fears whenever I work with you and Rüdiger.

What is being laid in this paper is the groundwork for viewing the quantum state in a way that people—even the Bayesians among us—are not at all accustomed to: Namely, taking the quantum state's subjectivity absolutely seriously and to the extreme. I can't understand how leaning heavily on the motivation for this work can hurt the paper. Indeed it seems far more crucial than the technical results in Section V if you ask me: if no one cares about the results, no one will read them in the first place. (It's not like this stuff can, with almost a single word, be advertised as a new quantum algorithm like Shor's.)

What's a little annoying is that I know that you (from among the three of us) are the one most up to the task of writing a beautiful, yet businesslike introduction. The only thing it seems that you need to be convinced of is that people will actually read this paper if it is well-written (and won't read it otherwise). Strangely, enough, my wacky 45-page papers get read (or at least skimmed): Explain that. It's not the substance a priori (and maybe not even a posteriori), but it might be the style.

Finally, in a last-ditch effort to shore up this point, I'm going to perform a new breach of faith (and just reconcile it with St. Peter when the day comes). [. . .]

OK, I'll say no more on the subject.

Cavesism 60 : *Example: Kimble sat through Rüdiger's talk at Caltech, nodding his head in agreement the whole time, but then it emerged in the discussion afterward that he thought each party had his own copy of the system. He and his student, Andrew Landahl, really had a hard time with understanding that there is any [difference] between "different states" and "different systems." They really just couldn't help using these interchangeability.*

This is an oddity I have encountered before with several people. I don't understand its origin, but it is weird. Even taking an extreme realist view that there are objective quantum systems and objective quantum states, one should be able to detect the matter-property dichotomy in that and not confuse the two. If you have a theory of the confusion's origin, I'd be interested to hear it.

04-01-02 *Once Again* (to C. M. Caves & R. Schack)

Cavesism 61 : *It IS interesting that strong consistency is required so that the firm part of your belief structure can be read off your probability assignments. I would have thought that a Bayesian would want to know what assumptions are required to translate beliefs into probability assignments.*

Let me put the relevant part of my take on that down again:

> It [strong consistency] says (at least in one case) my outward commitment *must* reflect my internal belief—not because I will be imprudent if I don't do so, but because I don't want my friends to see any discrepancy between my beliefs and my actions.

"Outward commitment" means acceptable odds for the bettor. What strong consistency says is that there are cases I should lay my precise beliefs on the table (for public view), even if I didn't have to in order to avoid a sure loss.

Nowhere else does Dutch book do this. For instance—with standard Dutch book—I could internally believe $p(X, Y)$, but nevertheless only accept bets according to $q(X, Y)$ so long as both these are coherent assignments. Is it part of the Bayesian creed to also require honest reporting of my internal beliefs? Maybe it is: but it seems to me that that is something on top of Dutch book (and in fact we know that it is).

I'm not "against" strong consistency, I just want to understand what motivates it other than that it leads to more equations in our paper . . . and thus leads to a more scientific look.

I'm going to try to get to a real library this weekend and dig up those J. Symb. Logic papers by Shimony etc. Maybe that'll demystify things for me.

07-01-02 *Correlation without Correlata* (to N. D. Mermin)

Let's see what kind of reaction the longer quote below gets out of you. "There are, so to speak, relations all the way down, all the way up, and all the way out in every direction: you never reach something which is not just one more nexus of relations."

> In the rest of this essay I shall be trying to sketch how things look when described in antiessentialist terms. I hope to show that such terms are more useful than terminologies

which presuppose what Dewey called 'the whole brood and nest of dualisms' which we inherit from the Greeks. The panrelationalism I advocate is summed up in the suggestion that we think of everything as if it were a *number*.

The nice thing about numbers, from my point of view, is simply that it is very hard to think of them as having intrinsic natures, as having an essential core surrounded by a penumbra of accidental relationships. Numbers are an admirable example of something which it is difficult to describe in essentialist language.

To see my point, ask what the essence of the number 17 is—what it is *in itself*, apart from its relationships to other numbers. What is wanted is a description of 17 which is different *in kind* from the following descriptions: less than 22, more than 8, the sum of 6 and 11, the square root of 289, the square of 4.123105, the difference between 1,678,922 and 1,678,905. The tiresome thing about all *these* descriptions is that none of them seems to get closer to the number 17 than do any of the others. Equally tiresomely, there are obviously an infinite number of other descriptions which you could offer of 17, all of which would be equally 'accidental' and 'extrinsic'. None of these descriptions seems to give you a clue to the intrinsic seventeenness of 17—the unique feature which makes it the very number that it is. For your choice among these descriptions is obviously a matter of what purpose you have in mind—the particular situation which caused you to think of the number 17 in the first place.

If we want to be essentialist about the number 17, we have to say, in philosophical jargon, that *all* its infinitely many different relations to infinitely many other numbers are *internal* relations—that is, that none of these relations could be different without the number 17 being different. So there seems to be no way to define the essence of seventeenhood short of finding some mechanism for generating *all* the true descriptions of 17, specifying all its relations to *all* the other numbers. Mathematicians can in fact produce such a mechanism by axiomatizing arithmetic, or by reducing numbers to sets and axiomatizing set theory. But if the mathematician then points to his neat little batch of axioms and says, 'Behold the essence of 17!' we feel gypped. There is nothing very seventeenish about those axioms, for they are equally the essence of 1, or 2, of 289, and of 1,678,922.

I conclude that, whatever sorts of things may have intrinsic natures, numbers do not—that it simply does not pay to be an essentialist about numbers. We antiessentialists would like to convince you that it also does not pay to be essentialist about tables, stars, electrons, human beings, academic disciplines, social institutions, or anything else. We suggest that you think of all such objects as resembling numbers in the following respect: there is nothing to be known about them except an initially large, and forever expandable, web of relations to other objects. Everything that can serve as the term of a relation can be dissolved into another set of relations, and so on for ever. There are, so to speak, relations all the way down, all the way up, and all the way out in every direction: you never reach something which is not just one more nexus of relations. The system of natural numbers is a good model of the universe because in that system it is obvious, and obviously harmless, that there are no terms of relations which are not simply clusters of further relations.

To say that relations go all the way down is a corollary of psychological nominalism: of the doctrine that there is nothing to be known about anything save what is stated in sentences describing it. For every sentence about an object is an explicit or implicit description of its relation to one or more other objects. So if there is no knowledge by acquaintance, no knowledge which does not take the form of a sentential attitude, then there is nothing to be known about anything save its relations to other things. To insist that there is a difference between a nonrelational *ordo essendi* and a relational *ordo cognoscendi* is, inevitably, to recreate the Kantian Thing-in-Itself. To make that move is to substitute a nostalgia for immediacy, and a longing for a salvatory relation to a nonhuman power, for the utopian hope which pragmatism recommends. It is to reinvent what Heidegger called 'the ontotheological tradition'.

For psychological nominalists, no description of an object is more a description of the 'real', as opposed to the 'apparent', object than any other, nor are any of them descriptions of, so to speak, the object's relation to itself—of its identity with its own essence. Some of them are, to be sure, better descriptions than others. But this betterness is a matter of being more useful tools—tools which accomplish some human purpose better than do competing descriptions. All these purposes are, from a philosophical as opposed to a practical point of view, on a par. There is no over-riding purpose called 'discovering the truth' which takes precedence. As I have said before, pragmatists do not think that truth is the aim of inquiry. The aim of inquiry is utility, and there are as many different useful tools as there are purposes to be served.

Common sense—or at least Western common sense—has trouble with the claim that numbers are good models for objects in general because it seems counterintuitive to say that physical, spatiotemporal objects dissolve into webs of relations in the way that numbers do. When numbers are analysed away into relations to other numbers, nobody mourns the loss of their substantial, independent, autonomous reality. But things are different with tables and stars and electrons. Here common sense is inclined to stick in its toes and say that you cannot have relations without things to be related. If there were not a hard, substantial autonomous table to stand in relation to, e.g., you and me and the chair, or to be constituted out of hard, substantial, elementary particles, there would be nothing to get related and so no relations. There is, common sense insists, a difference between relations and the things that get related, and philosophy cannot break that distinction down.

The antiessentialist reply to this bit of common sense ...

08-01-02 *Correlation without Correlata, 2* (to N. D. Mermin)

Merminition 82: *I don't like the stuff about 17 — very unconvincing. But after that it gets more interesting. It starts to get most interesting just as you cut it off.*

Of course it's not convincing: philosophical mumbles—it seems to me—can't serve that purpose. I was just curious whether it struck any chords with you on how to convey (whatever it is you've been trying to get at with) your "correlation without correlata." Is it a good metaphor? Does it carry any Ithacan soul?

Personally, I thought the analogy was nice from the second I read it. Even the primeness of a number, for instance, can only be defined by invoking the existence of all the other numbers. Numbers just don't have any properties in and of themselves (or at least none that I could think of).

You're not going to QIP at IBM next week, are you?

08-01-02 *Information → Belief → Hope ??* (to N. D. Mermin)

I started reading through the essay again and realized that if I were to fulfill your request, I might just have to copy the whole damned article. I give up! But at least I was kind enough to check that you have the source in your library at Cornell (call number and location below).

The essay is titled "A World without Substance or Essences." It should probably be read in conjunction with the essay previous to it, "Truth without Correspondence to Reality." The book as a whole is entertaining, but it is a little skimpy on firm argument. (Though, the author admits it is an attempt at popularization ... so that kind of makes it OK in my mind.) He's certainly not the devil that Steven Weinberg labeled him. But I will admit, his version of pragmatism may go too far for my tastes: I'll hold on to the final verdict for a while. (William James is still the best bet in my eyes.)

PS. The title to this note is a joke, based on Rorty's own title (and some of the discussions in his book). However, I am seriously toying with the idea of making a distinction between "beliefs" and "commitments." I.e., saying that a quantum state ascription is explicitly a "commitment" rather than a "belief"—a commitment to behaving one way or the other in the face of some experimental data (yet to be gathered). Sometimes commitments explicitly correspond to beliefs (as Dutch-book takes to be a definition), but it seems to me not always the case.

But as I say, I'm just toying with the idea: I know Caves and Schack will have a cow and beat me up if I have enough nerve to say anything about it. So, I'd better be sure of myself.

08-01-02 *Help with ET Quote* (to C. M. Caves & R. Schack)

Cavesism 62: *I've been trying to remember without success where ET discusses his ability to toss coins à la what we saw from Dan Greenberger in Växjö. Can you help?*

I don't know that I've ever actually read the example: I've just heard stories of it (probably through Rüdiger), and maybe words to that effect as a section heading or something. I have a faint memory that it was somewhere in Jaynes's big book, but I couldn't find it in the table of contents. Rüdiger's probably a better person to ask.

One interesting thing I did find in looking for the answer to your question though, is a Jaynesian diatribe against a Dutch-book foundation for probability theory. It's in Appendix A of his book. The fear he expresses there strikes me as not so different from what I was reading into your worries about my fall into "radical Bayesianism."

08-01-02 *Term Origin* (to C. M. Caves & R. Schack)

Here's a little (unfortunately inconclusive) discussion on the origin of the "Dutch book" term:

`http://web.archive.org/web/20060524181532/http://www1.fee.uva.nl/creed/wakker/miscella/Dutchbk.htm`.

08-01-02 *Rorty on Religion* (to J. W. Nicholson)

I wish I had had these quotes in stock when we were having our conversation the other night. But I hadn't gotten that far in the book yet ... if I were only a quick reader like you. [Disclaimer:

My copying these quotes for your thought (and our continued discussion) neither represents an endorsement for or against their content.]

From the essay "Religious Faith, Intellectual Responsibility and Romance" in the R. Rorty, *Philosophy and Social Hope*:

page 153:

> If one accepts that claim, one will have reason to be as dubious as James was of the purportedly necessary antagonism between science and religion. For, as I said earlier, these two areas of culture fulfill two different sets of desires. Science enables us to predict and control, whereas religion offers us a larger hope, and thereby something to live for. To ask, 'Which of their two accounts of the universe is true?' may be as pointless as asking, 'Is the carpenter's or the particle physicist's account of tables the true one?' For neither question needs to be answered if we can figure out a strategy for keeping the two accounts out of each other's way.

page 156:

> Pragmatists are not instrumentalists, in the sense of people who believe that quarks are 'mere heuristic fictions'. They think that quarks are as real as tables, but that quark talk and table talk need not get in each other's way, since they need not compete for the role of What is There Anyway, apart from human needs and interests. Similarly, pragmatist theists are not anthropocentrists, in the sense of believing that God is a 'mere posit'. They believe that God is as real as sense impressions, tables, quarks and human rights. But, they add, stories about our relations to God do not necessarily run athwart the stories of our relations to these other things.
>
> Pragmatist theists, however, do have to get along without personal immortality, providential intervention, the efficacy of sacraments, the Virgin Birth, the Risen Christ, the Covenant with Abraham, the authority of the Koran, and a lot of other things which many theists are loath to do without. Or, if they want them, they will have to interpret them 'symbolically' in a way which MacIntyre will regard as disingenuous, for they must prevent them from providing premises for practical reasoning. But demythologizing is, pragmatist theists think, a small price to pay for insulating these doctrines from 'scientific' criticism. Demythologizing amounts to saying that, whatever theism is good for, it is not a device for predicting or controlling our environment.

page 157–158:

> I said earlier that many readers of 'The Will to Believe' feel let down when they discover that the only sort of religion James has been discussing is something as wimpy as the belief that 'perfection is eternal'. They have a point. For when Clifford raged against the intellectual irresponsibility of the thesis, what he really had in mind was the moral irresponsibility of fundamentalists — the people who burnt people at the stake, forbade divorce and dancing, and found various other ways of making their neighbours miserable for the greater glory of God. Once 'the religious hypothesis' is disengaged from the opportunity to inflict humiliation and pain on people who do not profess the correct creed, it loses interest for many people. It loses interest for many more once it is disengaged from the promise that we shall see our loved ones after death. Similarly, once science is disengaged from the claim to know reality as it is in itself it loses its appeal for the sort of person who sees pragmatism as a frivolous, or treasonous, dereliction of our duty to Truth.

09-01-02 *Doin' the Dutch-Book Zombie* (to H. Mabuchi)

Hey MacArthur boy,

It's a funny thing being a parent of a newborn child. It leads to a kind of zombie-like state most every night: You're never neither really awake nor asleep. And then your mind gets hung up on some little thing—tonight being the Dutch-book argument—and you just repeat it over and over, as if in a trance. Does that build any imagery for you?

Anyway, in looking up Andrew's email address last night (or was it this night? — time stops), I ran across your web page. The flattery to be listed among your collaborators! (Keep it there!) But you need to get the affiliation right — Bell Labs, Lucent Technologies.

Philosophically, lately, I've been taken away by William James and John Dewey. I've been reading their stuff with a pretty voracious appetite (and there is a heck of a lot of it). But of course one thing leads to another—just like that marijuana—and last week I found myself picking up a copy of Richard Rorty's *Philosophy and Social Hope*. His flavor of pragmatism goes maybe too far even for me, but he writes well and I find it easy to read him. I guess I just write you all this to tell you he speaks highly of your friend Derrida! One of these days, I am going to get the nerve to approach that man. (By the way, Mermin told me recently that your old professor Bas vF has been reading my papers ... and, apparently, disagreeing with them ...)

I'm going to slip back under the covers now; like Nosferatu I keep a little fresh earth there for comfort.

Just a sleepy note to let you know I miss you sometimes.

> He did the mash
> He did the monster mash
> The monster mash
> It was a graveyard smash

12-01-02 *Raussendorf-Briegel* (to S. J. van Enk)

Just thinking a little more deeply about the Raussendorf-Briegel model, here's another thing I like about it. Note that in the Nielsen-Leung models, one has to make a strict assumption about the post-measurement states in order to make it work. That is, one is not free to have any old quantum operation (allowed by the Kraus specification) associated with the POVMs that are measured: The measurements must be of the class of "nondestructive measurements" that Debbie talked about yesterday. On the other hand the RB model has no such restriction. The reason for this is because as soon as each measurement is done, they can simply throw the measured qubit away; it's never touched again.

I know this was obvious, but it just had never quite stood out for me before. The main point it brings out—for me anyway—is that the exponential speedup of quantum computations really must just be a property of the nonclassical correlations that one can generate from such an entangled state. And in that way, the exponential speedup appears to be deeply connected (or at least deeply analogous) to the violation of Bell inequalities.

13-01-02 *Princeton Envy* (to H. Mabuchi)

Mabuchism 1: *Sounds like domestic life is treatin' you good!*

Wasn't it Freud who said, once a school girl sees your Princeton, she'll know what's missing from her life and be envious thereafter?

Well I'm not a school girl, but I saw your Princeton the other day (ahem), and it certainly did start a deep yearning in me. What a wonderful place! This was my first real trip there since moving to New Jersey, and I was enchanted all day. I found myself thinking, what I wouldn't give to live the rest of my life in this little cloister.

The thing that really struck me was the immense resources at one's finger tips. I found myself copying a little over $35 of articles in Firestone Library! I couldn't believe it: They had the complete collection of the *Danish Yearbook of Philosophy* and (shockingly) 35 years of the *Transactions of the Charles Sanders Peirce Society*, and I knew that those were just the tip of an iceberg. I was in heaven.

Emma and I play this game: I say, "When you go to college, I hope you'll go to Harvard." She says, "I want to go to Princeton." Or if I say Princeton, she says Harvard—it's always the opposite. (You can see a trend in our relationship starting to form.)

But that's just an aside (to tell you that the grass is always greener). Keep up the good work with all those good students. Get them to read William James' *Pragmatism* and tell them that quantum mechanics is a much better motivation for all that he said there ... but to never lose sight that the real goal is to get to where he wanted to go.

13-01-02 *Reality in the Differential* (to N. D. Mermin)

Merminition 83: *Actually I'm leaving it in the original form for now, but you're giving me a very hard time here.*

Let me say touché, and then little more than that. Strangely, actually, I've been having a little conversation of my own with You this week. And I've been planning to write you—i.e., the one with the little y—all about it. But what happens? Now that I've got a little time this Sunday morning, I'm finding that the inclination is leaving me.

So this note is going to come out far weaker than I had planned. The main thing was to build a conversation around another Rorty quote, and to tell you how pleased I am with the pragmatism movement in general. I'm finally finding a philosophy so close to what I'm looking for that I'm willing to advertise it to my friends.

Somehow they go a little too far for me, but there are so many beautiful gems I keep finding in their stuff that I find it better not to dismiss it outright. The second paragraph below struck me especially last week. It might as well be about my latest quantum interpretation thoughts.

The reality is in the differential. The quantum state represents a (gambling) commitment on the part of the agent; it never represents anything external to that agent. If you're looking for where the "reality" of the external world creeps into the formalism, you should look to how these commitments change. That's what I've been trying to say for a few months now ... but I guess you already understood that (as maybe witnessed by our last real conversation, during your visit to Morristown).

I had a pretty happy-sad week this week you might say. The happiness was that I visited Princeton for the first time since moving up here. I was like a kid in a candy store!! I ended up copying over $35 of articles in their wonderful library (which even subscribes to the *Danish Yearbook of Philosophy*!). The sadness was in that I had to leave that environment and go home at the end of the day; it wasn't home itself.

I'm going to write you that longer James-Dewey note eventually. But right now I'll just leave you with a reminder that the reality is in the differential. From: R. Rorty, "The Pragmatist's

Progress: Umberto Eco on Interpretation," in his book *Philosophy and Social Hope*, (Penguin Books, New York, 1999), pp. 131–147:

> As I see it, the rocks and the quarks are just more grist for the hermeneutic process of making objects by talking about them. Granted, one of the things we say when we talk about rocks and quarks is that they antedate us, but we often say that about marks on paper as well. So 'making' is not the right word either for rocks or for marks, any more than is 'finding'. We don't exactly make them, nor do we exactly find them. What we do is to react to stimuli by emitting sentences containing marks and noises such as 'rock', 'quark', 'mark', 'noise', 'sentence', 'text', 'metaphor' and so on.
>
> We then infer other sentences from these, and others from those, and soon—building up a potentially infinite labyrinthine encyclopedia of assertions. These assertions are always at the mercy of being changed by fresh stimuli, but they are never capable of being *checked against* those stimuli, much less against the internal coherence of something outside the encyclopedia. The encyclopedia can get *changed* by things outside itself, but it can only be *checked* by having bits of itself compared with other bits. You cannot *check* a sentence against an object, although an object can *cause* you to stop asserting a sentence. You can only check a sentence against other sentences, sentences to which it is connected by various labyrinthine inferential relationships.
>
> This refusal to draw a philosophically interesting line between nature and culture, language and fact, the universe of semiosis and some other universe, is where you wind up when, with Dewey and Davidson, you stop thinking of knowledge as accurate representation, of getting the signs lined up in the right relations to the non-signs. For you also stop thinking that you can separate the object from what you say about it, the signified from the sign, or the language from the metalanguage, except *ad hoc*, in aid of some particular purpose.

13-01-02 *Indulgence* (to G. Brassard)

By the way, did I ever tell what I ended up doing on the single malt end? I took all your suggestions: I bought a Glenmorangie 18, a Talisker 10, and a Laphroaig 15. (The Laphroaig wasn't cheap: $77.50.) It made for quite a Christmas!

Too bad you're not going to QIP this week. I'm pretty sick (some kind of ear infection along with conjuctivitis in my eyes), but I'm going to be there. (Just to infect everyone!) By the way, have you seen the Raussendorf and Briegel model of quantum computation? I.e., the model where one starts with a fixed entangled state for all computations (of a given spacetime size), and then simply performs a sequence of single qubit measurements thereafter to enact the particular computation one cares about. I think this is a really very deep achievement. Briegel will be at the meeting; I'm really looking forward to seeing that.

21-01-02 *R, B, and P* (to A. Peres)

Asherism 17: *I am happy that QIP2002 went well. I saw the papers of Briegel and Nielsen on* `quant-ph` *(please remind me the numbers, if you have them ready). I was not favorably impressed, maybe I misunderstood them, and I should read them again.*

Actually, the better work is the Raussendorf/Briegel stuff. If you were not favorably impressed, then I think you should give it another chance. I think it is a beautiful construction, and, in fact, the deepest thing I've seen in quantum computing for 2 or 3 years now. The first paper to start with is `quant-ph/0010033`. Then more details can be found in `quant-ph/0108067`, `quant-ph/0004051`, and `quant-ph/0108118`.

What is deep about this work is that all computations start off with the SAME given entangled state for the qubits. That is to say, a given entangled state is taken as a resource for the task. Thereafter the particular computation one is interested in is enacted by making single-qubit measurements alone: there are no further unitary evolutions. I think that is quite remarkable and quite lovely.

An interesting feature of the Raussendorf/Briegel model (as opposed to the Nielsen and Leung models) is that one need to take into account NO details of the post-measurement state for the measured qubits: they can be thrown away immediately after the measurement. And because the measurements are localized, the post-measurement state of the remainder of the qubits is fixed completely by the POVM (rather than the operation). That is to say, for the relevant qubits in this model, "an effect only has one operation."

23-01-02 *Book Review of Nielsen & Chuang's Book for American Journal of Physics* (to L. K. Grover)

Good review, except I disagree with the following statement violently.

Groverism 1: *Another rule that classical systems satisfy is something called the locality principle (anything that happens depends on local conditions, not on something that exists or happens far away). This is something that quantum systems frequently violate. This led to a number of paradoxical situations such as the EPR paradox. When Einstein and others first discovered this, they thought they had disproved quantum mechanics.*

If one takes the view (as, say, Caves, Cleve, van Enk, Heisenberg, Mabuchi, Mermin (somewhat), Milburn, Pauli, Peierls, Peres, Rudolph, Schack, Wheeler, Zeilinger, and I do) that quantum states are not objective properties of systems, but rather subjective states of belief or knowledge about systems, then quantum mechanics presents no evidence that the locality principle—as you define it above—is violated.

Beyond that, I would say you have the Einstein argument incorrect. Einstein held fast to the *assumption* of locality and never budged from it. The conclusion he drew from EPR situations—where localized measurements on entangled systems cause quantum-state updates for far away systems—is that the quantum state must stand for one's information/knowledge/belief rather than for something objective and observer-independent. In his own words, the quantum state can only amount to an "incomplete description." (See typical Einstein quote below.) Thus he never felt that he had "disproved" quantum mechanics: he only thought that there was *more* to say about nature than quantum mechanics had to offer.

You can find wordier versions of this argument, along with historical references, in Section 3 of my paper `quant-ph/0106166`.

The difference between Caves, Peres, Schack and myself—these guys' opinions I know for sure—from Einstein, is not that we reject his EPR-type argument for concluding that the quantum state must be subjective (i.e., dependent on the information any particular observer has gathered, etc.), but that we find no indication in this that quantum mechanics is incomplete ... and, thus, that there is more to say about nature than quantum mechanics can offer.

> Here is the way Einstein put it to Michele Besso in a 1952 letter [found in J. Bernstein, *Quantum Profiles*, (Princeton University Press, Princeton, NJ, 1991)]:

What relation is there between the "state" ("quantum state") described by a function ψ and a real deterministic situation (that we call the "real state")? Does the quantum state characterize completely (1) or only incompletely (2) a real state? ...

I reject (1) because it obliges us to admit that there is a rigid connection between parts of the system separated from each other in space in an arbitrary way (instantaneous action at a distance, which doesn't diminish when the distance increases). Here is the demonstration: ...

If one considers the method of the present quantum theory as being in principle definitive, that amounts to renouncing a complete description of real states. One could justify this renunciation if one assumes that there is no law for real states—i.e., that their description would be useless. Otherwise said, that would mean: laws don't apply to things, but only to what observation teaches us about them. (The laws that relate to the temporal succession of this partial knowledge are however entirely deterministic.)

Now, I can't accept that. I think that the statistical character of the present theory is simply conditioned by the choice of an incomplete description.

27-01-02 *What Would William James Say?, 1* (to J. W. Nicholson)

Of course I'm reading email in Texas! (Or at least that's what I'd say.) I'll send your regards to my Mom.

Nicholsonism 1: *I had just settled down to a lovely lunch with my new issue of* Scientific American *and was perusing the various articles, when I came across a regular column by Michael Shermer titled "Skeptic." Now normally I enjoy this column (it's all about debunking psuedo-science and public misconceptions) and this month's topic was evolution vs creationism. It got off to a good start with a quote by Richard Dawkins — "the universe we observe has precisely the properties we should expect if there is, at bottom, no design, no purpose, no evil and no good, nothing but blind, pitiless indifference." I rather liked that.*

That may have been true at one time, i.e., at some stage in the development of the world. That's how it got off to a start so to speak. But now, I go the experimentalist (who does the hard work in helping the theorist construct his theories), and ask him, "What ya doin?" He says, "Twiddlin' knobs." I ask, "How come?" He says, "I'm tryin' to hep this wacky friend of mine. He wants to get a theory of how iodine reacts to this and that? I'm chartin' it out, givin' him some clues." I ask, "How do you do that?" He says, "By twiddlin' these knobs."

The present stage of the universe doesn't look like it's full of blind indifference to me.

The initial condition is always left separate from the theory; there's a reason for that. How else would the experimentalist be able to twiddle his knobs?

27-01-02 *What Would William James Say?, 2* (to J. W. Nicholson)

Nicholsonism 2: *Anyway, I was far more interested in your reaction to the quote requiring God's absence from standard scientific theories.*

The point was, it doesn't even require the scientific agent's absence from the ultimate gears and pinions of the world, much less a god's. The scientific world view consists essentially of two components: theories and initial conditions. And, it seems to me, it is a tacit assumption of the whole scientific enterprise that the experimentalist can freely set the initial conditions he wishes to.

Nicholsonism 3: *If the universe really wasn't blindly indifferent, people wouldn't fly airplanes into buildings, convinced they were on their way to heaven.*

There's something about this sentence I just don't like. I'll try to put my finger on it in the next couple of days.

29-01-02 *Quotes That Moved Me Once* (to J. W. Nicholson)

Nicholsonism 4: *Only in the best of cases does an experimentalist have access to initial conditions. Consider astronomers or evolutionary biologist who are left to mine a data trail, long after the fact. And, I imagine a developmental psychologist who tried to monkey around with initial conditions would quickly find himself slapped with a malpractice lawsuit.*

Concerning your last note to me, here are some quotes that moved me once. Maybe they do a more convincing job than I did, maybe they don't. I'd be interested to hear your reaction.

- D. J. Bilodeau, "Physics, Machines, and the Hard Problem," J. Consc. Stud. **3**, 386–401 (1996). The parts of this paper on quantum mechanics and the practice of science in general are absolutely excellent.

> Even apart from the limits to measurement revealed by QM, there have been good reasons to doubt the power of physical observation to penetrate to ontological foundations. I will focus on one of these, which is fundamental but not widely understood—the idea of dynamics.
>
> The geometric idea of the physical seems simpler than it really is—there are simple geometrical entities (perhaps Newtonian particles) which inhabit physical space, which move and interact according to simple physical laws and form larger structures which are the objects of our ordinary experience. It might seem at first that, with the tools of modern science, the structure and nature of such a world would be open to observation with no conceptual difficulties. But, of course, actual observations require that we *use* this world in order to observe it. We must manipulate and modify certain parts of it in order to create situations (experiments) in which information about the structure of other parts can be conveyed to us. Some measurements necessarily preclude others. We cannot dissect a microscope at the same time we are using it to study a sample of brain tissue (much less use the same brain tissue to think about the microscope, etc.). In pure geometry, the intellect can wander over every detail of a geometric structure, as one can gaze over a blueprint or electronic schematic diagram, going here and there and back again at will. But the physical observer has no such freedom. It is impossible to examine every point in space and time. We will never be able to obtain more than an exceedingly tiny fraction of the total information contained in the structure of the universe (to the extent that it can be considered a structure).

and

The physicist *acts* and intervenes in nature. Typical situations are limited and determined in part by what the experimenter can manage to contrive. The idea of causality in physics depends on the freedom of the experimentalist to alter the conditions of the experiments. I first gained an appreciation of the importance of this idea from an argument by Roger Newton:

> The most practical and only foolproof method of scientifically testing a causal connection between A and B is 'wiggling' one of them and watching the response of the other. We are not interested here in what might be called 'historical causality' (establishing a causal connection in a single chain of events) but in 'scientific causality' (establishing such a connection in repeatable events) . . . It is the external control of A together with the correlation with B that establishes, in a good Humean sense, the causal connection between them, as well as the fact that A is the cause and B, the effect.

This observation contains a great profundity. The laws of physics are dynamical—they are not laws of being but laws of action. They are human constructions based on our experience of nature and in form and concept derive from our role as creative agents. [Footnote: When I write of the physicist's 'freedom' of action in setting up experiments and controlling parameters, I am not taking a position on the philosophical question of 'freedom of the will.' I mean here only a pragmatic freedom which is independent of the physical entitities being observed.] The importance of action can be seen in the advance of celestial mechanics from Kepler to Newton. Kepler observed the patterns of the motion of the planets and distilled them into three laws which described the elliptical shape of orbits and the speed with which the planets move along them at each point. These are purely geometrical and kinematical ideas. Newton took Galileo's work on the motion of physical objects developed in experiments and refined it and extrapolated the concepts of gravitational force and mass (both dynamical rather than purely geometrical notions) out into the solar system and so was able to derive Kepler's laws from his own dynamical laws of inertia and gravitation.

The dynamical description of cause, force, and law stands in contrast to the 'historical' denoting of particular things and events in the course of time. These are two 'modes of description' which are equally essential to any account of the physical world.

- D. Bilodeau, "Why Quantum Mechanics is Hard to Understand," LANL eprint `quant-ph/-9812050` (1998). This paper was submitted to and rejected from the journal *Foundations of Physics*; its most likely permanent home will be the LANL eprint archive.

A thing is historical insofar as it is objective (can be observed and treated as an object). It then enters into the realm of recordable objective occurrences which can be ordered in historical space and time. It is dynamical insofar as it is defined as an abstract element of the dynamical theory which explains causal relationships between objects. . . .

Imagine that we could see the universe as omniscient external observers, all space and time at once, and that what we "see" is a tangle of intersecting particle world-lines (cf. Ch. 1 of Misner, Thorne, and Wheeler). We might detect some patterns which would constitute physical rules or laws in some sense, but it would be quite difficult or impossible to know whether we had found all the important patterns, or to distinguish significant relationships from accidental ones. Even more difficult would be to translate this omniscient description into the kinds of relationships and laws which would be observed by the huge clumsy bunches of world-lines which constitute ourselves.

When we set out to investigate Nature, we are not like that external omniscient observer at all. We look for relationships and patterns in the behavior of objects we know. We want to find out—does this kind of object always behave this way under these circumstances? The phrases "this kind," "this way," and "these circumstances" imply the ability to abstract relevant or significant features from what are really unique events. They also imply that we can find or (even better) set up many instances of these typical situations. The result is that the concepts we develop to describe physical phenomena depend not only on what we can observe, but also on what we can do.

To say that A affects or causes or influences or interacts with B implies a counterfactual: If A had been different, B would have been different, too. The most convincing way to establish a connection is to "wiggle" some parameter in A more or less randomly and then observe the same odd pattern showing up in some property of B. If I want to know whether a wall switch controls a certain light, I can flip the switch on and off and observe whether the light follows my actions. There is always the possibility that the light is being controlled by someone else or goes on and off spontaneously; but if I put the switch through a very irregular and spontaneous sequence of changes and the light still follows along, then the probability of a causal connection is very high (barring a conspiracy to deceive the experimenter).

Physical theory is possible because we *are* immersed and included in the whole process—because we can act on objects around the us. Our ability to intervene in nature clarifies even the motion of the planets around the sun—masses so great and distances so vast that our roles as participants seems insignificant. Newton was able to transform Kepler's kinematical description of the solar system into a far more powerful dynamical theory because he added concepts from Galileo's experimental methods—force, mass, momentum, and gravitation. The truly external observer will only get as far as Kepler. Dynamical concepts are formulated on the basis of what we can set up, control, and measure.

- H. Primas, "Beyond Baconian Quantum Physics," in *Kohti uutta todellisuuskäsitystä. Juhlakirja professori Laurikaisen 75-vuotispäivänä* (Towards a New Conception of Reality. Anniversary Publication to Professor Laurikainen's 75th Birthday), edited by U. Ketvel (Yliopistopaino, Helsinki, 1990), pp. 100–112.

The methodology of experimental scientific research and engineering science is to a large extent characterized by the regulative principles emphasized by Francis Bacon. It is a tacit assumption of all engineering sciences that nature can be *manipulated* and that the initial conditions required by experiments can be brought about by interventions of the world external to the object under investigation. That is, *we assume that the experimenter has a certain freedom of action which is not accounted for by first principles of physics.* Without this freedom of choice, experiments would be impossible. Man's free will implies the ability to carry out actions, it constitutes his essence as an actor. We act under the idea of freedom, but the topic under discussion is neither man's sense of personal freedom as a subjective experience, nor the question whether this idea could be an illusion or not, nor any questions of moral philosophy, but that *the framework of experimental science requires the freedom of action as a constitutive though tacit presupposition.*

> The metaphysics of Baconian science is based on the confidence that only the past is factual, that we are able to change the present state of nature, and that nothing can be known about nature except what can be proved by *experiments*. Francis Bacon's motto *dissecare naturam* led to a preferred way of dividing the world into object and observing systems. An experiment is an *intervention* in nature, it requires artificially produced and deliberately controlled, reproducible conditions. In *experiments* in contradistinction to *observations* – one *prepares* systems in initial states, *controls* some of the variables, and finally *measures* a particular variable. The regulative principles of Baconian science require *power to create initial conditions*, stress *the facticity of the past* and *the probabilistic predictability of the future*, and reject *teleological considerations*.

29-01-02 *Qunix* (to J. M. Renes)

Renesism 6: *In other news, I discovered a really interesting paper (actually an undergrad thesis) by a guy at Oxford, who argues against Deutsch's view of the quantum world. One thing he takes to task is the notion that information is physical (which I think I've now discarded).*

Yeah, I met Timpson in Ireland and really enjoyed his company. I'll definitely look at his thesis. Right before Rolf died, I had wanted to write him a letter telling how much I had come to disliking the phrase "information is physical." I wanted to tell him that I think a far more appropriate phrase would be "information carriers are physical." In fact, I told Charlie Bennett about this—at the time—and he told me, "Too late; Rolf just had some fraction of his brain removed last week."

Concerning myself, I've gotten further carried down the path of pragmatism. I've even read some of the Rorty blend now. Indeed my latest little epiphany hit me last week (during an operating-systems talk in our center) when I came up with the following slogan: "A physical theory really amounts to little more than a programming language." Its rules, its specifications are more about the ways we've come to naturally manipulate the world than anything intrinsic to that same world. I tried to say this in my Oct 4 letter to Carl ("Replies on Pots and Kettles" in the new mini-samizdat), but I think the new slogan says it better.

29-01-02 *Växjö Contribution* (to C. M. Caves)

You know, if my true love is philosophy—Bennett calls it theology in my case, actually—yours is certainly sports. You're just not going to let this go without one hell of a fight, are you?

Cavesism 63: *So it appears that I'm in a pickle with evolutions that are mixtures of unitaries, since quantum operations don't have unique decompositions. But of course, all the decompositions into things other than unitaries aren't of interest, and I've been able to "show" (a number of half-baked steps here) that mixtures of unitary EVOLUTIONS are unique, at least in a sense that's good enough for me. To put it more precisely, I've shown it for qubits and think I can go further.*

I'm wondering what the "sense that's good enough for me" is? For instance, I already think of the depolarizing channel, where it doesn't matter which x, y, and z axes I use for defining the Kraus operators. But you probably have something up your sleeve that will be more instructive than that.

Cavesism 64: *For pure states the problem shows up as an inability to make a clean distinction between objective and subjective probabilities,* And for the channel maps, I would say the problem shows up as an inability to make a clean distinction between objective and subjective probabilities. [Just like my double footnote in the NATO paper, I meant this to be taken seriously.] The only difference now is that the probabilities are of a conditional type, $p(y|x)$. But I know that this is too cryptic for you to make any sense of it at the moment, and I already write you too much preachy email: I just need to try to write a damned paper and be done with it.

29-01-02 *Lock In* (to A. M. Steane)

I'm sorry, I haven't kept you up to date on how this special issue project of SHPMP is going. Anyway, it is now definitely going to happen, and I hope we can still count on your commitment of publishing the "one universe" paper there.

So far, we've got definite yes's from Ben Schumacher, Howard Barnum, Richard Jozsa, and Itamar Pitowsky. We've got a high-probability yes from Charlie Bennett. And we've just heard from Carl Caves clamoring to write a paper on "Can Hamiltonians Be Taken as an Ontology for Quantum Mechanics?" if Jeff can be convinced that it's appropriate. Also there's a good chance that David Mermin will be saying yes.

All papers will be due mid-June of this year.

Hopefully Jeff Bub and I will be making an official announcement to all concerned sometime next week.

29-01-02 *A Summer Masterwork?* (to N. D. Mermin)

Merminition 84 : *Funny that you should find Rorty appealing. I've liked a lot of what he says too, although he is Public Enemy Number 1 for most of the scientists engaged in the Science Wars. No Geneva convention for him!*

You emerge! It's so good to hear from you again. If you have read Rorty, then why in the hell did you never tell me, "Chris, what you're shooting for in quantum mechanics really sounds a lot like pragmatism!"? You know you really might have saved me—more importantly this program I dream of—a lot of time! For instance, I might not have wasted years thinking that a pure-state assignment ought to be unique, if I had just read a little James, Dewey, and Rorty.

Anyway, I continue to go further off the deep end. Here's what I wrote Renes this morning:

> Concerning myself, I've gotten further carried down the path of pragmatism. I've even read some of the Rorty blend now. Indeed my latest little epiphany hit me last week (during an operating-systems talk in our center) when I came up with the following slogan: "A physical theory really amounts to little more than a programming language." Its rules, its specifications are more about the ways we've come to naturally manipulate the world than anything intrinsic to that same world. I tried to say this in my Oct 4 letter to Carl "Replies on Pots and Kettles" in the new mini-samizdat), but I think the new slogan says it better.

However, I write this letter for another reason. The way I view it, you play a unique role in our community: You really do "write physics" every bit as much as you exhort your readers to in that nice essay on your webpage. I say this because I would dearly love you to make a statement, a solid statement, of where you think quantum information can have its greatest impact on settling quantum foundations questions. Our community needs this kind of incitement, and you have the writing skills that might even convince someone to do something about it. Even if you wrote a paper of nothing but questions, it would be great and a great service.

Would you think hard about doing that? It could be your masterwork for the year. Jeff Bub and I have finally gotten to the point of organizing a special issue of SHPMP, and your contribution could help set a good tone for it.

Below, let me copy a couple of letters I've already written in this regard. They'll fill you in on all the details of the way Jeff and I see the project. [...]

What say you?

30-01-02 *Sweet Talk* (to N. D. Mermin)

Merminition 85: *Saying that I've read Rorty is a gross exaggeration. I've dabbled around and found a curious mixture of interesting and outrageous assertions. Beware of becoming a "postmodernist" yourself.*

Funny that so many are viewing this as a new kind of onslaught to science. By his own admission, Rorty is not saying anything particularly different from James and Dewey. And my reading is starting to confirm that. So, it looks like the train of thought started before the turn of the (last) century. What is postmodern about it?

That said, the only thing I have ever wanted is a sensible of view of what quantum mechanics is about. If it takes rearranging our thoughts about what the classical world (and classical physics) is about, then so be it. To that extent—I think—I run the danger of becoming a postmodern. The other day Hans Briegel was visiting and he saw James' book *The Meaning of Truth* sitting in the back seat of my car. He ended up asking what pragmatism is about. I said, "You know, these guys didn't know anything about quantum mechanics, but I might venture to say it can be summarized as a Copenhagen interpretation of classical physics."

Merminition 86: *Actually it's interesting the way foundations of QM have come up again and again in the science wars, from Shelly Goldstein's attack on all of physics in the notorious NY academy volume, to Mara Geller's attack on Bohr, to my occasional mutterings that nobody whose thought hard about foundations of QM could possibly think science is as simple as Gross and Levitt would like it to be.*

1) What is the "notorious NY academy volume"? You've piqued my interest.

2) I love it: you made the same spelling slip in Mara Beller's name in an email of November 28, 1999!

3) Who are Gross and Levitt?

Merminition 87: *As for your latest attempt to sweet talk me into doing something reckless, if I thought I had anything useful to say on that subject I would have said it, instead of beating "Whose Knowledge" into the ground (and possibly many feet under the ground). I will, however, keep the invitation in mind as I work my way through the second edition of my Qcomp course.*

If I thought it might help, I'd even say "Pretty please, with sugar on top." More seriously, I think the only thing that would be reckless would be for you to NOT use these post-65 years to act a little like a more sober version of John Wheeler and get the physics community going to its next great stage. I know that you believe that quantum information and computing have something deep to contribute to quantum foundations studies. Why do you believe that? Can you articulate it? Why do you think that Peierls might have been on the right track? Or do you even think that? Why have you changed your stand somewhat on nonlocality? Why have you privately backed out a little on your initial statement of the IIQM? What problems did you foresee? What problems were brought to your attention? What part of the interpretation still stands a chance of being useful? What troubles you about Everett and Deutsch's interpretation? What troubles you about Griffiths' interpretation? What troubles you about Bohm and Goldstein's interpretation? What troubles you about Zurek's interpretation? *All* of these people *claim* to have long since solved all the greatest mysteries of quantum mechanics. Why should we not be listening to them? Have you ever gathered all your thoughts on all these questions?

You can't tell me that you don't already have a LOT to say, even while . . . all the while . . . you are telling yourself that you have nothing useful to say. Most importantly, you have the means at your disposal for saying these things in a way that people will listen and think about them. Even a study in self-indulgence, i.e., a reflection on why you've come to the positions that you have and why you remain perplexed would be *immensely* useful to the community.

Have you ever analyzed why I send so much email to you? I mean, "you" in particular? If I had to put my finger on it, it would be for two reasons: 1) Because I've always felt that your high standard for your own writing has induced me to a higher standard for mine. And 2) because you are the least dogmatic and most clear-thinking devotee of quantum foundations I've ever met. It has made it a pleasure for me to discuss my ideas with you; it has induced me to sharpen and present in a more convincing fashion everything I have ever wanted to say. What I imagine for your contribution in this volume is that same charm working on a public (archival) scale.

I really want to be able to reserve you a spot in the volume.

30-01-02 *Qunix Redux* (to J. M. Renes)

Renesism 7: *OK i'm done ranting. I hope this makes some sense, or is at least enjoyable to read!*

Indeed it was, and I'll read it many times over!

Joe's Preply

> [CAF said:] I came up with the following slogan: "A physical theory really amounts to little more than a programming language." Its rules, its specifications are more about the ways we've come to naturally manipulate the world than anything intrinsic to that same world. I tried to say this in my Oct 4 letter to Carl ("Replies on Pots and Kettles" in the new mini-samizdat), but I think the new slogan says it better.

Ok, I see the pragmatism coming through — the concepts of the world arise because we get them from our observations and they're useful in our manipulations. Now that I've been learning computer science and complexity theory for the last few days (who knows why), this reminds me of Solomonoff's notion of science as data compression. He's got some notion of universal prior probability that I don't really know what to do with. somehow this subject seems interesting, important, and useful, but I can't quite put my finger on how, or if it jives with Bayesian views. A lot of that complexity stuff seems aimed at justifying "random number" so we can use Kolmogorov probability. Ugh.

However, things are beginning to come together in my mind, organized, as ever, in the logico-algebraic approach. A while back Carl and Howard were interested in bayesian views of computation; so am I. My strategy is to always link these things to some logical/algebraic framework and then make up probability distributions on the framework. Maybe computability can be thought of the same way; maybe it's possible to "understand the power of quantum computation" via this method. (Of course, I'm not particularly interested in quantum computation per se, but the idea of using the same framework to apply to physical theory and computer science is certainly interesting.)

I really like this overall approach; there's many levels to it philosophically, and tons of practical things to work out. I'm very amenable to the notion that physical theory isn't true because it corresponds to reality, but rather makes the most sense and use of our data and our models. Within this context, however, it will be useful to think of things as objective — there's a nice section in kant's critique of pure reason (in the transcendental aesthetic, the part on 'space') in which he goes to some pains to assert that space is empirically real, as it's objectively present in our sensation of the world, but it's transcendentally ideal since it's really/ultimately/truly a part of our intuition.

Perhaps we don't have to be that aggressive about what is really/truly/ultimately, and instead take the fact of our experience as given. Now we're really in with the pragmatist flow: from here on out what's true is what's useful. And part of that will be thinking that things are objectively real because it makes the most sense. So, maybe Hamiltonians can be 'real.' as real as anything, I suppose; though certainly not real in the ultimate sense. We're out of that game now. there's really not a lot we can say about it. It exists, inasmuch as 'it' is our experience. But not much more than that. Besides, we don't have to; we can get along quite nicely using what works.

That's it, back to computation, because I just realized what my mind has been trying to think all these days. I don't think quantum computation is fundamental, or as fundamental, in the logical sense. Computing, logic, math, all that is about true statements and can you prove them. Quantum logic, in this sense, is like fuzzy logic — you can't assign truth values to all the propositions. OK, this is the logical angle. QC is not in the class of things we think of when we think of computing because its logical structure is all wrong.

Now to the physical! In the physical domain there is a truth of the matter, of sorts. The result of experiment. In the physical realm we shift our focus a bit — our probability distribution is over what will happen, not what is the underlying truth value of the proposition in question. So we can use our physical manipulation rules and probability distributions for computation, if we like. But we're still performing a computation in the classical sense: the factoring algorithm will give the correct factors or not; there's a truth of the matter. But the fully quantum view of logical processing there's no such thing as the truth of the matter, as we know. Thus, in my mind quantum computation is divorced from the logical business of computation; it's merely concerned with the physical business.

Still not coming out well. Put it this way — it's the same idea as there's no such thing as quantum information. When we talk about using a quantum computer, we want one that we can put classical propositions into, and get classical propositions out of, albeit probabilistically. There's just no sense to the idea that it's doing some logical processing on quantum propositions. Physical processing to be sure, but not logical. We can use physical systems to perform computation, just as we can use them for information transmission, but we shouldn't conflate the physical carrier with the logical or semantic content.

OK I'm done ranting. I hope this makes some sense, or is at least enjoyable to read!

31-01-02 *Clean Sweep* (to A. J. Landahl)

Let me just say again how much I really enjoyed our conversations yesterday. Your visit prompted me to think, and it prompted me to re-look at your old emails to me.

Maybe it's time I moved at least a little on your last email, even if I don't attempt to give you an answer anywhere close to my own satisfaction.

Landahlism 23: *That said, I'm still not sure what you believe reality "is". It seems as though you wish to go in two different directions:*

reality = that which we cannot control/predict [Emma analogy]

reality = free will [Bacon citation].

Are these supposed to be the same? They don't appear that way on the face of things.

The short answer is, 1) yes, I take both these things to be components of reality, and 2) they are not supposed to be the same things. For each of us, one is an inward reality and one is an outward reality.

At heart, I think I am a "pluralist." Reality is made of lots of "stuff," samples of which—by definition—cannot be reduced to each other.

So, I say, randomness and free will appear to be two components of reality. At least as of today, I'm willing to say there may well be a few more things that we can glean from the structure of quantum mechanics and hypothesize as elements in the external world. Among these is the concept of systems (each of which with associated integer properties, commonly called the Hilbert space dimension) and certain ideals of behavior (usually going under the name of collapse rule, etc.).

I don't expect this last sentence to make too much sense to you on a first reading. But maybe a couple of passages from some of my correspondence with others will help. To that end, let me attach a small samizdat that I've put together. The relevant things to read are: A) a note to Mermin titled "Kid Sheleen" starting on page 78, and B) a note to Caves and Schack titled "Replies on Practical Art" starting on page 82. [See 03-10-01 note "Kid Sheleen" to N. D. Mermin and 03-10-01 note "Replies on Practical Art" to C. M. Caves & R. Schack.] In particular look at the table on page 84. (However, please keep this samizdat private: I haven't edited it for complete public distribution yet.)

Landahlism 24: *The part of your paper which smells the most like a lack of belief in reality is your portrayal of Bayesian agents. You say that Bayesian agents would like to align their predictions with some kind of underlying reality, and "they would if they could but they don't because they can't." Of course that doesn't mean that an underlying reality doesn't exist, only that it doesn't allow that kind of alignment. (The use of the word alignment here is unfortunate; it sounds like some kind of astrological prediction by Miss Cleo.) Do I understand correctly that you believe Bayesian agents instead attempt to align their predictions with each other as a sort of "plan B"? If so, then it sounds like all Bayesian agents learn through this process is what other Bayesian agents will have to say about things. How can it be that Bayesian agents learn anything about reality in such a process? Unless, of course, that is all reality is—correlations with other Bayesian agents' predictions.*

Maybe the most effective way to answer this is to include a note I wrote Mermin the other day. It is pasted below. [See 13-01-02 note "Reality in the Differential" to N. D. Mermin.] A hint of the external world is not to be found in the quantum states themselves, but in their changes. The world pings me when I ask a question of it, and I update from one (possibly nonsensical) belief to another (possibly nonsensical) belief, i.e., from one quantum state to another. Reality creeps into this description in two ways: 1) through the pressure that caused that very change, and 2) through the formal structure of quantum mechanics, as it makes possible—through its belief-update rules, i.e., the Krausian collapse rules—a convergence of our disparate beliefs.

I hope that helps. I understand that it is partially vague. But I view that predominantly as an effect of the fact that it is a point of view still under construction. I am not a prophet, just someone searching for a clear view of what QM is all about.

31-01-02 *Words, Only Words* (to A. J. Landahl)

I did a search on "information-information tradeoff" in my big samizdat `quant-ph/0105039` and found two hits, one in a letter to Mabuchi and one in a letter to Mermin. I'll place them below in that order. [See notes "Destinkifiers" and "Zing!" on pages 216 and 265, respectively, of C. A. Fuchs, *Coming of Age with Quantum Information*, (Cambridge University Press, 2011).]

Another reason I send you these, is that they also both explicitly tackle the question you keep asking me. What is real? What is real?! What is real!?!

The tentative answer here is the locus of all possible information-disturbance (or information-information) tradeoff curves for a system. The main idea that connects this to what I was saying to you yesterday is that that locus should be characterized by a single number. We call it the dimensionality of the Hilbert space. A little further explanation can also be found in the letter to Caves titled "The First Eye" on page 26 of the new mini-samizdat I just sent you. [See 08-08-01 note "The First Eye" to C. M. Caves.]

01-02-02 *Dublin Visit* (to C. King)

Here's my itinerary: [...] I'll place my title and abstract below.

> Title: Squeezing Quantum Information through a Classical Channel: Measuring the "Quantumness" of a Set of Quantum States
>
> Abstract: In this talk, I propose a general method to quantify how "quantum" a *set* of quantum states is. The idea is to gauge the quantumness of the set by the worst-case difficulty of transmitting the states through a purely classical communication channel. Potential applications of the notion arise in quantum cryptography, where one might like to use an alphabet of states that promises to be the most sensitive to quantum eavesdropping, and in laboratory demonstrations of quantum teleportation, where it is necessary to check that quantum entanglement has actually been used in the protocol. A more devious purpose for the talk, however, is to introduce some new concepts into current quantum foundations discussions. Time permitting, I'll tell you what I think is "real" about a quantum system.

02-02-02 *Colleague* (to C. G. Timpson)

Well, I still haven't read your anti-Brukner/Zeilinger paper, but I'm writing this small note to tell you that I just finished reading your undergraduate thesis *Information and the Turing Principle*. It's quite a work, and I very, very much enjoyed reading it!

I have to tell you, one of my first reactions after reading about the first third of the thesis was, "Finally there's something sensible coming out of Oxford!" It really was such a relief: I had been thinking that Deutsch had essentially brainwashed everyone in the quantum information community there (except for possibly Hardy and Steane).

Of course, what I like most is what I see as a significant overlap between our attitudes toward scientific theories, the Church-Turing thesis, the homunculus fallacy, and the misleadingness of the slogan "information is physical." But I learned a lot from you, and you helped me sharpen several points.

Here were some of my favorite pages: 4, 6, 8, 16, 24!, 32, 35-36, 38!, 46!, 47-48!, 52!, 60, 65!, 66, and of course chapter 5. (An exclamation means that something especially intrigued me.)

I know there are a few places where I distanced myself from the phrase "information is physical" in my large Samizdat (`quant-ph/0105039`), but I'm having trouble finding them right now. One is in a letter to Bennett starting at the bottom of page 34. However, the most intriguing moment in my mind is one instance I have not recorded in email before. Let me record it here.

I was visiting Bennett at his weekend home in Wendell, MA one weekend and somewhere in the night I got on a roll about how much I had started disliking the phrase "information is physical." In place of it, I was arguing that a much better, much more accurate call-to-arms we ought to be sending the physics and information-theory communities is that "INFORMATION CARRIERS are physical." Taking that into account is what is behind all the new questions we are asking in quantum information theory. Then I told Bennett, "I am starting to plan a long email that I would like to write to Rolf on this subject. But I know that I'm going to have to word it delicately if I'm going to stand any chance at all of catching his ear and not getting an immediate dismissal as a fool." Charlie replied, "Too late; Rolf just had about a quarter of his brain removed last week." Then he explained that Rolf was just found with cancer in the brain, and that chances were strong he would be dead soon. About a week later Rolf died.

The Shanker 1987 paper looks especially intriguing to me. I'll try to pick it up the next time I'm at Princeton.

By the way, the homunculus fallacy struck me on several levels. I think one might view William James's argument against the correspondence theory of truth in his a little book *Pragmatism* as a little bit along the same lines, for instance. But it also got me to thinking about one of the things that has long bugged me in the Zurek-style versions of quantum foundations. There, the starting point is how bad the word "measurement" is and how it should be banished from the foundation of the theory. Yet, inevitably (just watch them), whenever push comes to shove in their explanation of the true importance of decoherence, to get the idea across, they start saying things like "in essence the environment 'measures' the system." (Zurek always makes little quote motions with his fingers when he says it.) And that's supposed to lead us to a deeper understanding of that tabooed subject?!?!? (I thought I had put that complaint in a footnote in some recent paper, but for the present I couldn't find it either! I must be losing my memory or losing my mind ... or both!)

Anyway, again, I really enjoyed the thesis. Keep up the good work.

P.S. I also had a look at your webpage. From the schedule of your discussion group, it looks like you're trying hard to make sense of the notions of 'objective chance' and 'propensity' to yourself. I went down that path once—roughly from 1991 to 1996—and it was instructive. I found that I couldn't buy any of the theories, and that's what ultimately pushed me down the long road to Bayesianism. I keep my fingers crossed that you meet the same frustration!!

04-02-02 *Reverse Shannon* (to C. H. Bennett and P. W. Shor)

Thanks for sending me a preliminary version of the reverse Shannon write-up; I'm having fun reading it. And I'm happy to see that my little contribution—Eq. (5) and the eqnarray after it—was a useful thing.

Besides the full theorem, Lemma 1 is just plain nice conceptually. In fact, it seems pretty closely connected to the development between Eqs. (62) and (65) of my wacky paper `quant-ph/0106166`. There I kind of had a "teleportation" of a POVM, but I hadn't thought about applying it in addition to an arbitrary ancillary state. In my case, it was just half of a partially entangled pair. Your additional piece tickles me, and is making me think about its implications for my devious (theological) purposes.

Strangely, Andreas's matrices $\hat{\rho}_j$ in Theorem 1 also played a significant role in the same wacky paper. They played a crucial role in the rewrite of the Kraus rules that I was seeking—Eqs. (54) to (59)—in order to make quantum-state updating look more like Bayes' rule. In this case, though, it's probably just a coincidence. But it leaves me wondering.

I'll try to read the draft more thoroughly tomorrow, after I awake from this medicated fog. (Another middle ear problem.)

05-02-02 *Fighting Windmills* (to C. M. Caves & R. Schack)

Thanks for the revealing note on Feller (which I've finally had a chance to read).

Schackcosm 54: *Chris, do you know about any other book or paper that explains a "modern understanding of probability"?*

No I don't really. In fact I don't even really have a strong understanding of where most physicists have gotten their prejudices toward probability. Maybe a good place to start in such a quest is to look at the discussions of probability in the main graduate and undergraduate quantum mechanics textbooks used today (Cohen-Tannoudji or however you spell it, Merzbacher, Liboff, Bohm, and whoever else).

All I remember from my undergrad statistics course was that the professor told us that the Bayesian flavor of statistics was nonsense. Unfortunately, I don't remember the text we used. In fact I got very little out of the course that I remember at all.

06-02-02 *The Commitments* (to C. M. Caves & R. Schack)

Schackcosm 55: *The other problem is that your conversation is far too playful. State assignments are compilations of betting odds. They are COMMITMENTS."*

Dear old friends,

I'm going to try to write a note today that essentially has been sitting in my head for over a month. I'm sorry that I've held on to it for so long, but the great difficulty has been that time has just been stolen from me left and right ever since a few days before Katie's birth. (Katie herself, by the way, is the least of my problems; she's really a dream of a child.) Anyway, I think there were times in this period where the issues were so at the top of my mind that this note could have (or would have) turned out far more passionate and, thus, maybe clearer. But that time has past. Still I'll give it my best shot with the time I can muster today, and also hope that it's not so late as to clash with anything Carl has written for the newest version of the post-BFM paper. Here goes.

In a nutshell, what I'm going to say is that I now take Schackcosm 55 absolutely seriously—indeed probably far more seriously than it was ever meant to be taken.

I used to say that quantum states are "states of knowledge," or "states of information." But, you both know that brooding over the BFM paper caused me to disabuse myself of that. Then I got into the habit of calling quantum states "states of belief" in analogy with what the more left-wing, de-Finetti-flavored Bayesians say of classical probabilities. Now, what I'm going to tell you is that in contemplating the points you *two* think are important in our reply to BFM, I've gotten into the habit of calling quantum states "states of commitment." A quantum state should be viewed most properly as a compendium of commitments, gambling commitments.

Indeed you guys almost nudged me directly there by your love affair (or at least Carl's love affair) with strong coherence. I'll come back to say what I mean by this in much greater detail in a minute, but for the moment let me bring the postulate into a clearing so that you can go ahead and start aiming your arrows at it:

> A quantum state corresponds to a compendium of gambling commitments (i.e., just like the gambling odds of a Dutch-book argument) one is willing to make in various given practical situations. However, the key new point is that these commitments are with respect to ALL THINGS CONSIDERED. There are times when one's commitments correspond to one's (internal) beliefs—and because of that the quantum state remains just as subjective as ever in my mind—but that need not always be the case. There are times (and these are probably the vast majority of all real cases) where the quantum state one ends up ascribing to a system is something less than a compendium of ANYONE's beliefs.

I know that I don't have to remind you that I tried pretty darned hard to choose all my words very carefully in that definition.

Now let me tell you about the sorts of thoughts that lead to this by explicitly replying to some of your old notes to me.

Rüdiger wrote:

Schackcosm 56 : *I don't quite understand Chris's problem. Strong consistency DOES have a motivation which is very similar to ordinary consistency, and which DOES have the same flavor. It's just stronger. If you violate strong consistency, you are imprudent in the sense that you accept a bet in which, according to your own state belief, you never win, but you lose for at least one outcome that you believe is possible. That qualifies as imprudent, I think. Actually, I believe that the term "imprudent" fits better here than in the case of ordinary consistency, where "outright crazy" seems more appropriate.*

And then Carl wrote:

Cavesism 65 : *I agree completely with the above, especially with the distinction between "imprudent" and "outright crazy." I think a violation of strong consistency is somewhere between imprudent and outright crazy, but I haven't been able to think up the right [word]. People who take imprudent actions expect to win big, I think; they are judged imprudent because soberer people can see that the chance of [a] big win is small, whereas the chance of serious losses is large.*

First, let me try to settle the issues of language in these two remarks, or at least try to say more clearly why I was concerned—actually in a rather offhand way in the beginning (see my note of 12/5/01, titled "Dear Prudence")—with the appropriateness of the usual terms, "coherence" and "consistency." Then I'll tackle the more substantial issue Rüdiger brings up before that.

I once had an officemate who committed suicide. That is an action I would call (and did call) "outright crazy." Seeing the pain and the soul-searching it put everyone through who was near him, I might even have called it "moronic." And that is important. For, the point I was trying to make explicit to you in my earlier (shoddy) note, is that that kind of craziness is of a much less absolute character than the kind of craziness one would be committing by asserting both A and $\neg A$. In the first case, the craziness is conditioned by one's culture and one's customs, or you might say by the instinct for one's survival. In the second, the craziness is in the breaking of a timeless, Platonic, a priori, ideal "law of thought."

To me, the word "inconsistency"—and therefore the word "consistency"—seems far more to connect to such an ideal Platonic stasis than one's willingness to be taken to the cleaners by a Dutch-bookie. Similarly with the word "incoherent." However, being Dutch-book coherent strikes me much more as an expression of the survival-instinct type than anything else. It is a formal expression of "thou shalt not commit suicide." Why should that be considered an inherently "logical" commandment? Why should it have the right to live in the Platonic realm of Boolean logic? If you ask me, I would say it is probably much more a manifestation of simple Darwinian evolution. We try to stay Dutch-book consistent—it is our ideal of behavior—precisely because of the survival tool it represents for our kind. However, we know by recent experience, that some cultures bask in the idea that, at times, there are reasons to override one's personal aversion to suicide. Do you know of a culture that, at times, finds it useful to override Boolean logic in its mathematical proofs?

When I wrote my original offhand note, I never imagined the backlash I would get from you guys. Nor did I intend to make another proposal to change established nomenclature. I thought I would just simply get a reply of the sort, "Yes, we understand your concerns, but in this case it really is too late to change the nomenclature. A good fraction of the Bayesian community has been using the terms 'coherence' and 'consistency' for almost 70 years. The best you should hope for is an extra paragraph in the paper's appendix assessing why one ought to consider Dutch-book coherence compelling." And I'll still stand by that.

But I actually think there is a point of more substance in this—one that starts to bite much harder when one debates the relative merits of regular Dutch-book coherence versus its stronger cousin (i.e., strong consistency, strict fairness, or what have you). And the new problem is no longer just a problem of language. To say it again, Rüdiger writes:

Schackcosm 57: *Strong consistency DOES have a motivation which is very similar to ordinary consistency, and which DOES have the same flavor. It's just stronger. If you violate strong consistency, you are imprudent in the sense that you accept a bet in which, according to your own state belief, you never win, but you lose for at least one outcome that you believe is possible.*

You don't know how I ALMOST agree with the first sentence of this! In fact, I could agree with it completely if you would just let me change the first instance of "does" to "can."

> Strong consistency CAN have a motivation which is very similar to ordinary consistency, and which DOES have the same flavor.

I said before that strong consistency was of a different flavor than standard consistency, but let me be more careful now—i.e., now that you've helped me sharpen my point. It is not that the flavor is a priori different; it is that in paying the price of strong consistency, you actually get two flavors for the price of one. That is to say, I cannot agree that strong consistency is "just stronger"—it is that and something more.

Here is a very different (and ostensibly much less satisfying) way of motivating strong consistency:

> AXIOM: Whatever an agent's personalistic beliefs, i.e., whatever personalistic probabilities he has managed to write down in his head for some event, when placing a bet (with a Dutch-bookie or otherwise), he MUST place it precisely according to the gambling odds his beliefs afford.

Clearly a special case of this is that when a person believes $p = 1$ for some event, then he MUST bet as if he is certain that it will occur. I.e., he must be strongly consistent.

But you probably ask, "What is wrong with that?"

I will tell you. In doing such a thing, you would throw away loads of freedom, loads of wiggle room that the standard Dutch-book argument generally leaves in your command. In essence you throw away the freedom to concatenate your Dutch-bookie-game commitments with any of a number of other games. Or still another way to say it—though it's not so nice—you throw away your freedom to lie, even when it is in your best, overall, total interest.

An easy case to see this in is the "double agent" Dutch book argument that I wrote you about on 8 Sept. 2001 in a note titled "Negotiation and Compromise" (starting on page 64 of the mini-samizdat). Suppose that Kiki and I draw our money from the same bank account, and that for some given event I ascribe $p = 1$, whereas Kiki ascribes $p = 1/2$. We've talked about our disparity in assignments many times, but I simply cannot convince her to accept the evidence that led me to $p = 1$; she holds her ground, and I know she would do that in any circumstance, come hell or high water. Now suppose I'm later approached by a Dutch-bookie that I am fairly sure has already gambled with Kiki. What should I do? If I don't want to lose my shirt, then I had better not declare my adamant belief in the ultimate occurrence of the event we are betting. Instead, I should adjust my GAMBLING COMMITMENT to agree with Kiki's (sorely) less than optimal one. (Sorely less than optimal from my point of view, that is.)

If on the other hand, you say that in order to play the game of Bayesian probability, I must be strongly Dutch-book consistent, then I no longer have the option to save my own fortunes in this new game. The point is, standard Dutch-book consistency concatenates well with such a further, ancillary game, whereas strong consistency does not.

But this is just a contrived example. Similar, but maybe better, examples can also be found by looking at the old "Keeping the Expert Honest" game (see pages 20–21 in Ph.D. thesis). And I'm sure there are still other more realistic situations that we could come up with if we just tried.

So, what I am saying is Dutch-book consistency is only the tiniest check on one's gambling strategies, and that is a GOOD thing. A very good thing. If one imposes too much structure—apparently almost anything more than simple DB consistency—then one will be left in a lurch in the real world, a world where negotiation and compromise are the keys to survival.

I truly, truly, truly hope you will see the point of this, but I guess I have gained enough experience in the last email war to be prepared for the worst. Here is what I am mainly afraid of. By holding fast to strong consistency as a reasonable addition to standard DB consistency, one ends up in the quantum case with a nice, tightly mathematical looking theorem (almost) in the BFM style. You cannot tell me that at least the Carl among you is not far more attracted to results like that, than the willy-nilly result one is left with if only standard DB consistency is enforced. At the very least, it makes the paper look far more constructive than destructive . . . and that's got to be deemed a good thing, right?

What I guess I am saying is that, concerning what Carl wrote:

Cavesism 66: *I, as you know, like strong consistency and hope that in discussions of it, we can separate the a priori reasons for liking or disliking it from reasons based on the conclusions it leads to.*

I believe that I have done that. However, I hope that you will live up to these hopes too! Every bit of the discussion above (excepting the last paragraph) had nothing to do with quantum mechanics. The argument is purely classical and divorced from the BFM issue. In our post-BFM paper, I certainly have no problem whatsoever delineating the whole hierarchy of conditions, regular DB, strong DB, etc. What worries me though is how the present draft gives pretty short shrift to plain old regular DB — the very one that I myself find the most reasonable (for all the reasons above).

Of course, suspecting that you guys will try to wring me out after spouting this blasphemy, I had hoped to come armed with good knowledge of the literature. Unfortunately, as I already expressed way above, time hasn't been on my side these last few weeks. What I was at least able to do though, was run to the Princeton library one day and amass copies of a lot of papers. I ran from one paper to the next, following the citation trail that each gave. Below is the result: My complete collection of Dutch-book papers.

I wish I could say that I had read these, but for me the skim of a title and abstract doesn't count as "reading" a paper ... as it does for XXX, say. Nevertheless, a couple of points did stand out for me. The most important one is that maybe I'm not alone in thinking that strong consistency goes (far) too far. Hacking (1968) below writes, for instance,

> Abner Shimony called it *coherence*; John Kemeny called it *strict fairness*; today many people speak of *strict coherence*. According to Shimony's definition, a set of betting rates on a series of propositions h_i and e_i is strictly incoherent, when "there exists a choice of stakes S_i such that, if X accepts the series of bets at these stakes, then no matter what the actual truth values of h_i and e_i may be, X can at best lose nothing, and in at least one possible eventuality he will suffer a positive loss." De Finetti had a less demanding concept which is called *coherence*. A set of betting rates is incoherent if, no matter what the actual truth values of h_i and e_i may be, X will suffer a positive loss in every eventuality. Logicians usually think that Shimony has improved on de Finetti's concept of coherence, but statisticians, including de Finetti himself, have seldom been persuaded.

After that, he starts writing about nonBoolean algebras, and I haven't had a chance to try to decipher it. But what is really important to me is that this is the first indication I've run across that de Finetti himself thought about strong coherence and then rejected it. I ask, "Why?" I know that Carl has little use for relying on authority—I'm referring to his quick rejection of even wanting to hear de Finetti's opinion—but that is not what is at issue here. de Finetti is someone who thought long and hard about probability from the Bayesian view. I cannot see how it would not be worthwhile to at least hear his arguments. We might save ourselves time, and we might save ourselves from making mistakes that will make us feel foolish.

Then there is a large set of papers debating whether Dutch-book coherence really has to do with "rationality" or rather something else (as I alluded to above). The titles should give those papers away. I've hardly even skimmed those at all, but you can see from above where my present opinion lies. DB consistency defines an expedient for our actions, but it is hardly more rational or logical than that. Skyrms87 in particular, I am told, argues the opposite point of view. If that is a position that is near and dear to your heart, then maybe it would be worth understanding what he has to say.

OK, clearly I'm petering out and it's after midnight now. Soon I won't even be coherent myself; I'm already starting to see signs of it. Let me try to quickly summarize the whole argument in a few sentences, rather than checking and editing all the above to make it more eloquent, more complete, and more connected.

1. DB coherence strikes me as much more a pragmatic requirement than as any rule of rationality (as the law of the excluded middle is).

2. Thus one is more compelled to consider the pragmatic consequences of standard DB versus strong DB.

3. From that, one sees that strong DB is not just more of the same, but carries with it whole new flavors of behavior. In particular it forces us all to be little George Washingtons—"I cannot tell a lie"—when we have a $p = 1$ assignment in mind.

4. Eschewing that, I am forced to divorce our (pragmatic) gambling commitments from our actual beliefs. Our beliefs can be our commitments, but our commitments need not be our beliefs.

5. Thus it is better to say that "probabilities are our gambling commitments, ALL THINGS CONSIDERED." (with apologies to NPR)

6. Quantum states being compendia of probabilities are thus "states of commitment" full stop.

That's the argument. I'm sure this letter is riddled with typos, but I don't want to hold on to it anymore. France Telecom is coming Thursday and I've been tapped to convince them that quantum information is interesting and that our dabbling in it is a little value-added perk they'll get if they stay our customer rather than running away to Alcatel. Can you believe that?

Anyway, maybe Rüdiger will be a little happy to see this when he gets into the office tomorrow . . . to see that I haven't really abandoned you.

06-02-02 *How Did? What Did?* (to N. D. Mermin)

Merminition 88: *I don't remember the precise content of some of the issues you seem to be addressing, notably what is "strong consistency"?*

Then how on earth did you word your slide (where you gave our version of the theorem) when you gave your talk here in Murray Hill. Now my curiosity is piqued; maybe I didn't notice some inanity in your talk. One only gets something that looks even remotely like the BFM criterion if one assumes strong consistency. If you stick with standard Dutch book, you get precisely what I had been trying to tell you since the very beginning: namely, there are *no* constraints on the density operators required at all.

06-02-02 *Actually, the Both of You* (to C. M. Caves & R. Schack)

This morning I woke up and re-read the long note I sent you last night. In doing that, and looking back at your other notes again, I now think I was too harsh in singling out Carl when I wrote:

> By holding fast to strong consistency as a reasonable addition to standard DB consistency, one ends up in the quantum case with a nice, tightly mathematical looking theorem (almost) in the BFM style. You cannot tell me that at least the Carl among you is not far more attracted to results like that, than the willy-nilly result one is left with if only standard DB consistency is enforced. At the very least, it makes the paper look far more constructive than destructive ... and that's got to be deemed a good thing, right?

That's not fair to him. In particular, both Rüdiger and Carl wrote:

Schackcosm 58 : *Of course it is nicer to base one's approach on the weaker concept. What we are discussing in the paper, it seems, is reasons for why the weaker concept does not quite give us what we would like. These reasons are secondary, they have nothing to do at all with the Dutch book justification of strong consistency itself.*

Cavesism 67 : *Rüdiger's two paragraphs nicely illustrate what I was hoping for when I wrote that I "hope that in discussions of it, we can separate the a priori reasons for liking or disliking it from reasons based on the conclusions it leads to." The first paragraph is about the a priori reasons, and the second is about why its conclusions are important.*

Let me focus in particular on Rüdiger's sentence, "What we are discussing in the paper, it seems, is reasons for why the weaker concept does not quite give us what we would like." What is it that *we* would like? And, why would *we* like it?

Clearly, I am most happy with the willy-nilly result that standard DB coherence alone gives. I'm glad you guys made that nice and rigorous. For me, it says that B, F, and M were just way off the mark in trying to dictate what various observers MUST ascribe for their quantum states. It tucks nicely with my very first note to them where I registered some protest.

Now, what is nice about the strong coherence version of the argument is that it does at least get us the "if" part of BFM, and thus gives us something solid with which to compare to their campaign. But I suppose, I have always viewed that as a secondary, rather than the primary, point of our criticism. Its role is simply in that it tells us what we have to ADD to pure (de Finetti flavored) Bayesianism, to get something that comes close to resembling BFM.

So, my apologies to Carl, and my consternation to the both of you!

06-02-02 *Definition* (to C. M. Caves & R. Schack)

Let me go back to the NPR thing briefly while I've got a couple of moments. "All things considered," what does it mean?

I know that your knee-jerk reaction is going to be that it is a hopelessly vague term. However, I'm going to suggest that it is no more and no less vague (and mysterious in its origin), than "belief" was in the first place. It is just broader in scope. In fact, I think it amounts to little more than the sum total beliefs one possesses. (What more could one consider?)

Thus in setting a quantum state, one sets it according not only to what one believes about the system of particular interest . . . but also according to the situation one believes he will be encountering in the laboratory, the purposes of the information he will gather and how it will be used, who will share that knowledge so gained, etc., etc. It may even depend upon how the financial markets are doing, which political party happens to be in power, and so forth.

It just takes seriously the idea, that to any quantum system, what we say about it—i.e., what we are openly willing to bet on it—depends upon many things beside the system itself.

Maybe all of this goes back to a conversation I had with Marcus Appleby while I was in Northern Ireland, just after 9/11. I tried to explain my new point of view—that a quantum state is a state of personal belief—and he replied that he though that had the right feeling, but that he had some kind of "unpinpointable" fear that maybe the idea didn't go far enough. He seemed to be saying something to the effect that beliefs can never truly be considered in isolation from other beliefs. I didn't understand his worry at the time, but I think everything I wrote you yesterday starts to pick up on this line. In this regard, by the way, Appleby suggested I read a book by Michael Polanyi, *Personal Knowledge*. (Polanyi was apparently also a chemist of some renown, I believe he said.) Though I haven't had a chance to dig it up yet.

In any case, the COMMITMENTS one (potentially) makes in the sum total of all gambling situations quantify the quantum state. They give it an operational meaning—in terms of its "cash value"—which goes beyond niggling over the details and merits of "beliefs" versus "culture" versus "all relevant things considered," etc.

06-02-02 *The Great Quantum Well* (to C. M. Caves)

Cavesism 68: *Not willing to discuss the technical issues much at present because I'm not going to have time to flesh things out for a while. I get a long way by not being interested in Kraus decompositions, which aren't generally convex combinations of unitaries, and I get a good deal farther by insisting on time evolutions, not just single-time stuff. The rest is going to come from having available some operators that rigidify (and thus provide a physical interpretation) for the vectors in Hilbert space, without which the quantum questions (and Hamiltonians) aren't anchored to anything at all.*

I think the last sentence really captures what sets our goals apart. The image I carry around in my mind presently is that the quantum system is very much like an oracle. We ping it, and it provides us with something that we did not have before, something that we could not foresee ... and therein lies its reality. Therein lies its independence from us. Each quantum system is an instantiation of your great quantum well.

But the "interpretation," the "meaning," of the gifts those oracles give us is set from the outside. Completely from the outside. Or at least that's the point of view I'm pursuing.

I just don't see how that line of thought lies anywhere along the lines of your accusation that quantum questions will thus not be "anchored to anything at all."

07-02-02 *The Heisenbergs* (to J. B. Lentz)

I'm just reading some new revelations about Heisenberg's involvement in the Nazi A-Bomb project in the New York Times this morning, and I ran across the following:

> But others say questions about the meeting remain. One of Heisenberg's sons, Dr. Jochen Heisenberg, who is now a physicist at the University of New Hampshire, and Mr. Powers, say the documents show that Bohr never understood the message Heisenberg meant to convey in Copenhagen.

Didn't you tell me you met this guy?

Anyway, the whole article is at `http://www.nytimes.com/2002/02/07/science/07BOMB.html`.

08-02-02 *Samizdats and Dutch Book* (to B. C. van Fraassen)

I was talking to David Mermin a while ago and he mentioned that you had brought my name up in some email and seemed to be aware of some of my papers. (I hope I got the story straight.) Anyway, that piqued my interest: If true, then you are very likely the only philosopher who has ever noticed my existence! I would certainly love to hear your opinion—both con and pro—of my quantum foundational thoughts (forming as they are). Having the critique of a true-blue philosopher would be most useful for steering me to clarity, or even steering me away from the abyss!

My two most close-to-philosophical pieces can be found on the Los Alamos preprint archive: `quant-ph/0106166` and `quant-ph/0105039`. Or, they can both be found at my (almost empty) website with a couple of other pieces of supporting material.

Also I'm in Princeton from time to time making use of your wonderful library system. Maybe I could drop by for a chat? (Sometime in March or later, actually, since I'll be in Japan until essentially then.)

By the way, I was trudging through various Dutch-book arguments recently, and I came across your paper "Belief and the Will," [Journal of Philosophy **81**(5), 235–256 (1984)] in the process. It looks good. I'll let you know if I form an opinion.

11-02-02 *Oh Modern Wittgenstein, 1* (to N. D. Mermin)

Concerning points 1 and 2 in your *Tractatus Quantico-Philosophicus*, read the anecdotes below. [See letter to Chris Timpson, dated 2 February 2002.]

I exclusively use the word "qubit" for the physical system, i.e., the "carrier" of the information, i.e., the object of one's belief, i.e., the oracle the receiver consults at his end of the game. I never use qubit to mean a quantum state (and I don't think I ever have), but I know it's a serious problem in the community.

11-02-02 *Oh Modern Wittgenstein, 2* (to N. D. Mermin)

Merminition 89: *It's the Cbits I'm more concerned with. "bit" – which Charles wants to reserve for the classical physical system clearly has an important abstract meaning as well, relevant to both Qbits and Cbits.*

Aristotle called it matter, the receptacle for accidental properties (presumably some of which could be binary valued). When we turn our attention to a subset of such properties, and are completely ignorant of which of the two is inherent, then we say that we are missing a bit of information.

11-02-02 *A Wackier Idea* (to J. Preskill)

I wonder if you would indulge me with still another wacky idea (actually a wackier idea than usual) to distract you from your usual workaday duties. The only compensation I can give is my promise that in the long run—the long, long run—the world will be a better place if you make this effort. (As if I'm in a position to talk that way!)

Here's the wacky idea. Jeff Bub and I are putting together a special issue of the journal *Studies in the History and Philosophy of Modern Physics* on the impact (if any) of quantum information on quantum foundations and other philosophical issues. Here's what we've managed to line up so for for the issue. The *definite* commits are:

- Andrew Steane: "A Quantum Computer Only Needs One Universe," (extended version of `quant-ph/0003084`)
- Ben Schumacher: "Doubting Everett"
- Richard Jozsa: "On quantum information, and the sense in which it is a distinct notion from its classical counterpart"

- Itamar Pitowsky: "On Bayesian quantum probability (deriving the quantum rules from a gambling scheme in the spirit of de Finetti or Ramsey)"

- Howard Barnum: "On quantum logic and quantum information"

Beyond this we have "probable yeses" from Charlie Bennett and David Mermin. Charlie would write something on Maxwell demons and David would write something Merminesque.

You might be able to tell from this that the lineup is starting to get a little one-sided against Everett. I'm writing you because I'd like to find a little counterbalance to that. In particular, I'd like a scientist—a real scientist—to explain as best he can, what he finds pleasing in the Everett picture, in what ways he finds it useful, how it might make quantum computing's power easier to stomach, and to what extent he finds the view problem-free or, instead, to what extent he foresees it needing a patch.

I've already tried to get Charlie Bennett to take this bait (since in private he is such an avid fan of Everett and calls my own quantum foundations quest "theology"), but in his words, he "just can't get it up to write an article on that subject." (See the note below, along with further details about the goals of the project.) But I really think someone needs to do it, or at least try to do it. Honestly, you're the only person besides Bennett that I trust with such a task.

I want a scientist … not a counter-theologian like Deutsch or Vaidman. I think only in that way, will we really get at the root of what's really good in the Everett view or where it remains weak.

Would you do this? Could you do this? (If I were a doctor, I'd send a sample of Viagra along with the note!) We'd be able give you until about mid-June to get the article finished. And of course, I could volunteer as much (constructive) feedback as you'd like for your drafts, if you're worried about the oddball audience you'd be writing this for.

I hope you'll think hard about the proposal. There are few people that have such a broad overview of the field as you, and I'm banking that'll give you the resources to make a first-class contribution along these lines.

As soon as we hear from you one way or the other, Jeff and I will send out a more formal invitation to all involved, including deadlines, etc.

11-02-02 *A Wackier Idea, 2* (to J. Preskill)

Preskillism 3: *Seems to me that you need someone who is passionate about this, and I'm not.*

No, you're hitting the nail on the head with the latter part of the sentence, and that's exactly why I would like for YOU to write an article. To the extent that you seem to find Everett a pleasing or satisfying picture, you have *always* seemed dispassionate about it. That's a perspective that this debate on the subject seems to sorely need—the working scientist's point of view, without a religious fervor. (I tried to convey that to you in my last note.) A calm, collected account of why you find it a useful working picture.

Preskillism 4: *Actually, Deutsch seems like a natural, since he ought to be able to pitch his message to an audience of philosophers, and you seem to want that.*

Deutsch really is only about religious fervor (probably much like I am, if Charlie's accusations are on the right track). I think what needs pitching to an audience of philosophers—for this particular subject—is what I said above. You, like Bennett, think that the Everett picture has a certain cash-value in your everyday work (or, you wouldn't have taken the time to write about it in your lecture notes). I think it would be useful for us all to understand that better (in general, but also with some explicit examples).

Deutsch would say the same things he has said a thousand times before. He would invoke Popper, and Plato, and whatnot, and say that anyone who does not believe as he does is "refusing to contemplate the implications of science." You would say things that John Preskill would say, in John Preskill's way. And they may turn out to be the same things that Deutsch would have said, but then that will be a useful datum too.

11-02-02 *Viagra Sample* (to C. H. Bennett and J. A. Smolin)

Below I'm gonna send the note again that I sent you on January 2 concerning the special issue of SHPMP that Jeff Bub and I are putting together. Plus let me also send you the lineup of other authors for the issue we've put together since then. I'm hoping you'll find it as stimulative as I find it!

Beyond these guys, Mermin and Preskill are also giving it some serious thought.

I sure would like to hear a "definite yes" from you guys soon. (The deadline on the paper would be mid-June.) Jeff and I are hoping to send out a more formal "invitation letter," closing the ranks and sort of tying the whole project together by the end of this week.

The *definite* commits are:

- Andrew Steane: "A Quantum Computer Only Needs One Universe," (extended version of `quant-ph/0003084`)
- Ben Schumacher: "Doubting Everett"
- Richard Jozsa: "On quantum information, and the sense in which it is a distinct notion from its classical counterpart"
- Itamar Pitowsky: "On Bayesian quantum probability (deriving the quantum rules from a gambling scheme in the spirit of de Finetti or Ramsey)"
- Howard Barnum: "On quantum logic and quantum information"

11-02-02 *Viagra Sample, 2* (to B. W. Schumacher)

I thought you might enjoy this too. (And I send it as a subtle reminder.) [See 11-02-02 note "Viagra Sample" to C. H. Bennett and J. A. Smolin.]

But let me also ask you a technical question related to your project. Have you ever thought about what (if anything) it would change of your conclusions if one didn't augment the universe's Hilbert space with a fixed (preferred) basis—which definitely would demolish your whole point, as you have made clear in your talks—but instead one augmented it with a fixed (preferred) tensor-product decomposition? Indeed, does that even quite make sense?

12-02-02 *The Will to Believe* (to B. C. van Fraassen)

Thanks for the note. You warmed my heart with the sentence, "We were all very intrigued with this 'Bayesian' approach to probability in QM." We (i.e., Caves, Schack, and myself, and sometimes Mermin) know that it's all very much at the beginning stages, but things are starting to fall into place so exponentially fast it evermore gains the air of an inevitability. We've now got a load of material that we haven't published yet (and are working very hard to write up), and I in particular have made a strong phase transition in my attitude toward quantum time evolutions (i.e., their level of subjectivity versus objectivity). So things are just flying.

Thanks very much for putting me on the meeting list. But also I hope to meet you before then. In any case, know that I am always, always available on email. (And as one of the documents I advertised in the last note will attest, that is even my preferred means of communication!) So, please feel free to get a dialog going if you wish: I would relish it.

12-02-02 *Samizdats and Dutch Books* (to P. F. Scudo)

I'm glad to hear that you are not frightened by de Finetti's ghost! My whole life is tied up in it now. Sometimes when one hits the right path to a solution, one just knows it—the feeling is overpowering. And that is the case with me on this round. I dare say there is no deeper, no more direct path to the quantum foundations than through Bayesianism.

13-02-02 *Another Kent Paper* (to G. Brassard)

Brassardisme 4: *What do you think of this?*

I think "nonlocality" and especially questions about the restrictions enforced on physical theory—in particular, the description of quantum phenomena—due to no-signaling criteria are red herrings. Our brain pulp is better left for deeper matters. You see, in playing the sorts of games that people have been playing along these lines, the very starting point is to take the idea seriously that the quantum state is a physical property, rather than a description of information, knowledge, belief, betting-odds or what have you. And that is an idea I stopped taking seriously a good while ago.

See Section 6 (and its closing paragraph) in my paper `quant-ph/0106166`. By the way, there is a (relatively minor) technical mistake in that section; let's see if you can find it!

13-02-02 *One More for James* (to C. M. Caves)

Cavesism 69: *Curt? Emphatically so. Snide? I don't think so. But I can see that my habitual curtness has led to more than its usual negative reaction, so let me go back to square one.*

William James likes to say that all beliefs are "numerically additional" to the reality they take as their target, even "true" beliefs.

Thanks for the note.

I similarly need to automate my Outlook better: maybe that'll be one of the great triumphs of our time together in Brisbane.

15-02-02 *Friendship Call* (to L. Hardy)

I discovered yesterday that you'll be in New Jersey in March for the Wheeler-meets-rich-man-desperately-wanting-to-live-forever thingy. I'm not sure whether I'll be going to that yet, but I wonder if I could interest you in dropping by my neck of the woods while you're in the state. I should be around March 11 through 19 (inclusive). March 19 at 6:00 PM I fly out for the little meeting in Dublin (quantum channel capacity stuff).

I can't offer you any travel funds, but I could put you up in our guest room and offer you some of my wife's home cookin'. Also I've got a decent collection of single malts that might lead us to some insight. (There's a great line in a Tom T. Hall song, "'We must've drank 10 quarts of German beer; my conscience and my sinuses were clear.") Also we're a 1 hour and 10 minute straight-shot train ride to New York City; so you could use us as a base of operations for a couple of days if you wished.

If you've got the time and haven't settled your plans yet with respect to this trip, I'd certainly love to see you. I've got a load of things quantum I'd like to talk to you about. (I'll be the poetaster—that's actually a word—and you can be the concrete master.)

I'm off to Japan for 10 days tomorrow, but I'll be in email contact every day.

16-02-02 *Some Things Should Not Pass* (to several friends)

Some things should not pass without our best effort to make them indelible. Yesterday, February 15, Kiki and I had to put our golden retriever Wizzy to sleep. He was the most loving and faithful dog either of us had ever had.

As things happen, Wizzy's last day of life marked exactly eight years from the time he first entered my apartment in Albuquerque; it was my second date with Kiki. I had schemed all day about how I might meet her that evening, and the solution was to cook a meal, a large meal. Hopping around the corner from my apartment to hers, I said, "Would you be interested in dinner tonight? I accidentally made too much." She said, "Sure; I was only going to warm up some potatoes and cheese anyway. I'll be over in about 20 minutes." A couple of minutes later, I got a phone call asking if she could bring her dog with her. I said, "No problem." It was a sweet and touching sight: Wizzy was a dog so insecure at the time, he never left Kiki's side—he didn't sniff around or explore like most any other dog would have; he stayed in bodily contact with her from the moment he entered until the moment he left.

About four months before that night, Kiki had rescued Wizzy from an animal shelter. He must have had a hard life, we surmise, judging from the scar on his head and the fear he had of brooms at the beginning. We'll never really know how old he was, but comparing him to our other golden, Albert, he was probably 12 or 13 years old when he passed.

The day Kiki met him, she had the intention of looking at two dogs before making a decision of which one to take home. Wizzy was the first. When the attendant let him out of the cage, he so leaned his whole body into Kiki and seduced her with his big, loving eyes, that she knew she couldn't put him back.

Wizzy in fact played a predominant role in my meeting Kiki. For some time I had seen her walking him around the neighborhood, and it dawned on me that since no one was ever with her, she had a chance of being single. I waited for my moment, and it came one morning as I walked across a neighborhood park. I introduced myself by going directly for Wizzy. I said, "What a beautiful dog; what's his name?" She told me, and then I asked in a sort of quizzical way, "Is he a purebred?" She said, "Yes." I said, "I don't think so. I have a golden myself, and they don't look very much alike." Why she accepted a date with me a few weeks later remains a mystery.

This morning I broke the news to Emma, and she became sad. She asked, "Where did he go?" I said, "Back to nature." When she's ready to think about it harder, I'll tell her my (presently) favorite metaphor for what happened: Our finite lives are like little drops of water that have parted from the sea. For a small time we have the chance to move around and determine our courses as we please—to leave a trail behind us. But we all eventually run back into the sea. We never stop being; we just become part of something bigger.

Kiki and I put Wizzy into the ground at sunset yesterday, like Egyptians. We gave him his blanket of eight years so that he would never be cold. We gave him his leash so that he could have an infinity of walks, his bone so that he could have an infinity of chews, and his rubber ring so that he could retrieve it for eternity. I told him that I had always known he was a purebred.

17-02-02 *Long Letter, Way Longer Flight* (to D. B. L. Baker)

"Baker-san. Kon-nichiwa. Fuchs-desu." [...]

I've got such a long day ahead of me still, I don't even know where to start. This time I'm going to the city of Sendai. I think it's maybe 200 miles north of Tokyo. So, once I get to Narita airport, I have to take a train to Tokyo station. That ride lasts a little over an hour. But then, after a 45 minute wait, I have to take a train from Tokyo to Sendai. Even though it's labeled a "super-express," that will also take over two hours.

For a while I was pretty frightened about navigating Tokyo station: You wouldn't believe the ant hill that place is!! But luckily after enough whining, my hosts thought it best to contact someone in Tokyo to meet me at the incoming train and lead me to the outgoing one! These people—the Japanese—are so sweet and polite. I've never seen anything else like it anywhere in the world. [...]

About myself, I'm just plodding on—trying to act the part of a scientist/philosopher. And trying not to worry too hard about the downfall of Lucent (and hence Bell Labs). Philosophically, I've become an absolute junkie for the "pragmatism" movement. There's hardly a day when I can be parted from my Willy. William James that is. But also, John Dewey, F. C. S. Schiller, George Herbert Mead, Richard Rorty and so on. Do you know any of these names?

It's sort of interesting how the first letter in my big samizdat—it's one to you—opens up by describing what a great respect I have for William James' writing style. But the truth of the matter is I really didn't start reading the man in depth until last August. So, my knowledge of him is really very young. Here's how I finished that letter to Mabuchi:

> But that's just an aside (to tell you that the grass is always greener). Keep up the good work with all those good students. Get them to read William James' *Pragmatism* and tell them that quantum mechanics is a much better motivation for all that he said there ... but to never lose sight that the real goal is to get to where he wanted to go.

I'll tell you the same thing. Read him; it's a philosophy for living, and writing the future.

Concerning the quantum world—the real world of my every waking moment—in the last six months, I think I've made the greatest progress I've made in years. Go have a look at my paper: `quant-ph/0106166`. That was just the beginning of the transition in me. Since then, I really believe I've climbed a peak that no one else has even been able to see from the ground. Presently that insight is captured in about a 120 page document of emails (much like the bigger samizdat I published on the web), but I'm hoping to distill it into a real paper within the next month or so. (As you can already tell from the size of this letter, I'm hoping to use this Japan trip to get a whole lot of writing done.) [...]

I haven't been to New York City nearly as much as I would like to; but I keep hoping for the day when I'll be able to increase the frequency of my visits. The last time I was there (about a month ago), I had a pretty amazing experience. I went to see this philosopher friend of mine who was in town to visit his sister. He sent me her address and suggested that we meet at her apartment and then go to lunch. The address was essentially the corner of Broadway and Bleeker Street, right in the middle of the Village. I thought, "Wow, that's in the thick middle of things. The apartment has got to be an absolute shoe box; how else would an academic afford it?" So I got quite excited about going there: I thought I'd be able to see first-hand what squalid lengths people will go to just to live in an intellectually stimulating environment. Well, it was anything but squalid. It turned out to be a penthouse apartment on the top of the building. Three levels of its own! In square feet, it was essentially the same size as my house in Morristown! Many millions of dollars worth of Manhattan space. Here's the rub: Arkady's sister was not an academic as I had assumed. She's an investment banker, and her husband is an architect. Arkady's girlfriend told me, "You ought to see her place in the middle of Paris; it's ten times this big."

It was funny: One of the windows was placed explicitly so as to "frame" the World Trade Center. It's kind of an empty view now. I visited the old WTC site, by the way, sometime in early December. It was quite a stirring experience. The whole affair certainly caused me to think much harder about our finitude. And it caused me to think much harder about what we all, each of us, might hope to do in this life. Hence also the extracurricular reading of James. (But I'm not quite sure which came first, the chicken or the egg—i.e., my seeking the books or the books seeking me.)

17-02-02 *The Process* (to C. H. Bennett)

Bennettism 8: [Thoughts on Wizzy] *Sorry to hear about the big change in your lives, lives that would have been unimaginably different without Wizzy. My favorite metaphor for death is being dropped into a black hole. The main worthwhile thing left behind is not your physical remains, nor even their information content (which presumably reemerges as Hawking radiation) but rather the relative state you leave behind in the Church of the Larger Hilbert Space. If I were you, though, I wouldn't beat about the bush with Emma, but just tell her that Wizzy died. She's plenty smart, and probably knows about death already, so euphemizing will not make it any less painful.*

I'm sorry; I didn't mean to give a misimpression to you. Emma's asking "Where did he go?" came a while after we had already discussed that Wizzy died (literal phrase). That was exactly how I introduced the subject in fact: "I have some bad news. Wizzy died last night." (All this happened, by the way, as I was getting her dressed so that she and Kiki could take me to the airport at 6:30 yesterday morning. I'm in Sendai, as I write to you.)

I knew that she was a little familiar with the concept since she had seen a Babar movie where Babar's mother gets shot. So she understood what was going on a little, but she didn't have all the aspects of it down yet. She started by saying, "I don't want Wizzy to die. Why did he die?" I said, "Because he was old and his time had come." She said, "I don't want him to be old; I want him to be new." I explained that we had buried him in the back yard, and that she could go to the spot and talk to him—"pretend talk"—whenever she wanted. It was when I finally took her outside to show her the grave that she asked "Where did he go?" She was moving into a little more contemplative mode by then, so I thought I'd run with it.

Kiki said that after they returned from the airport, Emma wanted to go to the grave and talk. When they got there she asked, "When's he going to come out, Mom?"

Bennettism 9: *My favorite metaphor for death is being dropped into a black hole. The main worthwhile thing left behind is not your physical remains, nor even their information content (which presumably reemerges as Hawking radiation) but rather the relative state you leave behind in the Church of the Larger Hilbert Space.*

I don't suppose it's ever struck you what an excessive sort of universe that would be. In a way, everything appears twice over. Once in the state and once in the relative state. (If you accept the existence of the universal wave function, the one determines the other uniquely.) What so moved God that he should make two copies of everything? (Redundancy for the purpose of error correction won't do as a reply!)

18-02-02 *Psychology 101* (to J. Preskill)

Let me reply to some of your points in a way that doesn't reflect their original order.

Preskillism 5: *In the past I have sensed that you and I differ in how we regard ourselves. I believe that I am just another physical system governed by the same fundamental laws as any other system. You seem to think there is a fundamental distinction between yourself and the system you are observing. To me the Everett view is appealing because it turns away from this egocentrism.*

It's funny, but when I read this, my reaction went in two rather peculiar directions. First I thought, "I wonder if, in the end, the only thing the great quantum foundations struggles will leave behind is a few psychological observations? If so, what a shame." But secondly, I imagined Galileo hoisting me up to the top of the Leaning Tower of Pisa and dropping me off it along with his two famous stones. Even though I cursed and screamed the whole way down, I went "splat" at the same time that they went "thud."

Here's the psychological thought in a little more detail. One of the things that bugs me about the Everett view is what *I* consider *its* extreme egocentrism! Now, how can that be—both of us accusing the other's view as *the* egocentric view? I'll tell you what I think, trying to express the problem from both sides of the fence.

My side gets to go first. What I find egocentric about the Everett point of view is the way it purports to be a means for us little finite beings to get outside the universe and imagine what it is doing as a whole. And what is it doing as a whole? Something fantastic? Something almost undreamable?! Something inexpressible in the words of man?!?! Nope. It's conforming to a scheme some guy dreamed up in the 1950s.

This whole fantastic universe can be boiled down to something representable within one of its most insignificant components—the brain of man. Even toying with that idea, strikes me as an egocentrism beyond belief. The universe makes use of no principle that cannot already be stuffed into the head of an average PhD in physics? The chain of logic that leads to the truth of the four-color theorem (apparently) can't be stuffed into our heads, but the ultimate operating principle for all that "is" and "can be" can?

It's a funny thing: I don't think I've met anyone who would imagine that mathematics will ever come to an end. Or even that it *can* come to an end. There'll always be new axiom sets to play with, new formal structures to write down. But with physics it's a completely different story. People are always wanting to say, "Well we've finally gotten there." Or, "Even though we're not there, we're pretty damned close." It's OK, even condoned, to have Dreams of a Final Theory. From this point of view, all the mathematics yet to come is worthless as far as the essence of the universe goes; the wad was already shot.

You get the point. It's a psychological one, but it's one that I find overwhelmingly powerful. It is that anytime any of us ever has the chutzpah to say, "Here's an ultimate statement about reality," or even a potentially ultimate one, what we're really doing is painting the world in the image of man. We're saying that the measly concepts we've managed to develop up to this point in time fit the world in a way that none of our previous concepts have, that none in the future will ever do better, and, most importantly, we view this not as a statement about ourselves and the situation set by our present evolutionary and intellectual stage, but rather as a property of the universe itself.

Now let me start moving toward the other side of the fence. The question someone like me—someone who has these kinds of blasphemous thoughts—has to ask himself is, how can I ever hope to be a scientist in spite of all this? What can science and all the great achievements it has given rise to in the last 400 years be about if one chooses to suspend one's dreams of a final theory at the very outset? (Or, to tribute Johnny, how can one have law without law?)

I think the solution is in nothing other than holding firmly—absolutely firmly—to the belief that we, the scientific agents, are physical systems in essence and composition no different than much of the rest of the world. But if we do hold firmly to that—in a way that I do not see the Everettistas holding to it—we have to recognize that what we're doing in the game of science is swimming in the thick middle of things. We're swimming in this undulant sea, and doing our best to keep our heads above the water: All the concepts that arise in a physical theory must be interpreted to do with points of view we can construct from *within* the world.

That is to say, we have to loosen the idea that a physical law is a mirror image of what "is" in the world, and replace it with something that expresses instead how each of us can best cope with and hope to take advantage of the world exterior to ourselves. This, it seems to me, is something that by its very definition can be stuffed into the human brain. The current state of science is our presently best known means for survival. A scientific theory indeed, from this point of view, is yet another expression of Darwinian principles. Scientific theories evolve and survive because the survivors have a kind of staying power that none of the rest of the competition have. Not because they are part of the blueprint of the universe.

The situation of quantum mechanics—I become ever more convinced—illustrates this immersion of the scientific agent in the world more clearly than any physical theory contemplated to date. That is because it tells you you have to strain really hard and strip away most of the theory's operational content, most of its workaday usefulness, to make sense of it as a reflection of "what is" (independent of the agent) and—importantly—you insist on doing that for all the terms in the theory.

I know you're going to find the last sentence debatable, but that is what I see as the danger in the Everett point of view: You are able—or at least purportedly so—to view the universal state as a reflection of something, but at the cost of deleting all the concrete things it was meant to reflect in the first place. What I mean by this is, if we take any concrete situation in quantum mechanics—a system, a measuring device, and some kind of model for the beginning stages of a measurement—we can indeed construct a Church-of-the-Larger-Hilbert space description of it. I'll grant you that. But try to go the other way around without any foreknowledge of the "measurement": Start with the Church, and try to derive from it that a concrete measurement has taken place, and you encounter an embarrassment of riches. You don't know how to identify the valid worlds, etc., etc. (And, if you ask me, invoking decoherence as a cure-all is little more than a statement of faith that some guy from Los Alamos has the all the answers to all the tough questions the rest of us are too lazy to work out.)

So, I myself am left with a view of quantum mechanics for which the main terms in the theory—the quantum states—express nothing more than the gambling commitments I'm willing to make at any moment. When I encounter various other pieces of the world, if I am rational—that is to say, Darwinian-optimal—I should use the stimulations those pieces give me to reevaluate my commitments. This is what quantum state change is about. The REALITY of the world I am dealing with is captured by two things in the present picture: 1) I posit systems with which I find myself having encounters, and 2) I am not able to see in a deterministic fashion the stimulations (call them measurement outcomes, if you like) those systems will give me—something comes into me from the outside that takes me by surprise.

OK, now let me put myself squarely in your pasture. You worry that having those main terms in the theory refer to *my* (or *your*, or Joe Buck's) gambling commitments, is committing a kind of egocentrism. What respectable theory would refer to my particular vices, my desires, my bank account in making its most important statements?

This is going to surprise you now, but I agree with you wholeheartedly. Even enthusiastically so. Where I seem to disagree is that I do not find this a good reason to promote those vices, those commitments to an unearthly realm and call them "states of the universe" (or relative states therein). Instead, it seems to me to be a call to recognize them for what they are and to redouble our efforts for getting at the real nub of the matter.

Let me try to give you a way of thinking about this that you might respect. What was Einstein's greatest achievement in getting at general relativity? For the purposes of the present exposition, I would say it was in his recognizing that the "gravitational field" one feels in an accelerating elevator is just a coordinate effect—it is something that is induced purely with respect to the description of an observer. In this light, the program of trying to develop general relativity thus boiled down to trying to recognize all the things within gravitational and motional phenomena that should be viewed as consequences of our coordinate choices. Or to use a phrase I've come to like, it was in identifying all the things that can be viewed as "numerically additional" to the observer-free situation which come about purely by bringing the observer (scientific agent, coordinate system, etc.) onto the scene.

Now the point is, that was a really useful process. For in weeding out all the things that can be viewed as "merely" coordinate effects, the fruit left behind could be seen in a clear view for the first time: It was the Riemannian manifold that we call spacetime.

What I dream for in my foundational program for quantum mechanics is something just about like that. Weed out all the terms that have to do with gambling commitments (I used to call it information, knowledge, or belief), and what is left behind will play a role much like Einstein's manifold.

This much of the program, I hope and suspect you will understand even if you are not sympathetic to it. But, I don't know, you might be sympathetic to it. (Especially if I've done a good job above.) However, it is also true that you have rightly suspected some tendencies in me that go further. In particular, in opposition to the picture of general relativity, where reintroducing the coordinate system—i.e., reintroducing the observer—changes nothing about the manifold (it only tells us what kind of sensations the observer will pick up), I do not suspect the same of the quantum world. This is why I recommend to all my friends that they read William James's little article "The Sentiment of Rationality." It sort of sets the right mindset, even though it has nothing to do with quantum mechanics (other than in the efficacy of taking gambles) and goes much further on religion than I myself would go.

Anyway, here I suspect that reintroducing the observer will be more like introducing matter into pure spacetime, rather than simply gridding it off with a coordinate system. "Matter tells spacetime how to curve *when it is there*, and spacetime tells matter how to move *when it is there*." Observers, scientific agents, a necessary part of reality? No. But do they tend to change things once they are on the scene. Yes. Or at least that's the idea.

Does that mean that the scientific agent is something outside of physical law? Well, to give this an answer, you've got to go back and be very careful to use the picture of "physical law" that I built up at the beginning of the essay. What we are "governed" by, God only knows. He's the one, if anyone, who sits outside the physical universe and has a chance to look back at it whenever he pleases. Our task is to build up as good and solid a set of beliefs as we can from within it. In that way, we increase our survival power, and use our spare time to try to bring forth a few progeny of our own. (I used the word "governed," by the way, because you had used it above.)

If Galileo had dropped me from the tower, I feel pretty confident that I would have gone splat.

Aye yi yi, I wrote a lot. That's the dangers of being jetlagged in a foreign country without one's wife and kids. (I'm in Sendai visiting Ozawa.)

I'm going to have to reply to the other points of your note later.

18-02-02 *Still Thinking* (to W. K. Wootters)

I've been meaning to write you for some time about your inside/outside distinction for entangled systems, i.e., the stuff you wrote in your last philosophical note to me. Well, I'm still not quite able to say what I want to say, but let me set the stage by forwarding you the note I just wrote to John Preskill this morning. [See note just above.] It's probably just my jetlag, but I felt like I was being particularly clear in it. The note is almost completely self-contained and refers to John's embrace and my disembrace of the Everett stance. A good part of it was greatly inspired by two discussions I had with you (one in Princeton and one in Montréal). Maybe it'll show you the monster you created!

I hope to get my reply on your inside/outside idea off before this Sendai visit is over.

Bill's Preply

> You apologized for taking 20 days to respond to my note, and now I've taken a couple of months to respond to yours! Sorry about that!
>
> You quoted William James on the temperaments that underlie apparently dispassionate philosophical arguments. His observations are certainly correct. Maybe one reason I have not written up my little graph model is that it doesn't fully jibe with all my underlying prejudices. It captures one idea—that the universe we experience gets its form partly from being a *collective* experience—but in other respects I'm not satisfied with it.
>
> This semester I've been participating in a seminar at Williams on science and religion. It's been very interesting, and it has forced me to articulate, as least to some extent, my interpretation of quantum mechanics. I certainly don't have a fully worked out interpretation, but I do seem to hold firmly to two principles: (i) there is no physical breakdown of unitarity, and (ii) mind is crucial to the establishment of definite "facts" (such as a definite pointer reading, as opposed to endless entanglements and superpositions). In these respects I find myself in line with most versions of the many worlds interpretation, in which definite "facts" occur in one's subjective experience, not in the true reality. (Of course there are facts about the wavefunction of the universe, but that's not what I mean by "facts" in quotation marks.) But I deviate from the many worlds interpretation in that I would like to attach a greater ontological status to the world of our experience and a lesser ontological status to the wavefunction of the universe. That is, I want to say that the world of experience is a closer approximation to *reality* than is the wavefunction of the universe. (The latter would be more like a mathematical device, something that defines the range of possibilities.) This is pretty clearly a metaphysical distinction that cannot be tested by any conceivable experiment. But it makes a difference for the questions that arise in the science/religion dialogue. For example, I am led to say that mind is a crucial component of the structure of reality; and this makes it easier to say that God has something to do with the world. If

the ultimate reality is the wavefunction of the universe, then the ultimate reality seems much more mechanical and less God-friendly, like the world of classical physics.

Or maybe there *is* a possibility of testing the above distinction, at least in principle. (It depends on how I finish my interpretation.) Let's consider David Deutsch's thought experiment in which a sentient computer measures, in a reversible way, some property that doesn't have a definite value for the object being measured. Later, the computer will report that he observed a definite outcome but did not record which one, and the various possible paths will have been brought together successfully to exhibit interference. That's David's prediction. I would agree that interference should be possible, but I may disagree about what the computer will report. If it is true that one needs to have a *shared* world in order to have a sensible world, then when the computer was all alone in his private entanglement with the object he measured, who knows what he experienced? Maybe he experienced nothing more about that measured object than what one electron in a singlet pair experiences about the other electron. Maybe he cannot honestly report later that he saw one outcome or another.

But I have to admit that this idea of "sharing" a world with others is very spooky. I wonder if, by pushing the idea to its logical conclusion, I will have to embrace the possibility of telepathy. I don't automatically reject this possibility, but I think it's time to change the subject!

What I'm actually working on these days is the subject of entangled rings. I'm looking for a possible analogy between the *entanglement* among particles arranged in a lattice and the *action* associated with a lattice gauge field, but so far my lattices are just one dimensional (rings) and I have very little to offer in the way of an analogy. Nevertheless, I'm in the process of writing a short paper on the subject to be posted on `quant-ph` in the next week or two; so you'll see it there.

I hope your work is going well.

19-02-02 *Re-Tackle* (to L. Hardy)

I'm in Japan for a couple of weeks at the moment, and I'm finally getting some time put in the 16-hour days again. (Like I used to in the good old days.)

Anyway, I thought I'd tell you, though it is long overdue, I am finally tackling your 5-Axiom paper again. I'm starting to appreciate it much more for sure. If you just weren't so damned non-Bayesian!!! There's a lot of good stuff in it. My main difficulty at the moment is that you have a couple of moves that I know I don't want to allow into my porn: 1) taking mixtures of states (i.e., allowing probabilities of probabilities) as a fundamental step, and 2) invoking extensions to the Church of the LHS.

But I definitely think you are on the right track. And it's probably just a matter of my searching harder for some Bayesian ways of looking at what you've already done. (I'm doing that as we speak.) The most essential things that strike me are 1) the move to column vectors and thinking of measurement as a decomposition of the state, and 2) invoking a relation between K and N. I think those ingredients are definitely here to stay in my mindset. Also I'm warming up to the continuity axiom. I'll try to write you the reasons why soon. (But I've made promises before.)

Anyway, I'm super-looking forward to your stay.

19-02-02 *Where to Stop?* (to J. Preskill)

You know I've got a million ways of saying why I don't like the Everett interpretation—none of which you find very convincing—but here's a new thought that dawned on me as I was writing my last note to you, and I wonder what you think. Let me try it out on you.

Everett says, "You know Chris, all these silly things you do like leaving measurement as an undefined primitive, etc., will disappear and find a more satisfactory solution if you'll just lay back, relax, and recognize that the quantum states you're working with are really just relative states ... ones derived from the universal wavefunction under one or another decomposition."

I say, "Aha, OK. Then what is this wavefunction of the universe?"

He says, "Well for that, we ought to consult the Hartle-Hawking paper. Here it is: It's $|\psi\rangle$."

Then it dawns on me. How do I know that that state they wrote down isn't just the relative state of our universe with respect to some super-universe? And how do I know that that state is not itself some relative state with respect to some super-super-universe? And so on ad infinitum.

The point is, what principle of science tells you where to stop? None, I'd guess. Is that troubling? I don't know. But it seems a little fishy to me.

Everett tells me, "You've just got to recognize that the wavefunctions you use on a daily basis simply don't have the same ontological status as my universal wavefunction. You might call them 'states of knowledge' in a way. But my universal wavefunction, now that's the real thing; it's here independently of every man, woman, and child." But then I ask, "Well, why does yours get that exalted position? I claim that it itself is a relative state and you can't prove me wrong."

Like I say, I don't know what I think of this yet, but it does strike me as fishy. Once you get into the game of building a Church of the Larger Hilbert Space, who tells you how many pews to put there? That's not something it seems to me you can ever discern from within the universe. It's an article of religion, it seems to me, much like the imagery the appellation seems to provoke.

19-02-02 *One More Before Lunch* (to J. Preskill)

Here goes. Let's see if I can be brief enough to finish in time. No easy task for me!

Preskillism 6 : *Still, I'm flattered by your persistence. Or are you (as I can't help but suspect) slyly recruiting an Everettite who will make a weak case?*

No, I was honest in all that I wrote in the flattering note.

... Damn! Didn't make it. It's after lunch now.

What I was going to say was that I was absolutely honest in why I want you to write the sort of paper that you might for the special issue. The point being that if a physicist really, really does find Everett completely adequate to his needs ... and can argue that it's not a superfluous addition to what he's actually doing when he's doing a calculation, then that would be an interesting datum for the freaky types like me who see it as an ugly picture of the world.

I wasn't slyly recruiting you to make a weak case. But, of course, I actually did have an ulterior motive—something much bigger in my mind than the needs of the special issue—and now that you've forced my hand, I ought to be up front about it. I was banking that if you really did put your heart into making a convincing case for the Everettistas—i.e., the sort of thing that having to write a paper on the subject might draw out of you—then your intellectual honesty would cause you to see how much of the point of view really hasn't been worked out (yet? or maybe ever will be?). I.e., that they have no convincing/relevant argument for the probability rule, that they seem to require a preferred basis, that they seem to require a preferred tensor product structure, that to make sense of two systems, they need to invoke a third, and so on. And when you started to add all those things up, you would also realize that the Everett picture really wasn't much help after all in getting you to the point understanding what measurement is. That's how I was being sly.

19-02-02 *More Psychology 101* (to J. Preskill)

Preskillism 7: *Sure, scientists are arrogant. That our puny brains can grasp anything about how the world works is a miracle, and I can't pretend to be able to explain it. But I believe it is so.*

It's not the claims of "anything" that worry me so much. It's the claims of "everything." I.e., that our puny brains can grasp everything (in the sense of an "ultimate physics") is the thing that seems implausible to me. And if we can't have that, then we—or more realistically, those who are inclined to do so—ought to be asking what it is we're shooting for.

Sorry I hit a nerve.

19-02-02 *Sendai Morning* (to N. D. Mermin)

Thanks for helping pick me back up from my preskillsplat. (That could almost be a real German word.)

I'm enjoying Sendai and Ozawa's company greatly. And I'm once again thinking harder about complete positivity. The fact that the trace-preserving completely positive maps are isomorphic to the density operators on a larger space has got to be a truly deep point (in my quest to shore up my argument that the time evolution map is itself a subjective belief). But I just can't quite figure out how to put that into a convincing physical context.

Also, by the way, I'm going through Hardy's five axioms again. It's making a much bigger impression on me this time around. It's got a lot of good stuff in it. If it just weren't so damned non-Bayesian! The point is, I think it's got a hell of a lot of cleaning up to be done on it, but it really does have potential.

20-02-02 *Out Loud* (to W. K. Wootters)

Thanks for thinking out loud. I'll just respond to one point.

Woottersism 1: *Let me think out loud for a minute here about your note to John. I can think of a* pragmatic *reason for being an Everettista. (At those times when I am particularly attracted to the Everett view, this is what attracts me.) Even if we can't hope to* know *reality, if we can* guess *a model of reality, this guessing helps science progress. What Everett gives us is a guess at ultimate reality. So let's guess that Everett is right, and then work to falsify this guess.*

It's about the guessing part. I had meant to cover that case with the word "potentially" in this paragraph:

> You get the point. It's a psychological one, but it's one that I find overwhelmingly powerful. It is that anytime any of us ever has the chutzpah to say, "Here's an ultimate statement about reality," or even a potentially ultimate one, what we're really doing is painting the world in the image of man. We're saying that the measly concepts we've managed to develop up to this point in time fit the world in a way that none of our previous concepts have, that none in the future will ever do better, and, most

importantly, we view this not as a statement about ourselves and the situation set by our present evolutionary and intellectual stage, but rather as a property of the universe itself.

That's actually the point you first inspired in me with your aphorism about the dog. There are some things a dog will never understand; there are even questions he can never understand. Why should we expect the evolutionary chain to stop with us? In a way, this cluster of thoughts that I'm starting to think is a rather strong kind of anti-Church-Turing thesis. That is, I think we've gotten into the habit—and Deutsch tried to codify it in his 1985 paper—of thinking that the Church-Turing thesis implies that once you've got a universal machine (people like to say the human brain is one), then you've reached the end of the line. But one should not forget that what Turing was up to in his 1936 paper was to formalize the notion of what is "humanly computable." This was a point brought home to me by Chris Timpson's excellent undergraduate thesis

`http://web.archive.org/web/20010307183244/http://users.ox.ac.uk/~quee0776/thesis.html`.

By the way, not that it matters too much, but I refined one of my paragraphs in the note before I archived it away:

> The situation of quantum mechanics—I become ever more convinced—illustrates this immersion of the scientific agent in the world more clearly than any physical theory contemplated to date. That is because it tells you you have to strain really hard and strip away most of the theory's operational content, most of its workaday usefulness, to make sense of it as a reflection of "what is" (independent of the agent) and—importantly—you insist on doing that for all the terms in the theory.

And that—by the way again—may have been a point also inspired by someone else, namely Schrödinger. Though I haven't been able to completely track its origin in my mind. Somewhere—maybe his 1935 paper in Wheeler and Zurek—he says something like, "understanding quantum mechanics may not require the addition of more variables, but rather taking some of them away."

20-02-02 *WQRST Revision with Figure* (to C. H. Bennett)

Thanks for the new draft. Apparently we're both in Asia. I'm in Japan right now. I'm visiting Ozawa. (By the way, I think in the past you've confused him with Ohya. It was Ohya who said the wacky things about quantum computers solving NP-complete problems ... or at least that's what Ozawa says. Ozawa is quite a good guy and not so silly ... and he likes to laugh, so you'd probably like him.)

BTW, you never answered my last two questions:

1. Are you going to that Wheeler thing?
2. Can I count on you for a Maxwell-Demon and/or I-Love-Everett article?

Wish you were here, instead of there.

21-02-02 *Quantum Fest, Bell Labs Style?* (to H. Mabuchi)

I just read your proposal for the Wheeler book. Sounds good. (And by the way, you smooch ... adding that flattering remark.)

I've been having a good time with Ozawa. He's got some awfully good stuff, though he's not Bayesian enough for my taste. I suggested to him that he ought to visit Caltech. (And I'll suggest to you that you ought to invite him. He'll be in America in the July-August time frame, with a little time free between QCMC and the Feynman Fest.) I told him about your experimental interest in going beyond the SQL. But also he's got some interesting new stuff that even goes beyond the uncertainty principle! (Well ... that is, if you mean by that roughly the thing Heisenberg meant with his microscope model of attempting to infer position and moment simultaneously.) Anyway, I think it could make an awfully good splash for you, and he tells me he's in the process of distilling a potentially relevant / Q-optics realizable model that would do the trick. I've promised to help him work a bit on the style of the paper, so he can send it to *Nature*. (I always get myself into trouble with my promises.)

BTW, Ozawa is contemplating visiting Bell Labs in March too. So I might have a bang-bang-bang quantum fest: Hirota comes on March 12, Hardy will come for maybe two days before the Wheeler meeting, though the dates aren't settled yet. And you'll give us a talk on March 18. When were you thinking of coming into town? Would you be staying the night of March 17, or the night of March 18, or both, or neither. If Ozawa does come, he said he might try to line up with you.

On another subject, let me send you a little essay of my own. [See 18-02-02 note "Psychology 101" to J. Preskill.] I got carried away with replying to one of John Preskill's comments in a note to me the other day, and the end result was something I was particularly proud of as a statement of my quantum foundational ideas (broad sweep). John, of course, hated it and almost reacted violently. But Mermin and Wootters loved it. So, I'm probably doing something right.

22-02-02 *Sendai Thoughts* (to H. J. Folse)

Greetings from Sendai, Japan! I'm here for a small time of about 11 days, visiting Masanao Ozawa. (He's done some of the most interesting technical work on the uncertainty relations that's been done in a long, long time.)

Anyway, I just thought I would tell you I was thinking of you. Just a few moments ago at the university bookstore, I bought two volumes of Bohr's philosophical writings, translated into Japanese. The total came up to maybe about $11, so it seemed like a good investment. I think I will write a little something in each and give them to my daughters.

By the way, while I'm here, let me remind you again to send me that article of yours I still haven't gotten: H. J. Folse, "The Formal Objectivity of Quantum Mechanical Systems," Dialectica **29**, 127–136 (1975).

Also, if you could, I'd like to get your Växjö paper.

Let me also send you a little food for thought. It's a little essay I wrote in response to a remark John Preskill wrote me the other day. [See 18-02-02 note "Psychology 101" to J. Preskill.] I'm a little proud of it. I think it's maybe one of my best expressions yet of where I'd like to see quantum foundations studies go.

22-02-02 *Getting the Mindset* (to P. F. Scudo)

You asked for some materials to help you get more familiar with the problem I'd like you to work on.

OK, I'm ready to send you some now. And I'll inundate you, but don't let that frighten you. Only try to understand things to the extent that you've got some free time. (And I well expect you may have none at all!)

The first thing to do is read the Brun, Finkelstein, Mermin paper, "How Much State Assignments Can Differ," `quant-ph/0109041`. This is really the thing that started my thoughts off in the present direction, for I completely disagree with them. Their statement is in ultimate conflict with the Bayesian idea of what a quantum state can be. So, understand their argument.

After that, start reading my new samizdat (i.e., underground publication), which I will send you in a separate email. It's quite large (150+ pages), with plenty of repetition, but it mounts an attack on B, F, and M from just about every direction conceivable. Also there is the fact that as time went on, all the issues became clearer and clearer with me, and so I found crisper and crisper ways of expressing myself. Still reading it (and reading it carefully) might help you get in the right mindset for any number of problems we might be discussing.

The upshot of much of the samizdat is that, for consistency in one's Bayesianism, one must accept that the *assignment* of a POVM (living on a piece of paper) to a measuring device (living in a laboratory) is a subjective judgment at exactly the same level of subjectivity as the quantum-state assignment. Thus one is presented with a cross-roads. Either one accepts pure Bayesianism and gives up the idea that POVMs and quantum time evolutions have objective ascriptions (i.e., gives up the idea that they are independent of the agent assigning them), or one continues with the belief of objective POVMs and time evolutions and adjusts oneself to the idea that probability has to be objective too.

The direction I personally take is that probabilities are subjective, always. They are never objective. Therefore one must make sense of what one means when one speaks of an "unknown POVM" or an "unknown quantum operation." This is where a new kind of de Finetti representation must come in ... and hence your summer work.

But the most important thing for the present is understanding all the motivation leading up to that point. When you are ready to see a sketch of how the theorem ought to go, look at the note of 19 November 2001 to Caves and Schack titled, "A Lot of the Same."

For completeness sake, I will also send you a draft of the paper that Caves, Schack and I are presently constructing to make some of this official. The part that is maybe the most relevant for your education is the appendix on Dutch-book arguments. You might try to understand that. And I'll write you more about that later.

24-02-02 *Consistency* (to J. W. Nicholson & K. M. Fuchs)

Consistent coffee quality the world over! I'm just writing to report to both of you that I saw a Starbucks about an hour ago and ... despite my significant need for coffee and my overbearing homesickness for all things American, I want you to know I resisted it. More than that, I want you to know I shunned it! I'm sitting in a Japanese coffee shop as I write to you—itself a Starbucks wannabee, but not a Starbucks—drinking the most godawful mud-thick coffee, BUT I SHUNNED IT!!! And in the grand scheme, I know I'll come out the better for this.

A big hello from breezy cold Sendai,

25-02-02 *A Wonderful Life* (to W. K. Wootters)

Thanks for the two notes, and wow, thanks for reading the James essay. Your questions were anything but naive. In fact, they were much needed. In trying to answer them, I think I significantly clarified—to myself even!—what I'm hoping to get at. Besides, I certainly don't have a final stand yet; the whole point of view is in the process of formation and questions like yours really help.

I'll do my best to reply to your questions below, and in the process I think I'll finally compose what I've been wanting to say about your "private-world-within-entanglement" musings. At the end of the note, I'll list some of the open questions on my mind. (These are likely to be the naive ones!)

Woottersism 2: *Of course I'm very sympathetic to the perspective you express in this paragraph . . . but couldn't one still argue that as a matter of methodology, the tactic of pretending that we can know the whole story has served science well? We make up a model of the world, and this model gives us something to shoot at. We hang on to the model until we have found an explicit flaw in it (other than the flaw of hubris). And then we move on to a new model.*

I find this an interesting question. On the one hand, I think this strategy does work well in advancing science. On the other hand, scientists (and others) are much too prone to accept as true the pragmatic lie that says we can fully understand the world.

Your note to John P. goes some way toward laying out an alternative methodology. You speak of science in Darwinian terms: the most successful theories survive. How then do we proceed as scientists? I suppose the answer is that we still make up theories and test them, but the theories are not tentative descriptions of the world. Rather, theories are schemes for making predictions. But you obviously also want to say that our theories tell us something *about reality, even if they are not descriptions of reality. Moreover, our theories will tell us more about reality if we identify and remove from them those aspects that are subjective. So your view of science is not entirely operational. There is realism in the background.*

Have I understood you correctly?

Yes there is certainly a kind of realism working in the back of my mind, if what you mean by "realism" is that one can imagine a world which never gives rise to man or sentience of any kind. This, from my view, would be a world without science, for there would be no scientific agents theorizing within it. This is what I mean by realism: That man is not a priori the be-all and end-all of the world. (The qualification "a priori" is important and I'll come back to it later.)

A quick consequence of this view is that I believe I eschew all forms of idealism. Instead, I would say all our evidence for the reality of the world comes from without us, i.e., not from within us. We do not hold evidence for an independent world by holding some kind of transcendental knowledge. Nor do we hold it from the practical and technological successes of our past and present conceptions of the world's essence. It is just the opposite. We believe in a world external to ourselves precisely because we find ourselves getting unpredictable kicks (from the world) all the time. If we could predict everything to the final T as Laplace had wanted us to, it seems to me, we might as well be living a dream.

To maybe put it in an overly poetic and not completely accurate way, the reality of the world is not in what we capture with our theories, but rather in all the stuff we don't. To make this concrete, take quantum mechanics and consider setting up all the equipment necessary to prepare a system in a state Π and to measure some noncommuting observable H. (In a sense, all that equipment is just an extension of ourselves and not so very different in character from a prosthetic hand.) Which eigenstate of H we will end up getting as our outcome, we cannot say. We can draw up some subjective probabilities for the occurrence of the various possibilities, but that's as far as we can go. (Or at least that's what quantum mechanics tells us.) Thus, I would say, in such a quantum measurement we touch the reality of the world in the most essential of ways.

With that said, I now want to be very careful to distance this conception of reality, from what I'm seeking in the foundation game of quantum mechanics. Here's the way I originally put it to John the other day. Let me repeat a good bit of it so that it's at the top of your mind:

> OK, now let me put myself squarely in your pasture. You worry that having those main terms in the theory refer to *my* (or *your*, or Joe Buck's) gambling commitments, is committing a kind of egocentrism. What respectable theory would refer to my particular vices, my desires, my bank account in making its most important statements?
>
> This is going to surprise you now, but I agree with you wholeheartedly. Even enthusiastically so. Where I seem to disagree is that I do not find this a good reason to promote those vices, those commitments to an unearthly realm and call them "states of the universe" (or relative states therein). Instead, it seems to me to be a call to recognize them for what they are and to redouble our efforts for getting at the real nub of the matter. ...
>
> What I dream for in my foundational program for quantum mechanics is something just about like that. Weed out all the terms that have to do with gambling commitments (I used to call it information, knowledge, or belief), and what is left behind will play a role much like Einstein's manifold.
>
> This much of the program, I hope and suspect you will understand even if you are not sympathetic to it. ... However, it is also true that you have rightly suspected some tendencies in me that go further. In particular, in opposition to the picture of general relativity, where reintroducing the coordinate system—i.e., reintroducing the observer—changes nothing about the manifold (it only tells us what kind of sensations the observer will pick up), I do not suspect the same of the quantum world. ...
>
> Anyway, here I suspect that reintroducing the observer will be more like introducing matter into pure spacetime, rather than simply gridding it off with a coordinate system. "Matter tells spacetime how to curve *when it is there*, and spacetime tells matter how to move *when it is there*." Observers, scientific agents, a necessary part of reality? No. But do they tend to change things once they are on the scene. Yes. Or at least that's the idea.

From some of my choices of words, I think you probably got the impression that this thing—this structure within quantum mechanics—that I'm hoping to find at the end of the day is meant to be a model of "reality." Or at least our "current best guess" of what reality is. But no, that's not really what I want. And your questions helped make that much clearer to me. Remember, for me, the mark of reality is its indescribability.

What I'm asking for instead is something like what one finds in the old movie, *It's a Wonderful Life*. That is to say, in our scientific theories, we codify some fraction of what we know about manipulating the world and conditionally predicting the phenomena about us. However, suppose we wanted to get at a measure of our place in the world. How would we quantify it, or at least qualify it? That is, how might we ask how important our lives and agential actions are with respect to the theory we ourselves laid out?

Our only tool, of course, is the theory; for it defines the frame for optimal thinking (and imagination) at any given moment. We can only gauge our measure by deleting the free variable that is ourselves and seeing what is left behind. You surely remember what George Bailey found when his guardian angel granted his wish in *It's a Wonderful Life*. He found that his life mattered. So too is what I suspect we will find in quantum mechanics.

But all of that is the sort of thing I won't be able to say in a conference presentation for quite some time. It's the sort of thing that we discussed once before, in the context of some Jamesian quote. It's the underground reason for the philosophy.

At the level of convincing our peers, let me put it to you this way. Within quantum mechanics, there is an invariant piece which is common to all of us by the very fact of our accepting the theory. That is what we are in search of because in some sense—which need not pertain to a realistic conception of a theory's correspondence to nature—it is the core of the theory. It is the single part that we agree upon, even when we agree upon nothing else. In the direction I am seeking to explore, the quantum state is "numerically additional" to that core. (That is, the quantum state is a compendium of Bayesian "beliefs" or "gambling commitments" and is thus susceptible to the type of analysis James gives in his "Sentiment of Rationality." Our particular choice of a quantum state is something extra that we carry into the world.)

I hope that clears up some of the mystery of my thoughts for you—it did for me. Given John's implicit acceptance of the idea that "a true theory is a mirror image of nature," I should not have said in my note that I agreed with him "wholeheartedly." I do not intend for *any* part of the formal structure of quantum mechanics to be a mirror image of nature (in the sense of a proposed final theory). However, I do not intend to give up the reality of our world either.

From my point of view, the only "true" reality that creeps into quantum mechanics is "in the differential"—i.e., in the changes we induce upon our (personal) quantum states for this and that due to any stimuli we give to or take from the outside world. That, however, is a pretty amorphous thing as theoretical entities go. It is little more than what might have been called in older language, the measurement "click."

There is a temptation to go further—to say that the POVM element E_b associated with a measurement outcome b is itself an element of reality. But I think that has to be resisted at all costs. There are several arguments one can use to show that the *ascription* of a particular POVM to a measurement phenomenon is a subjective judgment at the same level of subjectivity as the quantum state itself. (In fact the two go hand in hand, one cannot support the subjectivity of the quantum state without also taking the subjectivity of the POVM.) Instead, one should view the (theoretical) ascription of a POVM to an actual measurement device as an attempt to set the significance and meaning of the "click" it elicits. Similarly for the Krausian quantum operation associated with the measurement: It describes the subjective judgment we use for updating our quantum-state assignment in the light of the "click." (If you want more details about these arguments, I can forward you some of my old write-ups on the subject.)

So, you probably ask by now, "What does that leave for the core of the theory? Aren't you throwing away absolutely everything?" And the answer is, "No, I don't think so." Let me give you an example of something which I think is left behind. Recall my favorite argument for why the quantum state cannot be an element of reality—it's the Einstein argument I wrote about in Section 3 of my NATO paper. Once I posit a state for a bipartite system, even though by my own admission my actions are purely local, a measurement on one of the systems can toggle the quantum state of the other to a large range of possibilities. Thus, I say that the quantum state of the far-away system cannot be more than my information or the compendium of subjective judgments I'm willing to ascribe to that system.

Notice, however, that in positing the original state, I had to also implicitly posit a tensor-product space for the bipartite system. Let me ask you this: Once this tensor-product space is set, is there any way to toggle one of the factors from afar just as with the quantum state? As far as I can tell there is not. Thus I would say that the Hilbert space of the far-away system is a candidate for part of the theory's core. Well, the Hilbert space—once the choice of a particular quantum state within it is excluded—really carries no substance beyond its dimensionality d. Thus, in a more refined way of speaking, what I really mean to say is that when I posit a quantum system, I am allowed to also posit a characteristic property of it. It is a property that can be captured by a single integer d.

There are some other things which I can argue will be "left behind" in such an analysis, but I don't want to clutter this note too much. Mainly I presented the example above so that I could give you a clearer sense of how I want to draw a distinction between the rawest forms of "reality" (the surprises the world gives us) and the "core of a theory."

It is the core of the theory (along with the theory as a whole) that I am starting to view in Darwinian terms. But don't we have every right to posit that core as a property of the world itself, at least as long as that belief serves us well? This, as you point out, has been the predominant image of what science is about heretofore.

The only answer I can give you is "yes, we can" (just as indeed we have heretofore). So, your point is well-founded. What I am worried about is whether we *should* posit it so. You say that this view has guided science well in the past. But how do you know? In a world with a view that there is no ultimate law, how do you know that we would not be a thousand years more advanced if we had only better appreciated our role as the substratum of our theories? I think it boils down to the difference between an active and passive view of what existence is about. Or maybe the difference between a positive and a negative view.

To make this point, let me try to put things back into the context of regular Darwinian evolution. Consider the word "elephant." Does it denote anything that exists in a kind of timeless sense, in a way that we usually think—or in my case, previously thought—of physical theories as existing? If the concept of an elephant is worthy of treating as a candidate for an element of reality, then so too will a theory's core.

Well, if we have bought into Darwinism in any serious way, then I would say, no, there is nothing particularly timeless about the concept of an elephant. There was once a chance that it might not even arise in the world. The "elephant" is merely a function of the selective pressures that cropped up in our world's particular history. And, ashes to ashes, dust to dust, the poor elephant may eventually disappear from the face of the universe, just like so many species that arose in the course of evolution only to be never discovered by a single archeologist.

But now, contrast the evolution of the elephant with the possible future evolution of the human species. The elephant was an accident pure and simple, from the strictly Darwinian view. But I would be hard pressed to apply pure Darwinism to the future of mankind. The birth of my oldest daughter, for instance was no accident. Her traits were selected based on personal visions that both her mother and I had for the future. Similarly, but not so excitingly, with the golden retriever, and all our other domesticated species. The key point is that in the present stage of evolutionary development, we have it within our power to move beyond strict Darwinism. This is what our industry of genetic engineering is all about.

However, we would have never gotten to this stage if we had not first realized that the concept of a species is not immutable. As strange—and as crazy and as scary—as it may sound, this is where my thoughts are starting to roam with physical theories. This does not mean, however, that we can have exactly what we want with our physical theories—that they themselves are little more than dreams. Just as the genetic engineer can make a million viruses that will never have a chance of surviving on their own, there is more to the story than our whims and fancies: There is the ever-present selective pressure from the outside. But that does not delete the genetic engineer's ability to make something that was never here before.

But now, I go far, far, far beyond what I needed to say to answer all your questions. Mainly, I just wanted to emphasize why I intentionally placed the words "a priori" in my definition of reality way above.

I fear now slightly that you're going to realize I'm one of the craziest people you've ever met! And, trust me, I'm not sure I really believe all that I said in the last three paragraphs. But it does strike me as a productive, or at least hopeful, train of thought that someone ought to explore. I guess I offer myself as the sacrifice.

— — — — — —

There. I think that's enough of my going around your questions in a rather wide way. Let me now zoom back to the center of one of them for purposes of a final emphasis.

Woottersism 3 : *But you obviously also want to say that our theories tell us* something *about reality, even if they are not descriptions of reality.*

I hope you can glean from all the above that I do indeed believe our theories tell us something about reality. But that something is much like what the elephant tells us about reality. Its presence tells us something about the accumulated selective pressures that have arisen up to the present date. A theory to some extent is a statement of history. It is also a statement of our limitations with respect to all the pressures yet seen, or—more carefully—a statement of our limitations with respect to our imaginations for classifying all that we've yet seen. (I for instance, cannot jump off the leaning tower of Pisa unprotected and hope to live; you, for instance, cannot get into your car and hope to push on the accelerator until you are traveling beyond the speed of light.) Finally, to the extent that we the theory users are part of nature, the theory also tells us something about nature in that way.

But for any theory, there is always something outside of it. Or at least that's the idea I'm trying to build.

PS. Way above, I said I would finally say a few words about your "private-world-within-entanglement" musings. But somehow it didn't quite fit in with the flow of the rest of what I wanted to say. So, let me try to present the statement in isolation. From my point of view, the quantum state, and with it entanglement, never pierces into the quantum system for which we posit a parameter d (the "dimension"). Similarly for any bipartite system for which we posit two parameters d_1 and d_2. The quantum state is only about what I'm willing to bet will be the consequences when I reach out and touch a system. Otherwise, indeed, a quantum system denotes a private world unto itself. And similarly with bipartite systems. We have very little right to say much of anything about the goings-on of their insides. (This part of the picture is something I've held firmly for a long time; it even shows up in my *Physics Today* article with Asher.) Thus, I guess what I'm saying is that I can find a way of agreeing with what you wrote me:

Woottersism 4 : *Or maybe there* is *a possibility of testing the above distinction, at least in principle. (It depends on how I finish my interpretation.) Let's consider David Deutsch's thought experiment in which a sentient computer measures, in a reversible way, some property that doesn't have a definite value for the object being measured. Later, the computer will report that he observed a definite outcome but did not record which one, and the various possible paths will have been brought together successfully to exhibit interference. That's David's prediction. I would agree that interference should be possible, but I may disagree about what the computer will report. If it is true that one needs to have a* shared *world in order to have a sensible world, then when the computer was all alone in his private entanglement with the object he measured, who knows what he experienced? Maybe he experienced nothing more about that measured object than what one electron in a singlet pair experiences about the other electron. Maybe he cannot honestly report later that he saw one outcome or another.*

But maybe I'm coming at it from a different point of view.

PPS. I also promised to end with some open questions. But I'm petered out now. And if you've gotten this far, you're probably exhausted too. So I'll just leave it for the future, depending upon how interesting you find the ideas above, or how much you think they're nonsense!

Only two and half days left in Japan.

26-02-02 *New Jersey Trip* (to L. Hardy)

I'm about to start on the long journey back to NJ this morning. (I'm in Japan.) There's a little good news on my end. Within your framework, I finally found an absolutely simple Bayesian justification for the linearity assumption of the probability rule. I hope to write you an explanation of that on the flight. I think there's no doubt in my mind now: Your axioms (or maybe only a very small variation thereof) are certainly the most promising starting point for what I've been hoping to see in quantum mechanics. For the first time in my life I've understood (roughly) where the vector-space structure comes from. Sorry it took me so long to come around. If I were only smarter …

So, again, hopefully I'll write you a longer explanation on my flight. (If I don't snooze the whole way.)

26-02-02 *A Tired Old Man* (to G. Plunk)

I wrote the note below to David Mermin the other day, and he gave you a pretty good grade. Besides that, I understand from my superiors that there is still a *chance* (nothing certain) of filling at least one more position in our summer program.

Thus what it boils down to is for me to decide whether I've got enough spunk in me to take on a summer student this year … and/or whether this note will frighten you away. You unfortunately have written me at a time when I have just had a bad experience with a summer student. That is, though the summer went well for her (by what she tells me), I felt that my summer was used for little more than giving basic lectures in linear algebra and giving emotional support to a kid on her first excursion to summer camp. I lost a lot of time during the summer when I could have and should have been writing papers. I hope that builds some imagery.

Thus if I'm going to take on a student, it has to be a student who will:

a) Ask *some* of his own questions of nature, and not rely upon me for every input beyond the bigger picture and a reasonable amount of direction.

b) Use the resources available at Bell Labs to seek out an answer, which includes knocking on other people's doors besides mine some fraction of the time. I.e., I want a team player.

c) Handle my being away for a good piece of the summer, with only email contact.

d) Be emotionally secure in the sense of not needing me as a den mother. And,

e) Believe that issues to do with quantum foundations are the most exciting ones in the physics of our day.

The pay here is good. The towns are dull. But you'd live near a train station, with Manhattan about 50 minutes down the line.

I'll give you a shot at convincing me. Feel free to talk with Mermin before composing your reply (or deciding I'm not worth the bother). In fact I'll CC this note to him, so he knows what's up. But I'll need a reply pretty quickly, due to Bell Labs' time constraints … and my own time to let a decision percolate through my mind.

I've got a long trip from Sendai back to New Jersey tomorrow, so I may not be in email contact again for a couple of days.

27-02-02 *An Even Tireder Old Man* (to N. D. Mermin)

I forgot to include you as a recipient of the note below as I had promised. Let me not tell a lie: It's attached this time around.

I made good progress on several fronts in Japan. Maybe the most important—though most trivial—was that I finally found a rather natural Bayesian motivation for the linearity of the probability rule in Lucien's system. (Lucien is a trickster; he sneaks axioms in left and right that he doesn't call axioms.) Anyway, at the very beginning of the paper already, I couldn't accept his motivation for linearity, falling back as it does on the idea that a state refers in an objective way to (a class of) preparations. That is, he didn't take states to be Bayesian beliefs pure and true, and that's crucial to me.

Here's the solution; it's as simple as can be (now that I see it). The upshot of Lucien's formalism is that a measurement is any "I-know-not-what" that causes a refinement of one's initial beliefs (consistent with the other axioms). Thus a measurement is simply an application of Bayes' rule by its very definition—moreover, any application whatsoever within the allowed range. OK, that's good enough for the single observer and already thrills me (because it expresses in a more rigorous way a claim I made in the NATO paper at the level of density operators).

But when there are two observers and you view measurement as nothing but an application of Bayes' rule, you have to have some method of saying when they agree that it is the same measurement (so that you don't fall into the infinite regress I tried to warn you of when you were going full-steam-ahead with BFM). Well, here again the solution is simple: Two observers should call a refinement of their beliefs the same measurement, precisely when they draw the same meaning for the data they obtain. Thus as long as both observers ascribe the same $P(\text{data}|\text{hypothesis})$, we will say they "agree" upon the measurement.

And that's it. That does the trick. That and that alone gives linearity. No Gleason's theorem; not even anything fancy. I'll make this prediction right now: Quantum mechanics will turn out to be one of the simplest structures we've ever seen in physics, and for 75 years we've just been too pigheaded to see it.

Somewhere over the Pacific,

28-02-02 *Bell Labs!!!* (to G. Brassard)

I'm just back from 11 days in Japan, and on what fuel I'm running I'm not sure. In fact I'm deeply asleep as I write this. But in my slumber I sifted through my pile of mail and found the CRM theme year poster. What a delight to see our meeting listed! But what horror to see Los Alamos as my affiliation!! I hope Kiki will wake me up from this nightmare …

28-02-02 *Which Day?* (to L. Hardy)

What title would you like me to give the talk? And while I'm at it, do you have an abstract? Certainly talking on your axioms would be great. Though—for business appearances—you might want to throw in a word or two (but no more than that) about how getting the essence of quantum mechanics straight may shed some light on what it is that powers quantum computing ... or some such money-grubbing sort of thing.

01-03-02 *Drunken Nights* (to J. W. Nicholson)

I almost forgot to send you the two letters I told you about. I'm very proud of these. In fact, I think they're my best written and most provocative pieces in a year. This is what we've been talking about those drunken nights. [See 18-02-02 note "Psychology 101" to J. Preskill and 25-02-02 note "A Wonderful Life" to W. K. Wootters.]

In what follows, `\bjp` and `\ejp` mean the beginning and ends of a John Preskill quote. `\bbw` and `\ebw` means the same for Bill Wootters. `\bq` and `\eq` mean the beginning and ends of some general quote. The Everett point of view refers to the many-worlds interpretation of quantum mechanics. Otherwise I think the two notes are self-contained.

You can see by the time stamp of the present note, jetlag has me by the nads. I kind of doubt I'm going to come in today, so, sorry, probably no usual-Friday-lunch thing.

02-03-02 *Mermin Festschrift, 2* (to C. M. Caves)

Cavesism 70: *I'm inclined to think that the Mermin festschrift would be just the right place for my speculations about the reality of Hamiltonians, especially since he has kind of encouraged this idea. What do you think?*

I think, "I wonder why you ask *me* this!?!?" Are you contemplating that we might have dual submissions? Abbott and Costello, Crosby and Hope, Lewis and Martin, the Smothers Brothers? The problem is, both of us would want to be the straight man.

OK, enough sarcasm. To answer your question, yes, that probably would be a good idea.

By the way, here's a little technical meat for the hungry wolf. Suppose I were willing to go with you on the objectivity of *the* interaction Hamiltonian or unitary in a measurement interaction. (I'm not willing in actual fact, but that's beside the point for this question.) If we write down the POVM such an interaction ultimately leads to, then we will get something like this for its elements E_b:

$$E_b = \mathrm{tr}_{\mathrm{A}}\Big((I\otimes\sigma)U(I\otimes\Pi_b)U^\dagger\Big)\ ,$$

where all the terms have the usual interpretation. I believe, according to you, there should be only one subjective piece to the right hand side of this equation, namely the ancilla's initial density operator σ.

Here's my (innocent, first) question. The subjectivity in σ will afford a range in our interpretation of which POVM was actually measured in any such interaction. What is that range? How large is it?

A corollary question—this one is more rhetorical and less innocent—is this. You know I have never liked the above formulation of what a measurement is because one has to invoke a second measurement (the Π_b) to explain the first (the E_b). This leads to an infinite regress because one can ask (as von Neumann did), where do the Π_b come from. Thus, just to make sure we're on board, let me reconfirm that I got the setting in your mind right in my elaboration above. Namely, that the only truly subjective term you would accept in the displayed equation is σ? The range in E_b is consequent only to that? If that's the case, I would also like to understand how you invoke a stopper at the level of the Π_b. That is, why do the Π_b not have some of their own range, induced by a higher level measurement model?

You can tell I'm still deeply jetlagged.

03-03-02 *De Finetti and Strong Coherence* (to P. F. Scudo)

Thanks for the ghost story.

Scudoism 1: *Will tell you more as soon as I finish my calculations for this paper.*

Not to worry at all. I have a hard enough time leading a rushed life. You should not expect that I expect that out of you when I cannot live up to that standard myself! When you arrive here you'll have plenty of time to practice the macabre.

But still, if you've got the interest, who am I to get in your way. Here's some historical investigative work that you might tackle if you find that have nothing better to do. In fact, your friend Regazzini might be a wonderful resource in this regard. In the draft of the anti-BFM paper that Caves, Schack, and I are putting together, we make a distinction between simple "Dutch-book consistency or coherence" (i.e., the notion that de Finetti and Ramsey first introduced) and "strong Dutch-book consistency." The latter is a notion that apparently Abner Shimony first introduced, though Caves and Schack stumbled across it independently in one of our many wars. (See reference 12 on page 139 of the samizdat I sent you for the original citation.) [See 06-02-02 note "The Commitments" to C. M. Caves & R. Schack.]

Starting on page 133 of the samizdat, I write a fairly strong polemic against the "requirement" of strong-consistency—it seems to me that regular Dutch-book consistency is the most we can demand. Here's my question. As you'll see from the quote of Ian Hacking on page 137, de Finetti was aware of Shimony's addition to coherence and apparently rejected it. Do you think it might be possible to find out where he wrote about this? More importantly, what were his particular reasons for rejecting the stronger notion?

04-03-02 *Sliding Off the Deep* (to H. J. Folse)

I was able to print out your paper without a hitch. And thanks moreover, for your detailed notes on my letter to John Preskill. Let me try to answer some of your questions (in particular the one about Popper and propensities) by sending you still more rubbish. It's in the form of a follow-on letter (to the Preskill one) that I sent Bill Wootters while still in Japan. [See 25-02-02 note "A Wonderful Life" to W. K. Wootters.] Of course, I would appreciate any further comments like your last ones if you've got the time!

Let me quickly reply to two of your points explicitly.

Folsesm 5: *Do any physicists still think this way? I realize cosmologists talk about a TOE, but surely the conduct of contemporary research is not animated by the thought that we're closing in on some "final" description of the universe? That was true enough a century ago, but I think that the weight of philosophy of science at least in the 20th century has pulled against that sort of image of science – certainly in a post-Kuhnian era. It is curious perhaps that this kind of attitude might* *still persist in so-called "foundational" studies, whereas I would suppose in something like biological research everyone would have become much more historicized by now.*

Nope, the attitude runs pretty rampant in the quantum information and computing community. (I'm definitely one of the outsiders there.) Have a look at David Deutsch's *The Fabric of Reality*. I think he expresses much of the majority opinion of our little clique there. But I think you'd be surprised to know that the "dreams of a final theory" attitude runs pretty rampant even in such workaday fields as laser physics. I just got the following message from an experimentalist friend of mine whose work is predominantly used for the design of better fiber optics:

Nicholsonism 5: *One of the thoughts that continues to strike me is your optimism in the continual evolution in physical theory. I will admit that on bad days I feel like we are in the twilight of physics - only incremental progress is left to be had.*

Of the physicists I have met who have even heard of Kuhn or Rorty—there aren't that many—almost all of them view what little they know of their thoughts (i.e., Kuhn and Rorty's) with a little contempt. (By the way, John Preskill's reaction to my letter was particularly violent. So I think it is the ideas, and not the men, that bug their sensibilities.)

By the way, I have indeed just discovered Rorty and I find him wonderful. I've read the two collections of essays *Philosophy and Social Hope* and *Consequences of Pragmatism*. It won't be long, and I'll move on to the book of his that you recommended. Also since Växjö, I've gotten a good feel for James (I read *Pragmatism*, *The Meaning of Truth*, and Perry's massive biography of him), and also of Dewey (though I've only read *John Dewey: The Essential Writings*).

Thanks for telling me about Kitcher; I hadn't heard of him. And thanks for the pointer to Toulmin; I'll look more deeply into him than I have in the past.

Concerning one of your other points,

Folsesm 6: *It is arrogant perhaps, but I don't see this as the egocentricity. Every attempt to sketch a conception of the universe from our best theories at any date in human history in effect commits such arrogance. Were the Newtonians of the end of the seventeenth century being "egocentric" to think that Sir Isaac had done nothing less than peer into the mind of the Divine and discerned God's blueprints for the universe?*

Yes. (In my opinion.) And you might interpret James and pragmatism in general as a reaction to that. However, I think in our modern age with quantum mechanics we have a motivation and opportunity in front of us that James did not have. Try to give quantum mechanics a naive realist interpretation—you can do it, or at least both Everett and Bohm tell us we can—and you find yourself contorting yourself beyond belief. It's as if nature is telling us for the first time, "Please don't interpret me in a naive realist fashion. I can't stop you, but please don't."

OK, the sun is rising and the vampire must return to his native soil.

04-03-02 *The Good Questions of Nicholson* (to J. W. Nicholson)

Nicholsonism 6: *So. My question to you is two-fold. Do you still feel the same way about particle physics experiments that try to continually increase the energy of interactions between particles? And, if not, what extrema in physical theory should we be poking at in order to continue the evolutionary progress?*

You ask a good question old friend—the second one—and I shall have to think a while before I reply. Or at least compose myself before I reply.

In the case of your first question the answer is easy. Yes, I still feel that way. And the feeling is not that the SSC would not have been worthwhile science per se; it might have been. It was just the cost versus insight-and-control-of-nature ratio that doomed it in my mind. Furthermore, the paradigm the high-energy types presuppose certainly puts me off. They think they are doing something deeper than tabulating the Hamiltonian of an iodine atom, say, but I don't think they are. They are just tabulating the Hamiltonian of another system, and that has the value it always has.

But let me think harder about how to answer your second question. For my present project (i.e., quantum mechanics), it strikes me not so much as poking at the extrema that we ought to be spending our time on, but in poking at the consistency of the worldview we wish to embed the theory in. To revert to my analogy of the construction of general relativity, it was only consistency that Einstein was seeking when he first started contemplating how gravitation fit within the framework of special relativity. Seeing that it did not (and weeding out all the coordinate effects as I expressed earlier) is what led to the bending of the manifold.

But don't take that as my definitive (or exhaustive) reply. I'm still thinking.

04-03-02 *Green Light* (to A. Y. Khrennikov)

Khrennikovism 7: *I am waiting for your papers for proceedings. Please send me a signal that you are working! If yes, I shall wait one-two weeks.*

Yes, please do wait for me. I am working, and I am trying to find a way to respond to your "Växjö interpretation" both directly and indirectly.

05-03-02 *A Hardy Reminder* (to C. H. Bennett)

OK, it's set, Hardy's going to give his talk on Thursday March 14, from 2:00 to 3:00. And as I told you, Osamu Hirota will also be around. (Not to mention the pleasures of my goofy laugh and van Enk's dry wit.) So, you've got every reason to come. We'll look forward to seeing you Thursday.

06-03-02 *Poetry on Concrete* (to L. Hardy)

I decided to write this letter in LaTeX so that I would have a small chance of being clearer. A few months ago, you wrote me this:

Hardyism 1: *[M]y basic picture of preparation/transformation/measurement is rather similar, though considerably less poetic, than your picture of humans interacting with a world. . . . After the poetry you need to make the journey from vision to concrete construction.*

You're quite right. I think your paper has finally started to mix the right sort of concrete to support a building like the one I want to see built.

In what follows, all I'm going to do is keep true to this word I learned—poetaster—and try to write a little amateur poetry at your construction site. There are three things that really intrigue me in your paper, and one that really confuses me. I'll take them one at a time.

The first is simply the absolutely beautiful ease with which you bring us to a vector space structure. I had known about the concept of "informationally complete" POVMs for years[17]—they're even a crucial part of the proof of our quantum de Finetti theorem[18]—but before your work I had never appreciated so clearly that the probability distributions they generate ought to be taken as the very most primordial representation of a quantum state.

> *What is a quantum state? Nothing more than one's gambling commitments with respect to the outcomes of a fiducial measurement. Full stop.*

Or at least, that's the way I want to view it.[19]

Now, what you write presently is not completely consistent with that characterization. I'm going to do my best to try to make that plain to you. You write, "I don't believe that my approach needs to adopt a particular approach to interpreting probability." There is a sense in which that is certainly true for the mathematics you've already performed. However, if we're ever going to get past this foundational impasse in quantum mechanics, I would say firmly that we cannot leave the story there.

Here is the difficulty. If you take an objective approach to probability, then you are necessarily left with the conclusion that a measurement "here" in general changes something objective (or physical) over "there." And you will never get around that. Just consider any entangled state. Making a measurement on Alice's side changes her ascription—without any considerations of time or distance—of the state on Bob's side. If a state is purely equivalent to a set of probabilities and probabilities are not subjective degrees of belief or gambling commitments, but rather objective and independent of the agent, then something physical must change at Bob's site with that far away measurement. And if you believe that, then you end up with conundrums out the wazoo.

I know that may not be your stand yet, but it is mine. Thus I'm left with the task of putting your mathematics into a framework I can accept. The first and clearest example of a technical mismatch between our views is what we each might consider as a valid motivation for the convex-linearity rule in your Eqs. (41)–(43).[20]

I think if we were to trace the roots of our mismatch, we would find it in that I do not subscribe to your "basic picture of preparation/transformation/measurement" ... which I think you think is common to both of us. Here's the way I put it to Asher Peres when we were constructing our Physics Today paper:

> In general I have noticed in this manuscript that you lean more heavily on the word "preparation" than we did in our letter to Benka. ... Unless I misunderstand your usage of the word, it may actually be a little too anthropocentric even for my tastes. The problem is this: consider what you wrote in the paragraph about the wave function of the universe. It seems hard to me to imagine the wave function of those degrees of freedom which we describe quantum mechanically as corresponding to a "preparation." Who was the preparer?

[17]I think the idea can be traced back to E. Prugovečki, "Information-Theoretical Aspects of Quantum Measurements," Int. J. Theo. Phys. **16**, 321 (1977).

[18]See Section IV of `quant-ph/0104088`.

[19]And I say this even though I was saying things right after the Växjö meeting like I said to Khrennikov in the letter of 4 July 2001 attached below. Somehow, I just never took the idea so seriously as I do now, i.e., after reapproaching your paper in Japan. "Fiducial measurement" + "a notion of transformation from one measurement to another that carries the probabilities with it" is what tells the whole story!

[20]By the way, I have to take a little exception with your accounting rules for your axioms. In similar treatments from the "operational school," say of Kraus, Holevo, and Ozawa, a convex-linear or affine assumption (of exactly the same spirit as your Eqs. (41)–(43)) is always listed as a distinct axiom.

> It is for this reason that Carl Caves and I prefer to associate a quantum state (either pure or mixed) solely with the compendium of probabilities it generates, via the Born rule, for the outcomes of all potential measurements. And then we leave it at that. Knowing the preparation of a system (or the equivalence class to which it belongs) is one way of getting at a set of such probabilities. But there are other ways which surely have almost nothing to do with a preparation. An example comes about in quantum statistical mechanics: when the expected energy of a system is the only thing known, the principle of maximum entropy is invoked in order to assign a density operator to the system. There may be someone beside me in the background who knows the precise preparation of the system, but that does not matter as far as I am concerned—my compendium of probabilities for the outcomes of all measurements are still calculated from the MaxEnt density operator.
>
> To help ensure that I was not jumping to conclusions on your usage of the term, I reread today your paper "What Is a State Vector?" [AJP **52** (1984) 644–650]. There was a time when I agreed with everything you wrote there .... But as of today at least, I think a more neutral language as in our letter to Benka is more appropriate.

Thus what I seek is a picture that involves only measurement and transformation. (And if the truth be known, I'd like to get rid of transformation *in a sense*, leaving only measurement behind from your trinity. But that's a longer story, and I'll only give hints of it below.) However, I do think your formalism is just about up to the task, despite your Figure 1 on page 4.

The way I see it, this thing called the "preparation" is just a token for the *right and true* quantum state you imagine for a system. But from a steadfast-Bayesian[21] point of view, there is no such thing as a right and true probability assignment for anything. Consequently, if a quantum state is to be solely a probability assignment for the outcomes of a fiducial measurement, from the steadfast-Bayesian view, there can also be no such thing as a right and true quantum state.[22]

Let me emphasize this once more at the purely classical level before going on. For the Bayesian there is no such thing as a *right* probability assignment; there is no such thing as a *wrong* probability assignment. A probability assignment is a set of numbers that signifies which gambles one is willing to make, period. How those numbers are set in any given instance is an issue that has nothing to do with nature. Instead it has everything to do with all the ugly things we try to keep out of science: one's emotions, one's intelligence, one's hopes, the rumors one has heard recently, and so on. In fact, a probability assignment has nothing to do with the world itself—in a sense it floats above the physical world.

What this boils down to is that—*within a Bayesian paradigm*—your argument for convex-linearity cannot make any sense:

> Assume that the preparation device is in the hands of Alice. She can decide randomly to prepare a state $\mathbf{p}_A$ with probability λ or a state $\mathbf{p}_B$ with probability $1-\lambda$. Assume that she records this choice but does not tell the person, Bob say, performing the measurement. Let the state corresponding to this preparation be $\mathbf{p}_\mathbf{C}$. Then the probability

[21] Some would say "radical Bayesian."

[22] I have argued this point at great length in a correspondence with Caves, Schack, and Mermin predominantly. I'm going to post that on my website at just about the same time I send this note off to you. The file is called "Quantum States: What the Hell Are They?," and the relevant part with respect to my remark starts on page 19 and winds up somewhere around page 97. However, the most relevant notes are the ones to Brun-Finkelstein-Mermin dated 7 August 2001, to Caves-Schack dated 22 August 2001, and to Mermin dated 2 September 2001. I hope you will have a look at those at the same time as reading the present note.

Bob measures will be the convex combination of the two cases, namely

$$f(\mathbf{p}_C) = \lambda f(\mathbf{p}_A) + (1-\lambda) f(\mathbf{p}_B) \tag{1}$$

> This is clear since Alice could subsequently reveal which state she had prepared for each event in the ensemble providing two sub-ensembles. Bob could then check his data was consistent for each subensemble. By Axiom 1, the probability measured for each subensemble must be the same as that which would have been measured for any similarly prepared ensemble and hence (41) follows.

Here's the difficulty. What does the distribution $(\lambda, 1-\lambda)$ refer to? From the Bayesian view, it can only refer to a belief (or better yet, a gambling commitment) that Bob possesses concerning Alice's actions. On the other hand, the numbers $f(\mathbf{p}_A)$ and $f(\mathbf{p}_B)$ refer to a couple of alternate beliefs a completely different person, Alice, might possess. However—*from the Bayesian standpoint*—there is nothing *a priori* that can be used to rigidly identify Bob's beliefs as a function of Alice's ... as Eq. (1) above would imply. Alice has every right to believe anything she wants; Bob has every right to believe anything he wants.[23]

For the Bayesian, all the action—all the science—is not in the probability assignments themselves that various individuals might make, but in how those assignments change upon the acquisition of new data (steered by the influence of rationality).[24] In particular, the important things to ferret out are the conditions in any situation where two observers will converge in their beliefs when they agree that they are acquiring the same data. Bernardo and Smith put it in a beautiful way:

> The subjectivist, operationalist viewpoint has led us to the conclusion that, if we aspire to quantitative coherence, individual degrees of belief, expressed as probabilities, are inescapably the starting point for descriptions of uncertainty. There can be no theories without theoreticians; no learning without learners; in general, no science without scientists. It follows that learning processes, whatever their particular concerns and fashions at any given point in time, are necessarily reasoning processes which take place in the minds of individuals. To be sure, the object of attention and interest may well be an assumed external, objective reality: but the actuality of the learning process consists in the evolution of individual, subjective beliefs about that reality. However, it is important to emphasize, as in our earlier discussion in Section 2.8, that the primitive and fundamental notions of *individual* preference and belief will typically provide the starting point for *interpersonal* communication and reporting processes. In what follows, both here, and more particularly in Chapter 5, we shall therefore often be concerned to identify and examine features of the individual learning process which relate to interpersonal issues, such as the conditions under which an approximate consensus of beliefs might occur in a population of individuals.

> What is the nature and scope of Bayesian Statistics within this spectrum of activity? Bayesian Statistics offers a rationalist theory of personalistic beliefs in contexts

[23]Nor does it help to try to divert the discussion from a two-player situation and stuff all of these beliefs into a single head (Alice's say). For at any instance, Alice believes what she believes. And there is nothing within the Bayesian creed to force what she ought to believe in various other hypothetical situations—for example, where the distribution $(\lambda, 1-\lambda)$ might describe the amount of amnesia she has concerning a previous belief that she's just forgotten.

[24]Read my note to Mermin titled "Reality in the Differential" starting on page 128 of my previously mentioned posting.

> of uncertainty, with the central aim of characterising how an individual should act in order to avoid certain kinds of undesirable behavioural inconsistencies. The theory establishes that expected utility maximization provides the basis for rational decision making and that Bayes' theorem provides the key to the ways in which beliefs should fit together in the light of changing evidence. The goal, in effect, is to establish rules and procedures for individuals concerned with disciplined uncertainty accounting. The theory is not descriptive, in the sense of claiming to model actual behaviour. Rather, it is prescriptive, in the sense of saying "if you wish to avoid the possibility of these undesirable consequences you must act in the following way."
>
> — p. 4, Bernardo and Smith, *Bayesian Theory*

And, it is precisely this that I'm going to use to get to your Eq. (41) from a Bayesian starting point. But before I can do that, let me praise the second thing that I see as a deep contribution of your paper. This is the very *definition* of what a measurement is: It is *any* application of Bayes' rule consistent with your remaining axioms.[25]

To make some sense of this, let me put the problem into a notation that is slightly better for my purposes. Suppose the outcomes of a fiducial measurement are labeled by h and the outcomes of some other measurement we might contemplate are labeled by d. Then I will dually write the quantum state (via your identification of states with probabilities for the outcomes of a fiducial measurement) as a function $P(h)$ or as a vector $\mathbf{P}$. What I mean by an application of Bayes' rule is the supposition of a set of probability distributions $P(h|d)$ (or $\mathbf{P}_d$ in vector notation)—one for each d—such that

$$P(h) = \sum_d f_{\mathbf{P}}(d)\, P(h|d) \;, \tag{2}$$

or alternatively

$$\mathbf{P} = \sum_d f_{\mathbf{P}}(d)\, \mathbf{P}_d \;, \tag{3}$$

for some other probability distribution of $f_{\mathbf{P}}(d)$ over the variable d. When a particular data d is collected, one—at least tentatively—enacts the transition

$$\mathbf{P} \;\longrightarrow\; \mathbf{P}_d \;. \tag{4}$$

This is what I claim you have taught us is "what a quantum measurement is."[26]

A measurement is any "*I know not what*" that enacts a transition of the form Eq. (4). What is the variable d? How is it defined? It simply is not, except as a place holder in a particular instance of Bayes' rule. And that's it: That's the story of measurement.

Now, where does one get the convex-linearity of the probability rule $f_{\mathbf{P}}(d)$ in a Bayesian-happy way? The technique is to consider when it is that two observers will think they are performing

[25] There is no doubt that I have been predisposed to saying something like this for a long time. For instance, at the top of page 26 of my NATO paper `quant-ph/0106166`, I say, "Quantum measurement is nothing more, and nothing less, than a refinement and a readjustment of one's state of knowledge." The difference is, your paper brings this beyond just some metaphor. There I tried to capture the idea with my Eqs. (57)–(59), which are explicitly in terms of density operators. You on the other hand, do it with the real thing. I.e., you make it absolutely airtight that it is Bayes' rule operating in the background, and not just some noncommutative analog of it.

[26] Note carefully that I used the word "tentatively" in this description. That is because there is a possibility of the further quantum phenomenon that measurement can be more invasive than supposed classically. What this means operationally is that the $\mathbf{P}_d$ may not ultimately concern the original fiducial measurement, but may instead be about a completely different fiducial measurement at the end of the process. See my discussion centered around Eqs. (57)–(59) of `quant-ph/0106166`.

the same measurement. That is to say, I could walk into the room and think to myself that the measurement device in front of me gives me warrant for the decomposition in Eq. (2). You on the other hand, with a completely different set of beliefs and experiences, may think that the device warrants you to the decomposition

$$Q(h) = \sum_d f_{\mathbf{Q}}(d)\, Q(h|d)\ . \tag{5}$$

When shall we say that we actually agree upon the measurement? Classically, the answer is when the statistical model made use of by each of us is the same:

$$Q(d|h) \equiv \frac{f_{\mathbf{Q}}(d)\, Q(h|d)}{Q(h)} = \frac{f_{\mathbf{P}}(d)\, P(h|d)}{P(h)} \equiv P(d|h)\ . \tag{6}$$

That is, if we had hold of which one of the fiducial outcomes actually obtained, then we would draw the same meaning from it. Here, by "meaning" I mean how much we would feel warranted in revising our beliefs that a d would have popped up if we had instead performed an appropriate measurement for it.

By the way, notice one thing. If this account deviates from standard Bayesianism any at all, it is only in this. Never once did I invoke the *necessity* of a joint probability distribution

$$P(h,d) \equiv f_{\mathbf{P}}(d)\, P(h|d) \tag{7}$$

in my description of Bayes' rule. Of course, such a function exists as a mathematical artifice—i.e., it has all the properties of a joint probability distribution—but one should not try to make any meaning for it beyond that. In particular—and, especially with regards to the quantum context—one should not feel it necessary to interpret the function as a degree of belief of the simultaneous *existence* of a true h and a true d.

OK, let me use that now to start talking about convex-linearity again. Suppose there are at least three agents on the scene, Alice, Bob, and Charlie. And suppose Alice subscribes to Eq. (2) for her description of what the device in front of her is about, whereas Bob subscribes to Eq. (5), and Charlie still further subscribes to,

$$R(h) = \sum_d f_{\mathbf{R}}(d)\, R(h|d)\ . \tag{8}$$

If that is as far as it goes, then there is nothing whatsoever we can say about the relation between $f_{\mathbf{P}}(d)$, $f_{\mathbf{Q}}(d)$, and $f_{\mathbf{R}}(d)$. Indeed there need be no relation whatsoever.

However, suppose Alice, Bob, and Charlie share the minimal belief that actually the same measurement is being performed with respect to each of their descriptions. Then by definition

$$P(d|h) = Q(d|h) = R(d|h)\ . \tag{9}$$

Fine. Now consider those cases where, as it turns out,

$$P(h) = \lambda Q(h) + (1-\lambda) R(h)\ . \tag{10}$$

Letting

$$G(d) = f_{\mathbf{P}}(d) - \lambda f_{\mathbf{Q}}(d) - (1-\lambda) f_{\mathbf{R}}(d)\ , \tag{11}$$

we see immediately that

$$G(d) = \sum_h \Big[P(h)P(d|h) - \lambda Q(h)Q(d|h) - (1-\lambda)R(h)R(d|h)\Big] \tag{12}$$

$$= \sum_h \Big[P(h) - \lambda Q(h) - (1-\lambda)R(h)\Big]P(d|h) \tag{13}$$

$$= 0 \tag{14}$$

since

$$f_{\mathbf{P}}(d) = f_{\mathbf{P}}(d)\sum_h P(h|d) \equiv \sum_h P(h)P(d|h)\ , \tag{15}$$

and so on.

And that's it, from this perspective.

$$P(h) = \lambda Q(h) + (1-\lambda)R(h) \qquad \Longrightarrow \qquad f_{\mathbf{P}}(d) = \lambda f_{\mathbf{Q}}(d) + (1-\lambda)f_{\mathbf{R}}(d) \tag{16}$$

when and only when the agents who hold the beliefs **P**, **Q**, and **R** "agree" to the meaning of the d-"clicks" the measuring device will elicit.

Part of me fears that you're going to view all this as little more than rhetoric. It took me five pages of explanation to do what you did in one paragraph. So let me try to reiterate the point of this exercise from my perspective one last time, before I throw in the towel. Here's the point. If you believe that the quantum state is rigidly (or even loosely) connected to reality, then—it seems to me—you will never find a way out of the conundrum of "unreasonableness" associated with "state-vector collapse at a distance." I.e., our community will always be left with a search for the *mechanism* that makes it go. Our community will always be left with the embarrassing questions to do with its clash with Lorentz invariance. And, maybe most importantly, we will be left with the nagging question of why we can't harness this mechanism for more useful purposes.[27] I view these questions as a distraction from the ultimate goal we all ought to have, of building a more interesting, more fantastic physics.

In connection to the present discussion, I would claim that THE preparation is little more than an anchor for such a rigid connection. It is, even if implicitly, a reversion back to the old issues that led to all the trouble in the first place. Thus I am compelled to find a way to absolutely disconnect the quantum state from the physical world. Yet I am still required to make sense of what it is that we're doing when we practice quantum mechanics. For this, the trail has already been blazed by (radical) Bayesian probability theory, and thus I take that as my cue. Getting at Eq. (16) from within a subjectivist framework is one of those first steps you just have to take ... and then hopefully never have to think about again.

OK, with that, I'm ready to praise you my third and final time in this letter. But I think you'll probably hardly feel it's a praise. Let me tell you another goal of seeing how much of quantum mechanics can actually be run through with complete airtight consistency from the subjectivist standpoint. And that is to pick the theory apart. For, you see, I see no difficulty whatsoever in imagining that any theory can consist of two basic components—the completely subjective and agent-dependent, and the completely objective (or intersubjective if you will) and thus, agent-independent. What is the distinction between these components (I hope you ask)? It is this: Once

[27]If we can't see angels, why posit them? If we can't see superluminal communication, why posit it? Alternatively, if we do posit angels, the natural question to ask is how might they help save our souls. I would be suspicious of a world where the angels served little purpose other than rounding out a theology and not aiding in our souls' deliverance.

an agent posits one of the objective components in any particular instance (whether it's "really" there are not), there is no move *within* the theory that will allow him to change that supposition.

Let me give you an example of the latter. Posit a bipartite system with Hilbert spaces $\mathcal{H}_{d_1}$ and $\mathcal{H}_{d_2}$ (with dimensions d_1 and d_2 respectively) and imagine an initial quantum state for that bipartite system. Now, I would say that the quantum state must be a subjective component in the theory because the theory allows me localized measurements on the d_1 system that can change my quantum state for the d_2 system. In contrast, I would say that the number d_2 that was posited for the second system is an objective component in the theory. There is nothing I can do at the d_1 site that will allow me to change the numerical value of d_2. The only way I can change that number is to scrap my initial supposition. Thus, to that extent, **(on first pass)** I have every right to act as if the numbers d_1 and d_2 are potential "elements of reality."[28]

Here's where I really think you sell yourself short by advertising your system as an extension or generalization of classical probability theory (with classical probability theory as a special case that's gotten by deleting one of the axioms). For I would say that your framework of "states" as vectors and "measurements" as applications of Bayes' rule is *classical probability theory*, full stop. Or, I should just say "*probability theory*, full stop"—for, the word "classical" seems to imply that it is a subject somehow within empirical science (rather than "law of thought" that antecedes science). In showing me that even quantum "measurements" can be viewed legitimately as nothing more than applications of Bayes' rule, you have done me a great service. For you demonstrate to me more clearly than ever that the concept of POVM ought to be put onto the subjective side of the shelf when I tear quantum mechanics into its two components. But your other intriguing axioms—like the simplicity and composite-system axioms—which you think give the possibility of generalizing upon classical probability, I would say are nothing of the sort. Instead, I would say they express just the opposite. These axioms seem to me to say something about what we are positing of nature. They express something that is not subjective and is not "law of thought." They in fact form part of the restriction to probability theory that I asked for over and over in my `quant-ph/0106166`. Thus drawing those axioms out explicitly strikes me as great progress.[29]

Thus to come back to my example of Hilbert-space dimension. As I have already explained, I would say that quantity is a (potentially) objective feature of nature. But now, after understanding your paper better, I would say the same of your composite-system axiom. In fact, that axiom is a way of elucidating the very meaning of the dimension d. As such, it forms part of the "manifold-structure analogy" behind quantum mechanics which I tried very hard to explain to Preskill and Wootters in two further letters I'll paste below. (I hope you will read them along with this note, as I think they greatly elucidate what I was hoping to convey in the previous four paragraphs.)

There. Three praises; take them for what they're worth. They are the three things that really intrigue me about your paper. But I've only started my digestion process. I'll leave a discussion of the confusions until we get some single-malt in front of us next week.

08-03-02 *Your Webpage* (to H. J. Folse)

Thanks a million for the link to your webpage. I had a quick flip though it before my flight this morning, and it looks great. (I'm on my way to Atlanta for an AMS meeting.) I'll have a much deeper read through it upon my return; I can tell you that it will certainly help orient me with respect to the various schools. Just a snap judgment—maybe not to be taken seriously, since

[28] Please note that I emphasized the qualifier "on first pass." The reason for this emphasis will become clear if you read the letters to Preskill and Wootters that I have pasted into the present letter to you.

[29] And that is why this minor spanking counts as a praise!

I've only mildly skimmed the page—but it looks like I might be closer to an "entity realism" than anything else.

I'll tell you how my van Fraassen impressions go after I meet him. There's no doubt I'm more Bayesian-optimistic than ever. In particular, I've now become convinced (during my Japan stay) that a combination of my NATO paper (`quant-ph/0106166`) and Hardy's "five-reasonable-axioms" paper tells us unequivocally that collapse (or Lüders' rule or Kraus's generalization of it, or whatever you wish to call it), is NOTHING OTHER THAN an application of Bayes' rule along with a possible redefinition of which "observable" (POVM generally) the information is relevant to. In other words, collapse is after all an utterly trivial notion—it is refinement and readjustment (to a new context) of information and nothing more.

BTW, I met Plotnitsky and his girlfriend in Manhattan a few weeks ago. You should have heard the praise and the descriptions of beauty they gave your home! This report came, by the way, as were sitting in one of Plotnitsky's sister's homes: a three level penthouse on the corner of Broadway and Bleeker Street in Manhattan! Surely, a multi-million dollar affair.

12-03-02 *Wheeler Link* (to R. Pike)

Pike-ism 1: *Wheeler in* The Times*:*

- Dennis Overbye, "Peering Through the Gates of Time," *New York Times*, 12 March 2002, `http://www.nytimes.com/2002/03/12/science/physical/12WHEE.html`.

Thanks. That was good. Typical Wheeler.

15-03-02 *Ice Cream and Reciprocity* (to C. H. Bennett)

Thanks for taking care of Lucien last night. After a night of alternating between sweat and shivers, I seem to be on the road to recovery. A comment and a question.

Comment. I think you said that I should make an overlay for my quantum-axiom slide that says "Give an ice-cream reason, if possible," for each of the axioms. By this, you were indicating that my "Give an information theoretic reason, if possible," is a rather arbitrary thing to be asking. But, I say that it is not arbitrary precisely because the main object of our attention in the theory, the quantum state, specifies *probabilities*. It specifies how we ought to be taking nature into account when we make our mortal decisions. The quantum state does not specify flavors of ice cream. Thus it seems to me like an entirely natural question to ask: If the main object of the theory is of an information theoretic (or decision theoretic or call it what you will) character, then how much of its support structure might also be of the same character?

I think I put the goal of this program in a particularly clear way in a note to John Preskill. [See 18-02-02 note "Psychology 101" to J. Preskill.] I'll paste it below. Read it if you have the time.

Question. On the other hand, I rather liked what you said about wanting to base quantum mechanics on the idea that interactions are more symmetric in this theory than in classical physics. In interaction, both observer and observed are changed in the process. Could I get you to write your own version of that in a small paragraph, so that I can have something solid to read and think about?

24-03-02 *Leaving Dublin* (to C. King)

I just wanted to let you know, I absolutely enjoyed my little time alone with you today. Even if there had been nothing else to the rest of the meeting—and there was much to the rest of the meeting—today's discussions would have made it worthwhile for me to make the trip! I hope I can repay you one day likewise.

Concerning the part of today's conversation about Darwinist conceptions of scientific theories, I told you that I would give you an exact pointer to my write-up of that. The place to look is at the file titled *Quantum States: What the Hell Are They?* posted at my website (link below). In particular, have a look at the letter to Preskill titled "Psychology 101" starting on page 143 and the letter to Wootters titled "A Wonderful Life" starting on page 149.

The references I owe you concerning characterizations of completely positive maps are these:

- J. A. Poluikis and R. D. Hill, "Completely positive and Hermitian-preserving linear transformations," *Linear Algebra and Its Applications*, vol. 35, pp. 1–10, 1981.
- G. P. Barker, R. D. Hill, and R. D. Haertel, "On the completely positive and positive-semidefinite-preserving cones," *Linear Algebra and Its Applications*, vol. 56, pp. 221–229, 1984.
- L. J. Landau and R. F. Streater, "On Birkhoff's theorem for doubly stochastic completely positive maps of matrix algebras," *Linear Algebra and Its Applications*, vol. 193, pp. 107–127, 1993.

Take care and enjoy your visit with your wife and children.

24-03-02 *Packing Your Suitcase* (to F. Verstraete)

I'm just about to get on the road home from a week-long stay in Dublin. Today I had the greatest conversation with Chris King where we mapped out a good load of mathematical questions that arise naturally from my musings about the Bayesian nature of quantum time evolution operators. So, if you're amenable, I think I'll have you work on precisely those problems during your visit to Bell Labs. (CK, in fact, thought these questions were exactly up your alley ... based on a paper you wrote recently characterizing CPMs.)

Anyway, here's the stuff to be reading to start to get ready for the project. (That is, if you've got any spare time. If you don't, then certainly don't worry about this.) The easy stuff is my new collection of letters posted at my website (link below). The title is "Quantum States: What the Hell Are They?" and pay particular attention to the parts where I give arguments for the "subjectivity" of the Kraus operation (and POVM) that one associates with a measurement. Anyway, that forms my personal background and motivation for the technical questions I've got for you.

But you don't have to worry: The technical questions stand alone and will be worthwhile to you even if you buy in to none of my particular motivation. As a little preparation for that, you might obtain the following papers:

- J. A. Poluikis and R. D. Hill, "Completely positive and Hermitian-preserving linear transformations," *Linear Algebra and Its Applications*, vol. 35, pp. 1–10, 1981.
- G. P. Barker, R. D. Hill, and R. D. Haertel, "On the completely positive and positive-semidefinite-preserving cones," *Linear Algebra and Its Applications*, vol. 56, pp. 221–229, 1984.

- L. J. Landau and R. F. Streater, "On Birkhoff's theorem for doubly stochastic completely positive maps of matrix algebras," *Linear Algebra and Its Applications*, vol. 193, pp. 107–127, 1993.

Is everything settled now for your visit? Can you send me the schedule of when you'll be arriving? We're gonna have to find a place for you to live.

25-03-02 *Company from Hybernia* (to A. Plotnitsky)

This is just a small note to tell you I'll be traveling with you today. I'm in Dublin right now, but soon to go home. I was in a bookstore yesterday, and I ran across a copy of Paul Feyerabend's posthumous book *Conquest of Abundance*. Seeing your recommendation printed on the back pushed me over the edge and I bought it!

26-03-02 *Popper and Detractors* (to R. Pike)

Pike-ism 2: *From Adam Gopnik's article about Karl Popper in the latest* New Yorker*:*

> The reason science gave you sure knowledge you could count on was that it wasn't sure and you couldn't count on it. Science wasn't the name for knowledge that had been proved true; it was the name for guesses that could be proved false.

Thanks, I ought to have a look at the full article.

Here's the way I put my own take on exactly the same subject in a letter to Bill Wootters recently. [See 25-02-02 note "A Wonderful Life" to W. K. Wootters.]

27-03-02 *Still More Zing!* (to J. Gea-Banacloche)

Thank you for the long, beautiful note. I loved it, and it makes me so wish that I had had enough time to get to the rest of my talk in Dublin—i.e., the part where I try to give some substance to the word "Zing!" I introduced on one of the early slides. (Recall, "Zing!" was meant to be a place holder for the answer to the question "What is real about a quantum system?")

Gea-Banaclochesm 1: *You seem to have a pretty good idea of how to make most of the postulates (on probability, tensor space structure, and even wavepacket reduction) flow in a more or less natural way from some reasonable information-theoretic ideas, once you are given the basic formal structure of operators and Hilbert spaces. The main question would appear to be, where does this formal structure come from, and what does it actually say about the physical universe?*

That is the main question. And—*in spirit*—I believe our proposed answers appear to be essentially the same:

Gea-Banaclochesm 2: *the basic physical fact at the heart of quantum mechanics is the uncertainty principle, which one could formulate very generally as follows–*

(P1) The nature of quantum mechanical systems is such that, even when we have all the possible information we can have about them, we cannot, in general, predict the outcomes of all the possible experiments we could carry on them. Specifically,

The only issue in my mind is how to carry out the word "specifically" in a way that would satisfy the aesthetic I'm seeking. In particular, I would really like to pin down where the noncommutativity comes from in a way that does not make a priori use of the notions of "compatibility" and "incompatibility." In other words, I'd even like "incompatibility" to be a secondary notion, rather than a primary one. I think it is possible, and my present thinking is that it can be made to come out in a pretty way as a natural consequence of the mismatch between the number of bits that can be reliably stored in a quantum system and the number of measurement outcomes required for an "informationally complete" representation of a quantum state. (That is to say, something along the lines of the mismatch between the numbers N and K in Lucien Hardy's treatment in `quant-ph/0101012` and `quant-ph/0111068`.)

In any case, I have a discussion of "Zing!" in several places in my paper `quant-ph/0106166`. Especially in the closing section. Since then, I've come quite a way toward what I was trying to express above, but you'd have to dig harder for that—it's not exactly published properly yet. The place to look at the moment is in the file titled "Quantum States: What the Hell are They?" posted on my webpage (link below). The upshot is the following (working) statement: Each quantum system can be postulated to have an intrinsic amount of "sensitivity" to our experimental interventions upon it, and that sensitivity can be captured by a single parameter d (call it the dimension). From that, everything about the algebra of observables for a system follows from a basic statement about the very meaning of Bayes' rule in that context.

I'm working hard to get some of this in a proper paper presently.

By the way, I loved your Teilhard de Chardin quote:

> The history of the living world can be summarized as an elaboration of ever more perfect eyes within a cosmos in which there is always something more to be seen.

In my own way, I tried to express something similar in two pieces that I've come to be pretty proud of. Have a look at my letter to John Preskill titled "Psychology 101" starting on page 143 and my letter to Bill Wootters titled "A Wonderful Life" starting on page 149 of the file I mentioned above.

I hope that you yourself made it home safely and comfortably from Madrid, and also that you found your family doing well there. Emma's chicken pox are already clearing up: So maybe I was gone just the right amount of time!

27-03-02 *Invited Submissions* (to J. H. Shapiro)

Attached below are two pdf files. One, titled `QCMC02.pdf`, contains the abstract to my invited submission. The other, titled `honest.pdf`, represents a joint (contributed) submission with Patrick Hayden. I hope that the organizing committing will still consider it a valid contributed submission even though we have missed the deadline. (The missing of the deadline was entirely my fault, as I somehow got the impression that all submissions were due April 1.)

In any case, of the second submission, Hayden would give the actual presentation. Just to let you know, Patrick Hayden is presently a Prize Postdoctoral Fellow at Caltech and one of the young movers of quantum information. (He also had a Rhodes Scholarship for his graduate work at Oxford, and has recently been offered a faculty position at McGill University in Montréal.) So, having him there, would certainly do well for the conference's reputation.

28-03-02 *Men in Power* (to P. Hayden)

Sorry to get back to you so late. (If you haven't discovered by now, it's a habit with me.) The trouble was, I was in Ireland last week and part of this week, and, of course, I got carried away with all the conversations of the moment.

Anyway, I finally sent in the abstracts yesterday. Here's the reply I got from Jeff Shapiro today:

Shapiro-ism 1: *Thanks for submitting your title and abstract in such a timely fashion. As for the "*`honest.pdf`*" paper, I am sorry but I feel that I must be absolutely bureaucratic and reject it. We have 182 submissions for QCMC'02 as it is, and even with posters this number is considerably more than we'll be able to accept. I have already rejected several late submissions, and it would be unfair of me to create an exception for you and Patrick Hayden.*

I am sorry about this. Maybe just maybe if I had gotten off my duff and read your email before just leaving for Ireland ...

In any case, I do think we should pursue doing something for real this summer. I'll try to write you soon about scoring function issues.

Below, let me attach the abstract I actually sent Shapiro. Mainly I made only the most minor of changes so that it would fit in two pages: I.e., I killed the last section and took out the associated reference. Also I shortened the acknowledgements just a tad. Stylistically, I changed all the "non-"s to "non"s (it's a pet peeve of mine) and changed the title to "Keeping the Quantum Experimentalist Honest". Oh yeah, I also used a `\Big` in Eq. (28). And I think that's it.

Like I say, I've got a lot more to write to you about scoring functions, but let me give you the short of it. The main reason I'm attuned to the issue has to do with some of my recent debates with Caves and Schack concerning the strength of axioms one should assume in a Dutch-book foundation for probability theory. I say the axioms should not be so strong as to keep an agent from lying (no matter what the case). This is important when one considers concatenating probabilities for various events. Something of an account of where I last left the story can be found on my webpage in the file "Quantum States: What the Hell Are They?". The most relevant part appears in a letter titled "The Commitments" starting on page 133. A link to my webpage is below.

Again, I'm sorry about the QCMC thing, and I'm sorry you spent the time writing the abstract for nothing. But maybe still something good will come out of this in the end.

Keeping the Quantum Experimentalist Honest

Christopher A. Fuchs and Patrick Hayden

von Neumann entropy and the honest expert

There are a number of compelling axiomatic characterizations [AczelD75, OhyaP93] of the von Neumann entropy $S(\rho) = -\mathrm{Tr}\rho \log \rho$ of a density operator ρ and the quantum source coding theorem provides what is certainly its most important functional characterization [Schumacher95, JozsaS94, BarnumFJS96]. Here we give what could be the *simplest* characterization of the von Neumann entropy, generalizing an idea of Aczél's for characterizing the Shannon entropy [Aczel80]. The approach is to show that the entropy arises as the optimal expected payoff in a type of game between a cash-strapped experimentalist and her employer. Thus, it provides a meaningful interpretation of the von Neumann entropy in a completely nonasymptotic setting, when only one realization of the density operator ρ is available.

Alice, an ambitious scientist attempting to build a quantum computer, manages to produce states that, to the best of her knowledge, are described by the density operator σ. She then sends a note to her employer, Bob, saying that she has succeeded in producing the state ρ. Bob, as a conscientious scientific administrator, would like to ensure that Alice does not lie about her progress. In other words, he would like to guarantee that $\rho = \sigma$. Therefore, from time to time Bob will visit Alice's lab and perform a measurement, conditioned on the data ρ that she sent him. Her future funding will depend on the outcomes of these measurements. The question is, what measurement should Bob perform and how should he structure his payments to Alice such that she never has any incentive to deceive him?

We propose the following strategy for Bob. He should perform a measurement in the basis $\{|e_i\rangle\}_{i=1}^n$ that diagonalizes $\rho = \sum_i r_i |e_i\rangle\langle e_i|$ and, upon getting outcome i, pay Alice $C + D \log nr_i$ dollars, for nonnegative constants C and D. Notice that if ρ described a maximally mixed state then $r_i = 1/n$ and, regardless of the outcome, Bob pays Alice C dollars, ensuring that she will be able to support herself even if her lab produces completely random states.

Now, assume to start that Alice has prepared a state σ such that $[\sigma, \rho] = 0$. We can then write $\sigma = \sum_{i=1}^n s_i |e_i\rangle\langle e_i|$ and the expected payment from Bob to Alice is

$$C + D \log n + D \sum_{i=1}^{n} s_i \log r_i, \tag{17}$$

which is maximized if and only if $s_i = r_i$ for all i, giving an expected payment of

$$C + D \log n - DS(\sigma). \tag{18}$$

Thus, under the assumption that Alice reports a state ρ that commutes with her σ, she maximizes her payment by choosing $\rho = \sigma$. Moreover, there is a built-in incentive for her to try and produce pure states since she is penalized by an expected amount $DS(\sigma)$.

Now consider what happens in the general case. The probability that Bob will measure outcome i is $p_i = \mathrm{Tr}(\sigma |e_i\rangle\langle e_i|)$ and the expected payment is

$$C + D \log n + D \sum_{i=1}^{n} p_i \log r_i. \tag{19}$$

Again we find that

$$\begin{aligned} -\sum_{i=1}^{n} p_i \log r_i &\geq -\sum_{i=1}^{n} p_i \log p_i && (20) \\ &= H(p_1, p_2, \ldots, p_n) && (21) \\ &\geq S(\sigma), && (22) \end{aligned}$$

where the second inequality holds because the output entropy of a complete projective measurement is always at least as large as the entropy of the input density operator. (See, for example, Ref. [NielsenC].) Thus, the expected payment is

$$\begin{aligned} & C + D \log n + D \sum_{i=1}^{n} p_i \log r_i && (23) \\ \leq\ & C + D \log n - DH(p_1, p_2, \ldots, p_n) && (24) \\ \leq\ & C + D \log n - DS(\sigma). && (25) \end{aligned}$$

Equality in the first line occurs if and only if $p_i = r_i$ for all i and in the second line if the measurement is a complete projection in the eigenbasis of σ. (Again, see Ref. [NielsenC].) Therefore, under the assumption that the payment as a function of the outcome probabilities is unique, the proposed measurement strategy is the unique solution to the problem of keeping Alice honest.

The following theorem of Aczél's guarantees this last fact for density operators with $n \geq 3$. It is notable for the extremely weak assumptions made of the payment function.

Theorem 1 (Aczel80) *Let $n \geq 3$. The inequality*

$$\sum_{i=1}^{n} p_i F_i(q_i) \leq \sum_{i=1}^{n} p_i F_i(p_i) \tag{26}$$

is satisfied for all n-point probability distributions $(p_1, \ldots, p_n)$ and $(q_1, \ldots, q_n)$ if and only if there exist constants $C_1, \ldots, C_n$ and D such that

$$F_i(p) = D \log p + C_i, \tag{27}$$

for all $i = 1, \ldots, n$.

The efficient gambler and accessible information

The accessible information $\mathrm{Acc}(\mathcal{E})$ in an ensemble of states $\mathcal{E} = \{\rho_i; p_i\}$ is defined to be the maximum over all possible POVM measurements $\{M_j\}$ of the mutual information $I(i:j)$, where $p(j|i) = \mathrm{Tr}(\rho_i M_j)$. Despite the enormous effort that has been spent studying the accessible information [Fuchs95], however, justification for the definition remains unclear. One motivation, which we won't describe in detail, is via asymptotic coding [HausladenJSWW96, Holevo98, SchumacherW97]. The approach yields the accessible information as the maximal rate at which bits can be sent using quantum codewords whose marginal distribution is given by $\mathcal{E}$ but only if severe restrictions are imposed on the encoding and decoding. Namely, the codewords must be product states and the decoding must be performed by product measurements. If the second restriction is relaxed, it is the Holevo χ quantity

$$\chi(\mathcal{E}) = S\Big(\sum_i p_i \rho_i\Big) - \sum_i p_i S(\rho_i) \tag{28}$$

which answers the coding question, not the accessible information. Thus, the delicacy of the asymptotic problem provides yet another incentive for finding a single–realization interpretation of the accessible information.

Such a realization exists, as the quantum analog of an old idea of Kelly's [Kelly, CoverT]. We imagine that Alice is a bookie who takes bets on the mutually exclusive events $\{i\}$, which occur with probabilities p_i. For simplicity, we assume that Alice gives fair odds and does not collect a fee, so that if the gambler Bob wagers S_i on event i, he is paid S_i/p_i when i actually occurs. Now suppose that Bob is given private information about which outcome occurred prior to it becoming public knowledge, so that he could still place bets at the original odds. Moreover, imagine that Bob's source of information is a *noisy quantum channel* which outputs ρ_i when event i occurred. Bob's task, therefore, will be to perform some POVM measurement $\{M_j\}$ and then use the information gained from the measurement to make a wager, all done in such a way as to maximize the exponential rate of growth of his capital

$$G = \lim_{n\to\infty} \frac{1}{n} \log \frac{C_n}{C_0}, \tag{29}$$

where C_0 is his initial capital and C_n his capital after n rounds of betting. We show that this maximal rate of growth is the accessible information: $G_{max} = \mathrm{Acc}(\mathcal{E})$.

28-03-02 *And a Short Reply* (to R. Campos)

Thank you so much for your kind letter. I just printed out your PLA paper, and I look forward to understanding it. [R. A. Campos and C. C. Gerry, "A Single-Photon Test of Gleason's Theorem," Phys. Lett. A **299**, 15–18 (2002).] Sorry it has taken me so long to reply, but I was tied up with a meeting in Dublin from the 19th through the 26th and then it took me still a couple days beyond that to recover from the travel.

Just a couple of very quick remarks on your manuscript. 1) In your second sentence, you say "Starting from the description of physical states as $\hat{\rho}$ as vectors in a Hilbert space, and observables as projectors $\hat{\Pi}$ in that space, Gleason proved that the ..." That however, is a little inaccurate and downplays Gleason's achievement. Gleason does not start at all with states as vectors in a Hilbert space. He only starts with the observables that you mention and then, in the process of his proof, *derives* that the states can be represented as density operators. Thus, in a sense, he gets the states for free. In any case, from the rest of the paper it looks that you do understand this. I'm just pointing out that the wording of the introductory paragraph of the paper is misleading. 2) In reference 5, you write C. C. Caves instead of C. M. Caves.

As I say I really haven't had a chance to understand your paper yet, but I will indeed study it. How could I but help to with so many flattering remarks in it about me!

You ask about simplifications to the standard Gleason theorem. There are two places to look (one you've already known):

- R. Cooke, M. Keane, and W. Moran, "An Elementary Proof of Gleason's Theorem," Math. Proc. Camb. Phil. Soc. **98**, 117–128 (1981)
- I. Pitowsky, "Infinite and Finite Gleason's Theorems and the Logic of Indeterminacy," J. Math. Phys. **39**, 218–228 (1998).

Unfortunately I don't have copies of either of these papers any more.

However, there is a far greater simplification than the above, which can be found if one is willing to embrace the notion that POVMs can be taken as a basic concept of measurement in quantum mechanics. I explain this in detail in my paper `http://xxx.lanl.gov/abs/quant-ph/0106166` and prove a version of Gleason's theorem in an absolutely trivial way. (Also you can pick it up off my webpage: the link for it is below.) In particular the proof by this method works also for 2-D vector spaces and even vector spaces over the field of rationals, in both cases of which the standard Gleason theorem fails.

Certainly keep up the good work. This quantum mechanics is a wonderful thing.

28-03-02 *Quantum-Information Information* (to R. Duvenhage)

I just want to write you a very short note to tell you how much I enjoyed your paper `quant-ph/0203070`, "The Nature of Information in Quantum Mechanics" and to express how much similarity I think I see between our points of view. In particular, I think you expressed some things so very clearly that I would love to co-opt your phrases!

Here's where I think we agree the most:

1. "A measurement is by definition the reception of information by the observer."
2. "This renders many problems surrounding the measuring process in quantum mechanics no more difficult than in classical physics." And consequently,

3. Your discussion of the Heisenberg cut.

You can find some reflection of these ideas in my own paper quant-ph/0106166, though not put quite so succinctly as in yours. In particular I'm thinking of my discussion on pages 27 and 28 of that paper, following the earlier discussion on page 11. Also, I agree with your point about B's information being "invalidated" in your discussion on page 13 of your paper. Similar ideas make an appearance on pages 39 through 41 of mine. Finally, I also enjoyed your discussion of the linearity of time evolutions. That was the sort of thing, I was trying to describe in my notes of 22, 26, and 27 September 1999 on pages 408, 284, and 285, respectively, of my samizdat quant-ph/0105039.

However, I think I've come a long way since that paper and those notes. In particular, I think I'm no longer really willing to say that "quantum collapse is a noncommutative [generalization of] conditional probability." I think there is a sense in which quantum collapse is *precisely* an application of Bayes' conditionalization rule, modulo only a final redefinition of what the posterior probability is relevant to. What I mean by this in more detail can be found in my letter to Lucien Hardy beginning on page 159 of my collection "Quantum States: What the Hell Are They?" (which can be found on my webpage, link below), especially toward the end of the letter. In fact, I'm presently striving to write that up in an updated version of quant-ph/0106166, and I hope to place it on the server soon.

Anyway, I really want to point out the similarities in our thoughts rather than the contrasts. I think you've done the physics community a good service with your paper. It's very well written, and a lovely piece actually.

I really have the greatest hope and enthusiasm that we, the quantum information community, are on the verge of something very big in our understanding of quantum mechanics. I'm glad to see some good young minds joining into the enthusiasm as well!

29-03-02 *Building with Bayes* (to B. C. van Fraassen)

Sorry to take so long to acknowledge your note: I've been running around Ireland with some bad phone connections and probably a few too many pints.

But I'm back now, and I did find your flyer waiting in my mailbox. I tacked it to the wall, but the subject's not likely to attract any of the physicists in my immediate vicinity. I would like to bring a visiting student with me though. Her name is Petra Scudo, and her present email address is scudo@techunix.technion.ac.il. She, as things turn out, did some undergraduate work in Pavia under a guy named Regazzini, who in turn was a student of Bruno de Finetti. While Petra is visiting (for a month and a week), I'm going to have her work on trying to pin down a kind of quantum de Finetti representation theorem for time-evolution maps. I.e., a theorem in answer to the question, "What is an 'unknown' quantum operation?" (In this context, the term "quantum operation" refers to the generalization of unitarity that is common in quantum channel theory — namely, the trace-preserving completely positive linear map. Sometimes people call it "open-system dynamics" but, from the Bayesian perspective, it is little more (nothing more?) than a noncommutative generalization of a conditional probability, connecting as it does the prior (quantum-state) assignment to the posterior (quantum-state) assignment.)

Technically, I've made a breakthrough of sorts recently. I now know how to think of quantum collapse as *precisely* an application of Bayes conditionalization (importantly, followed by a redefinition of which measuring instrument the posterior probability assignment is relevant to). I call this a breakthrough because until recently (for instance see page 25 of my NATO paper, quant-ph/0106166), I continued to think of collapse as a noncommutative *analogue* of conditionalization. But now, using a representation of the quantum state similar to the one Hardy harps on, I can see that what is going on is the true-blue thing (i.e., simply Bayes in disguise). At the moment I'm working hard to get this written up in a sensible way . . . or at least give my readers a hint of it, until I can do it properly.

By the way, in coming to all this, I've taken a more radical Bayesian turn than I had expected at the outset. I.e., though I started my career in an Ed Jaynes kind of "objective Bayesian" camp, I'm now finding myself in the left of the de Finetti camp and maybe a little beyond that. In case it interests you, I've documented a lot of this transition in a new samizdat which I've placed on my webpage. The title of the file is "Quantum States: What the Hell Are They?" and it contains a lot of new correspondence with Mermin and others along these lines. (As an aside, I've significantly revamped my webpage; it's not so minimalist anymore, and maybe thus a little more attractive.)

While I'm here and I've invested this much into a long letter to you, let me make the thing even longer by tacking on two pieces from the above-said collection. I'll put them immediately below—one is a letter to John Preskill and one a letter to Bill Wootters. Both letters should be self-contained. Anyway, I place them here because I had forwarded them to Henry Folse a while ago, and he wrote me back a rather excited letter saying that I'm starting to explore some philosophical ground not so dissimilar from where Bas van Fraassen has gone. I wish I were in a position to judge the validity of that! But I just haven't read enough yet. (I'm trying to, believe me. But, being a physicist, I've got a lot of material to catch up on.) Anyway, until then, I'll keep my fingers crossed that maybe I can get some reaction directly from the horse's mouth. Are there similarities between our views? And what other pieces of your work should I be reading if there are?

Finally, concerning your seminar with Elga, I'd love to attend! So, please do keep me on the list.

29-03-02 *Historical Rampage* (to A. Peres, N. D. Mermin, A. Cabello, H. J. Folse, and A. Plotnitsky)

I am finally sitting down to write an introduction to the Växjö proceedings, and I am wondering if I can bother any of you to give me some help in this regard. The help I would like is related to a paragraph I just wrote:

> Quantum theory in its full-fledged form has been with us for 75 years. Yet in a very real sense, the struggle for its formation remains. Indeed, not a year has gone by since 19?? when the world has not seen at least one meeting of physicists or philosophers devoted either explicitly or implicitly to the foundations of quantum theory. Our very meeting in Växjö, "Quantum Theory: Reconsideration of Foundations," is just one of a long lineage of meetings with this tormented soul.

What I would like to do is back up that claim with some substance, and also make the year "19??" look as dramatic as possible.

Here is the way you can help me if you have some time. Please just send me a list of the meetings you are aware of. What I would like is 1) the title of the meeting, 2) the location of the meeting, and 3) its date. Even if you only have partial information for any of these things, I would still like you to send me what you have: it may give me enough clues to piece together the rest. (Furthermore, if you know of any good resources that may help me in this quest, please let me know.)

For instance, just in looking in my own CV I have been able to dig up the list below.

For whatever help you can give, I will thank you lavishly in the article's conclusion!

- Workshop on Squeezed States and Uncertainty Relations, College Park, Maryland, March 1991
- Fundamental Problems in Quantum Theory: A Conference Held in Honor of Professor John A. Wheeler, Baltimore, Maryland, June 1994
- Sixth UK Conference on Conceptual and Mathematical Foundations of Modern Physics, Hull, England, October 1997
- Second Workshop on Fundamental Problems in Quantum Theory, Baltimore, Maryland, August 1999
- Chance in Physics: Foundations and Perspectives, Ischia, Italy, November 1999
- Quantum Foundations in the Light of Quantum Information and Cryptography, Montréal, Canada, May 2000
- NATO Advanced Research Workshop on Decoherence and its Implications in Quantum Computation and Information Transfer, Mykonos, Greece, June 2000
- Quantum Theory: Reconsideration of Foundations, Växjö, Sweden, June 2001
- 10th UK Conference on the Foundations of Modern Physics, Belfast, Ireland, September 2001
- American Mathematical Society Meeting, Special Session on Quantum Logic, Atlanta, Georgia, March 2002

31-03-02 *Progress Report* (to A. Peres, N. D. Mermin, A. Cabello, H. J. Folse, and A. Plotnitsky)

With the predominant help of Adán, here's what I can show so far. If any of you know of a way to fill in any of the gaps, that would be great. (Also if you know the data for the double question marks ??, that would be wonderful.) However, there's no need to waste your times sending me things from the years where I already have an entry. (Of course, I only really want the list for dramatic effect, not for complete completeness.)

Tomorrow, when I have the resources of a library, I'll try to fill in as much as I can. Of course it'd be great if I could get a continuous run ever since 1970 (or even earlier).

01-04-02 *Broadcasting and Petra* (to A. Peres)

Asherism 18: *Only many years later there was the no broadcasting theorem, then some better understanding of distinguishability, the proof that completely positive maps did not improve distinguishability, etc. Could* you *please give me a brief survey with references?*

That CPMs never create distinguishability in the sense of "relative entropy" between two states—this is perhaps the very strongest statement of the notion of "distinguishability nonincrease" —was first proved by Armin Uhlmann. Unfortunately, I cannot find that reference.[30] However, I do know the paper is cited in Ohya and Petz's book *Quantum Entropy and Its Use*. The property to be looking for is called the monotonicity of relative entropy.

In terms of operationally measurable quantities (the relative entropy is not really one such thing), like the fidelity or the trace-norm distance, I think we, in our no-broadcasting paper were the first to prove the property in the former case. Here's is the reference:

[30]But 11 years later Blake Stacey could: It is A. Uhlmann, "Relative Entropy and the Wigner-Yanase-Dyson-Lieb Concavity in an Interpolation Theory," Commun. Math. Phys. **54**, 21–32 (1977).

- H. Barnum, C. M. Caves, C. A. Fuchs, R. Jozsa, and B. Schumacher, "Noncommuting Mixed States Cannot Be Broadcast," *Physical Review Letters* **76**(15), 2818–2821 (1996).

With respect to the trace-norm distance, I don't know who was the first. I've certainly done it independently of anyone else, but on the other hand, I've never published. (And, actually, I don't know if anyone has ever published it.)

Better work on the no-broadcasting theorem, i.e., an algebraic proof, can be found in the work of Göran Lindblad:

- "A General No-Cloning Theorem," Lett. Math. Phys. **47**, 189–196 (1999).

I am very proud of that reference because, in it, he called our proof of the no-broadcasting result "ingenuous" (though from the context he meant "ingenious")! He set as his task to simplify the proof, though he ended up with a stronger theorem.

The very best work yet and the strongest (possible) result along these lines is due to Koashi and his boss Imoto, `quant-ph/010114`, "What is Possible Without Disturbing Partially Known Quantum States?".

I hope that helps you. Incidentally, I knew that Ghirardi had rejected the Herbert paper. He told me the story in Ischia in November of 1999. Later, upon my request, he sent me all the documentation. Unfortunately, I lost those papers in the Cerro Grande fire.

Asherism 19: *Please take good care of her. Her health is not very strong.*

I will do my best to take care of her. (And extract a good, lasting result in physics from her too!)

Asher's Preply

> I found your "rampage" letter, and I'll look at home for all the conference proceedings I have — quite many! Now I'll need similar help from you. When I was at the Trieste meeting, someone who was speaking about the no cloning theorem said that the Herbert paper "FLASH…" was wrong. He repeated it so many times that this antagonized me. When time came for questions, I said that I was a referee of that paper and I had recommended its publication. Obviously it was wrong, because it violated special relativity, but Herbert knew that very well. I wanted someone to find what was actually wrong in the amplification mechanism that he proposed, and I thought that a serious discussion would lead to progress. Indeed it led!
>
> Then I had a big surprise: Ghirardi came to the podium, with a transparency that he had ready. He said that he was a referee of that paper and had rejected it. His reason: the no cloning theorem that he had proved first. The transparency was a letter from the editor of *Found. Phys.*, certifying "to whom it may concern" that Ghirardi had proved the theorem in his confidential referee's report. He never bothered to publish it, until it was too late! I want to write all that in my contribution to the proceedings.
>
> However I also said that Ghirardi should not have rejected the paper, because Herbert had no exact cloning. All he had in his laser was a mess, perhaps described by a density matrix, and the no cloning theorem did not apply. Only many years later there was the no broadcasting theorem, then some better understanding of distinguishability, the proof that completely positive maps did not improve distinguishability, etc. Could *you* please give me a brief survey with references?

I was so excited after this exchange with Ghirardi that I had to take a tranquilizer, something I do very rarely. Also, a young man came to me saying: thank you for accepting that paper. The no-cloning theorem is my main source of income.

The San Feliu conference was also very good. Petra was there, and soon she will be going to you. Please take good care of her. Her health is not very strong.

02-04-02 *Desist* (to A. Peres, N. D. Mermin, A. Cabello, H. J. Folse, and A. Plotnitsky)

Just in case any of you are still looking, I've now filled all the slots between 1972 and present. So, you can wipe your brow and call it a good day's work. Thanks to all of you for all the help.

02-04-02 *A Little Urgent* (to J. Bub)

I'm trying to put together a dramatis personae for my latest lambasting of the existence of quantum foundations conferences—i.e., I'm trying to make a case that we should work toward the conference to end all conferences—and I would like to exhibit 30 full years of conferences in it. And I'm only missing one!! It's for the year 1978. I wonder if you can help.

I discovered that you have a 1979 paper titled "The Measurement Problem of Quantum Mechanics" which appears in a book *Problems in the Philosophy of Physics* (72d Corso), Bologna: ... Could this paper, by chance, have been due to a Conference Proceedings in 1978?? If so, can you give me the following things: 1) the title of the conference, and 2) where it was held.

Thanks, and if you can help me, I'd be ever so grateful.

06-04-02 *The Early Morning* (to A. Plotnitsky)

I laid in bed this morning, reading and thinking about your review of Feyerabend's book. What a pleasant way to wake up. I think you are right: the most important issue is, what is the right balance of construction? It plays a role—I am convinced—but how big of a role?

You flatter me by sending me your newest book! How can you be so productive, while all the rest of us just twiddle by? I will cherish the book and have it read before you know it.

07-04-02 *Latour* (to A. Plotnitsky)

Plotnitskyism 2: *You got my point on Feyerabend exactly right. Besides, it is, I think, far more interesting, at least at this point, to think through that which is unconstructible, or, if one prefers, could be "constructed" as irreducibly unconstructible. (I am writing, among other things, a review of Bruno Latour's book, where this is a central issue as well.)*

Please send me that review when you've gotten it written!

07-04-02 *My (Hard-Earned) Pomposity* (to G. L. Comer)

Comerism 1: *Really? There's nothing to be learned from it* [Penrose's book]*? I mean I read Hawking's thing, didn't agree with everything, but did learn a few things.*

Sure, there's plenty to be learned by way of mathematical ideas and mathematical definitions and results. It's his implicit philosophy that I shun now, a philosophy that he's not even completely aware of (I think). And it's that philosophy (and the very troubles it causes) that makes up the two books' whole reason to be. [...]

Let me come back to this Penrose thing again. It has to do with the words "rational," "logical," and "sane." Penrose is a believer in a kind of other-worldly realm beyond the physical world called the realm of mathematical truth. In that realm logic and rationality are defined in a timeless fashion, in a way independent of human frailty.

I've now come to think that that is hogwash. In positing such a thing, one misses the whole point of this wonderful world — that it is still under construction, and can be made *to some extent* in the image we want to make it. By this account, what is rational and logical is not in what is timeless and "right," but in what gives us the most *long-term* survival value. Survival value so that we can give rise to the most progeny (genetically and intellectually); survival value so that we can stand a chance to shape things. And that, as Darwin taught us, is not something set intrinsically, but is a function of our cumulative environmental pressures.

09-04-02 *Thanks* (to H. J. Folse)

> **IMPORTANT**: See the correction to the present note in my note "Doing It and Doing It Right," dated 15 April 2002, to Henry Folse.

Folsesm 7:

> That is, the quantum state is a compendium of Bayesian "beliefs" or "gambling commitments" and is thus susceptible to the type of analysis James gives in his "Sentiment of Rationality." Our particular choice of a quantum state is something extra that we carry into the world.

Whoa, this paragraph eludes my comprehension. I thought the measurement chose the state of the outcome.

That's a long story. Yes, measurements can determine states, but my latest greatest realization is that they determine states in a way not so different from the way probability distributions $p(x)$ and $p(y|x)$ determine $p(y)$. $p(x)$ is the classical analog of the initial quantum state. $p(y|x)$ is the classical analog of the projection operator in the collapse rule. $p(y)$ is the classical analog of the final state. To the extent that in the Bayesian view *all* probabilities—even conditional ones like $p(y|x)$—are completely and utterly subjective, so are the meanings of the outcomes of one's quantum measurement (i.e., so are the basis vectors to which the collapses occur).

10-04-02 *Evidence 2* (to G. Brassard)

I did say two pieces of evidence: I almost forgot to go on to the second one. The one below is an excerpt from a long(er) letter by Jeff Bub. [See 10-04-02 note "Bitbol-ization" to J. Bub.] I'll try to read up on Bitbol soon. It sounds like he indeed embraces a position similar to ours. (I.e., that QM may come out of the idea that the observer cannot be detached ... i.e., (hopefully) that QKD exists.) So, the "waiting list" for our meeting grows.

But really, we need to give our more important attendants (i.e., the ones on the poster) some more concrete plans.

10-04-02 *NSERC Funding* (to R. W. Spekkens)

Spekkensism 8: *Incidentally, I was reading an old paper the other day which I thought might resonate with you. It is by Arthur Fine, "Do correlations need to be explained?", in* Philosophical Consequences of Quantum Theory*, edited by Jim Cushing.*

I am aware of that paper, and indeed was mightily impressed with it for a while. Have a look at my Samizdat, pages 373–379. Ultimately, however, I shook myself of the hidden hand. The only reason I'm a (subjectivistic) Bayesian is because of all the hard work I put into trying to be a propensitist.

10-04-02 *Bitbol-ization* (to J. Bub)

Sorry myself for taking so long to get back to you. Bitbol sounds interesting. I've put in a good word for him to Gilles; we'll see what happens. I absolutely love that phrase "blinding closeness."

Bubism 2: *Back to Bitbol and your earlier letter to me with replies to Preskill and Wootters. The essential point there seems to me very close to the neo-Kantian view about quantum mechanics that Bitbol has been developing in several books and articles.*

At the risk of getting into deep waters with a philosopher, I would say the point I'm pushing has a much deeper affinity to the philosophical tradition of pragmatism (James and Dewey's versions in particular) than anything of a Kantian flavor. But I've learned my lesson about saying the words "Copenhagen interpretation" to physicists. (See the story on the bottom of page 70 in the big Samizdat.) And similarly I'm learning a lesson about saying the words "James," "Dewey," and "pragmatism" in front of philosophers. The reactions I've gotten from Timpson, Brown, Donald, and Butterfield! Even when, in other contexts, I got such pleasant reactions from them about the ideas I was talking about ... namely pragmatism without the explicit label. Sometimes a few words are worth a thousand (mental) fences.

Jeff's Preply

Apologies for being out of touch. I am now in my house in Quinson in Provence for another couple of weeks, after spending an interesting week in Paris, where I met a philosopher of quantum mechanics by the name of Michel Bitbol whom I think you should get to know (more of Bitbol later).

To answer your question about my paper ...

Back to Bitbol and your earlier letter to me with replies to Preskill and Wootters. The essential point there seems to me very close to the neo-Kantian view about quantum mechanics that Bitbol has been developing in several books and articles:

> I think the solution is in nothing other than holding firmly—absolutely firmly—to the belief that we, the scientific agents, are physical systems in essence and composition no different than much of the rest of the world. But if we do hold firmly to that—in a way that I do not see the Everettistas holding to it—we have to recognize that what we're doing in the game of science is swimming in the thick middle of things. We're swimming in this undulant sea, and doing our best to keep our heads above the water: All the concepts that arise in a physical theory must be interpreted to do with points of view we can construct from *within* the world.

> That is to say, we have to loosen the idea that a physical law is a mirror image of what "is" in the world, and replace it with something that expresses instead how each of us can best cope with and hope to take advantage of the world exterior to ourselves.
>
> ...
>
> The situation of quantum mechanics—I become ever more convinced— illustrates this immersion of the scientific agent in the world more clearly than any physical theory contemplated to date.

What seems to me closely related to Bitbol's position is your emphasis on replacing the idea of a physical theory (you say 'law') as a mirror image of what is in the world (in what Pauli called a 'detached observer' sense), with an opposing view that takes seriously the fact that our science can only reflect points of view we can construct from *within* the world. I agree with you that this is the right way to look at quantum mechanics (although in my book I argued for the 'detached observer' view, which I identified with an Einsteinian view). Now I would say that quantum mechanics is not so much a descriptive theory of new sorts of non-classical objects (particles that are also wave-like, or particles with properties that hang together in a non-Boolean way, for example), as a theory of mechanics constrained by certain explicit limits to the process of objectification. (So, as Bohr said, there are no quantum objects. Quantum mechanics is not about how nature is, but about what we can say about nature. In this sense, it's a mechanical theory at the information-theoretic level, unlike classical mechanics – and the claim is that we are stuck at this level just because we are not 'detached observers.') Bitbol talks about the 'blinding closeness' of the world in the title to one of his books – a much more apt image than d'Espagnat's image of a 'veiled reality.'

Here's a suggestion: Take a look at Bitbol's website (you'll find him just by looking up Michel Bitbol on Google). If you like what you see (most of his publications are in French, but there are some things in English you can download from his website), why not invite him to the Montréal quantum commune meeting in the Fall? Note that he's more of a philosopher trying to make sense of quantum mechanics than someone who works with the formalism, but he does seem to know what he's doing.

11-04-02 *Zing D* (to I. H. Deutsch & C. M. Caves)

I am finally writing up my contribution to the Växjö conference proceedings, and in it I plan to make a statement about which elements of quantum theory I would be willing to call "ontological" if push came to shove. As Carl knows well, my favorite is the D. That is, for each system, when I ascribe to it a Hilbert space of some dimension D, what I am really doing is ascribing it an integer parameter of some (potentially) ontological significance. I do not let myself, however, assume such a significance for the states *in* the Hilbert space or the operators *on* it.

When I have that discussion, I would like to cite the stuff I saw Ivan present at the ITP meeting. (I saw it via the web.) Do you have paper written on that? If so, what are its coordinates? What I'll say is something like: If you're looking for the magic ingredient that powers quantum computing, it's not going to be first and foremost in the subjective elements of the theory. It's going to be in those things that stand a chance of being objective.

By the way, Ivan. I remember seeing one slide where you talked about the various points of view for just the question above—i.e., what might give quantum computing its power. In it you had one bullet devoted to "information-disturbance tradeoff." That was flattering, but surely it must be such a minority opinion as to not be an opinion at all!! (However, you ought to know what I'm aiming for: that that and D are the same thing, after all. So thanks in advance!)

13-04-02 *Quantum Locality* (to R. Garisto)

Thanks for sending me your draft; I will try to have a deeper look at it after my present project lets me come up for a bit of air. But, yeah, you're right, I can already tell I'm going to disagree with it. "What is the speed of quantum information?" It doesn't have a speed. It could only have a speed if you endow the state vector with an objectivity it does not have. QUANTUM STATES DO NOT EXIST (in and of themselves). They merely express the gambling commitments one is willing to make when one encounters a quantum system. But that does not leave the world empty; it just means that the quantum state is not part of its substance. Why is it that I should choose my gambling commitments to be in accordance with the structure of quantum mechanics? When we can answer that, we will have learned something clean and simple about the substance of the world. But until then, encumbering the world with an idea—nonlocality—that is clearly wrong-headed (without a heck of a lot of contrivance to try to make it go) will only distract us from the straight course to that great goal. What is it that makes quantum mechanics go? It is something deeper and far more interesting than the quantum state—that much I firmly believe.

I'm glad to hear that things are going well with you cancer-wise. Every time I think of you, I cross my fingers mentally for your health and happiness.

13-04-02 *An Address* (to L. Hardy)

Can you send me the name and email address of the guy who invited you to the Wheeler conference? I want to get in touch with him for a little help with regards that big reference document I'm putting together ("The Activating Observer").

By the way, I think I've got a better Bayesian-styled argument for linearity than the one I sent you in the big note. [See note titled, "Poetry on Concrete."] It allows me to conglomerate the three protagonists there into one. I'll ultimately write that up and send it off to you, but probably not for a while. By the way, I've got a summer student coming in from Cornell this summer, and I've decided on a technical project for him that has to do with connecting our (i.e., yours and mine) views of your paper.

15-04-02 *Doing It and Doing It Right* (to H. J. Folse)

I was just looking my last note to you over again, and I was appalled at what I had written. Namely, I really botched my description of the classical analog to collapse. How I could do that, I don't know. And I am ashamed of myself.

Here's the proper way to say it, and in fact the way I am just writing it up for a paper:

> In Section 8, "**What Else is Information?**," I argue that, to the extent that a quantum state is a subjective quantity, so must be the assignment of a state-change rule $\rho \to \rho_d$ for describing what happens to an initial quantum state upon the completion of a measurement—generally some POVM—whose outcome is d. In fact, the levels of subjectivity for the state and the state-change rule must be precisely the same for consistency's sake. To draw an analogy to Bayesian probability theory, the initial state ρ plays the role of an a priori probability distribution $p(h)$ for some hypothesis, the final state ρ_d plays the role of a posterior probability distribution $p(h|d)$, and the state-change rule $\rho \to \rho_d$ plays the role of the "statistical model" $p(d|h)$ enacting the transition $p(h) \to p(h|d)$. To the extent that *all* Bayesian probabilities are subjective—even the

probabilities $p(d|h)$ of a statistical model—so is the mapping $\rho \rightarrow \rho_d$. Specializing to the case that no information is gathered, one finds that the trace-preserving completely positive maps that describe quantum time-evolution are themselves nothing more than subjective judgments.

16-04-02 *Oh Grammarian* (to C. M. Caves)

I don't think I ever got the rules for "farther" and "further" straight. Which would you have put in the paragraph below (and why)?

> The complete disconnectedness of the quantum-state change rule from anything to do with spacetime considerations is telling us something deep: The quantum state is information. Subjective, incomplete information. Put in the right mindset, this is *not* so intolerable. It is a statement about our world. There is something about the world that keeps us from ever getting more information than can be captured through the formal structure of quantum mechanics. Einstein had wanted us to look further—to find out how the incomplete information could be completed—but perhaps the real question is, "Why can it *not* be completed?"

Thanks for (far?, fur?) your advice.

Carl's Reply

> Get yourself a copy of Strunk and White, and read it cover to cover. Here they are on your question (p. 46–47):
>
>> Farther, further. The two words are commonly interchanged, but there is a distinction worth observing: *farther* serves best as a distance word, *further* as a time or quantity word. You chase a ball *farther* than the other fellow; you pursue a subject *further.*
>
> I'd say you want *further*, unless you are thinking of Einstein as literally looking into the distance.

16-04-02 *My Own Homeopathy* (to C. H. Bennett, T. A. Brun, C. M. Caves, P. Grangier & N. D. Mermin)

I thought of all of you with a smile as I was writing the footnote below for an upcoming paper. I'll send it to you now. Maybe I really do practice homeopathy. (Wait till you see the undiluted version.)

> In the previous version of this paper, `quant-ph/0106166`, I variously called quantum states "information" and "states of knowledge" and did not emphasize so much the "radical" Bayesian idea that the probability one *ascribes* to a phenomenon amounts to *nothing* more than the gambling commitments one is willing to make with regards to that phenomenon. To the "radical" Bayesian, probabilities are subjective all the way to the bone. In this paper, I start the long process of trying to turn my earlier de-emphasis around (even though it is somewhat dangerous to attempt this in a manuscript

that is little more than a modification of an already completed paper). In particular, because of the objective overtones of the word "knowledge"—i.e., that a particular piece of knowledge is either "right" or "wrong"—I try to steer clear from the term as much as possible in the present version. The conception working in the background of this paper is that there is simply no such thing as a "right and true" quantum state. In all cases, a quantum state is specifically and only a mathematical symbol for capturing a set of beliefs or gambling commitments. Thus I variously call quantum states "beliefs," "states of belief," "information" (though, by this I mean "information" in a more subjective sense than is becoming common), "judgments," "opinions," and "gambling commitments." Believe me, I already understand full well the number of jaws that are going to drop by the adoption of this terminology. However, if the reader finds that this gives him a sense of butterflies in the stomach—or fears that I am or will become a solipsist[1] or a crystal-toting New Age practitioner of homeopathic medicine[2]—I hope he will keep in mind that this attempt to be absolutely frank about the subjectivity of **some** of the terms in quantum theory is part of a larger program to delimit the terms that actually can be interpreted as objective in a fruitful way.

1. P. Grangier, private communication, 2001.

2. C. H. Bennett, T. A. Brun, C. M. Caves, and N. D. Mermin, various vibes, 2001.

16-04-02 *Rushdie Quote* (to D. R. Terno)

> Scientists get angry when laymen misunderstand, for example, the uncertainty principle. In an age of great uncertainties it is easy to mistake science for banality, to believe that Heisenberg is merely saying, gee, guys, we just can't be sure of anything, it's so darn *uncertain*, but isn't that, like, *beautiful*? Whereas he's actually telling us the exact opposite: that if you know what you're doing you can pin down the exact quantum of uncertainty in any experiment, any process. To knowledge and mystery we can now ascribe percentage points. A principle of uncertainty is also a measure of certainty. It's not a lament about shifting sands but a gauge of the solidity of the ground.
>
> — Salman Rushdie, *The Ground Beneath Her Feet*

Thanks for the Rushdie quote. It's quite nice, especially the last line: "It's not a lament about shifting sands but a gauge of the solidity of the ground."

I think it's something a little in the spirit of what I wrote in my NATO paper:

> The complete disconnectedness of the quantum-state change rule from anything to do with spacetime considerations is telling us something deep: The quantum state is information. Subjective, incomplete information. Put in the right mindset, this is *not* so intolerable. It is a statement about our world. There is something about the world that keeps us from ever getting more information than can be captured through the formal structure of quantum mechanics. Einstein had wanted us to look further—to find out how the incomplete information could be completed—but perhaps the real question is, "Why can it *not* be completed?"

18-04-02 *Urgent Reference* (to H. Barnum)

Can you send me some full references on where the idea of "noncontextuality" of the probability rule was introduced? I think you told me it was Mackey. Also, though, can you give me the reference, to the criticism of the idea: I think you said something like Hilgevoord?

Howard's Reply

The easiest thing is probably to attach my draft for the Cesena proceedings, which you may already have. Refs. 6 and 7 are probably what you want.

[6] G. W. Mackey, *The mathematical foundations of quantum mechanics*, W. A. Benjamin, New York, 1963.

[7] R. M. Cooke and J. Hilgevoord, "A new approach to equivalence in quantum logic," in Current issues in quantum logic, E. Beltrametti and B. van Fraassen, Eds., New York and London, 1981, Plenum.

I'll see if I can get the page nos. from my copy of Cooke & Hilgevoord (but they may be unnecessary since its an edited vol, not a journal). They are 101–114. Mackey's statement is part of his Axiom II on page 63. There is also an article which I haven't read, "Quantum mechanics and Hilbert space", *American Mathematical Monthly* **64**, pp 42–47 (1957), which was apparently "expanded into a book" (the one I cited), so this is probably the original source for Mackey. Note that Cooke and Hilgevoord, while citing Mackey, attribute the idea of probabilistic equivalence to Bohr, but I think they aren't specific about where (I can't find the article right now).

As you probably know, I think there was also a lot of discussion of noncontextuality in the papers around von Neumann's hidden variables result, notably Bell's paper on it, but I can't remember the details.

18-04-02 *Reference* (to F. E. Schroeck)

Can you give me the full reference for the paper in which you introduced the idea of informationally complete POVMs? (By full reference I mean title, journal, volume, beginning page number, ending page number, and year.)

Frank's First Reply

The earliest reference I can find to informational completeness is in a 1977 paper by Prugovečki. It is listed in my book *Q.M. on Phase Space*. The earliest reference in my own work is in a 1989 paper entitled "An Overview of Q. M. on Phase Space". I'll have to look up a reference to see where it was published! In this paper, I refer to it being present in two papers of 1989 — Busch and S., Found. of Phys. **19** (1989), 807–872; and Brooke and S., Nuclear Phys. B (Proc. Suppl.) **6** (1989), 104–106. I'll have to check these two references at home to see if "Info. Compl." is even defined in them. I also refer to it being in a paper that was not published, it being part of a package prepared for a grant; it was surpassed by another paper. Anyway, I'll send you a copy of that paper (and all other papers that I will mention here) in two days. The paper that surpassed this is "On Informational Completeness of Covariant Localization

Observables and Wigner Coefficients," D. M. Healy, Jr. and S., J. Math. Phys. **36** (1995), 453–507.

The first(?) unambiguous reference of mine to it appeared in "Unsharpness in Measurement Yields Informational Completeness," in *Symposium on the Foundations of Modern Physics 1990*, P. Lahti and P. Mittelstaedt, eds., World Scientific, 1991. In this paper I talk about its ramifications in quantum signal processing and natural biological systems.

There were a whole series of papers that I wrote, with an occasional collaborator, on representations of groups, pattern recognition, frames, ...

And then there is my book.

I'm going to send all this because the applications of info. compl. are everywhere, and the references are sometimes hard to come by. You have a day or two of reading ahead of you!

I'll get back to you on the three early references.

Frank's Second Reply

I found one that predates the one from 1990. It is in "Coexistence of Observables," F. E. S., Int. J. of Theor. Phys. **28** (1989), 247–262. I'll send that one also. I presume you don't any longer need the page no's from the paper mentioned below.

I also found info. compl. mentioned in a later paper from 1989. ("On the Reality of Spin and Helicity") It is enclosed as well.

So, there you have it!

19-04-02 *Lovely Circuits* (to N. D. Mermin)

Is there a typo in your paper, third paragraph? Two consecutive "before"s. If it's a clever construction, I didn't get it.

What do you use to draw your lovely circuits? I'm contemplating putting a figure of a circuit in my present paper, and I've never taken that bold step before.

"What the story demonstrates is the ability of entangled states to store interaction in a highly fungible form that need not be cashed in until the need arises." In comparing entanglement to classical correlation and making a point similar to yours, I once called entanglement "all-purpose correlation." This was great fun because it set me up to mention "Martha White's All-Purpose Flour," a product I remembered from my youth. What tickled me the most was that I got to cite Lester Flatt and Earl Scruggs, who sang the "Martha White Theme" during commercial breaks at the Grand Ole Opry. You might know them for the Beverly Hillbillies theme. It's the little things that keep me going, you know.

I'll tell you how if the paper stirs me.

20-04-02 *Yes* (to T. Rudolph)

It just turned 5:30 AM, and clearly I ain't got nothin' better to do.

This note is just to acknowledge that your question is a good one. Can one give a primary quantum state assignment $\rho^{(n)}$ that captures the idea of n draws from a fixed set $\{\rho_i\}$ of quantum states (distributed according to some probabilities p_i). Let me call such a source, a Bernoulli source.

That is, the question is how to characterize the class of density operators that look like this

$$\rho^{(n)} = \sum (p_{i_1} p_{i_2} \cdots p_{i_n}) \rho_{i_1} \rho_{i_2} \cdots \rho_{i_n}$$

where the summation is over all strings $i_1 i_2 \cdots i_n$. It would indeed be nice to have a characterization of the flavor of a de Finetti representation.

That is, in a Bayesian account, how can one take into acknowledge the receiver's state of knowledge is more than simply $\rho^{\otimes n}$, without inserting a man in the box? Or is the only way to do it to explicitly insert a man in the box? I'm not clearheaded enough right now. But it might indeed be the latter. See, for instance, in the case of quantum cryptography (B92, say), with respect to Eve there is always a "man in the box"—it's Alice, the source of the states. Similarly for all the other cases I've ever thought about: They're always communication games, where there is explicitly a sender and receiver. A sender sending messages (or a key), and a receiver (or eavesdropper) trying to decode them.

Concerning your A matrix account yesterday, Howard Barnum has thought a little bit about that. In particular he used the A to define some notion of "coherent superposition" of density operators. I'm not quite sure what he did with that, but it's written up as one of the chapters of his PhD thesis.

I'll cc this note to our friend Professor Schack, as he might have some interest in it too.

20-04-02 *Wacky Paper à Moi* (to G. Brassard)

I'm writing another wacky foundations paper, and I want to give one of the section headings a title like, "Le Bureau International des Poids et Mesures à Paris" (to express the phrase "International Bureau of Weights and Measures in Paris"). My question to you is, should the opening "Le" be there in a title? Also, am I safe assuming that the "à" translates to my "in"?

My French is atrocious. (In case you didn't know.)

20-04-02 *Helping a Friend* (to A. Cabello)

Yesterday, it was brought to my attention that you had increased the size of your massive bibliography since its first posting. I hadn't noticed. What an amazing document!

But really, I write you to ask if you have a BibTEX version of that database? One of our visiting grad students here, Frank Verstraete, had a hard disk failure on his laptop, and he very literally lost three years of work! (Of course, he is an idiot for not backing it up—he had never done it, not even once. But then again, I am an idiot for not grabbing my two-thousand pages of calculations as my wife and I fled Los Alamos.) I'm just trying to think of ways to help him. One thing he mentioned was that he had an extensive BibTEX file built up on quantum information things.

I noticed that your file is not written in BibTEX format. But is there a version of it in which it is? If so, it'd be nice if you could help him to this extent.

I am putting together a bibliographic project of my own—very different subject matter than yours. But I'll certainly cite your lovely work in it, for the purpose of cross-connections. I'm calling mine "The Activating Observer: Resource Material for a Paulian-Wheelerish Conception of Nature." It's sitting at four hundred and something references right now, many of which I've got annotated extensively. You can read the abstract of it at my new webpage (link below), but I don't have it posted yet. I was hoping to get it complete for the second anniversary of the Cerro Grande Fire, but I'm almost surely going to miss that deadline. Maybe I'll be able to do it for the 1.5 year mark.

21-04-02 *No BibTEX Version, Sorry* (to A. Cabello)

Oh well; we tried.

Cabello-ism 2: *By the way, I've recently realized that there was an international symposium on "Quantum Theory and Reality" in Oberwolfach, in July 1966. The proceedings, edited by M. Bunge, were published by Springer-Verlag, NY, in 1967 (before I was born!).*

I actually knew about that one. We have its proceedings in our library here at Bell Labs. I didn't work too hard on the things before 1972 because I decided that 30 years might be a good cut-off mark.

It would kind of be interesting to know when the earliest conference ever on quantum foundations was. I know that there was at least one sometime in the 1950s. Let me dig up the reference. Here it is: *Observation and Interpretation: A Symposium of Philosophers and Physicists*, edited by S. Körner (Academic Press, New York, 1957).

The earliest ever can probably be found in one of Jammer's books.

21-04-02 *Walton's Mountain* (to G. L. Comer)

Today is the gloomiest, most drab day as far as the weather is concerned. But I like that. I always feel academic and reflective on such days. Kiki tells Emma, "If nature doesn't supply Daddy with a few clouds, he makes his own."

Lucent has been doing awfully poorly again in the market. [...] And the rumors are flying that about 10,000 more are going to get the pink slip Monday (after this quarter's losses are announced). [But] I'm not feeling too panicked at the present though. [...]

[F]or the present, I'm just happy being a high-payed philosopher, and I'm not worrying too much.

And the philosophy I've been doing! I can't put the pragmatists down; I read them in the morning, I read them in the night. I am so taken by the thoughts of James *et al.* I don't know how I could have missed these guys for years! It's a crying shame and certainly has stunted my growth. The pragmatists are all about the things John Wheeler was about (in his heyday), but oh so much deeper. John was an absolute amateur in comparison.

23-04-02 *Mermin's Mysterious Ways* (to A. Peres)

Asherism 20: *What happened to David Mermin:* `0204107` *"deconstructing dense coding", which follows deconstructing teleportation in* PRA **65** (2002) 012320*? Can you understand his motivation?*

Did you read his acknowledgements in the first paper? He writes, "I thank ... Chris Fuchs for asking why I found it interesting." I don't know that he ever gave me an answer that I understood. (He attempted to do it in the paper's present introduction.) I think part of it is surely in the fact that he is presently teaching a quantum information course, and he is trying to be very pedagogical for the students. But then, why he is not publishing in AJP, I don't know.

Petra went off to Amherst and then to Williamstown to visit Bill Wootters this weekend. She returns by bus (to NY) and train (to Murray Hill) today. She called me last night to tell me that everything is OK. She is doing quite well in her research, and I am very pleased with her.

Tomorrow I post a rather philosophical paper on `quant-ph`. [See "The Anti-Växjö Interpretation of Quantum Mechanics," `quant-ph/0204146`.] I think it will be my first document there with zero equations. (But Seth Lloyd does almost the same in many of his *Nature* papers!) The reactions it's gotten in pre-circulation have been quite interesting. For instance, Bill Wootters seemed to love it, but John Preskill seemed to hate it. Julio Gea-Banacloche seemed to love it, but Charlie Bennett seemed to hate it. And so on.

23-04-02 *Music in the Musician* (to G. L. Comer)

Thanks for the thoughtful note. I found myself thinking about it on and off all last night, in both my periods of wake and sleep. I think you expressed the issues to do with chemistry versus consciousness especially vividly.

I think we just have to get rid of this imagery that we are "made" of atoms. Or none of us are ever going to make any progress in our emotional lives OR our physical understanding. By my present thinking, a much better imagery is this. Take me and an old log: we both float in water. That is to say, we have that much in common. But there are a heck of a lot more things that we do not have in common. For any two entities, we can always find some characteristics they have in common, if *we* are willing to ignore all the ways in which they are distinct. And that, I think, is the story of atoms. The atomic picture has something to do with what we all have in common. (Or, maybe more potently, it has something to do with what is common in the *part* of existence that we have chosen not to ignore for the moment.) But to see the atomic picture shine through, we have to dim down all the things that are unique in us. Who said the particular shape of that rock is not important? Who said the pain you are feeling is only epiphenomena?

Such a picture of what physics and chemistry is about is every bit as consistent as the worldview Steven Weinberg, say, would have us believe. And I would say that it is more so; for it gives us a power and a hope for control in our lives that his can't even imagine.

Let me do two things for you. First, I'll paste in two old emails, that have to do with your music-on-the-page versus music-in-the-musician imagery (which I think it is so apt and so beautiful). [See stories from *Notes on a Paulian Idea* pasted into my 05-12-01 note "Lucky Seven" to B. W. Schumacher.] Mostly I'm pasting them because your note caused me to go back and read them this morning. And I'm just reconfirming that I'm on the same wavelength.

But then I want to quote William James. (That will come in a little later note.) I know you're not much in the mood to read any philosophy right now. But if you read the *right* stuff, I cannot see how it cannot help. My side of the conversations with you, in any case, is just a poor reflection of what William James already said with such flare.

23-04-02 *Installment 1* (to G. L. Comer)

From *Pragmatism*, pages 30–32:

> And do not tell me that to show the shallowness of rationalist philosophizing I have had to go back to a shallow wigpated age. The optimism of present-day rationalism sounds just as shallow to the fact-loving mind. The actual universe is a thing wide open, but rationalism makes systems, and systems must be closed. For men in practical life perfection is something far off and still in process of achievement. This for rationalism is but the illusion of the finite and relative: the absolute ground of things is a perfection eternally complete.
>
> I find a fine example of revolt against the airy and shallow optimism of current religious philosophy in a publication of that valiant anarchistic writer Morrison I. Swift. Mr.

Swift's anarchism goes a little farther than mine does, but I confess that I sympathize a good deal, and some of you, I know, will sympathize heartily with his dissatisfaction with the idealistic optimisms now in vogue. He begins his pamphlet on 'Human Submission' with a series of city reporter's items from newspapers (suicides, deaths from starvation, and the like) as specimens of our civilized regime. For instance:

> "After trudging through the snow from one end of the city to the other in the vain hope of securing employment, and with his wife and six children without food and ordered to leave their home in an upper east-side tenement-house because of non-payment of rent, John Corcoran, a clerk, to-day ended his life by drinking carbolic acid. Corcoran lost his position three weeks ago through illness, and during the period of idleness his scanty savings disappeared. Yesterday he obtained work with a gang of city snow-shovelers, but he was too weak from illness, and was forced to quit after an hour's trial with the shovel. Then the weary task of looking for employment was again resumed. Thoroughly discouraged, Corcoran returned to his home last night to find his wife and children without food and the notice of dispossession on the door. On the following morning he drank the poison.
>
> "The records of many more such cases lie before me [Mr. Swift goes on]; an encyclopedia might easily be filled with their kind. These few I cite as an interpretation of the Universe. 'We are aware of the presence of God in his world,' says a writer in a recent English review. (The very presence of ill in the temporal order is the condition of the perfection of the eternal order, writes Professor Royce (*The World and the Individual*, II, 385).] 'The Absolute is the richer for every discord and for all the diversity which it embraces,' says F. H. Bradley (*Appearance and Reality*, 204). He means that these slain men make the universe richer, and that is philosophy. But while Professors Royce and Bradley and a whole host of guileless thoroughfed thinkers are unveiling Reality and the Absolute and explaining away evil and pain, this is the condition of the only beings known to us anywhere in the universe with a developed consciousness of what the universe is. What these people experience *is* Reality. It gives us an absolute phase of the universe. It is the personal experience of those best qualified in our circle of knowledge to *have* experience, to tell us *what is*. Now what does *thinking about* the experience of these persons come to, compared to directly and personally feeling it as they feel it? The philosophers are dealing in shades, while those who live and feel know truth. And the mind of mankind—not yet the mind of philosophers and of the proprietary class—but of the great mass of the silently thinking men and feeling men, is coming to this view. They are judging the universe as they have hitherto permitted the hierophants of religion and learning to judge *them*. . . .
>
> "This Cleveland workingman, killing his children and himself [another of the cited cases] is one of the elemental stupendous facts of this modern world and of this universe. It cannot be glozed over or minimized away by all the treatises on God, and Love, and Being, helplessly existing in their monumental vacuity. This is one of the simple irreducible elements of this world's life, after millions of years of opportunity and twenty centuries of Christ. It is in the mental world what atoms or sub-atoms are in the physical,

primary, indestructible. And what it blazons to man is the imposture of all philosophy which does not see in such events the consummate factor of all conscious experience. These facts invincibly prove religion a nullity. Man will not give religion two thousand centuries or twenty centuries more to try itself and waste human time. Its time is up; its probation is ended; its own record ends it. Mankind has not aeons and eternities to spare for trying out discredited systems."

24-04-02 *Leibniz on de Finetti* (to T. Rudolph)

Rudolphism 2: *"Two things are identical if one can be substituted for the other without affecting the truth."*

But neither de Finetti nor I believe in "truth." How does that affect things?

24-04-02 *A Stapp in the Right Direction?* (to B. W. Schumacher)

I just ran across the abstract below on the archive. Maybe it's relevant to you doubting project.

John Preskill told me you'll be at Caltech for 10 months, starting in September. He was trying to use his siren song to lure me too for a little while. I'm pretty sure I can't do it this year. But I'm gonna try hard to do it next year while you're still there.

> Quantum Physics, abstract
> `quant-ph/0110148`
> From: stapp@thsrv.lbl.gov
> Date (v1): Thu, 25 Oct 2001 17:11:21 GMT (13kb)
> Date (revised v2): Tue, 23 Apr 2002 18:24:28 GMT (15kb)

> The basis problem in many-worlds theories
> Author: Henry P. Stapp, (Lawrence Berkeley National Laboratory)
> Comments: This extended version is to be published in The Canadian Journal of Physics
> Report-no: LBNL-48917-Rev
>
> It is emphasized that a many-worlds interpretation of quantum theory exists only to the extent that the associated basis problem is solved. The core basis problem is that the robust enduring states specified by environmental decoherence effects are essentially Gaussian wave packets that form continua of non-orthogonal states. Hence they are not a discrete set of orthogonal basis states to which finite probabilities can be assigned by the usual rules. The natural way to get an orthogonal basis without going outside the Schroedinger dynamics is to use the eigenstates of the reduced density matrix, and this idea is the basis of some recent attempts by many-worlds proponents to solve the basis problem. But these eigenstates do not enjoy the locality and quasi-classicality properties of the states defined by environmental decoherence effects, and hence are not satisfactory preferred basis states. The basis problem needs to be addressed and resolved before a many-worlds-type interpretation can be said to exist.

24-04-02 *The Program* (to B. W. Schumacher)

Schumacherism 6: *Next-to-last week of classes, and things are really humming. Hope all is well with you and yours.*

By the way, I'm gonna post a slightly weird paper on `quant-ph` tomorrow or the next day. [See "The Anti-Växjö Interpretation of Quantum Mechanics," `quant-ph/0204146`.] If you've got a few moments between the bars of your hum, maybe have a look at it. (It's easy reading; no equations.) Especially the parts titled Preskill and Wootters. Just to see the kind of strange friends you hang out with. (Tell me whether you'll disown me if I go through with this!)

25-04-02 *Two Nonorthogonal Pure States* (to P. Grangier)

I apologize for taking so very long to reply to your note. It's just that I've had a million things tugging at me from all directions.

Your reply to me was thoughtful, and requires no less of a thoughtful reply in return. And I'm finally writing you now because I think I've done that to my satisfaction. It just so happens to take the form of a paper which will appear on `quant-ph` tomorrow (`quant-ph/0204146`). I will attach a copy. I hope you will read it, especially the last two sections (concerned with Preskill and Wootters). At heart, I think there is no doubt that you and I are both realists. The only place we disagree is where we hope to see a hint of reality in quantum mechanics. I think in that paper I paint the clearest picture yet of the direction I am seeking. I sincerely hope you're reading it will delete some of the mystery of my ways to you.

Grangierisme 5: *Just a question: you are strongly insisting on gambling, but aren't you not surprised that a (pure) quantum state allows one to predict many things with probability ONE? This is a fairly strange behaviour for a "belief, state of belief, judgment, opinion" etc, that is usually far less efficient . . .*

Indeed this is quite an interesting question. And it is one I have thought quite a lot about in the last year. There was a time when I would have been surprised, but I am over that now. I say there is no right and true quantum state for a system, even when two distinct observers ascribe two distinct pure states to it (whether they are commuting or not). I talk about this in great detail in my web document "Quantum States: What the Hell Are They?" and eventually I'll be putting a lot of those arguments into a proper paper. Nevertheless, I think our discussion could benefit from your reading those pages. The link to my webpage is below. The places to look in particular are pages 19–23, 35–38, 42–48, 49–50, 53–54, 55–64, 72–75, 79–88. And then there are many more places beyond that in the same document on the same subject. In general, I think the explanations get better and more convincing on the later rather than the earlier pages. (So you might read it backwards.) However, it is certainly true that I tried to be clear in my writing throughout. So, if you end up not agreeing with me, I hope you will still find the effort entertaining.

25-04-02 *Two Nonorthogonal Pure States, 2* (to P. Grangier)

Grangierisme 6: *Exchanges of emails are hard to read, I prefer more concise formulations . . .*

You ought to know by now that my emails are more soliloquies than conversations! I might play off a couple of lines from my correspondents, but then they're almost solely just me spouting my mouth off. The technique is to read them as if they were independent papers.

Grangierisme 7: *By the way, may be you have seen* `quant-ph/0203131` *which is as short as I could do (3 pages only . . .). You will find . . .*

I have indeed read it, twice now.

25-04-02 *Short Thoughtful Reply* (to C. H. Bennett)

Thanks for the picture of the skunk cabbage. I've always wanted one. I'm sorry I wasn't able to reply to you earlier, but with all the students visiting, etc., I've had a gazillion things going on at once.

Let me give you a very short reply, for what it's worth.

Bennettism 10: *My main wonder about your beliefs is why do you find it so important to emphasize the subjectivity of quantum states, . . . What difference does it make in any case?*

I am just trying to do what scientists always try to do: understand how things "hang together." I.e., build a (satisfying) picture of the world that has nothing to do with my personal qualities. It just so happens, that my favorite problem happens to be different from your favorite problem.

Bennettism 11: *Do you think Katie really exists, or is she just a mathematical symbol for a set of bets you would [be] willing to make?*

Of course I think there is a sense in which Katie exists (i.e., some large remnant of Katie as she is now would be here even if I were killed tomorrow). I just make a distinction between all the stories I might write about her in my samizdats and whatever it is that she *is* in herself. What I don't understand about you is why you find that such a foreign concept.

In particular, I don't think I could ever write a sentence like this:

Bennettism 12: *My main wonder about your beliefs is why do you find it so important to emphasize the subjectivity of quantum states, but not other kinds of information, such as the dinner you just ate, your shoes, or other people?*

I don't think I've ever thought of the dinner I just ate as the information I just ate. Presumably there is something substantial to broccoli independently of my subjective judgments about how it tastes. Information, as motivated by Shannon, has something to do with the concept of surprise. If I believe strongly that broccoli tastes bad, then I will be surprised if I find that I actually like it. In that sense I will find that I have gained a lot of information when my subjective judgment makes a transition from its old value (Yuck!) to its new value (Mmm!). But that has nothing to do with broccoli as it is completely independently of me.

Even if I thought of a quantum state as an objective rather than a subjective quantity, I still don't think that I could ever talk as you did above. There is a difference between "systems" and "properties." And there is something in your language that seems to blur the distinction.

To make this concrete, take a classical description of a pendulum's motion in terms of phase space. I would never call the phase space point (x, p) "the particle." The particle is what *carries* the property (x, p). Within classical physics, both the particle and its property might as well be assumed to exist even when there are no physicists about. But let me ask the same thing about the Liouville distribution for a *single* instance of the particle. Can the single particle be said to "carry" a Liouville distribution in the same way it "carries" the coordinates (x, p)? I think you would be hard pressed to say that it does. For if I were to delete the physicist who is ignorant of the phase-space point the particle actually possesses, then I would delete the Liouville distribution. But I would not delete the value (x, p)—whichever one it is—that the particle can be safely assumed to have.

And that is all I am striving for in quantum physics. To figure out what properties we might safely ascribe quantum systems even when there are no physicists about. I think there are awfully good reasons for thinking that "the" quantum state is not such an "objective" thing. And thus the quantum state carries more of an analogy to the Liouville distribution than to the phase space point. However, that does not mean that I think our beloved theory gives us no hint of what the properties are that I can safely treat as objective. It is just that, among them, I do not see the quantum state.

Bennettism 13: *When you say a quantum state is just a set of bets you would be willing to make, what is the ontological status of you the bettor? Are you just a collection of bets some other bettor would be willing to make?*

Don't blur the distinction between the system and the state!

There, that's my short reply. As I say, I wish I could have replied to you earlier, but I had so many things tying me up. I wonder if I could make a birthday wish of you? Since my birthday was the 21st, would you give me this much of a present? Just read the parts of the paper I posted for `quant-ph` tomorrow, to do with Preskill and Wootters. I'll send it to you shortly. It's not long reading, and it's not hard reading. (Certainly no harder than a New Yorker.) And just give me two binary digits of satisfaction: After reading those passages, would you 1) say that you still do not understand my views of Katie, and 2) does it still look like a tower of turtles to you?

With enduring friendship (and a picture of skunk cabbage hanging on my wall),

25-04-02 *King Broccoli* (to C. H. Bennett)

Bennettism 14: *I relish the taste of broccoli (especially broccoli rabe) and brussels sprouts and cabbage, and I assume you don't.*

Actually, broccoli is my favorite vegetable of all time. Well, more particularly, broccoli as my mother—Texan through and through—makes it: overcooked, with a lot of butter and a lot of salt.

I loved your reply, but I don't think you answered either of my two questions.

Charlie's Preply

> Happy birthday. I read your last 3 sections, including the Acknowledgement [of `quant-ph/0204146`]. I knew when I wrote you my passionate and polemical words, in reply to your passionate and polemical words, that we were talking past each other. Basically I think the state vector is more like the point in phase space than like the Liouville probability density, and I think you think the reverse, but the big lesson we should draw from this is that it doesn't matter enough to get so passionate about. Passion distracts from doing science which I think is much more fun. For example I was recently reading your excellent paper with Caves and Schack about the quantum de Finetti theorem, which I became very interested in lately in connection with the quantum reverse Shannon conjecture, and after a while I was able to filter out the polemical remarks as effortlessly as all the ads for get-rich-quick I get in my email and enjoy the science almost as much as if I they had been absent, or had been ones I agreed with.

To return briefly to unimportant matters, I think all three—quantum state, classical state, and classical probability density—can be viewed either as autonomous realities or as bets someone is willing to make. Despite the strong feelings one may have, it's a fool's errand to try to prove that something is or isn't real. The scientific content of any quantum theorem or algorithm, such as de Finetti or teleportation, can be mapped almost effortlessly from one interpretation to another, by devices such as my favorite, the Church of the Larger Hilbert Space—with its unexplained preferred basis—or your favorite, the humble but undefined classical observer, and all we are left with to prefer one interpretation over another is its good or bad flavor, which ultimately is determined by our genetic makeup or early influences of our respective pedophiles. I relish the taste of broccoli (especially broccoli rabe) and brussels sprouts and cabbage, and I assume you don't. I conjecture that there is a correlation between love of broccoli and sympathy for the Everett interpretation. David Deutsch doesn't count, because he apparently doesn't much like any sort of food. Unlike the interpretations, this is a scientific question, susceptible to experimental proof or refutation. While we're at it, how do you feel about the Korean pickle known as kim chee?

25-04-02 *Quant-ph Number* (to C. M. Caves)

The `quant-ph` information is below. Of course I'd like to be cited at the second sentence in your abstract—"Whereas Hilbert space itself is an abstract construction, the number of dimensions available to a system is a physical quantity that requires physical resources."—but you can't do that. And, unfortunately, I don't find such a nice crisp statement with the same thought anywhere else in the paper. You know that I still don't buy into this business that, "A Hilbert space gets a physical interpretation … through privileged observables." And I don't really want to be associated with that thought. (From my way of thinking, I think it is safer to say that a Hilbert space gets its interpretation from the outside, not from the inside. I.e., From the subjective judgments an agent uses to give meaning to the measurement "clicks" he finds.)

25-04-02 *Guilt* (to U. Mohrhoff)

I am writing at the present moment because I have not been able to shake the feeling of guilt. To my shame, I still have your letter of 9/9/2001 sitting (with about seven others from other long-neglected correspondents) in the inbox of my email program. It stares at me every day and calls out for a reply. And one of these days, I'm going to do just that.

But in the mean time, as I say, I feel overwhelmingly guilty. This is because tomorrow morning another one of my foundational papers will hit the airwaves (`quant-ph`), and I know that I will be caught red-handed in having NOT neglected the subject. Also, next week I am going to put a rather large extension of my NATO paper on `quant-ph` too.

I can give you little in the way of compensation for my bad behavior, other than to let you know what I am feeling. Also, maybe I can let you know that I acknowledge your input in the larger paper (which will appear in the paper next week).

Acknowledgments

I thank Carl Caves, Greg Comer, David Mermin, and Rüdiger Schack for the years of correspondence that led to this view, Adán Cabello, Asher Peres, and Arkady Plotnitsky for their help in compiling the dramatis personae of the Introduction, and Andrei

Khrennikov for infinite patience. Special thanks go to Charlie Bennett, Steven van Enk, Jerry Finkelstein, Philippe Grangier, Andrew Landahl, Hideo Mabuchi, Masanao Ozawa, John Preskill, Terry Rudolph, Chris Timpson, and Alex Wilce for their many comments on the previous version of this paper—all of which I tried to respond to—and particularly, to Howard Barnum, for pointing out my technical mistake in the "Wither Entanglement?" section. Finally, I thank Ulrich Mohrhoff for calling me a Kantian; it taught me that I should work a little harder to make myself look Jamesian.

26-04-02 *Objective QM?* (to P. Grangier)

Let me answer your easy questions first:

Grangierisme 8: *PS In your paper you strongly "recommend" the work by Lucien Hardy. I have two comments:*

- *it surprises me that you adhere with the "relative frequency" approach to probabilities that is used by Lucien (his first axiom). I certainly agree with it, but I thought you would not.*
- *Lucien is trying to make QM look like a new probability theory. In my opinion, this cannot work because I am convinced that there is an inherent "geometric" (in Wigner's sense) content to QM. My views on this are explained in the* `quant-ph` *preprints.*

It is good that you picked up on that. Because those are two things that I dislike the most about Lucien's paper. I explain this in great detail on pages 147 and 159–166 in the document I wrote you about yesterday. [See 19-02-02 note "Re-Tackle" and 06-03-02 note "Poetry on Concrete" to L. Hardy.] (These are both examples of letters that need absolutely no background—other than having read Hardy's paper itself—in order to be read. So, do give it a shot.) However, that does not take away from the mathematical structure Hardy has set his focus on. And that is what I think is important, and worth wider recognition.

So yes:

1. quantum probabilities, like all probabilities, I take to be gambling commitments, and
2. I view quantum mechanics as plain old probability theory plus some further restrictions, NOT a generalization of classical theory. (Those further restrictions are what—I claim—carry the ontological content of the theory.)

And in both these opinions I contradict Hardy's paper. But I would rather accentuate the positive in his efforts for the moment.

26-04-02 *Transformation Rules* (to A. Peres)

Let me quote the piece of the paper you were concerned about:

> But the contexts are set by the structure of the Positive Operator-Valued Measures: one experimental context, one POVM. The glue that pastes the POVMs together into a unified Hilbert space is Gleason's "noncontextuality assumption": where two POVMs overlap, the probability assignments for those outcomes must not depend upon the context. Putting those two ideas together, one derives the structure of the quantum state.

What I was referring to with the point about the overlap is that one can derive the quantum probability law purely from the following simple assumption: there exists a function f from positive operators to the unit interval, such that the value of f sums to one over all positive-semidefinite resolutions of the identity. With this assumption (and nothing else, like continuity or differentiability), one gets that there must exist a density operator ρ such that $f(E) = \mathrm{tr}(\rho E)$. This is the modification to Gleason's theorem that I describe in `quant-ph/0106166` (section 4). So, it's not a completely trivial result of the standard probability rule; instead one can take it as an assumption and get the standard rule back out as a little gift.

Anyway, with this linear rule, comes for free the idea that probabilities transform linearly when one changes from one (sufficiently informative) POVM to another (sufficiently informative) POVM. And it is the transformations from "context" to "context" that Andrei has been making such a big deal about.

I hope that clarified a little bit.

03-05-02 *Accepting Quantum Mechanics—The Short of It* (to B. C. van Fraassen)

I'm feeling horribly guilty because I promised you a note over two weeks ago and everything—just everything—has conspired against me getting it constructed. I'm sorry. But still I want to write you something before I meet you next week. Let me try to do what I can in the next hour and then call it quits until Monday: The details of what I am about to say will be in a paper that I plan to have finished and can bring with me then.

van Fraassenism 1: *Now when it comes to theories that give us probabilities, whether absolute or conditional, I'll agree with scientific realists that literally read they say that there are objective probabilities in nature. But accepting such a theory does not involve believing that. Rather it involves appointing the theory as an 'expert' for guidance of our subjective probabilities concerning observable events. The metaphor of 'expert' is cashed out (as by Haim Gaifman) as follows. Suppose that I appoint Peter as my expert on snuffboxes. That means for my subjective probability P and Peter's subjective probability q the constraint:*

$$P\Big(A \,|\, q(A) = x\Big) = x$$

with generalizations of this to intervals, odds, conditional probabilities, for statements A that are about snuff boxes.

Thus the issue of whether there are objective probabilities in nature or whether to believe in them is finessed: there are only the theory's probabilistic <u>*pronouncements*</u> *accepted as input and my own subjective probabilities.*

That is clearly not how you are approaching it overall. But perhaps there are connections? I'd like to know how the QM probabilities are fed into your subjective probability as a whole – I wonder if it will not be similar. After all, even if a quantum state is read as a compendium of probabilities, and you say something like "this material is in quantum state such and such", your own subjective probability function has a domain much larger than facts pertaining to this material.

Yes, you are right, I don't like (ultimate) experts, and I don't think quantum mechanics has any more need of them than weather forecasting, say. In fact, I think any attempt to hold on to objective probabilities—even in the finessed form that you talk about, where there is a higher authority in whose judgment we place our faith—will only get in the way of our finding the deeper heart of quantum mechanics. Thus, I hold fast to the idea that there is no right and true quantum state EVER—just as de Finetti held fast to the idea that there is no right and true probability distribution EVER—and I take it as the very definition of my foundations program to see what is left behind. From my view, the theory does not pronounce probabilities; it only pronounces what we ought to be doing with them once we have set them just as subjectively as the next guy. (And to make the issue as pointed as possible, I even mean this for pure quantum states.)

What does it mean to accept quantum mechanics then? The imagery I am starting to build looks something like this.

If one generalizes the notion of quantum measurement to the one that has become essential in quantum information theory—namely to the positive operator valued measure (POVM)—then, for each quantum system, one can contemplate a *single*, fiducial quantum measurement for which the probabilities of its outcomes completely specify the system's quantum state. That is to say, whenever I write down a subjective probability distribution $p(h)$, for the outcomes h of such a fiducial measurement, I completely specify a quantum state ρ (pure or mixed). Imagine now that that fiducial measurement device is tucked away safely in some vault in Paris at the International Bureau of Weights and Measures.

A quantum state can be viewed as very literally nothing more than my subjective judgment for what would happen if I were to ever bring my quantum system up to that standard measurement device. What now can one say about a real-world measurement device, like one that we might have here at Bell Labs? Well, bringing my quantum system up to it will generally evoke a click of some sort that I might label d. Using all that I believe of the device, all that I might believe of Lucent's technical prowess, etc., etc., I would be a bad subjectivist if I didn't allow the click to update my beliefs about what would happen if I were to approach the fiducial device. Thus I end up with some updated probability distribution $p(h|d)$. (I.e., some updated quantum state.)

In what sense is this subjectivism connected to Bayesianism? This in part is what this paper of mine is about that I'll give you a copy of Monday. One can show that the usual story of quantum collapse can be viewed as the conjunction of two things: 1) Bayesian conditionalization, and 2) a final rotation of the axes of the probability simplex for the fiducial measurement. That is to say, quantum collapse in this description is only a pretty damned mild generalization of the Reverend Bayes.

But, again, what does it mean to accept quantum mechanics? It is this. If one studies the properties of these kinds of fiducial measurements, one finds that for no initial quantum state (in the usual Hilbert space picture) and no outcome is it ever the case that $p(h) = 1$. That is, when one accepts quantum mechanics, one eschews certainty for the outcomes of a fiducial quantum measurement. In fact, the set of allowed distributions $p(h)$ forms a convex set that is strictly contained within the probability simplex (i.e., the set of all imaginable probability distributions over an appropriate number of outcomes).

Thus, accepting quantum mechanics is not accepting the existence of an expert, but—in large part—accepting the two ingredients above:

1. voluntarily accepting a restricted range for one's beliefs $p(h)$
2. accepting a slightly modified form of Bayesian conditionalization for updating one's beliefs (i.e., standard Bayes + rotation)

The NEED for 1) a restricted range and 2) a minor modification of Bayes, is where I say we should be looking if we want to be looking for the "meaning" of quantum mechanics. What is it about the world as we view it that compels us to accept those two ingredients? That I see as the important question. And the ever more convoluted moves I see from some of our friends who want to hold on to a nonsubjectivist view of the quantum state, I see as a waste of good brain power.

That is to say, I agree with you in that, "Be a realist if you want to be." But I add to it with respect to the interpretation of quantum mechanics, "Don't do it for those parts of the theory where it is not productive to do so." If you're looking for a little realism in quantum theory, fine, but then look for it in a more clever place than in the state vector.

Anyway, that's my present take.

And I lied: that took me an hour and 35 minutes. I hope it's a little clearer at least for the extra time. See you Monday!

PS. You wrote:

van Fraassenism 2: *The two articles of yours that we took up in our discussion group in the fall were clearly only the beginning, and you have now taken the program much farther.*

Can you tell me which two articles you're referring to? That would give me a clearer vision of which views I've changed since your reading and which views I need to be careful not to let be propagated in your mind.

05-05-02 *Wigner and Clones* (to A. Peres)

I just skimmed your new paper. Near your sentence, "Why wasn't that theorem discovered fifty years earlier?" I think you ought to cite Wigner as a case example. Below is a little review of his paper I published at `quickreviews.org`.

The original volume might be hard for you to get hold of, but the paper can also be found in Wigner's later collection *Symmetries and Reflections*, page 200. The spot where he just misses getting the no-cloning theorem—i.e., the spot where he actually gets it wrong—is in the second paragraph after the paragraph containing Eq. (5). (In the S&R version of the paper, it's at the very bottom of page 205.) He writes, "Let us denote the n vectors which represent living organisms by v^k ... Then every linear combination of the v^k will also represent a living state."

Here's the story Bill Wootters told me, when I first told him about the Wigner paper in 1998:

Woottersism 5: *Thanks a lot for your note. I find it amazing that Wigner didn't quite realize that cloning was fundamentally impossible. Frankly, I'm still not impressed with the cloning paper Wojtek and I wrote. I remember asking [Professor X] for his opinion of a draft of that paper, and he said, in a very friendly way, that it would be a tough paper to referee, because on the one hand lots of people already knew the result, but on the other hand it may not have ever been written down.*

Review of:
Eugene P. Wigner, "The Probability of the Existence of a Self-Reproducing Unit,"
in *The Logic of Personal Knowledge: Essays Presented to Michael Polanyi on his Seventieth Birthday* (Routledge & Kegan Paul, London, 1961), pp. 231–238.

The no-cloning theorem first discussed by Wootters and Zurek and (independently) by Dieks is now understood to be a significant part of the foundation of quantum information theory. But have you ever explained it to another physicist and received a reaction of the form, "Is that it? That's the big deal everyone is talking about?" I have. And it's no wonder: the issue of no-cloning boils down to almost an immediate consequence of unitarity—inner products cannot decrease. In fact, Wigner's famous theorem on symmetries even shows that the group of time-continuous, inner-product preserving maps on Hilbert space is strictly equivalent to the unitary group. Therefore, it comes as quite a shock to see that Wigner himself just missed the no-cloning theorem! In this paper, Wigner tackles the question, "How probable is life?" He does this by identifying the issue of self-reproduction with the existence of the types of maps required for the cloning of quantum states. He doesn't tackle the question of cloning for a completely *unknown* quantum state head on, but instead analyses the "fraction" of unitary operators on a tensor-product Hilbert space that can lead to a cloning transformation for at least some states. Nevertheless, he states quite clearly that an arbitrary linear superposition of clonable states ought also to be clonable. But this, of course, cannot be.

I think this paper is quite interesting from the historical point of view of our field: it gives us an appreciation of the beauty and simplicity of that little theorem in a way that simply learning about it cannot provide. It gets at the heart of something deep in very present physical terms, terms that even a great mind like Wigner's missed.

07-05-02 *This Tape Will Self Destruct* (to G. Plunk & N. D. Mermin)

I don't know that I've ever told either of you how I started down this slippery slope of quantum foundations studies. It probably started officially in about 1985, when I took an undergrad research course with John Wheeler. He assigned ME a problem in computational general relativity. On the other hand, he assigned THE HONORS STUDENT who also took the course—I wasn't an honors student—the project of "deriving quantum mechanics." I was so jealous! I guess I never worked out that frustration. (I think the honors student dropped out of physics.)

So, now it's my turn with Gabe. And guess what I'm thinking about assigning him?

The problem is about fixing up (in a outlandishly Fuchsian way) the death and destruction I have tried to heap upon the Brun, Finkelstein, Mermin paper. That is, if you can't say a state is right and true, what can you say? The note below to Bas van Fraassen explains what I mean by all this in lay terms. [See note to van Fraassen dated 03-05-02, "Accepting Quantum Mechanics — The Short of It."]

The particular research project I have in mind for Gabe is to get a handle on the possible shapes for the convex set I describe below, as I range over all possible "standard quantum measurements." We'll start with single qubits. In particular, what I would like to know is what are the invariant properties of all these convex sets? (Read below and this question will start to make sense.) Could it be the volume? Something more esoteric? We can start with numeric work, and, if we get lucky, do something analytic.

Thus you see, what I want to say is, "When an agent accepts quantum mechanics, what he is doing is accepting a convex region on the probability simplex with such and such characteristics." It would be nice if the characteristic had a simple characterization.

This tape will self destruct in five minutes. Tell me whether you think this is a problem that could turn into a good senior thesis for a Cornell undergrad. I think it would.

07-05-02 *Failed Jokes* (to G. Plunk & N. D. Mermin)

I wrote:

> This tape will self destruct in five minutes. Tell me whether you think this is a problem that could turn into a good senior thesis for a Cornell undergrad. I think it would.

But of course, the title would have made more sense if I would have first said, "This is your mission if you accept it."

08-05-02 *Updated Version* (to B. C. van Fraassen, J. Butterfield, J. Bub, T. A. Brun, and D. Wallace)

Dear friends …

to whom I gave an early version of my paper "Quantum Mechanics as Quantum Information (and only a little more)". I astonished myself yesterday by having the time to clean it up to the point of publication. In particular, I think the introduction goes more smoothly now and I've made some different choices of words throughout that I think clarify things.

So, if you haven't looked at the version I gave you yet—and I know you haven't, with all the activity of the meeting—I'd encourage you to go to the real thing (when you have some time for sleepy reading). It'll be posted on quant-ph as of Thursday morning. Here's the link: `http://xxx.lanl.gov/abs/quant-ph/0205039`.

(And for Bas, in particular, you'll be able to find a PDF version there too; so you shouldn't have trouble printing.)

08-05-02 *The Big Eye* (to H. J. Bernstein)

Check out my new paper. It's titled "Quantum Mechanics as Quantum Information (and only a little more)" and you can find it at my webpage (link below). It'll also appear on `quant-ph` tomorrow.

I give you and your book with Mike Fortun a little advertisement at the beginning of Section 10.1 and in the Appendix, Point 21.

08-05-02 *The QMP* (to H. M. Wiseman)

Thanks for the letter, and particularly, thanks for skimming the paper. I chose a provocative title for the paper in an attempt to draw in the crowd, but the content of the two letters to Preskill and Wootters was pretty serious for me. What I'm looking for, in particular, is a way to make sense of science from a point of view that says at the same time, "Don't even think the terms in your theory ARE or CAN BE a reflection of reality. For the universe is big, and your head is small. And maybe reality is not static and unchanging—and thus describable in any finite terms, like in terms of GR and QM—anyway."

That's a sweeping statement, but I think it may be one of the two great lessons of quantum mechanics. (I'll keep my opinions secret on the other great lesson.) Anyway in particular, the way I see it, we as a community should be working as hard as we can to STOP trying to see the wavefunction as anything of a reflection of nature. Wavefunctions live in our heads. They live and die in our heads. And when they do their changing, they do that in our heads too. That's the point of view I'm trying to run through with as much consistency as possible. I.e., how can I hold to it, and still have quantum mechanical practice be what we all think it is? How can I hold to it, and not have everything that we say of nature be just a dream?

I'm sorry I've delayed so long in replying to you, but I wanted to do it right, and that required that I finish up a paper so that I could point you toward it. The paper's finished now, and I posted it on `quant-ph` this morning; it'll appear tomorrow. But if you wake up before `quant-ph` does, you can also get it at my webpage (link below). The title is, "Quantum Mechanics as Quantum Information (and only a little more)." The parts that are particularly relevant to our discussion are Section 4.2 and all of Section 6.

Wisemanism 4: *He implies that the same problems apply in classical theory. I disagree. The problem is that noncommutative algebra does not apply to the information in our brains. ... I'm not saying that it is impossible to do that, but it is an extremely difficult problem which he dismisses.*

Let me give an analogy that I think is apt. I would say Bohr's great genius in developing his model of the hydrogen atom lay solely in one little move: In dismissing the research program his predecessors laid out before him. That is, in dismissing the idea that the atom's spectrum required a mechanical explanation. Beyond that, the rest of his work was just details. Likewise, I think it is the case here.

I think that wavefunction collapse simply calls out for no explanation at all. And that is because I see it as nothing but a variety (and, in a way, an extension) of Bayesian conditionalization. To that extent, the problem—or, by my view, the nonproblem—was already there long before quantum mechanics ever showed up on the scene. Imagine that physical theory really were like the Newtonians wanted it to be: nice and deterministic, Laplace's demon and all that. Now consider a weatherman immersed in the world. He wakes up in the morning, thinks about all the weather readings he has taken the previous days, complains about the fact that his computer can't do as much number-crunching as he would like it to do, scratches his butt, decides whether he is feeling optimistic or pessimistic (that, of course, might depend upon how his girlfriend has been treating him lately), and so on and so on. He churns that all into a big mental pot, and finally comes up with a set of numbers $p(h)$ to describe his beliefs about what the weather will be doing tomorrow. In fact, at the same time, he'll probably come up with a whole set of numbers $p(h, d)$ to describe not only the weather tomorrow, but also the weather today.

Now, suppose he goes and has a look at the weather today and finds that it is d. Then, using Bayes' rule, he will update his belief for tomorrow from $p(h)$ to $p(h|d)$. It's a gut-wrenching, horribly discontinuous transition. But does it call out for an explanation? And if it does, does it call out for an explanation that has anything to do with the system the weatherman is modeling, i.e., the earth's atmosphere? For after all, in this world, when the weatherman looks out the window, one value of d was true and always remains true; one value of h was true and always remains true. The only discontinuous change is in his beliefs ... and those beliefs are presumably a property of his head.

So, yes, I think Duvenhage is absolutely right on this point. It's a point I've been trying to make for years—it's what Asher and I were up to in our *Physics Today* article—but of course sometimes it takes a long time to get the expression right. And I think Duvenhage did a particularly nice job on this particular score.

Now you and I both know that there's something more going on in quantum mechanics than there is for the weatherman. It's just that I don't think that "something more" is localized in the issue of "collapse." As far as the discontinuous change of belief goes—if you ask me—that happens both quantumly and classically, and in fact has nothing to do with any particular scientific theory. It is pre-science; it is simply a part of one's living and changing his beliefs in response to stimuli from the world outside himself.

By my present thought, part of the "something more" that goes on in quantum mechanics (as opposed to simple Bayesianism) is that we no longer have the right to assume that the things we do in our laboratories to change our beliefs (i.e., quantum measurements) leave the world unscathed in the process. I.e., we ought to be taking into account that when the world stimulates us, we stimulate it back in the process. But how do we take it into account in our description? My answer is that there's only one place to put it in a formalism, and that is in a further change in BELIEF up and beyond that dictated by Bayes' rule.

Thus, quantum collapse deviates from Bayes' rule, but not because it has anything to with something going on outside our heads. It deviates from Bayes' rule because the subject matter we are talking about when we are doing quantum mechanics (i.e., quantum systems) have an implicit action-reaction principle that Bayes, Cox, Ramsey, and de Finetti overlooked when they first worked out the calculus of belief change—i.e., Bayes' rule.

Now, you say things like,

Wisemanism 5 : *The problem is that noncommutative algebra does not apply to the information in our brains. . . . If we could believe that non-commutative algebra did apply to our knowledge then of course that would solve the quantum measurement problem. But how can we reconcile that with our experience?*

but, by my present view, using words like that is a red herring. (And Duvenhage is much more guilty of it than you.) The way I would say it now—please read the sections in the new paper I told you about—is that any kind of noncommutativity in quantum mechanics is just an artifact of a certain representation. The usual representation is a useful one to be sure—I could hardly calculate anything without it—but for the present issue I think it detracts from the clearer understanding we can hope to obtain if we'll just suppress it. (The "it" meaning the usual representation.) In fact, I think we're only going to get that understanding by exploring quantum mechanics as 1) a restriction on the space of probabilities (the probability simplex), with 2) a conditionalization rule that goes just a bit beyond Bayesian conditionalization.

And all this causes me to reject it when you say,

Wisemanism 6 : *The QMP is to find (i) a cut, and (ii) a way to bridge the cut, between the quantum systems that do have non-commutative information (in his terminology) and classical systems that do not.*

That is not the quantum measurement problem for me. People, experimentalists, scientific agents, have information or lack information when they are trying to talk about something outside themselves. Systems are just systems, and when they are treated as such, I would say the concept of information has nothing to do with them. Information is something I have or lack about a system. For instance, when I am speaking about you—thinking of you as a physical system—I lack quite a bit of information in the sense that your behavior could surprise me at any moment. But that means nothing about any kind of "information" intrinsic to you.

So, when you say what you said above IS THE QUANTUM MEASUREMENT PROBLEM, I would say that that is a problem that comes from trying to think of the quantum state, or the algebra of observables, etc., as literal properties of the things you are describing . . . and failing to recognize that the quantum state is a property of the observer and not the system. The quantum state is the full compendium of gambling commitments you would be willing to make about what the system will cause a measuring device to do.

What I myself see as the quantum measurement problem is to give compelling reasons for the two items I listed above. By compelling, I mean in the terms I lay out in the paper. When we can finally do that, then we will finally understand what properties we are really assuming for the "reality" of a quantum system.

Anyway, I hope that helps explain my position. I'll attach another piece of correspondence below with Bas van Fraassen that takes a different tack on some of the same issues. Maybe that'll help supplement the paper. I hope you'll get a chance to take a look at it. By the way, I quote one of your papers in Footnote 33.

Thanks for giving me the opportunity for trying to say these things a little more clearly. And certainly feel free to question or comment on anything that still doesn't make sense. (Anything that doesn't kill me might just make me stronger!) Hey, I'm coming to Brisbane May 25 to June 17. Do you think we'll get chance to talk sometime during then?

09-05-02 *Physics 7 Months Ago, Today* (to A. Peres)

Asherism 21: *I received* Physics Today *of October 2001 (I have not received September, because they took a cheap mailing service via India, and almost nothing is being retransmitted — a well known swindle). There is a gloomy article on Lucent. What is really the situation, seven months later?*

I'm sorry I haven't had a chance to write you before now; I have a backlog of email that is a mile high.

When I joined Lucent there were about 120,000 employees. Now, there are 50,000 … with Wall Street rumors running that Lucent will have to cut 5,000 to 10,000 more beyond that to return to profitability. So, things are a bit gloomy. We are now encouraged to try to bring in military grant money, etc. I doubt Bell Labs will ever be again what it was in the glory days, but so far it has been a safe haven for my nonsense. We shall see how long it will last.

Today Petra left. The group will miss her indeed. Frank Verstraete left last Friday. It was a very good month we all had together.

Petra told me today that she has decided not to return to Israel immediately. I suspect that was sad news to you.

Tomorrow Kiki and the family and I make the long drive to Ithaca for David Mermin's retirement party. Bill Wootters, Charlie Bennett, Gilles Brassard, Abner Shimony, and Lucien Hardy will be there among many others that I don't know. (Well, I've heard of some like Michael Berry.) In any case I'm sure looking forward to seeing the ones I do know! I will lecture on Sections 4.2 and 6.1 of my new paper, `quant-ph/0205039`.

10-05-02 *Go Ask Alice* (to G. L. Comer)

Well the days have come and gone, and now the week is just about over. I finally finished up my extension of the NATO paper posted on the LANL archive the other day. (I thank you in it, by the way. Have a look at `quant-ph/0205039`.) And the last of my visiting students, left yesterday. So I guess I'm getting ready for some kind of denouement in the coming week. [. . .]

Your note has had me singing that old Jefferson Airplane tune in my head all morning. (I got up a little before 5:00.) Torturous old man. I did really like that line of yours "Dualism is a Degeneracy." It strikes a chord in me with respect to my efforts to overthrow the idea that a scientific theory is (potentially) a mirror image of nature. I.e., it is not even potentially.

But I guess I have a hard intellectual time with the idea you express with: "[L]anguage is necessarily limited; beautiful, but just crude enough that my BElongINGs can never be completely shared." You can blame it on the Richard Rorty in me. You presume that there is a "person on the inside" that goes deeper than what can be built from language. That if we were able to conceptually strip all the rest of the world surrounding Greg Comer away, there'd still be something left. It's a long story, but I guess I don't buy that. The self is just a local "center of narrative gravity," Rorty put it. See his "Ethics without Principles" in his book *Philosophy and Social Hope*.

10-05-02 *Compatibility* (to D. Poulin)

Thanks for pointing me to your paper; in fact, I had already noticed it. Caves, Schack, and I are long overdue in our finishing up our criticism of the BFM paper. The manuscript made it up to 12 pages, and was essentially complete. But then I started to complain about "strong coherence," as opposed to the normal Dutch book argument. Anyway, hopefully we'll settle our differences and finish up the project in the late part of May when we all meet in Australia. Regardless of that, though, I certainly do find your measure of compatibility interesting.

14-05-02 *No BC's Role* (to R. Schack)

Thanks for the flurry of letters. They provoke a lot of thoughts in me and I am grateful.

I'm not sure how I'm going to reply to you, maybe just randomly (as the details occur to me).

Schackcosm 59: *In my discussions with classical cryptographers, I am often forced to concede that QKD is really quite limited in scope. You either assume an unjammable channel (which I believe cannot be assumed if you use the internet for communicating) or you use classical authentication, which means you share some initial key. Given these limitations, I am not convinced that QKD deserves such an exalted status as suggested by the Bub quote above.*

Has anybody taken the Brassard/Fuchs speculation any further?

Good point, of course. But I never meant for those two "axioms" to be read so literally. Perhaps my best expression of the idea is captured in a letter to Jeff Bub, 10 December 2000. It starts at page 100 of the old samizdat. The main point is that I see information-disturbance as the key idea, along with the commitment that information can never be completely locked away. Read those passages; I think they'll clear some of this up.

That said, precise versions of the no-bit-commitment ideas are coming to the top of my head again for their foundational value. Namely, as part of the extra assumptions that might get us to proper density operators in the "Wither Entanglement?" entanglement section (rather than simply linear operators). The thing that really powers the no-bit-commitment theorem is the Hughston-Jozsa-Wootters result that localized measurements on one system of two (described by a bipartite pure state) can "induce" any decomposition one wants for the other system's density operator. It turns out that the "pure states" of those other wacky operators in my bipartite-Gleason construction don't necessarily have this property. So, it looks like an assumption of such a nature might get me a little closer to the goal. (Though—even if I found it completely acceptable, and I'm not sure I do—it still wouldn't get me all the way to the goal.) But all of this is a long story, and maybe it'd be easier to talk about at a chalkboard.

14-05-02 *More Toenails* (to R. Schack)

Schackcosm 60: *Why are you so harsh on entanglement? In my quantum information lectures, I postulated the tensor product structure, as a natural formalism to deal with local operations on several particles. Entanglement is then derived, an unexpected consequence of the tensor product* *structure. You make this line of reasoning more compelling by showing that there is really no alternative to the tensor product structure. Far from being withered, entanglement emerges invigorated from your analysis.*

The main point is that entanglement can be thought of as secondary to the structure of quantum observables on localized systems. To that extent, one realizes that one can focus on the structure of simple observables in one's foundational efforts and forget about entanglement. In other words, it seems to me entanglement is not, as Schrödinger said, "the characteristic trait of quantum mechanics, the one that enforces its entire departure from classical lines of thought." It is derived and secondary.

Now what is the structure of observables? The thing I try to argue in the paper is that a measurement is *anything* that gives rise to *any* convex decomposition of a one's original density operator. In that sense, measurement is nothing more than an arbitrary application of Bayes' rule.

Entanglement thus arises from the more basic idea of Bayesian conditionalization in conjunction with the idea that the allowed probabilities for a standard quantum measurement device do not explore the whole probability simplex.

Let me put two notes below that might clarify where I'm trying to go with this. I'd like to think that they add nothing beyond the paper, but it has been my experience that I can just never say enough. (I know what you're thinking: "You've got it backwards. If you'd just say it all in fewer words! That's what you really need.") [See notes to van Fraassen and Wiseman, dated 3 May 2002 and 8 May 2002, respectively.]

14-05-02 *Emphasis De-emphasis* (to R. Schack)

Schackcosm 61: *I am not sure I like your emphasis: You describe what I think is the exciting part as a "further readjustment of the posterior state".*

Yeah, I think I agree with that. There's no doubt that that's the most exciting part for me. That extra adjustment strikes me as capturing our beliefs about how we are stimulating the system (rather than how it is stimulating us). And to that extent, I would like to emphasize it. However, I guess I chose the tack I did because I wanted people to stop thinking of quantum collapse as something so different from "mere conditionalization."

Schackcosm 62: *Personally I like the concept of a compendium of probabilities better than your bureau, but it is very interesting to see how far one can get with the Bayes' rule alone.*

Again, here, it is a point of emphasis. The message I am trying to get across is that the structure of observables comes from Bayes' rule. They (measurements) are not defined independently of it. The SQMD struck me as an effective way to badger that point. "Compendium of probabilities" really stands for "compendium of ways of applying Bayes' rule." That is, I think it builds a stronger case for the idea that it is Bayes' rule all the way down when it comes to quantum measurement. The theory gives us no overt means to identify the objective thing that goes on behind a quantum measurement outcome. The only grounding we have is to *declare* a point somewhere off in the distance for which we will do no further updating. And that is the role the SQMD plays.

14-05-02 *Deletions and Their Obverses* (to R. Schack)

Schackcosm 63: *I think that taking William James and Darwinism seriously means to acknowledge that quantum mechanics is most likely to be superseded one day by a theory with even more* *cash value. This new theory may not have any of the features that we regard as the core of quantum mechanics. How then is Darwinism or pragmatism going to tell us anything about the foundations of quantum mechanics?*

You're right, I think you are definitely missing what I was hoping to express. But that probably just means I didn't express it so effectively.

No, I did not mean that Darwinism and pragmatism tell us something about quantum foundations. Just the opposite. I see quantum mechanics as giving us a great hint that there is still something deeper. Quantum mechanics is the first rip in the old fabric that told us our place in the world is a nullity. That is to say, I think quantum mechanics only gives us even better arguments for pragmatism.

Schackcosm 64 : *It looks to me as if your desire to find the objective core of quantum mechanics is against the spirit of both Darwinism and pragmatism.*

I think the core of the theory—I don't think I ever used the words "objective core"—is just our best guess of what we cannot change with our present level of skills. It is our best attempt to imagine what it would be like if we were not here. Obversely, when we have ferreted the core out, we will have a quantitative indication of how much of the world we can hope to control (given our present skills, present evolutionary level, etc.)

My desire for delimiting the core is expressed particularly in the passages below (taken from the paper). Maybe this makes no sense without A) watching the movie *It's a Wonderful Life*, and B) reading the "Sentiment of Rationality." Have you done either of these things? Probably not.

Your point certainly makes it clear to me that my paper is not self-contained! (The movie is an American classic and I think a large fraction of Americans have probably seen it; but James is another story.)

14-05-02 *Imaginations* (to R. Schack)

Continuing again . . .

Schackcosm 65 : *Actually, I found the part where you mention the selection of traits for your daughter outright disturbing, without any compelling connection to the discussion on quantum mechanics.*

Yes, me too. Because read in the wrong way—and maybe there was no other way to read it—it surely evoked images of Nietzsche (at the least) and Nazi Germany (at the worst).

But on the other hand, I don't know how to draw a meaningful distinction between our tools and ourselves. (Remember my point about the prosthetic hand in the paper?) Should we stop pursuing medical research because it goes against the grain of nature? Should we stop pursuing genetic techniques for controlling AIDS? Should we stop falling in love based on an attraction to our partners' complementary (positive) traits to our own? Traits that we would like to see (even if subliminally) appear in our children?

I guess I say no, no, no. Instead we need to cultivate at the same time a respect for everything in its time. Children of Down's Syndrome, say, deserve respect, not deletion. The Nazi experiment with nature was an atrocity. But, at the same time, I would say we cannot stop pursuing progress in genetic engineering.

The point you make is a deep one. I have no solution. Only an intuition of fear and promise, both at the same time.

If you get a chance, read Richard Rorty's book *Philosophy and Social Hope*. It's all about fear and promise and quite easy to read.

14-05-02 *More Still* (to R. Schack)

Schackcosm 66: *Everything you write suggests that you want more than just the theory with the highest cash value: you are looking for some form of absolute truth, something that transcends looking for the theory that makes the most accurate predictions.*

Yes, I guess so. I am looking for an indication that the world can be moved. I am looking for an indication that the only law in physics is the law that there are no laws. I am looking for an indication that the world is still writable.

I think if you want to call those things the pursuit of an absolute truth, you can. But they're only absolute in a pretty negative sense.

See, I told you you provoked a lot of thoughts in me.

14-05-02 *Qubit and Teleportation Are Words* (to C. H. Bennett, W. K. Wootters, N. D. Mermin, A. Peres, J. A. Smolin and others)

I doubt I will be of any use in constructing a short dictionary definition for the word teleportation, but let me try to explain my difficulty with the word "property" with regards to both quantum states and quantum entanglement. I do this with a little trepidation, but on the other hand, you're the ones who brought me into this discussion and I feel I ought to say something.

The trouble I have with the word "property" has to do with one of the main points Charlie brought up in his talk this weekend. What instantaneously and physically changes about Bob's system when Alice performs a measurement on hers? Charlie told us *nothing* and I agree with that. But then, I look in the *American Heritage Dictionary* and find:

> **property**:
> 1) Something owned; a possession. . . .
> 4) a. A characteristic trait or peculiarity, especially one serving to define or describe its possessor. b. A characteristic attribute possessed by all members of a class. See synonyms at **quality**.
> 5) A special capability or power; a virtue.

If you think of a quantum state as a property owned by the system of which it is about, then you—Charlie Bennett in particular—are obliged to continue propagating this thing you told us was a misconception. At the completion of Alice's measurement, there is a new quantum state for Bob's system. If the quantum state is interpreted as a "special capability or power" for the system at Bob's end, then you cannot get around the conception that Alice's twiddle caused a change to something localized way over there.

And that, it seems to me is dangerous business. What I am saying has nothing to do with hidden variables. It just has to do with the word "property". The trouble only has to do with the idea of a quantum state as a kind of feature possessed by a quantum system.

If you want to think of the quantum state as a property of something, it seems to me the best you can do is speak of it as a property of Alice's head (or Bob's head, or whoever's). For, the quantum state represents the *predictions* she can make about measurements upon the system in question. Similarly I could say all the same things about entanglement.

To my view, toying with the idea that a quantum state is a property, is to toy with a kind of pantheism or anthropomorphism that my materialist mind won't tolerate. Do all rocks have souls? You'd laugh at that, but it seems to me that's about what you're attempting to do in thinking of the quantum state as something possessed by the system itself. "That rock judges his chances of reacting to the measurement device to be such and such!" What could be more anthropocentric than that?

Bennettism 15: *"Properties" can reasonably be taken to be much broader than hidden variables, and may include all sorts of conditional and post-selected behaviors, eg "how a system would behave if I measured its Z spin component, after having watched my favorite horse lose at the race track."*

But, as I see it, conditional properties fare no better than the nonrelational type in this regard. At the completion of Alice's measurement, there is a new quantum state for Bob's system, and thinking of it as a conditional property in Charlie's sense still means something physical changed at Bob's end. This is because the system did not have that particular (conditional) property before Alice's action.

The main point is this: Whatever a property for a quantum system is, it should not be something changeable by someone's twiddles far, far away. For instance, take the dimensionality posited for a quantum system by the ascription of a Hilbert space to it. I think this is a perfectly good candidate for a property of a quantum system; it's one I would endorse. For, once set, there is nothing Alice can do at a far away location to change it.

So there, quantum systems do have properties—or at least I'm willing to bet they do. It is just that the properties do not include among them "the" quantum state ... and it is the quantum state that is transferred in the process of teleportation.

What I find miraculous about teleportation is that Victor (the guy who ascribes the original, unknown state) can transfer his predictions from one physical system to another at the cost of only two bits of physical action on the target system. In that sense, it is Victor's description that is teleported from one system to the other with almost nothing whatsoever traveling in between. But that'll never make it into a dictionary.

Of course, this is an ongoing debate between Charlie and me. I'll paste below one piece of our correspondence that has to do with the present conversation—it itself focused on the issue of properties. [See note to Bennett dated, 25 April 2002.]

By the way, I agree with Bill that the word "object" is better than "system." *American Heritage* writes this in its first two definitions for the word:

> **object**:
> 1) A material thing.
> 2) A focus of attention, feeling, thought, or action.

Asher's Reply 1, "Quantum Teleportation Defined: Nothing Happens at Bob's End"

> When the quantum teleportation process was conceived, we had no clear understanding of what was going on, and this may still be true today. I learnt a lot from Chris when we wrote our "Opinion" essay in *Physics Today*, March 2000, pp. 70, 71. Here is the passage about quantum teleportation, mostly due to Chris:
>
> > The peculiar nature of a quantum state as representing information is strikingly illustrated by the quantum teleportation process.[4] In order to teleport a quantum state from one photon to another, the sender (Alice) and the

receiver (Bob) need to divide between them a pair of photons in a standard entangled state. The experiment begins when Alice receives another photon whose polarization state is unknown to her but known to a third-party preparer. She performs a measurement on her two photons-one from the original, entangled pair and the other in a state unknown to her-and then sends Bob a classical message of only two bits, instructing him how to reproduce that unknown state on his photon. This economy of transmission appears remarkable, because to completely specify the state of a photon, namely one point in the Poincaré sphere, we need an infinity of bits. However, this complete specification is not what is transferred. The two bits of classical information serve only to convert the preparer's information, from a description of the original photon to a description of the one in Bob's possession. The communication resource used up for doing that is the correlated pair that was shared by Alice and Bob.

The crucial point is in the last five lines: Alice and Bob know nothing of the states of their particles (the one that the preparer gave to Alice, and the one that Bob finally has). To make the process simpler let the two bits be sent by Alice to the preparer, next to her, not to Bob, far away. Nothing happens at Bob's end. Only the preparer knows instantaneously what is the state that Bob can verify, if and when he receives the relevant information (same two bits).

How do you explain that to non-believers?

Asher's Reply 2, "Proposed Definitions: Qubit, Entanglement, Quantum Teleportation"

I tried to find definitions that are scientifically correct and do not depart too much from the style of the *American Heritage Dictionary*, so that they may be acceptable to them.

qubit − quantum bit

The smallest component in a computer designed to manipulate or store information through effects predicted by quantum physics. Unlike bits in classical systems, a quantum bit has more than two possible states labeled 0 and 1. It can also be in a combination of 0 and 1 according to the superposition principle, or even have no definite state at all, if it is entangled with other quantum bits.

entanglement

A quantum mechanical situation where a composite system has a definite state, but none of its constituents has a definite state. Moreover, if separate measurements are performed on these constituents, the results show strong correlations.

quantum teleportation

The instantaneous transference of our knowledge of the properties of a quantum object to those of another distant object, without physical contact with the latter.

This is not quite the same as our original paper, because here Bob (if he exists - he is not needed) does not perform a Pauli rotation to have an identical state. Anyway, if the state of his particle is publicly known, then the required Pauli rotation will eventually be known in the whereabouts of the second object.

Asher's Reply 3, "Instantaneous Remote State Determination"

Since Charles protested my use of the term "instantaneous" here is a paragraph of my paper "Classical interventions in quantum systems. II. Relativistic invariance." PRA **61** (2000) 022117:

> A seemingly paradoxical way of presenting these results is to ask the following naive question: suppose that Alice finds that $\sigma_z = 1$ while Bob does nothing. When does the state of Bob's particle, far away, become the one for which $\sigma_z = -1$ with certainty? Though this question is meaningless, it has a definite answer: Bob's particle state changes instantaneously. In which Lorentz frame is this instantaneous? In *any* frame! Whatever frame is chosen for defining simultaneity, the experimentally observable result is the same, owing to `\Eq{etcr}`. This does not violate relativity because relativity is built in that equation, as will now be shown in a formal way.

Indeed when Alice finds her result she definitely knows Bob's *potential* result if and when he performed or will perform his measurement.

14-05-02 *Chris's World* (to J. A. Smolin, C. H. Bennett, N. D. Mermin and others)

Good to see you in the morass.

Chris's world: It's a funny place with all these fancy words like "ascription" and "posit" to remind us that there's a head in the background of every quantum state, but there's no instantaneous action at a distance there—no one would have ever thought there might be. I know the language drives Charlie bonkers, and it probably drives you bonkers too. But mostly the complaints just remind me of what I used to hear in my hometown in Texas when the seatbelt law was first enacted. "Why that Majatek boy was thrown clean from the car! Not a scratch on him. If he'd have had a seatbelt on, his head would have been nothin' but mush now; we'd be at his funeral today. Damned politicians puttin' their noses into places where they ain't got no business."

So you see I view the language as a safety measure—one that I think will allow us to drive farther, longer, and ultimately faster. But first you've got to learn how to drive with a belt on.

John Smolinism 1: *One is naturally forced into Chris's world of saying all that changes is what people predict about the state, but that's a property properly defined as above.*

Chris would never say this. When I write down a quantum state, I think of it as my judgment or prediction for which of one or another measurement outcome will turn up. I don't predict things "about the state." I don't know what the TRUE state is or could be, and thus my ignorance cannot be about it. In contrast, I would say the ignorance is always about further measurement outcomes. Or a pleasing picture is that one can ground the ignorance with respect to a single device sitting in the National Bureau of Standards if one wishes. See Sections 4.2 and 6.1 of the fat paper I put on `quant-ph` last week (`quant-ph/0205039`).

That said, I also see the suppression of another crucial issue here—one that also flies in the face of the word property, especially with your emphasis on DEFINE in definition 4. If you will allow me to call a mixed density operator a quantum state, then I know even you will agree that there is no unique quantum state for a system. Thus it cannot be a property. So, I think you'll be left with being only willing to call a pure state a property. So be it. (I wouldn't do that, but I'll let you do that for the time being.) But now, let's go back to Alice and Bob. By your account, first Bob's system has no property, then Alice measures her system, and—Zing!—now Bob's system does have a property. I.e., first it has no quantum state, then it does. How does the system know it ought to have that property if there's no action at a distance? Alternatively, if it doesn't know it, why call it a property of the system?

It is because of that conundrum that it seems to me to be more fruitful to just give up thinking of the quantum state as a property of the system it targets.

I think a good analogy can be found in *classical* information theory. A homework problem in a textbook gives you a discrete memoryless channel by specifying the transition probabilities $p(y|x)$. Then it asks that you calculate the channel's capacity. One goes through all the work and gets a number. From that, one starts to get the feeling that the capacity can be an objective property for a real physical channel. Why else would it take so much work to calculate something if it weren't real? But it can't be real in any absolute sense. For, with respect to a Laplacean demon, there is never any noise in the channel at all; he can predict which bits will be flipped and which won't. The point is, the capacity is only objective WITH RESPECT TO a *subjective* judgment $p(y|x)$. Similarly, I would say with all quantum states. Just because a textbook says calculate such and such a property—the entanglement of formation, the distillable entanglement, or whatnot—of a quantum state, one finds that one gets into the same habit of thinking those properties have no subjective component.

You can do so, but then it's your burden to explain to young school children and journalists—who think of a property as something like the color red, a ball either has it or doesn't—what changes in Bob's system when Alice performs a measurement.

14-05-02 *Quick Answer about Quantum de Finetti* (to K. Jacobs)

Jacobsism 1: *Quick question about the Quantum de Finetti representation. The expansion for an exchangeble $\rho^{(N)}$ is unique — but does N have to be greater than or equal to 2 for this to be true?*

The de Finetti representation is something that applies to a *sequence* of density operators $\rho^{(N)}$ living on larger and larger Hilbert spaces $H^{\otimes N}$. The theorem says there is a unique decomposition of the form $\int P(\rho)\rho^{\otimes N}d\rho$. But of course, that does not negate the fact that for each N on can find many ways to decompose the mixed state. It is just that if one finds an alternative way of expressing the density operator at level N, that alternative expression will not work for level $N+1$. The case $N=1$ is especially relevant in that regard. There are a continuum of ways to decompose $\rho^{(1)}$, but only some of those ways will work to get you up to $\rho^{(2)}$, and even fewer will get up to $\rho^{(3)}$, etc. In the limit, only one of the original decompositions will work.

15-05-02 *And Only a Little More* (to W. K. Wootters)

I'm just taking care of some loose ends left from the meeting in Ithaca. While we were there, I had hoped to put a copy of my new paper into your hand. But every time I thought about it, I thought it would be awkward for you to have to carry it since you weren't carrying a briefcase. Then at our final encounter, just before your leaving, I didn't have a copy with me!

Anyway, here's the link in case you're interested:

> Quantum Mechanics as Quantum Information (and only a little more)
> `http://xxx.lanl.gov/abs/quant-ph/0205039`

Of course, feedback, both good and bad is always welcome. What I am striving for is consistency, and it's pretty hard to see lapses in that without an outside eye.

By the way, mention that philosopher's name again that you've been taken with. I'll look her/him up.

Bill's Reply

The book I mentioned is *Nature Likes to Hide*, by Shimon Malin, a physicist at Colgate University. The book is in three parts: (i) an introduction to the ideas of quantum mechanics (the book is for a very general audience), (ii) application of some ideas of A. N. Whitehead to the interpretation of quantum mechanics, (iii) presentation of a worldview based on quantum mechanics and ideas of Plotinus. I wouldn't follow Malin all the way, but there's something about part (ii) that struck me as exciting and worth exploring further. I had already been reading Whitehead and other writers inspired by him (especially Hartshorne), as well as C. S. Peirce, who inspired both Whitehead and Hartshorne.

Whitehead argued that a materialistic philosophy could never adequately account for mind. So in his view, the basic elements of the world are not material objects but are more like moments of awareness: they are more like events than persisting objects, and they always have both an interior and an exterior aspect. There is some similarity with Wheeler's view that the basic elements are quantum events, except that with Whitehead there is more of a balance between the interior and exterior aspects of each basic element. Wheeler thinks of quantum events merely as objective events, seen only from the outside, as it were. Whitehead says that at every level of being, there is always an interior view. At the higher levels, this interior view is what we call consciousness. At lower levels, it's not consciousness but it exists nonetheless. So consider a photon encountering a beam splitter, with a detector in each of the two possible paths. The firing of one of these detectors is an event that can be viewed objectively, but according to Malin (interpreting Whitehead), it can also be seen from the inside: the freedom to choose one detector or the other can be thought of as a kind of proto-experience. It's too primitive to be called either experience or consciousness, but it has some quality in common with consciousness (whereas a purely material object would not have this quality).

I think the above paragraph should give you a sense of the direction Malin is going. There are a lot of things about Whitehead's view, and Malin's view, that resonate with my own ideas. Of course I like the Wheelerian idea of taking quantum events as basic, and I like this question: Where does a quantum event reside? For example, where was the decision made to make one of those two detectors fire? It wasn't made at the location of the detector that fired, because then how would the other detector have known not to fire? And we know very well that the decision wasn't made at the beam splitter. Pretty clearly, the decision wasn't made at any particular place in spacetime. So I don't think a quantum event resides primarily in spacetime. A quantum event is more primitive than spacetime, as Wheeler has said many times. What I like about Whitehead and Malin is that they emphasize a commitment to consciousness as something central to existence and something that one has to have in mind even when talking about the most basic elements of existence.

15-05-02 *Not Even Vague Thoughts* (to R. W. Spekkens)

Spekkensism 9: *I've also been thinking that the analogy between the possibility of "steering" and the impossibility of cloning suggests that there is something, like the task of steering but different, that is analogous to broadcasting and which would truly separate the quantum from the classical. So far I've only got vague ideas. Have you given any thought to this?*

I like this line of thought you're pursuing, but no I haven't thought about it any more than the little I did in Princeton. I guess the first question is, what does entanglement buy you as far as steering is concerned? For, even with unentangled bipartite (mixed) states, Alice can steer Bob into noncommuting possibilities. So the line is not drawn at commutivity.

You might be able to prove something like this: Suppose Alice and Bob possess an unentangled mixed state, but one for which no decomposition exists in terms of commuting states on Bob's side. There can be no device on Bob's end that will make a tripartite state $AB'B$ for which the AB and AB' states are identical copies of the original. But then, what does that have to do with steering?

In any case, you know I hate the word steering. What one needs for No-QBC is simply that Alice be able to predict what Bob will find if he performs any valid measurement in the protocol. It has nothing to do with steering anything.

15-05-02 *Marburg, Strasbourg, Blunderburg!* (to A. Peres)

Asherism 22: *I started to read your QM as QI, a few pages each evening, when I am too tired to do anything productive, but not yet ready to go to sleep. Will this appear in the Växjö proceedings? Two misprints in the table page 2:*

> 1973 Marbourg → Marburg
> 1974 Strasbourg is in France, not in Germany (it was in Germany 1940-44 and before that 1871-1918, but it is in France since 1945).

Thanks for catching those mistakes. [See 01-04-02 note "Last Little Push" to A. Peres, N. D. Mermin, A. Cabello, H. J. Folse, and A. Plotnitsky.] I'm a little ashamed that I made them. And I am flattered that you are reading the paper; thank you for that independently.

Yes, an older version of the paper will appear in the Växjö proceedings. The version on `quant-ph` has 25 or 30 spots where the language has been changed somewhat. I have contemplated trying to send the final, final version to Andrei. But I don't know that it is worth my while. With Andrei's whirlwind methods, I suspect it is too late for me to send him revisions in any case. Of course, the only version people will ever read—if they read that much—will be the `quant-ph` version.

I just downloaded your no-cloning history to see how you took into account Wigner's paper. I was a little surprised when I didn't see you mention him. I would guess that you made that decision because you did not muddy Wigner's name. Still, though, I think his blunder only adds to the importance of the theorem (despite its mathematical triviality), and I wish the readers could have seen that at the same time that you defend your decision on FLASH.

Kiki and I arrived back home from Ithaca late Sunday evening, with a hobbling car. (It is our Honda mini-van, only one year old.) First Kiki had a crash Saturday morning that tore deeply into the left-hand fender and bumper. No one was hurt in the accident, only our pocketbook and insurance rate. But then Monday, while we were bookshopping, someone decided to even out the car's aesthetic for us: Somehow they hit the front of the car and tore the front bumper off. It was a hit and run, and no one in the neighborhood saw it happen.

The meeting in Ithaca was quite nice, with quantum informationists, quasi-crystalists, bioligists, magazine editors, science policy advisors, etc. I think the best thing that happened to me was that I met Michael Berry for the first time. He introduced himself as I was talking to Philip Pearle. He said, "Oh, you're Chris Fuchs?" I thought, "Michael Berry knows of Chris Fuchs?" It was quite a surprise to me. Anyway, he proceeded to tell me how much he liked our Physics Today piece, and how he quotes from it to his students. During the meeting, I also gave him copies of my two Växjö pieces and he gave me some good feedback on both. Sometimes, I need confidence builders like that.

15-05-02 *Berry, Etc.* (to A. Peres)

Asherism 23: *Michael Berry must know of you because you were offered a position in his department. Here is a frequent visitor to Israel because his wife has her parents here.*

I didn't quote Wigner. Why kick a dead horse? However I added a quote to Jozsa's recent `quant-ph`*, which is really very nice. It's Bill who called my attention to it.*

I accept your decision. But still I contend that you missed a good opportunity. The point is not to kick a dead horse, but to glorify a living theorem. Wigner was one of the greatest minds in physics this century—nothing can take that away—but yet he came to within an inch of the theorem and then missed it. I think that signifies something interesting psychologically. Perhaps it also signifies what a radical departure quantum mechanics is from classical lines of thought.

15-05-02 *Bayes, POVMs, Reality* (to A. Shimony)

It was good talking to you this weekend. If you wouldn't mind committing your story of meeting de Finetti to email, I will see to it that it is archived forever in one of my samizdats. (See my webpage; link below.)

Also, if you could send me your mailing address, I will send you copies of my two new papers on Bayesianism, POVMs, and good candidates for quantum reality. Alternatively, if you are accustomed to downloading things from the `quant-ph` archive, here are the links:

1. "Quantum Mechanics as Quantum Information (and only a little more),"
`quant-ph/0205039`

2. "The Anti-Växjö Interpretation of Quantum Mechanics,"
`quant-ph/0204146`

I wrote them both in an attempt to be entertaining. I hope you find them so.

Abner's Reply

> Here is what I recall of my conversation with de Finetti. In 1971 the 3rd International Congress of Logic, Methodology, and Philosophy of Science was held in Bucharest (where I had the dubious pleasure of meeting Ceauşescu in the receiving line at the Palace of Ministers; what an ugly hard face he had.) De Finetti was there, and I believe that I introduced myself, saying that I had some questions. The only question I recall was why he didn't use the strong version of coherence. He said that he was aware of the option of using it rather than the weak version, but he didn't like the consequence of the substitution: namely that $C(h/e) = 1$ only if e entails h. This consequence is part of my

(2') in Sect. 5 of my "Coherence and the Axioms of Confirmation", p. 136 in vol. I of my *Search for a Naturalistic World View*. I don't recall the details of his objection to this principle, but I think he said that it would cause trouble if one had a nondenumerable set of mutually exclusive possible hypothesis, as in the case of probability on continua. I vaguely recall agreeing with him that there would be a problem, because I discuss the problem on pp. 137–140, op. cit. I vaguely recall saying (or maybe just thinking) that epistemic probability doesn't apply well to nondenumerable sets of hypotheses, but thinking that the propensity interpretation of probability, usable in stat. mechanics, could properly deal with nondenumerable sets of possible outcomes. De Finetti surely would not have liked this discrimination, since he believed that the only clear sense of probability was epistemic, and in particular personalist. In my later paper, "Scientific Inference", op. cit. I suggest pragmatically reasonable strategies for dividing the entire set of hypotheses into as denumerable set, or even a finite set, by properly lumping subsets of hypotheses. This strategy seems to me in the right direction, partly because it is part of a program taking the Bayesian formalism as only a framework, which has to be supplemented by pragmatic and by a posteriori considerations.

16-05-02 *King Broccoli, 2* (to J. A. Smolin, C. H. Bennett, N. D. Mermin and others)

I'll close with this statement. But then after your rebuttal—if you care to make one—we should probably take this offline. I suspect no one cares to explore the issue further (not even you and not even me). But you said something so nicely, I thought I should emphasize it.

John Smolinism 2:

> [CAF wrote:] [F]irst Bob's system has no property, then Alice measures her system, and—Zing!—now Bob's system does have a property. I.e., first it has no quantum state, then it does. How does the system know it ought to have that property if there's no action at a distance? Alternatively, if it doesn't know it, why call it a property of the system?

It always had the property that IF Alice measured one thing, then it would behave as state ϕ. Conditional properties like that do, of course, imply a sort of action at a distance, but what's so bad about that? It's not the sort of violate-the-speed-of-light action at a distance that we should be concerned about. In the end, it means just what you want it to, except for the word property. To use a classical example, suppose I have a box that comes from the factory with either a red ball or a blue ball in it. Surely one can say that a property of the box is that it has either a red ball or a blue ball in it—that's the entire definition of the box. Now if I call up the factory and they tell me what color the ball actually is, never touching the box, does the box change? Was I wrong to call that other thing a property? But everyone understands what's going on. Entanglement doesn't really bring in anything new here. (Alternatively you could formulate it like Charlie sometimes does and say well, it was ALWAYS a red ball, but the measurement result travels backwards though time and fixes things up so it is ok to say "always," but I'm sure you won't care for that).

You said that perfectly, and, of course, I especially liked the concession that this choice of words does entail a kind of uninteresting action-at-a-distance … but action-at-a-distance nevertheless. Maybe my point is just, how is the non-quantum-practitioner supposed to know where to draw the line between the uninteresting and the interesting versions of the effect? Between the science and the science-fiction? How will he ever be able to shake the nagging feeling that we ought to be able to harness the uninteresting version and turn it into the interesting one? (For that matter, how will the quantum practitioner? Nicolas Gisin comes to mind.)

About the particulars of your box example, I think the common man would be hard pressed to take the textbook definition of a problem—like the one you describe above—as a property possessed by a physical system. How can the box containing the red ball know I've embedded it in a problem where the possible colors are {red, blue}, or instead in a problem where they are {red, blue, green}? People think of physical properties as the things physical systems carry around with them independently of the rest of the world. You may say that this is a limiting conception of the word "property," but I'm pretty sure it's the conception most people use. They would call the set {red, blue} a property of the problem you've defined, not of the system. Within classical physics, they would say the ball has whatever properties it really has (say, red OR blue) ... and it is the physicist's task to figure out which of the two it is.

The standard retort you and Charlie give me is that I am doing nothing more than encumbering the language by saying "a quantum state is ascribed to a system" rather than saying "a quantum state is possessed by a system." But, come on, the word count is the same. It is not that I am encumbering the language; it is just that I am beating on a prejudice you don't want to let go of. Or maybe to be more conciliatory, it is that you cannot imagine that this kind of language could ever be useful, whereas you think there are loads of examples where your own language has led to triumph. But I think Charlie's talk the other day about the public's perception of quantum teleportation as a kind of instantaneous action-at-a-distance (in the science-fiction sense) is a case in point.

Things are only interesting or noninteresting with respect to a context. I think there is a sense in which quantum teleportation is less interesting with respect to the conception that a quantum state captures a state of knowledge rather than a property possessed. What could be less interesting to say than that, "Quantum teleportation is the transference of one's predictions about one object onto another object that has never interacted with the first"? Maybe it's only this that's keeping you in the old bounds. Is it that if you keep a little bit of the science-fiction imagery alive, it'll help fuel the physics?

"In any case, none of this matters for doing physics," you say. But I think it does in the long run. (Certainly, you've got to concede that there's something that fuels me—and it hurts to think that you might think it is nothing more than irrationality.) When Charlie sent me the picture of a skunk cabbage in reply to these very issues, I found myself thinking of King Broccoli. The story goes that one day, by divine providence, it came to King Broccoli that broccoli, the vegetable, his namesake, actually tastes good. Good in a way that hitherto only gods and angels had known. Every child who had ever said, "Yuck, I don't like broccoli; it tastes awful!" was simply wrong ... or at least that's what the king realized. King Broccoli, being the head of state, decided to do something about it. Henceforward, all gardens in the kingdom should have a patch devoted solely to broccoli. It really wasn't much of a burden on the national product (except, perhaps, for the psychiatrists who had to treat all the movie stars who had never felt fulfilled in their broccoli experience). But think of the diversity of vegetables the kingdom might have raised if its citizens hadn't been encumbered with the king's notion that broccoli had an objective, but never verifiable, taste?

Moral? Maybe there's none. But it is a documented fact that the Kingdom of Broccoli eventually fell and was replaced by a liberal democracy (where the ideals rather than the particulars have an objective status).

Everyone in this mailing list knows by now—though Charlie and John seem to keep forgetting this, or maybe they've never let it sink in—that I think quantum mechanics is just the hint of something much deeper, some fantastic physics yet to come. But I also don't think we will ever stumble upon that physics until we truly get rid of our classical prejudices: seeing quantum states as "properties"—it seems to me—is one of these.

Signing off,

Chris

My own disclaimer: Though I implied above that quantum teleportation becomes less interesting within a subjective conception of the quantum state, I think effects like quantum cryptography become *more* interesting from this view. So there is a tradeoff.

16-05-02 *Words* (to C. H. Bennett)

Bennettism 16: *Sorry. Point well taken. You are a perpetual stimulus to me, if not always in the ways you hope, and I would miss it terribly if you stopped. I should be more grateful. Like the other day, when John was discussing your automotive metaphor, you inspired me to think that all the cautions you would have us take against quantum misconceptions are—for me, if I did them—like driving a car with the parking brake on all the time.*

Then it seems to me you should at least be consistent in your behavior. I interpreted your talk Sunday as a genuine concern for the perceptions the masses hold about some of our favorite quantum effects. Do you have a concern, or do you not? Is it that the world really has some kind of instantaneous action at a distance—like John's note yesterday supported—and we're just not allowed to say the phrase in polite company, or does it not? If the world does not, then so be it. But if it does, why should we try to so hard to delete the phrase from polite conversation? The main point I always wonder is how well you really have these issues worked out in your own head. If you care about misconceptions, then care about them—I say in this slightly grumbling state—and if you don't, then don't. But I have trouble understanding your mix of halfheartisms.

Charlie's Reply

> I think the world does not have instantaneous action at a distance, and it's important to find ways of speaking that do not encourage the frequent misconception that entanglement provides a means of faster than light communication. I am less interested, and think you should be less interested, in what seem to me to be hair-splitting arguments about "properties" or "changes in one's state of knowledge" that merely reflect different ways of talking about situations in which we entirely agree about the predictions of outcomes for any experiment. That seems a matter of aesthetics only, and the protections you find so reassuring I find merely annoying, like a parking brake, since they complicate my language and don't prevent me from making any wrong predictions, just what you would call wrong or fuzzy interpretations. I would say that if a way of thinking such as my own does not lead to wrong predictions, then it is not fuzzy in any serious way. Or to put in another way, the distinctions you would have me make because they seem so important to you are in fact less real than the wave function you don't want me to believe in.
>
> Talking with you first thing in the morning is way better than coffee.

16-05-02 *Exterior/Interior* (to W. K. Wootters)

Woottersism 6 : *Whitehead argued that a materialistic philosophy could never adequately account for mind. So in his view, the basic elements of the world are not material objects but are more like moments of awareness: they are more like events than persisting objects, and they always have both an interior and an exterior aspect. There is some similarity with Wheeler's view that the basic elements are quantum events, except that with Whitehead there is more of a balance between the interior and exterior aspects of each basic element. Wheeler thinks of quantum events merely as objective events, seen only from the outside, as it were. Whitehead says that at every level of being, there is always an interior view. At the higher levels, this interior view is what we call consciousness. At lower levels, it's not consciousness but it exists nonetheless.*

Of course I like the Wheelerian idea of taking quantum events as basic, and I like this question: Where does a quantum event reside?

There is also a similarity to Schopenhauer. He called the interior stuff the "will." Moreover, Schopenhauer also placed the will outside of space and time. But maybe that's where the similarity ends; I don't know enough about either philosopher to say. Let me place below two little paragraphs from my samizdat in which I had written about Schopenhauer. [See the note to Landahl, dated 10-07-01, titled "Replies on a Preskillian Meeting" and the note to Waskan, dated 07-08-01, titled "Kiki, James, and Dewey."] So I think there must be some significant overlap in what you and I are searching for.

But there are some differences:

> What I like about Whitehead and Malin is that they emphasize a commitment to consciousness as something central to existence and something that one has to have in mind even when talking about the most basic elements of existence.

though I'm not committedly against this. So, now thinking back on the long letter I wrote you, "It's a Wonderful Life" it dawns on me that you might have had trouble—at the very least!—accepting the part where I said something like "I eschew idealism in all forms."

I will try to come up to speed on Whitehead not too far in the future.

17-05-02 *Spekkens Summary* (to R. Pike)

Is this the sort of thing you're looking for?

> Robert Spekkens' research plan is to determine what sort of information-theoretic security can be achieved for two-party cryptographic tasks using quantum protocols. Two-party cryptographic tasks are those that are implemented between a pair of spatially separated parties that do not trust one another (like bit-commitment, coin-tossing, and remote gambling). These are some of the so-called "post-cold-war" applications of cryptography that may have commercial significance. Information-theoretic security is the security that can be achieved regardless of the technological capabilities of the adversary (including the capability to build a quantum computer). In other words, it is the security that can be guaranteed by virtue of the laws of physics alone. In addition to being of obvious foundational significance to cryptography, this research addresses the practical question of the extent to which quantum cryptographic protocols can take the place of classical protocols if the security of the latter are compromised (for instance, by quantum computers).

Spekkens is well-positioned to carry through with this research plan, since he has already demonstrated an ability to make original and significant contributions at the forefront of the field. In fact, some of his papers have defined the very field. The plan is to support Spekkens through a DIMACS postdoctoral fellowship—assuming he obtains it—which would pay for both his salary and benefits. The only burden to Lucent we foresee is the donation of some office space. He would most likely stay here through the tenure of the fellowship, which may be up to two years.

17-05-02 *No Nasty* (to T. Rudolph)

I won't be nasty; I enjoyed your note.

Your thinking has a lot of the flavor of the paper: A. Peres and W. H. Zurek, "Is Quantum Theory Universally Valid?," Am. J. Phys. **50**, 807 (1982). I'm not sure if you're aware of it. Asher once told me that he himself still likes the paper a lot, but Zurek basically disavows it now.

Rudolphism 3 : *what I'm trying to understand is the physics analogue of Turing's construction – what is it that I, a regular physicist, am doing in my interactions with the world and my construction of theories to explain those interactions?*

I like this question a lot, actually. Below is some of my own attempt to ask the same thing. In this regard, I suggest you read Richard Rorty's book, *Philosophy and Social Hope*. I think if I were to read it again, I would realize how much of an influence it's had on my own thoughts. In fact, my Anti-Växjö paper may be little more than a condensation of it.

I guess if you were to ask me now—in my present state of mind—I would say we are doing more than constructing theories. We are constructing the world (in part). See other note below. But beyond that, I don't know how to say more presently.

Keep thinking about your question! Don't listen to Spekkens.

By the way, I won't be around for essentially a month: Today, I leave for Texas until Thursday. Then the Saturday after that I'm off to Brisbane for a 3 weeks. I return to Bell Labs June 17. (I'm still looking for volunteers on the fence.)

Terry's Preply, "Musings on what the heck it is we're doing ..."

I'm trying to get a handle on what it is we (human) physicists actually take axiomatically (although implicitly) to be true before constructing our theories. From this, if Chris' many pages of papers are even an epsilon amount toward the truth, I should be able to get some glimmering about why quantum mechanics is the way it is – that is, if it really is only my way of describing my 'pushing on the world' to paraphrase Chris. [This latter statement is of course is NOT something that ALL physicists take to be true, so it can't be part of my list!]

So here's a brief synopsis of 3 things that I feel go, in some sense axiomatically, into any (rational) physicist's theories:

1. **Spacetime Invariance**

   We all believe, after some fashion, that an experiment can be replicated. Whenever we do so we implicitly neglect certain things that are not EXACTLY the same about the second experiment. The things we neglect generally vary from one situation to the next – we use our intuition about whether they're important or not and this can be dangerous. However, in all physics experiments, we presume that the fact the second experiment must take place at a different point in spacetime from the first (otherwise it WOULD be the first experiment) is not important with regards to its testing of our theory etc.

(Wild speculation aside: Since space/time translation invariance of a Lagrangian give, by Noether's theorem, conservation of momentum/energy, it would be interesting to conjecture that conservation of momentum/energy is a necessary consequence of a fundamental philosophical belief we have about the scientific method, and not a "truly objective" physical principle whatever the heck that is.)

2. **Universality of Physics**

   We often say blasé things along the lines of the universe is defined to be all we can observe. I think we all believe that physics, in principle, should be able to describe everything in the universe, that is, everything in the "natural" and not "super-natural" so to speak. If so then we must believe that it describes US as physical objects too. Anthropocentricity has failed us as an axiom too many times for anyone to rationally hold to it.

3. **Free Will**

   The whole study of science is meaningless without free will. I personally believe I have free will. By point 2, this means I must accept the possibility that other objects in the universe have free will – and since I assume you all claim that you do too I'll accept you as candidates for those other free will objects (you could be computers programmed to claim it, but not actually have it, for all I can really tell!)

What do I gain from all this? At the moment the only thing I can say is this. If I accept these three points, then I must conclude that any truly universal (complete?) physical theory we construct must be non-deterministic. Once there are two objects A, B in the universe that object A accepts have free will, then object A cannot rationally devise a deterministic theory that includes object B. So either we give up on Point 2 or we give up on 3, or we accept non-determinism as a inevitable consequence of performing physics as we currently know it. [Note that I am NOT saying the oft stated converse, which I think is completely pithy (and thus probably due to Penrose), namely that the free will we have will one day be found to be because of the uncertainty principle.]

Those are my thoughts in a nutshell. They have evolved from thinking a lot about the following:

A Physics Turing Machine

Turing was trying to capture the whole process of a mathematician's thinking. A mathematicians pen and paper were simply an extension of his mind Turing said. The symbols he drew came from a countable set he argued, and from arguments along philosophical line about the process of performing mathematical calculations came the Turing machine. Today we relegate this machine to the status of a Pentium. However what I'm trying to understand is the physics analogue of Turing's construction - what is it that I, a regular physicist, am doing in my interactions with the world and my construction of theories to explain those interactions? What sort of theories can object A devise about object A? [To call something which performs arbitrary unitary transforms a "universal quantum turing machine" is repulsive.]

So, what should I be adding or subtracting from 1–3 above?

And if you dont agree with something I've said don't be mean and nasty in your replies! Yes, I mean you too Fuchs.

17-05-02 *Dueling Banjos* (to W. K. Wootters)

Woottersism 7: *Well, it's true that there's a strong idealistic current running through me. Here's an interesting paragraph from Hartshorne about realism and idealism:*

> It appears, then, that the idealistic interpretation of reality as essentially relative to or consisting of mind, experience, awareness, that is, psychicalistic idealism, is entirely compatible with a realistic view of the independence of the particular object and the dependence of the particular subject, in each subject-object situation. It may also be urged that we need the word "realism" to refer to the mere thesis that every act of knowledge must be derivative from a known which is not derivative from that act. Thus the practice of contrasting "idealism" and "realism" as though they were contradictories, is of doubtful convenience. "Realistic idealism," or "realistic subjectivism," has a reasonable and consistent meaning.

Thanks for the Hartshorne quote. I had forgotten that I had sort of agreed with that a bit. Here's the way Martin Gardner put it in his essay "Why I Am Not a Solipsist":

> In this book I use the term "realism" in the broad sense of a belief in the reality of something (the nature of which we leave in limbo) that is behind the phaneron, and which generates the phaneron and its weird regularities. This something is independent of human minds in the sense that it existed before there were human minds, and would exist if the human race vanished. I am not here concerned with realism as a view opposed to idealism, or realism in the Platonic sense of a view opposed to nominalism or conceptualism. As I shall use the word it is clear that even Berkeley and Royce were realists. The term of contrast is not "idealism" but "subjectivism."

(The phaneron, by the way, was Peirce's term for "the world of our experience—the totality of all we see, hear, taste, touch, feel, and smell.")

Thus, in making the transition from the first paragraph to the first sentence of the second paragraph in the excerpt from my old letter below, I was making a non sequitur.

Let me ask you this about your "idealistic current." Does it run counter to what my first paragraph below says and what Gardner says above? I guess that's the main point for me.

I suppose if I were to start to label things, then this thing I was telling you about the other day—"the sexual interpretation of quantum mechanics (SIQM)"—would be a kind of dualistic theory. I said it metaphorically this way: When things bang together, something is created that is greater than the sum of the parts. Or again: When things—that's the materialistic aspect—bang together, something is created—that's the mentalistic aspect, for it is like an act of the will or a decision. But that's just a thought that's hitting me at 4:00 in the morning. (So trust it less than even the usual things that come out of my mouth.) I hadn't thought about it in this way before, and I'm not sure I want to continue to thinking about it this way. In general, I don't like dualisms. (Though even saying that is paradoxical; for I think I like "pluralisms" in the sense of James.) The excerpt from an old letter far below gives a slightly longer introduction to the idea of the SIQM.

Bill's Reply

I agree at least with the letter of Martin Gardiner's paragraph, because I don't think there's anything particularly special about *human minds.*

But I disagree with the spirit of your sentence:

> Yes there is certainly a kind of realism working in the back of my mind, if what you mean by "realism" is that one can imagine a world which never gives rise to man or sentience of any kind.

Let me explain. I think the sort of world envisioned by classical physics is in fact impossible. If we really understood what it takes to make a world exist *really*, and not just on paper, I think we would see that one needs the subject-object relation in order to hold things together. This is not to say that one needs dualism. In Whitehead's system, everything is both subject and object, depending on the point of view. There is no dualistic separation into two kinds of entity. But everything is related to something else as subject, and everything is also related to something else as object. In classical physics, there is no such relation. As Schrödinger points out, from the very beginning we eliminate the very notion of an experiencing subject. I agree with Schrödinger that this is too extreme an abstraction. In making this abstraction, we have removed something essential from our view of the world.

I know you will say that your realism is not the same as that of classical physics. But in what way, ultimately, is it not the same, other than by the absence of determinism? I think indeterminism is crucial, but I think one needs the further step of restoring the subject-object relation as fundamental.

I've heard some people argue as follows. "There are many conceivable physical worlds, because one can imagine all sorts of different physical laws, expressed as mathematical equations. Now, the mathematics certainly exists on its own. It doesn't need physical realization. But since the mathematics exists, and since the mathematical laws are the essence of the physical world that they would describe, then all these physical worlds must *actually exist.* They exist because the mathematics that describes them exists."

One is led to this conclusion (which I think is a wrong conclusion) because there really is hardly any difference between (i) an actually existing material world that follows definite laws, and (ii) a mathematical description of such a world. There's nothing important in the "actually existing" world that's not already present in its description. What difference does "existence" make in this case? What does existence mean in this case?

I would like to think that my view avoids the line of reasoning that takes the mathematical description as the essence of the world. As John Wheeler says, a set of mathematical laws will not "fly" by itself. I think the necessary added ingredient is something like *experience.* And that's what I find in Whitehead's view.

17-05-02 *Slide Show* (to N. D. Mermin & C. H. Bennett)

Boy you got me into a stink, didn't you, by getting me into that word debate! If you hadn't done that, I might have had some time to answer your other questions this week.

Below for your continued amusement, I'll include a side conversation I had with Charlie. Maybe this debate is at least edifying in some ways. Charlie sees me as hair-splitting; I see Charlie as being half-hearted and inconsistent.

I just read these words in a Martin Gardner article:

A third aspect of aesthetic theory that bores me even more are all those tiresome disputes, in book after book, about whether aesthetic values are subjective or objective. Here the situation is not quite the same as that of truth. In previous chapters I have argued that the least confusing way to talk about truth is to assume that the world and its structure are not mind-dependent. But beauty, so far as humanity is concerned (we will not consider what beauty may mean to birds or apes, to creatures on other planets, or to gods), obviously requires a human mind. Where is the red of an apple? As I have said, it is in the mind if by red we mean the sensation of red. It is on the apple if by red we mean the structure of a surface that reflects a pattern of visible light which causes a mental sensation of red.

I see no difference between this antique quibble and the question of whether beauty (however defined) is a property of an art object or a sensation in a brain. If by beauty you mean the pleasure aroused by a beautiful object, of course it is subjective. If by beauty you mean the structure of an object capable of arousing aesthetic pleasure, then the beauty is a part of the object. Or you may prefer a third approach and ground beauty in the combined dynamic structure produced by the interaction of an object and a mind. It is all such a weary waste of words. The last approach is the one taken by John Dewey in his influential book Art as Experience. Although I found fault with Dewey's attempt to redefine truth in pragmatic terms, I find his approach to aesthetics (essentially the same, by the way, as Aristotle's) a sensible way of speaking. Again, it is not a question of Dewey being right or wrong. It is a question of the most useful way to talk about aesthetic values.

And I find that I agree with most every word of this (except for the part about the Jamesian-Deweyan theory of truth). But the issue at stake with quantum mechanics goes much deeper than this, and it annoys me to no end that our friend Charlie lumps me in with the art critics.

If you have any words of wisdom that could take a little fire out of our relations, I'd love to hear them. Maybe I'll CC this note to Charlie too.

By the way, this was not intended to be the subject of this note. I wrote instead to tell you that I have now posted the slides from my talk at your party on my website. Maybe you'll enjoy seeing the second half, if not hearing it.

Charlie,

Bennettism 17: *Surely you must have something more sensible to say than some of us who have spoken.*

It would have been more neutral to say, "than those of us who have spoken." If I were trying to read between the lines, I might be tempted to write a note just like this one. But I'll refrain from reading between the lines.

Chris

Dear Chris,

Sorry. Point well taken. You are a perpetual stimulus to me, if not always in the ways you hope, and I would miss it terribly if you stopped. I should be more grateful. Like the other day, when John was discussing your automotive metaphor, you inspired me to think that all the cautions you would have us take against quantum misconceptions are—for me, if I did them—like driving a car with the parking brake on all the time.

-CHB

Charlie,

Bennettism 18: *Like the other day, when John was discussing your automotive metaphor, you inspired me to think that all the cautions you would have us take against quantum misconceptions are—for me, if I did them—like driving a car with the parking brake on all the time.*

Then it seems to me you should at least be consistent in your behavior. I interpreted your talk Sunday as a genuine concern for the perceptions the masses hold about some of our favorite quantum effects. Do you have a concern, or do you not? Is it that the world really has some kind of instantaneous action at a distance—like John's note yesterday supported—and we're just not allowed to say the phrase in polite company, or does it not? If the world does not, then so be it. But if it does, why should we try to so hard to delete the phrase from polite conversation? The main point I always wonder is how well you really have these issues worked out in your own head. If you care about misconceptions, then care about them—I say in this slightly grumbling state—and if you don't, then don't. But I have trouble understanding your mix of halfheartisms.

Chris

Dear Chris,

I think the world does not have instantaneous action at a distance, and it's important to find ways of speaking that do not encourage the frequent misconception that entanglement provides a means of faster than light communication. I am less interested, and think you should be less interested, in what seem to me to be hair-splitting arguments about "properties" or "changes in one's state of knowledge" that merely reflect different ways of talking about situations in which we entirely agree about the predictions of outcomes for any experiment. That seems a matter of aesthetics only, and the protections you find so reassuring I find merely annoying, like a parking brake, since they complicate my language and don't prevent me from making any wrong predictions, just what you would call wrong or fuzzy interpretations. I would say that if a way of thinking such as my own does not lead to wrong predictions, then it is not fuzzy in any serious way. Or to put in another way, the distinctions you would have me make because they seem so important to you are in fact less real than the wave function you don't want me to believe in.

Talking with you first thing in the morning is way better than coffee.

-CHB

17-05-02 *More Balking* (to R. Schack)

Schackcosm 67:

[CAF wrote:]

> Rüdiger said, "I am still convinced, despite your severe scolding, that a priori, without looking at the consequences, strong and weak coherence are similarly compelling axioms."

I don't see how you can make this distinction. It seems to me, axioms are only compelling or not compelling insofar as their consequences.

Then why would there be a difference between postulating the Kolmogorov axioms and postulating coherence? Why would we bother with the Dutch book arguments? Why do you bother looking for an information-theoretical reason for the quantum axioms?

It seems to me that the compelling reason to accept the axiom of (ordinary) coherence is that "whatever the consequences are, I certainly do not want to violate coherence, because I don't want to hand over money". It seems to me that a discussion of whether strong coherence is a compelling axiom has to be carried out at this level.

But that is not what is at issue. Strong coherence and regular coherence are *two different theories*, and a theory's worth can only be assessed by looking at the whole thing.

It seems to me a very simple issue. In the theory of strong coherence, there is a kind of normative behavior for all agents that regular coherence does not have. The theory says, in effect, "Thou shalt not tell a lie." If an agent writes down $p = 1$, then in the rigid world of strong coherence, I can trust his statement to be a reflection of his true inner belief. The world of regular coherence does not have that.

You can say that one theory is just more of the same with respect to the old theory. But that is to only look at one aspect of the problem. In another aspect of it, the two theories become qualitatively different.

There is a sense in which my mother-in-law is just a faster version of Kiki at times. That is, she's just more of the same when it comes to cooking, artistry, and a couple of other aspects. But I fell in love with Kiki, not my mother-in-law. This is because when I move past a few isolated features of my mother-in-law, I discover she is qualitatively different from the woman I love.

How can you reject that as a reasonable line of thought?

If you thought at the outset that probabilities could be proper properties of things—like Shimony does—then you might indeed accept strong coherence. For strong coherence grounds the very meaning of $p = 1$. A "$p = 1$"–statement is a TRUE statement. But if you start out from a strongly subjectivist stance on probability, then the only leg you have to stand on is the kind of argument you and Carl give: It is just more of the same of regular coherence; it is just slightly more sensible or cautious betting behavior. But I counter that by saying, carried through consistently and without exception, strong coherence makes it nigh on impossible to embed one's particular bets about particular events in the larger framework of all bets and all events.

It is an issue worthy of debate, I agree, whether my reason is a decent reason to reject strong coherence. (I think it is, clearly.) But it's not fair to say in distinguishing horses and zebras, we should all close our eyes and focus on tactile differences, eschewing all the visual information around us.

17-05-02 *The Divinity that Breathes Life* (to W. K. Wootters)

Woottersism 8: *I know you will say that your realism is not the same as that of classical physics. But in what way, ultimately, is it not the same, other than by the absence of determinism? I think indeterminism is crucial, but I think one needs the further step of restoring the subject-object relation as fundamental.*

To the extent that I could write something like the passages below, I don't think so. [See note to Renes, dated 20 November 2001.] Or, say, to the extent that I find myself liking this little quote, "I forbade any simulacrum in the temples because the divinity that breathes life into nature cannot be represented," I don't think so. I think there's more than simple indeterminism in my forming view; there is something lower level than determinism and indeterminism both.

But what I am not settled on is whether the "divinity that breathes life" is the subject-object relation. I will think hard about your point, and I will think harder about the impression my writings give.

18-05-02 *QM as QI, cont'd* (to A. Peres)

Thanks for the support. As I wrote Lou Hand, an accelerator physicist at Cornell, who wrote me something nice after my talk there, "My fragile self-confidence needs that sort of thing every once in a while."

Kiki, Emma, Katie, and I arrived in Texas late last night. We will visit my mother until Wednesday morning. It is her first time to meet Katie.

I hope Aviva and the rest of the family are doing well.

Asher's Preply

I read a few more pages of QM as QI, and I really enjoy it very much. [See C. A. Fuchs, `quant-ph/0205039`.] A few remarks:

- [21] Rosen also told me that I was a solipsist (about 40 years ago).
- Bureau International des Poids et Mesures is in Sèvres (not far from Paris), not in Paris itself.
- [27] is a bad reference for POVM. Their explanations and formulas are plainly wrong. I wrote it to them and they told me this will be corrected in a future edition.
- page 9: I loved "one can immediately write down a new state for the distant system". See the circular I just sent to Bennett et al.
- I loved footnotes 14–16.

More later.

20-05-02 *Denying Free Will* (to T. Rudolph)

Rudolphism 4: *This concept of free will bugs the hell out of me – in a sense when you say "I think we're constructing the world (in part)" I think any physicist would have to agree with you (in part) or else they'd end up denying free will.*

I know a lot of physicists who deny free will; Charlie Bennett and John Preskill come to mind.

Rudolphism 5: *Do you think there are more than the three "implicit assumptions" I mentioned?*

Yes and No.

20-05-02 *Dizzy in Texas* (to J. A. Smolin)

John Smolinism 3: *Now you guys are trying too hard not to think like Chris. Nothing is magic about the "instantaneous" first stage of teleportation, only knowledge is being changed. If I have two boxes, one with a ball in it and one without and send one far away, when I open the remaining one I instantly know if the ball is in the other one. Big deal. When I measure something, I find something out. Wow!*

I shouldn't let your note encourage me. (The sober side of myself won't.) But there is a way to make the sum content of all quantum measurements look exactly like your analogy above, even in a formal way. The mathematics may interest you, even if not the philosophy. You can find it in Sections 4.2 and 6.1 of the paper I put on `quant-ph` last week (`quant-ph/0205039`). Or you can see it sketched quickly in the Merminfest talk posted at my website.

The trick is to represent the quantum state as a probability distribution with respect to a fixed, fiducial informationally complete POVM. That is, one imagines a "standard quantum measurement device" sitting in the National Bureau of Standards beside the standard meter and the standard kilogram, and the quantum state captures nothing more than one's judgment for how the device will react if one were to throw one's quantum system into it. With that picture in mind, all a regular, everyday measurement does is update one's judgment concerning the outcomes of the standard measurement. The twist that comes with quantum mechanics (over regular probability theory) is that the update rule is Bayes' rule plus a little more ... it's not just Bayes' rule full stop.

24-05-02 *Snail Mail* (to S. L. Braunstein)

Tell me about some good places to go in Brisbane. Carl, Rüdiger, and I are converging there to work on this Rev. Mod. Phys. paper on Bayesianism in QM we're trying to write up. I have a small fear that the details of the paper may strain our relationship to the point of divorce, but let us hope for the best.

25-05-02 *Fun with Feyerabend* (to M. A. Nielsen)

I'm just putting some notes into my computer before I set off for travel again. At your recommendation, I've paid a little more attention to Paul Feyerabend. The quotations below summarize a little of what I see as likable and usable in his philosophy.

See you tomorrow.

From: P. Feyerabend, *Conquest of Abundance: A Tale of Abstraction versus the Richness of Being*, edited by B. Terpstra (U. Chicago Press, Chicago, 1999).

> *Humans as Sculptors of Reality.* According to the first assumption, our ways of thinking and speaking are products of idiosyncratic historical developments. Common sense and science both conceal this situation. For example, they say (second assumption) that atoms existed long before they were found. This explains why the projection received a response, but overlooks that vastly different projections did not remain unanswered.
>
> A better way of telling the story is the following. Scientists, being equipped with a complex organism and embedded in constantly changing physical and social surroundings, used ideas and actions (and, much later, equipment up to and including industrial

complexes such as CERN) to *manufacture*, first, metaphysical atoms, then, crude physical atoms, and, finally, complex systems of elementary particles out of a material that did not contain these elements but could be shaped into them. Scientists, according to this account, are sculptors of reality—but sculptors in a special sense. They not merely *act causally* upon the world (though they do that, too, and they have to if they want to "discover" new entities); they also *create semantic conditions* engendering strong inferences from known effects to novel projections and, conversely, from the projections to testable effects. We have here the same dichotomy of descriptions which Bohr introduced in his analysis of the case of Einstein, Podolsky and Rosen. Every individual, group, and culture tries to arrive at an equilibrium between the entities it posits and leading beliefs, needs, expectations, and ways of arguing. The separability assumption arises in special cases (traditions, cultures); it is not a condition (to be) satisfied by all, and it certainly is not a sound basis for epistemology. Altogether, the dichotomy subjective/objective and the corresponding dichotomy between descriptions and constructions are much too naive to guide our ideas about the nature and the implications of knowledge claims.

I do not assert that any combined causal-semantic action will lead to a well-articulated and livable world. The material humans (and, for that matter, also dogs and monkeys) face must be approached in the right way. It *offers resistance*; some constructions (some incipient cultures—cargo cults, for example) find no point of attack in it and simply collapse. On the other hand, *this material is more pliable than is commonly assumed*. Molding it in one way (history of technology leading up to a technologically streamlined environment and large research cities such as CERN), we get elementary particles; proceeding in another, we get a nature that is alive and full of Gods. Even the "discovery" of America, which I used to support the separability assumption, allowed some leeway, as is shown by Edmondo O'Gorman's fascinating study, *The Invention of America*. Science certainly is not the only source of reliable ontological information.

It is important to read these statements in the right way. They are not the sketch of a new theory of knowledge which explains the relation between humans and the world and provides a philosophical grounding for whatever discoveries are being made. Taking the historical character of knowledge seriously means rejecting any such attempt. We can describe the results we have obtained (though the description will always be fatally incomplete), we can comment on some similarities and differences that have come to our attention, and we can even try to explain what we found in the course of a particular approach "from the inside," i.e., using the practical and conceptual means provided by the approach (the theory of evolution, evolutionary epistemology, and modern cosmology belong in this category). We can tell many interesting *stories*. We cannot explain, however, how the chosen approach is related to the world and why it is successful, in terms of the world. This would mean knowing the results of all possible approaches or, what amounts to the same, we would know the history of the world before the world has come to an end.

And yet we cannot do without scientific know-how. Our world has been transformed by the material, spiritual, and intellectual impact of science and science-based technologies. Its reaction to the transformation (and a strange reaction it is!) is that we are stuck in a scientific environment. We need scientists, engineers, scientifically inclined philosophers, sociologists, etc., to deal with the consequences. My point is that these consequences are not grounded in an "objective" nature, but come from a complicated interplay between an unknown and relatively pliable material and researchers who affect and are affected and changed by the material which, after all, is the material from which they have been shaped. It is not therefore easier to remove the results. The "subjective" side of knowledge, being inextricably intertwined with its material manifestations, cannot be just blown away. Far from merely stating what is already there, it created conditions of existence, a world corresponding to these conditions and a life that is adapted to this world; all three now support or "establish" the conjectures that led to them. Still, a look at history shows that this world is not a static world populated by thinking (and publishing) ants who, crawling all over its crevices, gradually discover its features without affecting them in anyway. It is a dynamical and multifaceted Being which influences and reflects the activity of its explorers. It was once full of Gods; it then became a drab material world; and it can be changed again, if its inhabitants have the determination, the intelligence, and the heart to take the necessary steps.

and

> Pauli's views have much in common with the general picture that emerged from Aristotle's principle. In this picture we start with a world (which I shall call the primal world, or Being) which behaves in its own way and not necessarily in accordance with any one of the laws that have been discovered by scientists. (Here we still have an element of realism.) Humans are part of the primal world, not detached aliens, and they are subjected to its whims: Being can send scientists on a wild-goose chase—for centuries. On the other hand, it permits partial independence ... and it provides some of those acting independently (not all of them!) with *manifest worlds* they can expand, explore, and survive in (manifest worlds are in many respects like ecological niches). Inhabitants of a particular manifest world often identify it with Being. They thereby turn local problems into cosmic disasters. But the manifest worlds themselves demonstrate their fragmentary character; they harbor events which should not be there and which are classified away with some embarrassment (example: the separation of the arts and the sciences). The transition from one manifest world to another cannot be described in either except by excising large regions originally thought to be real—a good case for applying the notion of complementarity. Bell's request that a fundamental theory should not contain any reference to observation is satisfied, but trivially so. Being as it is, independently of any kind of approach, can never be known, which means that really fundamental theories don't exist.

25-05-02 *Becoming William James* (to G. L. Comer)

A thought struck me today as I was flying from Newark to LA reading Lloyd Morris's book *William James: The Message of a Modern Mind.* It is this: I think there's nothing I presently want more than to become a modern (quantum) incarnation of William James.

Let me leave you with a lovely quote from the end of Chapter 2.

> He conceived the individual's life, and all social progress, as a form of perpetual experiment. But he did not preach reckless faith. The "will to believe" for which he argued is best defined as courage weighted with responsibility. Contingency signifies that no precaution can absolutely eliminate all hazard of shipwreck. The individual must take everything into account that may tell against his success, and make every possible provision to minimize disaster in the event of his failure. But having done so,

he must act. And in this circumstance, James preached the right of the individual to indulge his personal faith at his personal risk. The part of wisdom would always be to believe what is in the line of one's needs, for only by such belief is the need fulfilled. Over a wide area of existence, possibilities and not finished facts are the realities with which we have actively to deal. So James argued, and pointed out that "as the essence of courage is to stake one's life on a possibility, so the essence of faith is to believe that the possibility exists." But his doctrine subordinated faith to action, for the real utility of faith is to make action genuinely dynamic. "These, then, are my last words to you," he told a group of Harvard students. "Be not afraid of life. Believe that life *is* worth living, and your belief will help create the fact."

Now I'm off to Brisbane. For my own self, I believe it is worth becoming William James.

27-05-02 *Late, but Never Too Late?* (to K. Svozil)

I hope you will excuse my horribly late reply to your letter of 4/19/02. I have just gone through a month of hell of traveling almost constantly, and I have gotten pathetically behind in all my correspondence. (Just check with Johann Summhammer there; he is also in my queue! I'm hoping to get to him later in the day, if not tomorrow.)

Thanks for the continued interest in having me around for the quantum structures meeting. Regrettably, I think I'm going to have to bow out of the possibility of coming. Presently I'm in Australia, separated from my wife and children for a month, and this trip is making me realize that I shouldn't take on any further travel than the stuff I'm already committed to for the summer. It's a shame really, because I am getting ever more involved in IQSA kinds of ideas, and it would be a great opportunity for me to learn a lot more about what is already "out there" mathematically … just waiting for me to plaster over with some words of Copenhagenish flavor. Beyond that though, I would love to have a chance to express some of my point of view to that audience. I think my talk at the quantum structures session at the AMS meeting in Atlanta two months ago or so went exceedingly well in that regard, and I found myself really enjoying conversations with Dave Foulis, for instance, afterwards.

I finally had a chance to read your paper "What Could Be More Practical than a Good Interpretation?," by the way. There are certainly large parts of it I agree with—I don't know if that will shock you or not. However, there was more to my paper with Peres than just the title! I do get a little shocked when I find people reading the title of the paper as its sum content. Here's the way I put it to Philippe Grangier a few months ago:

> **Grangierisme 9:** *By the way I also disagree with your point of view that "Quantum Theory Needs No 'Interpretation'," Phys. Today* **53***(3), 70 (2000). The fact that a physical theory ALWAYS needs an interpretation is in my opinion a central difference between physics and mathematics.*
>
> You won't find a disagreement with me here. The title and closing sentence of that paper were meant to be tongue-in-cheek plays on something Rudolf Peierls once said: "The Copenhagen interpretation *is* quantum mechanics." The whole paper is very definitely about an interpretation, and why one does not need to go any further than it to make sense of quantum mechanics as it stands. My paper `quant-ph/0106166` and the large (more personal) collection `quant-ph/105039` is about going the next step, i.e., what to do once we have established the belief that quantum states are states of knowledge.

When we do finally dig up an ontology underneath quantum mechanics, I'm quite sure it will be an interesting one!

And here was the way I put it to Paul Benioff a year before that:

> **Benioffism 1:** *To me that is an interpretation of QM. Interpretations are what give otherwise empty theories their meaning.*
>
> You're quite right about that. What Asher and I wrote about is indeed a kind of interpretation of the quantum mechanical formalism. The title and the ending words of the article were more for attention-getting than anything else. Also, though, the words were meant to be a small slap in the face to some of the extremes people have gone to (like Everett worlds, Bohm trajectories, and Ghirardi-Rimini-Weber stochastic collapses) just to hold on to a philosophic view that came around long before quantum mechanics was ever heard of. (Talk about people being set in their ways!)

I think the best renditions of my present views can be found in my new papers, `quant-ph/0205039` and `quant-ph/0204146`. I certainly would appreciate any comments you have on those. Especially I would love for you to articulate the weak points you see in the ideas. It is an evolving point of view. And what I want out of the effort is just what you suggest in your paper. I want new calculations, new effects to go search for, new mathematics, and *really* a new world view in total.

Will by chance you be at either the Oviedo, Spain meeting or the QCMC meeting at MIT this summer? Maybe we could talk then?

28-05-02 *Anti-Anti-Växjination* (to J. Summhammer)

Thank you for the beautiful long note of 4/29/02. Please allow to apologize for taking so long to reply. I've been almost completely incapacitated in my email efforts for a few weeks now by travels, family vacations, company duties, etc. Certainly I appreciate the efforts you take to read my things, and definitely your questions and comments are the best products of that!

Let me comment on a couple of your points.

Summhammerism 7: *But this 'core of the theory' is always tentative. New information, a wider frame of thought, can change it. And yet it is hard to deny that it captures something about that which has been observed. It is like clouds in the sky. For some time they do look like an animal, or the face of a witch, and anyone with eyes will agree, and a few minutes later they are gone. The immutable part here, as well as in physical theories, does seem to be the rules of thought. By the term 'core of the theory' you seem to want to say that they contain a timeless truth. But I have difficulties believing that a physical theory could ever achieve the degree of timeless truth as exhibited, for instance, by mathematical theorems, which are particular expressions of the rules of thought.*

Not quite. I would not say that this thing "the core of a theory" contains a timeless truth. Indeed I tried to be careful to squash that idea when I wrote:

> **Woottersism 9:** *But you obviously also want to say that our theories tell us* something *about reality, even if they are not descriptions of reality.*

I hope you can glean from all the above that I do indeed believe our theories tell us something about reality. But that something is much like what the elephant tells us about reality. Its presence tells us something about the accumulated selective pressures that have arisen up to the present date. A theory to some extent is a statement of history. It is also a statement of our limitations with respect to all the pressures yet seen, or—more carefully—a statement of our limitations with respect to our imaginations for classifying all that we've yet seen. (I for instance, cannot jump off the leaning tower of Pisa unprotected and hope to live; you, for instance, cannot get into your car and hope to push on the accelerator until you are traveling beyond the speed of light.) Finally, to the extent that we the theory users are part of nature, the theory also tells us something about nature in that way.

Thus even the core of the theory is as historical and contingent as the elephant. And just as the elephant could disappear from all historical record, so could the theory and, with it, its core.

Summhammerism 8: *I did not understand what you meant with the last paragraph on page 16 ('However, we would never haven gotten to this stage ....') Sounds as if you could envision that we could set the laws according to our wishes. Reminded me of an old view of evolution: The will (the basic entity) wanted a hand for this particular species, and so it came about ... Sometimes I like this idea, because it permits to look for other patterns and correlations in the history of life than 'mindless' Darwinism.*

Nor did I understand it really. But, yes, I suppose I'm imagining that we might have some control in shaping the "laws" of physics. However—and this is important—that control should be no stronger than the kind of control we might have for shaping a species with genetic engineering. The species has to be able to survive on its own after being produced in a trial. If it can't survive on its own, then one would be loath to call the monstrosity so produced a species to begin with. And so too with what I imagine for this malleable universe.

Did you see my larger paper `quant-ph/0205039`? There, I tried to incorporate some of these ideas in a more technical way. Also, I've now got a lot of supporting material posted at my website (link below).

Johann's Preply, "Anti Växjö"

Just read your Anti-Växjö paper (`quant-ph/0204146`). Despite its 17 pages, the assurance that it is free of equations was incentive to download it.

I like your distinction of the two aspects of reality (p.15): Its rawest form as the 'surprise of the sensations', and the 'core of the theory'. I would also see it this way.

The 'core of the theory' is an abstraction arrived at by applying rules of thought (a kind of immutable Platonic reality). But this 'core of the theory' is always tentative. New information, a wider frame of thought, can change it. And yet it is hard to deny that it captures something about that which has been observed. It is like clouds in the sky. For some time they do look like an animal, or the face of a witch, and anyone with eyes will agree, and a few minutes later they are gone. The immutable part here, as well as in physical theories, does seem to be the rules of thought. By the term 'core of the theory' you seem to want to say that they contain a timeless truth. But I have difficulties believing that a physical theory could ever achieve the degree of timeless truth as exhibited, for instance, by mathematical theorems, which are particular expressions of the rules of thought.

In physics, we are still haunted by the remnants of a naive picture of reality. We have thrown out the classical view, but still tend to think that our theories retain a kind of one-to-one link with 'the world as such'. We do no longer say we describe how something is, but that we describe what we know about that something. Thereby we still stipulate the existence of that something. But I think any statement about distinctions in the world, that should exist independent of us, is premature. We can say "The world is," but we cannot say "The world is such and such" and mean it to apply independent of our categorizations.

Take gravity, for instance. Invented by great minds, to be sure. But a statement that the universe contains masses which interact by gravity, better expressed as curvatures of a manifold in which all the masses are supposed to be located, is so obviously a human way of categorization of observations, that any alien would coil up in laughter, if we wanted to sell this as a deep truth (my human way of categorizing his/her/its reaction, further, that aliens would be individual lumps like us, further, that they would be interested in science at all — a consequence of that particular brain disease, which leads to an extreme slow down between observing and acting and manifests itself as language, etc.).

The human categorizations leading to gravity:

- spatial representation of sensory input (3-space as our mode of representation, the concept of distance as an unquestioned primitive)
- the separation of the sensory input into distinct 'things' according to some invariance principles
- mass (the 'cause' of muscular strain when lifting and moving around an everyday 'thing')
- force (the muscular strain itself)

and probably some more.

Nevertheless I grant the following: We will never get out of our categorizations. And as these are ultimately not our own inventions, the fact that *these* categorizations lead to *these* laws may — in combination — be seen as containing a higher 'truth'.

I did not understand what you meant with the last paragraph on page 16 ('However, we would never have gotten to this stage ....') Sounds as if you could envision that we could set the laws according to our wishes. Reminded me of an old view of evolution: The will (the basic entity) wanted a hand for this particular species, and so it came about ... Sometimes I like this idea, because it permits to look for other patterns and correlations in the history of life than 'mindless' Darwinism.

28-05-02 *Little Toes and a World of Experience* (to W. K. Wootters)

I'm finally down in Australia, with a little time to think. I'll be down here for three weeks. Kiki and the kids are in Munich, visiting Kiki's mom and dad.

If you don't mind, I'd like to ask you a couple of questions about your last letter.

Woottersism 10: *I think the sort of world envisioned by classical physics is in fact impossible. If we really understood what it takes to make a world exist* really*, and not just on paper, I think we would see that one needs the subject-object relation in order to hold things together. This is not to say that one needs dualism. In Whitehead's system, everything is both subject and object, depending* *on the point of view. There is no dualistic separation into two kinds of entity. But everything is related to something else as subject, and everything is also related to something else as object. In classical physics, there is no such relation. As Schrödinger points out, from the very beginning we eliminate the very notion of an experiencing subject. I agree with Schrödinger that this is too extreme an abstraction. In making this abstraction, we have removed something essential from our view of the world.*

I suppose I too have a gut feeling that your first sentence above is on the right track, but I wonder if you have an actual argument in mind for supporting the case? Also let me ask you this. Would you say the same thing about a world governed by quantum mechanics? Or do you think the quantum world differs from the classical world in this respect? Maybe, in a refinement of this, let me ask the same thing not about the quantum world in general, but the quantum world in the vision of the many-worlders, say David Deutsch and Charlie Bennett. The way I understand what they envision for quantum mechanics, it has never struck me as so very different from what I would call classical physics. (It is just now that the world as a whole has this thing called a "state" and it is it that goes along according to some mathematically precise law.)

Woottersism 11: *I would like to think that my view avoids the line of reasoning that takes the mathematical description as the essence of the world. As John Wheeler says, a set of mathematical laws will not "fly" by itself. I think the necessary added ingredient is something like* experience*. And that's what I find in Whitehead's view.*

Would you flesh out this thing you call the "subject-object relation" a little more? What do you mean by it? Let us focus on a simpler system than one usually thinks of as a sentient being. Say a rock or the little toe on my right foot. When we think of these systems in their capacities as subjects, rather than objects, what is it that defines those capacities? What are their characteristic traits?

When I think of a person as a subject, I think of him carrying around sets of probability distributions for this and that. That is, I think of a subject as something that can carry beliefs. However, I guess, I have a hard time thinking of a rock or my toe as carrying around beliefs. I also think of a subject as something that can play an active role in shaping other parts of the world because of those beliefs.

However, maybe you mean something completely different when you're thinking of a rock as a subject.

Beyond that, let me ask about this word "experience." What do you mean by that? I hope to try out one of Whitehead's shorter books soon but I haven't gotten to that yet. However, I did read another small book on James on my flight over and it got me into some territory that I haven't yet seen of his. Namely, his stuff from *A Pluralistic Universe* and *Radical Empiricism*, neither of which I've read yet. The book I read was *William James: The Message of a Modern Mind*, by Lloyd Morris. It's only 91 pages, and I found it an engaging little thing (at least for giving me a quick overview of all of James's views, even if not the arguments he used for getting there). Anyway, Chapter 5 was titled "A World of Pure Experience" and what he described there seemed to have some overlap with what you expressed in your last note. Morris wrote:

> "My thesis," James declared, "is that if we start with the supposition that there is only one primal stuff or material in the world, a stuff of which everything is composed, and if we call that stuff 'pure experience,' then knowing can easily be explained as a particular sort of relation towards one another into which portions of pure experience may enter.

> The relation itself is a part of pure experience; one of its terms becomes the subject or bearer of the knowledge, the 'knower,' the other becomes the object known."
>
> This doctrine is essentially monistic. But it is radically unlike the monistic doctrines of either idealism or materialism, which respectively affirm that mind and matter are the ultimate substance of reality. Pure experience is neither mind nor matter, but is the ground of both. In itself it is, as James asserted, neutral.

Morris also said that this had some feed-in to Whitehead's later thought, but he didn't elaborate. So I'm guessing there will be some overlap between this and what you're thinking about. But still I'm having trouble understanding what all this might mean, especially since I'm having trouble envisioning the mental life of my toe.

Now the other day I said the idea of a random outcome in a quantum measurement might be viewed as having a mentalistic aspect. From the outside, it looks like a random occurrence; however, from the inside one might think it looks like a "decision." But right now, I'm wondering what even I really mean by this.

Thinking of you from way down under.

28-05-02 *Australiocentrism* (to M. J. Donald)

Thanks a million for the letter of 4/27/02. Please let me apologize for not replying before now. I'm about a month behind in my email due to excessive travels, company business, etc. Just yesterday I arrived in Australia for a three-week stay without the family. So I'm hoping to finally get caught up a little!

Anyway, you flatter me by reading my drivel and taking the time to comment. But I wish you didn't think the universe is doing nothing.

One question:

Donaldism 1 : *I'm an idealist because in the course of making that explanation I'm prepared to throw away any ontological presuppositions.*

How do you define idealism? And how would you contrast your flavor of idealism with this little thing Martin Gardner says in his essay, "Why I Am Not a Solipsist":

> In this book I use the term "realism" in the broad sense of a belief in the reality of something (the nature of which we leave in limbo) that is behind the phaneron, and which generates the phaneron and its weird regularities. This something is independent of human minds in the sense that it existed before there were human minds, and would exist if the human race vanished. I am not here concerned with realism as a view opposed to idealism, or realism in the Platonic sense of a view opposed to nominalism or conceptualism. As I shall use the word it is clear that even Berkeley and Royce were realists. The term of contrast is not "idealism" but "subjectivism."

(The phaneron, by the way, was Peirce's term for "the world of our experience—the totality of all we see, hear, taste, touch, feel, and smell.")

And how would you contrast it to this thing Charles Hartshorne says:

> It appears, then, that the idealistic interpretation of reality as essentially relative to or consisting of mind, experience, awareness, that is, psychicalistic idealism, is entirely compatible with a realistic view of the independence of the particular object and the dependence of the particular subject, in each subject-object situation. It may also be

urged that we need the word "realism" to refer to the mere thesis that every act of knowledge must be derivative from a known which is not derivative from that act. Thus the practice of contrasting "idealism" and "realism" as though they were contradictories, is of doubtful convenience. "Realistic idealism," or "realistic subjectivism," has a reasonable and consistent meaning.

28-05-02 *A Comment on One of Your Comments* (to C. M. Caves)

Cavesism 71 :

> [CAF wrote:] But there's really more to the story. They can always come to agreement, indeed—regardless of how disparate their initial opinions—if they are willing to make an essentially infinite expenditure toward laboratory technique. That is to say, the only thing that will give assured agreement in all cases is a set of Kraus operators all of rank-one. Jacobs and I called those infinite strength measurements: the idea being that they are hard to actually do. In more real-world measurements, where the operators are never really rank-one, coming to final agreement will generally require some initial agreement. Whence the point in my August 7 letter to Mermin.

My puzzlement here is related to that above. How can it be that rank-one's lead to "assured agreement" when we can never be sure what measurement was made nor what rule to use for the post-measurement state?

You're getting off track with this in the same way that you were yesterday in our walk near the lake. The issue is solely this in all issues of "coming to agreement." When can some amount of previous agreement between two agents lead to an increased amount of agreement after an act of consulting the world?

In the view I'm trying to promote, a measurement and a state-change rule (i.e., a POVM and an associated conditional quantum operation) is a subjective judgment. When you say something like "we can never be sure what a measurement was," in my way of thinking it is exactly like saying "we can never be sure what the true quantum state was." To the extent that the latter is a non sequitur for me, your phrase is a non sequitur too. When two experimentalists walk into the same laboratory, one carries in with him a subjective judgment about the POVM and quantum operation of the measurement device, and the other may carry in a completely different conception. But both of them know what they themselves think. For neither of them is there a "true" quantum measurement working in the background.

Suppose they lay their beliefs on the table. The question is this, what must the characteristics of those beliefs be so that, upon the completion of a measurement, they will ascribe the same quantum state to the post-measurement system regardless of what each initially said about the system to be measured? The only claim is that it is sufficient that their separate POVM + operations be 1) identical *and* 2) consist of rank-1 elements.

I found myself laughing last night, by the way. After all your preaching to me about the ineffectiveness of email for conveying one's thoughts, you nevertheless wrote this note while we were in the same room!

Rüdiger, we can't wait until you get here!

28-05-02 *Strong Coherence?* (to M. C. Galavotti & E. Regazzini)

My colleagues, Caves and Schack, and I are once again having an argument about the foundations of probability. In particular, one of the things we are getting hung up on is the issue of requiring A) "strong coherence" as introduced by Shimony and Kemeny, or instead B) "normal de Finetti coherence" in Dutch-book arguments. I hope that you are aware of these distinctions.

Caves and Schack are attracted to strong consistency as a normative criterion because it leads to certain results that they would like to see when we apply the idea to quantum mechanical betting situations. I, however, am opposed to the criterion for just the opposite reasons. What I would like to ask of both of you is might you point me to some of the literature where the issue of "strong coherence" versus "regular coherence" is discussed?

I am aware of de Finetti's own rejection of strong coherence from his book. However, in particular, I am wondering if there are any independent arguments (i.e., other than de Finetti's, which concerns an infinite limit and probabilities on a non-discrete space) for rejecting strong coherence? Could you send me references if there are any?

Thank you so much for your help, and I hope to hear from you soon.

29-05-02 *I Think She'll Know* (to N. D. Mermin)

Remember what the dormouse said; feed your head.

You can tell I'm pretty darned behind in my email. I'm in Australia now, finally with a little time to think. Kiki and the kids are in Munich. Caves, Schack, and I are down here for three weeks doing Bayesiany things.

Merminition 90: *I don't see what your teleportation example (pages 11, 12) adds to ordinary EPR. Aren't all the issues exactly the same if Alice "in her laboratory prepares" the single qubit in (1) that she possesses by an appropriate measurement (to be sure, she can't control which outcome she'll get, but that doesn't seem to be central to your point, or is it?) after which she and only she knows what the outcome of the corresponding yes-no measurement on Bob's qubit will be.*

Yeah, I'd agree that it doesn't add a heck of a lot to the old argument. Mostly I wanted to say something about teleportation: Namely that if Einstein had known about it, then he might have used it to the same devious purposes he did with his old argument.

But still, I guess there were a couple of features of this version that I thought made it a bit cleaner than the old Einstein thing. 1) With the supplementation of *only* two bits of physical action on the part of Bob (i.e., one of four possible unitaries), Alice can put Bob's system into any state she wishes. So, in essence (i.e. up to two bits), there's nothing even random and uncontrollable about the process. 2) In the case of teleportation, even examining the measurement device before and after the measurement will tell you nothing about the posterior state for Bob's system that Alice ends up with. Very literally, only Alice ends up doing some updating. If it's she and only she, why not call the state her knowledge?

29-05-02 *That Damned von Neumann* (to N. D. Mermin)

Now let me try to answer more adequately the question you asked after my talk in Ithaca. The point is simply this: Suppose I tell you that I've got a device that measures a standard observable H. How do you know that you should accept my claim? Let's say you do this: You simply give me a supply of a gazillion nonidentical states you've prepared (anyway you wish) in your laboratory.

I'll perform my measurement on each of them and report the results I found. If you find that I'm giving you back outcomes with the (conditional) statistics you expect, then you'll have some warrant for believing I'm really performing the measurement I claim.

Now let me ask you this. Suppose you confirm my measurement to your satisfaction by that method. Do you now have warrant to say anything about the post-measurement state for each of the systems you gave me? The answer is "no" of course. The point is, you need to know more about the particulars of the device.

Now, von Neumann said that for an "ideal" device the post-measurement states for the systems will be eigenstates of the observable. But I claim that is an arbitrary notion of ideal, and Kraus's theory of "effects and operations" backs that up in a kind of technical way. The Kraus theory says that the state change can always be thought of as a collapse in the von Neumann sense PLUS a trace-preserving completely positive map.

Now, the standard quip that is made is that the CPM part of this is just extra noise that didn't need to be there. But again, I claim this statement is arbitrary. Here is a simple counter example. Suppose I perform the measurement H on half of an entangled pair. Then (via the entanglement), I can always think of this measurement as *really* a measurement of some sort on the other half. In fact I can think of it as simply the observable that is the transpose of the original one ... only performed on the second system rather than the first. What could be a more minimally disturbing way of measuring H^{T} on the second system than that? But does von Neumann's collapse postulate hold for this kind of measurement? Try it, and you'll find that it doesn't. The only state changes this kind of measurement can produce are of the pure-refinement kind.

Von Neumann brainwashed the generations in a needless way. Even something so simple and "ideal" as a standard photon detector does not follow the postulate. When there's a click, the photons are absorbed from the mode and the field is now in the $|0\rangle$ state.

I hope that helps make up for my lack of lucidity at your celebration.

29-05-02 *Notes from the Web* (to C. M. Caves & R. Schack)

[[**Note:** This is a quote I thought worthy of recording the time. Unfortunately I did not record its source.]]

> Note that traditional conditionalisation is a special case of Jeffrey conditionalisation. It is important that Jeffrey stressed that this rule of the kinematics of rational belief is all that is needed. It is never needed to give up propositions that are assigned probability one. The assumption is that only logical tautologies have probability one and only contradictions probability zero. This view is defended by means of the condition called strict coherence. A probability function obeys strict coherence if it is coherent and there is no set of bets consistent with it such that the better might lose, and cannot win. Jeffrey, among others, has argued that by assuming strict coherence it follows that no contingent proposition should have probability one, because no rational agent would bet his head on the truth of any contingent proposition.

29-05-02 *Strict Coherence?* (to B. Skyrms)

I doubt you remember me, but we met between 1996 and 1998, when I was a postdoc at Caltech and you had a visiting position there.

I dawned on me today that you might be able to help me in my plight described below. [See 28-05-02 note titled "Strong Coherence?" to M. C. Galavotti and E. Regazzini.] Is there any literature that you could send me to that expresses a dissatisfaction with "strong coherence"? I'd be very grateful for any pointers you could give.

29-05-02 *More Strict Coherence* (to B. Skyrms)

Skyrmsism 1: *Sure, I remember you. I think that the usual response to Shimony is just that strict coherence isn't a plausible requirement in the usual way of doing probability theory with continuous mathematics. Don't remember any good references, though.*

That's too bad. What I'm really looking for is anything that expresses a dissatisfaction with strict coherence with respect to discrete event spaces. It turns out that enforcing strict versus normal coherence can make a pretty drastic difference for some interpretive problems in (even finite dimensional) quantum mechanics. Unfortunately, with respect to the attractiveness of the conclusion, my coauthors and I have opposite opinions. Thus, I am inclined to require only normal coherence for the agents in our game; whereas they are inclined to require strict coherence.

The main point, even in the classical case, is that strict coherence requires that an agent ascribe probability 1 to an event if and only if he believes the event is a certainty. Whereas under the assumption of normal de Finettian coherence, a probability-1 assignment cannot be used to conclude a belief of certainty on the agent's part. He might be assigning probability 1, not because it reflects his true beliefs, but because it is advantageous for other purposes. That is, with respect to certainty, strict coherence compels an agent to never "tell a lie."

I think that goes too far as concerns a foundation for "rational behavior." Whereas normal coherence appears to me to strike a sweet spot.

In any case, what I am looking for is some confirmation of my troubles in the published literature ... to help me build a case for the inevitable battles I foresee with my coauthors.

By the way, you might be interested to know that we have been putting a substantial effort into interpreting quantum probabilities as personalist probabilities. Let me recommend four of our papers to you (along with the web links to get them) in case you're interested. [`quant-ph/0205039`, `quant-ph/0204146`, `quant-ph/0104088`, `quant-ph/0106133`]

As you climb from bottom to top in this list, you'll find us moving closer and closer to a personalist position. Also, there is a lot of supporting information posted at my website, link below.

31-05-02 *Poor Young Duvenhage* (to H. M. Wiseman)

Thanks yourself for your long note in reply to my long note! You can see I'm working with a much larger lag time than you in my emails. Anyway I'm in Australia now, and slowly working off the jetlag and becoming more productive as the days go by.

Let me say a few words on your last note.

Wisemanism 7: *Freedom taken, thank you. And I think you will be stronger if you don't try to prop up your position using another paper which I think goes fundamentally against your views in a number of places.*

If you believe that, you misconstrue my purposes for citing Duvenhage. My citation was to give attention to and encourage this young researcher. Of course, I don't agree with a lot of the paper;

but that is beside the point for me. There is one thing I certainly agree with and I think he said it particularly cleanly.

You can find where I said this outright to Duvenhage himself by looking at pages 167 and 168 of my web samizdat, "Quantum States: What the Hell Are They?" (It's in a 28 March 2002 letter; I hope you'll read it.) There you will find me expressing some of the same misgivings as you, though with less detail. As I told him, I would rather encourage the similarities at the moment than the contrasts.

Duvenhage's paper will appear in *Foundations of Physics*, and I think that is a good thing. Having the paper out in publication-land just encourages someone to write a comment on its deficiencies. Indeed, I would love for that to go further and get a discussion stirring. For, what might get more people to pay attention to the potential of a Bayesian approach to QM than a good stirring discussion? Moreover, if people start to pay attention to the potential of the approach, they might just get to work on filling its other (I would say, more real) deficiencies!

So, there. I can even imagine an eloquent writer to start the ball rolling ... (OK, a hint: His initials are HMW.)

Now, let me go back to the one thing I said "I certainly agree with."

Wisemanism 8: *But here is the difference between classical and quantal.*

In the classical theory the belief p of the weatherman could be given a precise formulation in terms of a set of classical variables (presumably related to his [brain]), and that belief would actually evolve (for a "true h" etc.) in a deterministic way from $p(h)$ to $p(h|d)$ as he looks out the window. That is, the belief of the weatherman can be treated ON THE SAME BASIS as the objects of that belief (i.e. the physical world). That is not to say it MUST be treated on the same basis, but it CAN be, and there is no NEED to have Bayes thm in the foundations of the theory.

In the quantum theory, our belief cannot be treated on the same basis as the physical world. We use a state matrix to encapsulate our belief about the world: our expectation for the results of a fiducial measurement if you like. In the absence of information gathering, this state matrix evolves in some well-defined way. But if we try to treat our belief on the same basis, as a function of physical brain variables, we run into the QMP.

I think this pinpoints in a pretty terse way the root of our disagreement. To say what you said is to 1) accept a kind of reductionism that I no longer think is healthy, and 2) to posit a strong faith that something *can* be done that, in actual fact, has *never* been done.

Concerning 1) I apologize for using the phrase "those beliefs are presumably a property of his head," for it evokes an imagery I would rather not have in this discussion. Perhaps it would have been better for me to use the word "possession" rather than "property."

Here's a belief I presently possess: With probability greater than .9, there will be another suicide bombing in Israel in the next month. Try to put that into physical terms. What can the word "suicide" mean in classical mechanical terms (or even quantum mechanical terms)? Or to make it look just a little more physical, here is another belief: With probability greater than .99, I will see at least one car today. But why didn't I say a lump of atoms with this characteristic, that characteristic, and the other characteristic? The point is: The world independent of man does not, and cannot, know that that lump of atoms signifies a car. My beliefs—at their starting points—are always about things denoted at such a level of *practical* existence.

Thus I would claim, concerning 2), that it is nothing but a religious faith to suppose that one can derive the form of Bayes' conditionalization rule from a mechanistic physics. It has never been done before, and I would venture to guess that it will never be done.

But still, let me suppose that it could be done after all—it's just that it hasn't been done yet. What would that do? In agreement with (a small part of) Duvenhage's paper, I would say we're left with one conclusion: We should call the difficulties so found the "classical measurement problem." For in classical physics we wouldn't know where the observer begins and the world ends … just as we don't presently know it with quantum mechanics. Nor as I said above, would we know how to get a Bayesian collapse in the beliefs of the observer (even once he has been identified).

So, with regards to this particular aspect of things, I hold firm with my assessment of Duvenhage. If there is a distinction between a classical and quantum conception of nature, it is somewhere else than in the updating of one's beliefs. I claim the same difficulties are either absent from both conceptions, or present in both conceptions.

But … maybe I say this all for nothing. For you also wrote this:

Wisemanism 9: *Duvenhage is quite specific about what he is saying. He says "the Heisenberg cut is therefore no more problematic in quantum mechanics than in classical mechanics". This is true if you are a committed Bayesian, because then the cut is necessarily there from the beginning of your conception of the world.*

and that seems to express that my previous quotation of you was directed more toward Mr. D than me.

In any case,

Wisemanism 10: *I accept that. This is your solution to the QMP. You say "there is no QMP", but isn't that the same as their saying "I've solved the QMP"? You don't have to answer that.*

I would say it doesn't solve anything; it just shifts the terms. For, where it dismisses old problems, it creates new problems. And it's the problems that keep us all young.

31-05-02 *'Reality'* (to M. J. Donald)

Thanks for the clarification on your form of idealism. I also had a nice time reading the FAQ on your webpage. I'm whiling away a little time in Australia at the moment, visiting Nielsen and trying to write some papers with Caves and Schack.

Donaldism 2: *If the "current wavefunction" is just the best description of our knowledge of the system, then what are we made of?*

Something that is not the wavefunction, but for which, once we have accepted its existence, compels us to a structure of reasoning and belief revision whose form is identical to what we once thought of as "quantum mechanics." My best shots so far at saying this in a clear way can be found in Sections 4.2 and 6 of the new paper `quant-ph/0205039`. Or you can see the same thing in pictorial form by looking up the talk "Where's a Good Weatherman When You Need One?" at my webpage.

And so the sparring match goes on …

01-06-02 *Finally, My Slides* (to R. J. Greechie)

I've been meaning to write you for a while. At the AMS meeting in Atlanta, you asked me if I could mail you a copy of my slides from the talk I gave there. Well, I still can't do that easily (I'm in Australia for three weeks), but you can download my slides from my website now. The link for it is below. I was hoping to get them printed out in color to mail to you before I left for Australia, but time ran out on me. I hope this will do as a substitute.

Also let me advertise some papers that outline what I would like to see happen in quantum foundations. The top paper in the list below (0205039) makes my strongest statement of that. All of them, I think you'll find to be pretty easy reading.

- "Quantum Mechanics as Quantum Information (and only a little more)"
  `http://xxx.lanl.gov/abs/quant-ph/0205039`
- "The Anti-Vaxjo Interpretation of Quantum Mechanics"
  `http://xxx.lanl.gov/abs/quant-ph/0204146`
- "Unknown Quantum States: The Quantum de Finetti Representation"
  `http://xxx.lanl.gov/abs/quant-ph/0104088`
- "Quantum Probabilities as Bayesian Probabilities"
  `http://xxx.lanl.gov/abs/quant-ph/0106133`

Unfortunately, I can't come to the IQSA meeting in Vienna this summer; time just became too short for me. But I get the feeling that there is a large mass of results I could use from the quantum logic community to further my program. "Results which are," as I wrote Karl Svozil recently, "just waiting for me to plaster over them with some words of a Copenhagenish flavor."

01-06-02 *Vienna and Amherst* (to D. J. Foulis)

I just wrote a letter to Dick Greechie giving links to some of my papers and talks. Rather than dreaming up some new things to say, let me just paste that letter into this one for your use. [See 01-06-02 note "Finally, My Slides" to R. Greechie.] If you can download it, I especially hope you enjoy my paper "Quantum Mechanics as Quantum Information (and only a little more)" … and don't find it too offensive!

I'm so happy to have met you in Georgia. You really helped build my confidence that this method of attack I keep trying to push the community into might just go somewhere. From time to time, I am in Amherst visiting Charlie Bennett (he's got a weekend home in Wendell) or Herb Bernstein at Hampshire College. It'd be great if I could swing by and have some further talks with you.

01-06-02 *Wheeler Compendium* (to K. W. Ford)

Lucien Hardy gave me your name as a contact. The reason I am writing you is that I am working to put together a rather large compendium of references and quotations from the literature with the title, "The Activating Observer: Resource Material for a Paulian–Wheelerish Conception of Nature." The compendium presently stands at 439 references and fills 107 printed pages. I expect it to be significantly larger than that when it is finished. As you can guess from the title, the thoughts of John Wheeler play a significant role in the project. In fact they started me down the course; John has long been one of my heroes.

The reason I am writing you is that I wonder if I could ask your help in making sure that I have the document as complete as possible. Also I would like to ask you if you have any ideas of where I might publish the thing once it is completed. I had originally planned to submit it to the journal *Studies in History and Philosophy of Modern Physics* but now I am starting to fear that the document is becoming much too long for that.

If you would like me to email you a copy of the manuscript-under-construction, I can do that. (Either as a raw REVTEX file, a DVI file, or a PostScript file.) I would certainly welcome any help you could give.

About myself—in case you worry about my legitimacy—I am a research physicist at Bell Labs working in the field of quantum information and computing, am 37 years old, and have had post-doctoral positions at Caltech and Los Alamos. My full CV can be found at my website (there is a link to it below). Also, you can read about me in the nice foreword David Mermin wrote for my samizdat *Notes on a Paulian Idea* published on the Los Alamos archive. Here is a link: `http://xxx.lanl.gov/abs/quant-ph/0105039`. In general, you can read my views on quantum mechanics and how it fits in with some of John Wheeler's larger questions by either consulting my website or perusing the Los Alamos `quant-ph` archive.

Anyway, I put all this information so that you won't think I am just another crackpot who has become smitten with John's words. It is a serious project.

I hope I hear from you soon.

01-06-02 *Back from the Grave* (to G. Brassard)

Good to hear from you. Our letters just crossed paths.

Brassardisme 5: *But can you tell me what's the homunculus fallacy?*

Sounds dirty, doesn't it? I think it's the same fallacy as the camera obscura fallacy.

01-06-02 *High Dispute* (to P. Grangier)

I hope you will forgive me for not replying to your letters for so long. The volume of email I have been getting lately has started to become something I am not equipped for. Sometimes I just crack under the pressure, and thus my silence. But at the moment, I've got a little time away from home: I am in Australia, visiting Nielsen and trying to write some papers with Caves and Schack. Beyond that, my wife, kids, and Bell Labs have all been left behind! So I am hoping for a productive three weeks.

Grangierisme 10: *If we speak about "objectivity", we have first to agree about what it is. To keep it simple, I stick with the "naive" view that if I do (or if a student does) a measurement in the lab, this is an objective process: this "did happen", and the fact that you don't know the result of the measurement will not change it.*

As far as I can tell, we do NOT disagree on this. So, it kind of annoys me that you keep bringing it up. Instead, I would say our disagreement lies right here: For some reason YOU think it is NECESSARY to uphold the idea that a pure quantum state is an objective property (of something in nature) in order for your sentence above to come about. Whereas I do not.

I know that I can function just fine with subjective quantum states, even with subjective pure quantum states. You will find no logical inconsistency in me; and I doubt I can find any in you. At the level of our squabble, it is to a large extent a matter of taste. However, you and I both know that matters of taste can lead to matters of fact with regards to the questions we will seek of nature. Your taste will lead you one way; my taste will lead me another. Only history will tell which of us will have had the more productive view. Only history will tell which one of us ended up asking the most interesting questions of nature. (Recently I tried to capture this in a little story to Charlie Bennett and John Smolin about the pleasures of broccoli. I will paste the story at the end of this note.)

Here is the way I put the whole point in a message to Matthew Donald just a minute ago. At the present time, I just do not know how to say it any more cleanly than this:

> If the "current wavefunction" is just the best description of our knowledge of the system, then what are we made of?
>
> Something that is not the wavefunction, but for which, once we have accepted its existence, compels us to a structure of reasoning and belief revision whose form is identical to what we once thought of as "quantum mechanics." My best shots so far at saying this in a clear way can be found in Sections 4.2 and 6 of the new paper `quant-ph/0205039`. Or you can see the same thing in pictorial form by looking up the talk "Where's a Good Weatherman When You Need One?" at my webpage.

The sections I recommended to him, in their focus on the Bureau International des Poids et Mesures, have direct implication on you. So I have a secret dream that you will read them ... and finally, finally something will click in your head, and you will say, "You know, Chris is not being so unreasonable after all."

Grangierisme 11: *it is quite enough that a complete (=self-defining) set of physical properties can be predicted with certainty. The crucial point is that there is no "ignorance" left (you must admit that each time you write that a pure state has zero entropy).*

It is fine to note that some observables can be predicted with certainty when a state is a pure state, but that does not delete the fact that there is plenty of ignorance left for other observables. One can even quantify that ignorance nicely. See equations (77) through (82) in my `quant-ph/0205039`. (But the result goes back to Wootters.) The von Neumann entropy—which is what you are thinking of in your statement—simply captures the BEST CASE predictability. So what?

Grangierisme 12: *PS In your paper you strongly "recommend" the work by Lucien Hardy. I have two comments:*

- *it surprises me that you adhere with the "relative frequency" approach to probabilities that is used by Lucien (his first axiom). I certainly agree with it, but I thought you would not.*
- *Lucien is trying to make QM look like a new probability theory.*

If you look at my paper, you will note that I said:

> Beyond that, let me recommend four other articles. The first two are the most technically important for the enterprise I promote in my other contribution to this volume: Namely, to secure a transfer from our present abstract, axiomatic formulation of quantum mechanics to a more physically meaningful one. I think some elements in Lucien Hardy's papers *almost* carry us to the brink of that. In his work, I think the right emphasis is finally being placed on the right mathematical structures. ...
>
> I should point out, however, that in all four of the above references, I think significant improvements could be made by adopting a sufficiently Bayesian stance toward the use and meaning of probability.

I said what I meant. (Just as the experimentalist should strive to perform his measurements accurately; the good theorist should strive to read his friends' papers carefully.) The interesting part of Hardy's papers, in my view, is the mathematics. Saying that constitutes an endorsement of neither 1) the relative-frequency interpretation of probability, nor of 2) Hardy's desire to generalize probability theory to a larger structure. Hardy and I, indeed, have had extensive discussions on this.

Grangierisme 13 : *Let us simply admit that local realism is dead, but that physical realism can do quite well without it. Why is that so difficult to accept?*

One more time: I do not deny realism. Moreover, just as you, I am happy with the death of local realism (if what one means by that is "hidden variable realism"). However, I simply do not find your proposed solution to the whole shebang of quantum interpretation problems to be as compelling as you find it.

Measurement clicks alone do not specify post-measurement quantum states. Rather, measurement clicks PLUS prior quantum states (for one's description of the measurement apparatus) do. Thus, where you think a measurement outcome prepares a unique quantum state, I say it has a subjective component. But you say, my measurement device is calibrated. And I say with respect to what? And on and on we could go ad infinitum. The Gordian knot of the state's subjectivity simply cannot be cut by your assuring me that I ought to think otherwise.

Grangierisme 14 : *admit that there is a "reality" attached to the pair of particles, but that there is no "reality" attached to each particle.*

This I see as an arbitrary move. Just as one man's unipartite system is half of another man's bipartite system, one man's bipartite system is half of another man's quadripartite system. And so it goes.

Instead, I would say *all* systems have a reality attached to them. It is simply that that reality has *nothing to do* with the quantum states one ascribes to those systems. A system has a Hilbert space, and a Hilbert space has a dimension that does not depend upon which state is "alive" within it. That dimension, I would offer you, can be treated as a reality for a quantum system. But there I stop, whereas you want to go further (by supposing a reality to some nonlocal quantum state).

Grangierisme 15 : *the "reality" attached to the pair makes no problem with Lorentz invariance, because it was created when the two particles interacted, and it simply follows them if they move very far away. The same conclusion apply to more fancy schemes like entanglement swapping, that requires classical communications to effectively prepare the remote entangled state.*

In the usual sense of what one means by the word "interacted," this—I would say—is just wrong. Suppose Alice and Bob possess two particles that interacted in the past so that they are now entangled (by your way of speaking). Further suppose Carol and Ted possess two particles that interacted in the past so that they are entangled. Maybe even make both states—the AB state and the CT state—to be singlets.

Suppose finally that Alice and Bob have never before seen Carol and Ted. A conclusion one can draw from this is that the A and C particles have never interacted in the past. And the B and T particles have never interacted in the past either.

Let now Alice and Carol meet by chance and perform a Bell measurement on their two particles. If Alice shares all her knowledge of the original AB interaction with Carol, and Carol shares all her knowledge of the original CT interaction with Alice, then they will both be warranted to update their assessments of the BT system. They each will immediately ascribe a pure Bell state (one of four possibilities to that system). With *respect* to Alice and Carol, the BT system will now be in a Bell state, even though B and T have never interacted in the past.

And this has nothing to do with Alice and Carol sending the information about their measurement outcomes to Bob and Ted. I'll say it one last time: *with respect to* Alice and Carol, the BT system will be in a Bell state after the measurement.

You see, you get hung up because you want to think of entanglement as a real objective property of two systems, not merely a property of an observer's judgment about those systems. Beyond that, your desire for Lorentz invariance makes you want to think of entanglement as only a consequence of local interaction. But that just goes too far, as the above example shows. Entanglement, just like quantum states, can arise from measurements in the distance.

You can call that a "contextually objective" affair if you wish, i.e., that the entanglement between B and T arises only with respect to the context set by A and C. But then I say—as I've said before—why not just call the state ascribed to the BT system Alice and Carol's information about it? Moreover, by calling it information, you will find that you will stop forgetting the prior (subjective) information that was crucial for defining the posteriori states in the first place.

By the way, I have read your FAQ posted on `quant-ph`; I have not ignored it.

Grangierisme 16 : *Bell's inequalities do not hold!!!! . . . if a measurement if performed on one side, ABSOLUTELY NOTHING happens on the other side.*

Well, at least we can agree on this. But look how many of your words I had to delete from the paragraph below to get us there:

Grangierisme 17 : *- since there is no "reality" attached to each particle, Bell's inequalities do not hold !!!! All the job is done by the fact that the individual particles have no quantum state, or no other property whatsoever that would decide on the result of the measurement. Then "action at a distance" simply vanishes: if a measurement if performed on one side, absolutely nothing happens on the other side.*

And we most certainly agree on the following:

Grangierisme 18 : *What next? QM is a fantastic theory that can only stimulate one question: why is it working so well? Then we may notice that QM was invented 75 years ago in a somehow anarchic way, as an attempt to understand atomic spectra. But we may speculate the following: QM is actually the answer to a question that was never clearly formulated. We have the answer, what about finding the question?*

Even if we do not see eye to eye in the secular world, we seem to dream of the same heaven.

PS. Don't forget the story below.

> King Broccoli
>
> "In any case, none of this matters for doing physics," you say. But I think it does in the long run. (Certainly, you've got to concede that there's something that fuels me—and it hurts to think that you might think it is nothing more than irrationality.) When Charlie sent me the picture of a skunk cabbage in reply to these very issues, I found myself thinking of King Broccoli. The story goes that one day, by divine providence, it came to King Broccoli that broccoli, the vegetable, his namesake, actually tastes good. Good in a way that hitherto only gods and angels had known. Every child who had

ever said, “Yuck, I don’t like broccoli; it tastes awful!” was simply wrong ... or at least that’s what the king realized. King Broccoli, being the head of state, decided to do something about it. Henceforward, all gardens in the kingdom should have a patch devoted solely to broccoli. It really wasn’t much of a burden on the national product (except, perhaps, for the psychiatrists who had to treat all the movie stars who had never felt fulfilled in their broccoli experience). But think of the diversity of vegetables the kingdom might have raised if its citizens hadn’t been encumbered with the king’s notion that broccoli had an objective, but never verifiable, taste?

Moral? Maybe there is none. But it is a documented fact that the Kingdom of Broccoli eventually fell and was replaced by a liberal democracy (where the ideals set forth in the constitution, rather than the particulars laws of any given day, have an objective status).

01-06-02 *Postmodernity* (to N. D. Mermin)

Ever since you wrote me this,

Merminition 91: *I liked the first half (the anti-Final Theory) part of your sermon to Preskill very much. You really could become the darling of the postmodernists if you put your mind to it.*

I’ve been wondering what the heck a postmodernist really is. Despite my occasional mention of Derrida and Baudrillard and the like, I’ve never really read any of their essays. The language barrier was always just too big.

In fact, I had never even read Sokal’s parody. Well anyway, I’ve started the process of remedying that now. Yesterday, I finished the book *The Sokal Hoax: The Sham that Shook the Academy*. It is a collection of maybe 50 or 60 articles and news reports that arose in the aftermath of Sokal’s paper. Here is the entry I put for Sokal’s article in my upcoming Cerro Grande II, the compendium “The Activating Observer: Resource Material for a Paulian–Wheelerish Conception of Nature.”

> A. D. Sokal, “Transgressing the Boundaries: Toward a Transformative Hermeneutics of Quantum Gravity,” Social Text **Spring/Summer 1996**, 217–252 (1996). This parody article contains a wealth of references.

There appear to be some good references there, some of which I have read I *know* that I like!

Anyway, reading the book was an eye-opening experience. Now that I know the perils, it should be interesting to look back 20 years from now and see how successfully or unsuccessfully I managed to navigate the waters.

By the way, I just noticed a mystical coincidence: The big samizdat last year was assigned the number `quant-ph/0105039`; whereas my fire and brimstone “Quantum Mechanics as Quantum Information” from this year was assigned the number `quant-ph/0205039`. Pretty cool.

Did I tell you that I’m in Brisbane now? I’ve been here for a week, and will be here for two more. Kiki and the kids are in Munich until June 18.

01-06-02 *Smaller than the Circle* (to G. Plunk)

The more I chew on what your graphs indicate, the more I like it. “Accepting quantum mechanics is, in part, merely accepting that one’s judgments for an SQMD ought to live within an ellipsoidal volume smaller than X. And X is the volume of the largest sphere that can fit within the simplex.”

The statement will get simpler and simpler as we think about it more, *if it is true*.

The question is, how can we ferret out its truth. I hope you downloaded the thing from Caves's webpage. I think there's one calculation you should be able to do pretty easily for the SICPOVMs. Namely, it shouldn't be hard to calculate the *average* distance (or distance squared) of a pure state (thought of as a probability distribution) from the center of the simplex. Just use the methods from:

- R. Jozsa, D. Robb, and W. K. Wootters, "Lower Bound for Accessible Information in Quantum Mechanics," Phys. Rev. A **49**, 668–677 (1994).

However, maybe it'll even be easier than that. Maybe you can just use the abstract properties that define a SICPOVM to show that the distance of a pure state from the origin is invariant. In fact, thinking about this in my head, it might just be a piece of cake. But I'm probably missing something. You never can tell until you sit down with a piece of paper and a pencil.

02-06-02 *Lamb* (to G. Brassard)

Brassardisme 6: *Is this the Lamb of Lamb shift? [Willis E. Lamb, Jr. and Jagdish Mehra (ed.), The Interpretation of Quantum Mechanics, ISBN 1-58949-005-3] Do you think it should be interesting?*

Yep, that's THE Lamb. Willis Lamb. But he is quite old (over 90) and a bit off his rocker now. I hear that he comes out a bit against quantum teleportation there. I was at a talk of his about 2.5 years ago when he said, quote, "quantum teleportation is beneath contempt," lumping it in the same set of things he was already putting down, like Bohmian mechanics and such. He didn't at all explain why he said that.

Buy it at your own risk.

02-06-02 *Too Silly?* (to M. A. Nielsen)

Nielsenism 2: *Can you send me a title and abstract for your talk this Thursday?*

I just plucked one off my webpage. If it sounds too silly to you, I can write something a little more staid and proper. Your choice.

> **The Oyster and the Quantum**
>
> I say no interpretation of quantum mechanics is worth its salt unless it raises as many technical questions as it answers philosophical ones. In this talk, I hope to convey the essence of a salty, if not downright briny, point of view about quantum theory: The deepest truth of quantum information and computing is that our world is a world wildly sensitive to the touch. When we irritate it in the right way, the result is a pearl. The speculation is that this sensitivity alone gives rise to the whole show, with the quantum calculus portraying the best shot we can take at making predictions in such a world. True to form, I ask more questions than I know how to answer. However, along the way, I give a variant of Gleason's theorem that works even for rational and two-dimensional Hilbert spaces, give another variant of Gleason's theorem that gives rise to the tensor-product rule for combining quantum systems, and finally derive a new form for expressing how quantum states change upon the action of a measurement.

02-06-02 *Spheres, Spheres, Spheres* (to G. Plunk)

Yeah, I did get your Saturday email, but it came after I wrote the note to you. (That's the danger of writing a note before logging in to a server.)

So, I'd say, try again. Today, I'm hoping to work on my project with Petra and Rüdiger. In your expansion of the state ρ in terms of the sicpovm, did you a) take into account that $\mathrm{tr}\,\rho = 1$, and b) take into account that $\mathrm{tr}\,\rho^2 = 1$. I think you mentioned one of them, but I don't know if you mentioned both. Also, did you make sure to tabulate the distance from the center of the simplex. I remember you mentioning something along those lines, but I got a little confused as to whether you thought you could ignore it.

It'll work out; I'm starting to have faith.

Gabe's Preply, "More on Spheres"

> So get this. I woke up this morning to head off to the lab because I'm itching to get back to this sphere problem (more on that later) and I run into Mark the neighbor who reminds me about the party tonite. Funny, I thought the party was tomorrow night. Then I start driving and there isn't any traffic—lucky break I think. But when I find an empty lot at Bell Labs it all finally clicks and I realize that it isn't Friday but Saturday! Anyway, the moral of this story is that Steven van Enk isn't here to help me with my problem so I'm gonna ask you.
>
> I feel it is almost definite that we should see spheres in the simplex for SICPOVMs. I have a simple plan to prove it too. Start with Caves' form: POVM $= \{(1/D)\Pi_\alpha\}$. Where Π_α are projection operators. The symmetric part comes in by requiring the inner product between these Π_α to be all equal to some number, $1/(D+1)$. OK, so now we have this set of D^2 lin. ind. operators which form this operator basis as Caves says. So the idea is that we want to decompose a general pure state, ρ, in terms of this operator basis. So I write
>
> $$\rho = \sum a_i \Pi_i \;,$$
>
> where the a_i all add up to one since ρ is a density matrix.
>
> But to make these rho pure we put an additional restriction on the a_i by demanding $\mathrm{tr}\,\rho^2 = 1$. This gives a little relationship for the a_i. So we take this arbitrary pure state ρ and the POVM and calculate the D^2 probabilities. These give the components of vector which reaches into the simplex to a point on the sphere. Take the magnitude of this probability vector and substitute the relationship for the a_i and I think what *should* happen is that the a_i drop out and we get a quantity that is just dependent on the dimension D. (Now this isn't the radius of the sphere since we didn't project the probability vector into the simplex but this isn't a problem since the component perpendicular to the simplex is constant so just adds in a constant when we calculate the magnitude of the probability vector. It's just as easy to first subtract the point $(1/D^2, 1/D^2, \ldots, 1/D^2)$ which is the center of the sphere and work forward from there.) So with a probability vector with constant magnitude we have proved our sphere (see previous parenthetical note).
>
> So that's it. But I think I goofed somewhere. Because I worked it out a hundred thousand times and it doesn't quite work. I've got residual a_i that won't die. So I tried it for the case that I've already done (rebits) and know for certain it should work … and it doesn't. What's wrong? Something with my construction of ρ? Some additional restriction on the a_i?

I guess I'm gonna head home.

Gabe's Reply, "Soccer Balls in the Probability Simplex"

Did you see Brazil play Turkey? It was a fun match. The world cup games must be at reasonable times in Australia. Here you have to stay up till 4AM or settle for a replay the next day.

We finally found those spheres. Steven showed me something that I'd missed. It becomes embarrassingly easy after that. The SICPOVM gives rise to a sphere in the probability simplex. Its radius squared is:

$$R^2 = \frac{D-1}{D(D+1)}$$

Right. So we'd like the volumes for all ICPOVMs to be ellipsoidal and less than the volume of the sphere. I'll see what can be done in that direction. I have some ideas.

Oh and I'll do out the qubit too, I've been neglecting it in favor of looking for these spheres.

02-06-02 *Postmodern Rags* (to A. W. Harrow)

Here are four representatives of what it is that Carl and Rüdiger and a I are trying to get at:

- "Quantum Mechanics as Quantum Information (and only a little more)"
`http://xxx.lanl.gov/abs/quant-ph/0205039`
- "The Anti-Växjö Interpretation of Quantum Mechanics"
`http://xxx.lanl.gov/abs/quant-ph/0204146`
- "Unknown Quantum States: The Quantum de Finetti Representation"
`http://xxx.lanl.gov/abs/quant-ph/0104088`
- "Quantum Probabilities as Bayesian Probabilities"
`http://xxx.lanl.gov/abs/quant-ph/0106133`

The thing that comes closest to a postmodern rag is my Anti-Växjö paper. (That's the one I thought you might enjoy reading for the literary value.) The top paper, however, "QM as QI," is my present pride and joy.

Below is a passage from my samizdat about Derrida and quantum mechanics. The samizdat, by the way, is `http://xxx.lanl.gov/abs/quant-ph/0105039`

By the time you see this note, I'll be sitting next to you in 161.

From a 09 June 1997 note to G. L. Comer, "Dictionaries and Their Problems"

How are you my friend? It's been so long since I've written you anything of substance, I almost wonder if I can still remember how! Lately, I've once again taken to reading about Bohr's (and the other founding father's) thoughts on the epistemological and ontological lessons of quantum mechanics. I suppose part of my reason for getting back to these things is just a general tiredness of looking at equations; maybe it's a form of procrastination—papers need writing, papers need revising, papers need refereeing, talks need preparing . . . and I'm getting a little tired of it all.

In any case, the exercise is having its own payoff. Maybe I'll share a little with you. Remember I told you that Mermin suggested that Derrida's mumblings shouldn't be written off? I guess I'm starting to think he was right (though I have to admit that I haven't yet read any of Derrida's own writings, only commentaries). It seems that the focal point of Derrida's thought centers around none other than your "problem of the dictionary"! Let me try to give you something of a flavor of how these things might be connected to the quantum. My starting point has been an excellent essay by John Honner titled, "Description and Deconstruction: Niels Bohr and Modern Philosophy" (found in *Niels Bohr and Contemporary Philosophy*, edited by Jan Faye and Henry J. Folse (Kluwer, Dordrecht, 1994), pp. 141–151). I hope you enjoy the quotes:

> Derrida undermines the notion that words and signs can capture present experience: our tracing of experience always discloses a supplement, a 'difference'. This attack is equivalent to a subversion of the notion of strong objectivity and correspondence theories of truth. For the deconstructionist, the foundations for knowledge are never securely laid: words do not correspond exactly to the world. "Presence" can never present itself to a present consciousness, and hence experience is always and already constituted as a text. [I use 'text' loosely here, of course, meaning any collection of signs—discourse, mathematical equations, pictures, poems, prose, drama, hand-waving—used to trace and express insight and experience.] A text is a collection of signs and any sign presumes a presence which it represents, but the sign is not the same as that which it represents. In signifying our awareness of a presence a move is made from the presence to sign. By the word 'presence' Derrida is indicating something like substance, essence, or object, but he rejects such 'totalising' categories as these, for such terms assume more about the presence than perhaps we are entitled to assume. The term may 'trace' the presence, but a remainder is always left over.
>
> Speaking and writing are, according to Derrida, 'linear' activities which lock us into space and time. "The great rationalisms of the seventeenth century", as Derrida describes them, fall into the trap of objectivity and neglect the timelessness of self-presence. The linearity of the words limits the conditions for the use of language: "If words and concepts receive meaning only in sequences of differences, one can justify one's language, and one's choice of terms, only within a topic [an orientation in space] and an historical strategy." Here we have a curious serendipity. Our usage of words is tied, arguably, to the reidentifiability of particular objects, which itself implies those bastions of classical physics, the conservation of position and momentum and an absolute space-time framework. And it was precisely these bastions that Bohr attacked. As I have argued elsewhere, Bohr's fundamental arguments entail a provocative hint at a link between the given character of ordinary language and a deterministic-mechanistic view of the workings of nature. For Bohr, classical physics is the inexorable result of the use of language based on the identification of experienced material particulars; or, vice versa, the use of language based on identification of experienced particulars will ultimately lead to a sense of the persisting presence and movement of material object in space and time, and hence to principles of conservation, causal change, and continuous space-time frameworks.

03-06-02 *I Think She'll Know, 2* (to N. D. Mermin)

Merminition 92: *Kurt Gottfried got me back to thinking about the old "derivations of probability" dating back to Hartle in the 1960's and going through the Sidney Coleman application to many worlds. Turns out Jeffrey Goldstone did something on it and there's a nice paper by Gutmann (*`quant-ph/9506016`*). To remind you, in the modern version one's only probabilistic assumption is that if* $\mathrm{tr}(\rho E) = 1$ *then* E *must happen. Combining that with some highbrow analysis of the nonseparable hilbert space formed by infinitely many copies of a system with itself, one derives all the usual probabilistic rules.*

As I remember you were quite scornful of this approach, saying that they were sneaking probability into the story without admitting it. Was this because as a good Bayesian you regard probability 1 as no different from any other probability — merely the current best guess. (Our conversation about Coleman took place before we had our arguments about the difference between probability 1 and "has to happen".) Or did you have some other leakage of probability into the argument in mind?

Yeah, I've still got loads of issues with that approach. But maybe just let me mention the simplest one again: $\mathrm{tr}(\rho E) = 1$ certainly should not be taken to imply "must happen" in an infinite setting. Take the converse. Consider an infinite sequence of coin tosses. Each individual outcome string has probability strictly zero, yet one of them does happen.

Shifting the problem to sets of measure 1 doesn't help either. For lots of inequivalent sets have measure 1. What principle of nature sets one out as important?

It's all ad hockery that these guys are up to . . . shined up with some high-powered mathematics so that it looks important.

04-06-02 *Random Questions* (to G. Plunk)

At least we can probably bank on this much (subject to proof). The volume of the maximal quantum state space is bounded above by the volume of the sphere with radius given by the number you sent me earlier. Here's a question. How does that volume compare to the volume of the simplex? It looks to me like it becomes a smaller fraction of the simplex volume, but I'm not sure.

Gabe's Reply, "Random Answers"

> I think we have easily that non-pure states will not touch the sphere. See the attached files (the `.txt` file is TEX output from Mathematica).[31]
> — — — — — — —
>
> The SICPOVM is defined using projection operators Π_i which satisfy
>
> $$\frac{1}{D}\sum_i \Pi_i = I$$
>
> and
>
> $$\mathrm{tr}(\Pi_i \Pi_j) = \frac{1}{D+1}\ .$$

[31] A key thing to note here is that Gabe presents an expression for ρ in terms of the SIC outcome probabilities. Somehow I missed this, perhaps not being able to open the files he had sent me at the time. Thus, the surprise in my 18-06-02 note "SIC POVMs" to C. M. Caves; apparently I still did not understand Gabe in the previous day's discussion. Just discovering this now, sadly I have never before given Gabe credit for this result.

The SICPOVM is thus $\{E_i\}$ with $E_i = \frac{1}{D}\Pi_i$.

Write an arbitrary state ρ as in terms of the operator basis $\{\Pi_i\}$:

$$\rho = \sum_i a_i \Pi_i \quad \text{with} \quad \operatorname{tr}\rho = 1 \implies \sum_i a_i = 1\ .$$

The probability of outcome α is

$$\begin{aligned} p(\alpha) &= \operatorname{tr}\rho E_\alpha \sum_i a_i \\ &= \frac{1}{D}\left(\frac{1}{D+1}\sum_i a_i + \frac{D}{D+1}a_\alpha\right) = \frac{1}{D}\left(\frac{1}{D+1} + \frac{D}{D+1}a_\alpha\right)\ . \end{aligned}$$

We can find the center of the sphere by calculating the probabilities with $\rho = \frac{I}{D}$. We get that all probabilities are $\frac{1}{D^2}$. Subtract this from $p(\alpha)$ to get the radius vector:

$$r(\alpha) = \frac{1}{D}\left(\frac{D}{D+1}a_\alpha - \frac{1}{D(D+1)}\right)$$

$$r^2(\alpha) = \frac{1}{D^2}\left(\frac{1}{D^2(D+1)^2} - \frac{2a_\alpha}{(D+1)^2} + a_\alpha^2\frac{D^2}{(D+1)^2}\right)\ .$$

Now sum over α to get the radius squared

$$R^2 = \sum_\alpha r^2(\alpha) = \frac{1}{D^2}\left(\frac{D^2}{(D+1)^2}\sum_\alpha a_\alpha^2 - \frac{1}{(D+1)^2}\right)\ .$$

Now we can learn about the quantity $\sum_\alpha a_\alpha^2$ by taking the trace of ρ^2:

$$\operatorname{tr}\rho^2 = \frac{1}{D+1}\sum_\alpha a_\alpha^2 + \frac{1}{D+1}\ .$$

Define $F = \sum_\alpha a_\alpha^2$ and note that $\operatorname{tr}\rho^2 \le 1$. And we get $F \le 1$, with equality if and only if ρ is a pure state. Plugging into R^2 ...

$$R^2 = \frac{1}{D^2}\left(\frac{D^2}{(D+1)^2}F - \frac{1}{(D+1)^2}\right)\ .$$

For pure states

$$R^2 = \frac{D-1}{D^2(D+1)}\ .$$

Otherwise it's less.

04-06-02 *Morning Headaches* (to G. Plunk)

I've got a huge headache this morning ... but you are my aspirin.

Plunkism 1: *It seems a reasonable hope that we could get that the surface created by the pure states is closed. Then we would have that the entire sphere is generated by the pure states (right?).*

The more I think about it, the less likely I think a miracle will happen here. The problem is that normalized pure states have a dimensionality of $D-1$, whereas the full set of states has dimensionality D^2. ... Though in saying that I'm a little comparing apples and oranges. (Because the pure states don't form a subspace in the space of operators.) So, it's worth further thought, but I fear ...

Maybe a better way to say it is that to parameterize the set of pure states you only need $2D-2$ real parameters (i.e., D complex numbers minus normalization), whereas to parameterize the full set of states you need D^2-1. When $D=2$, that means you get 2 and 3, respectively. So that means one can think of one set of parameters living in the sphere and the other on its surface. But, when $D>2$ that clean connection goes away.

Plunkism 2: *I found the n-Sphere paper. You said you'd like a copy–would you like me to mail it? Will Lucent do this for me?*

No, I just meant to make me a copy while you were making yours and hold onto it.

04-06-02 *Big File Coming* (to K. W. Ford)

Thanks for the encouraging email. In the next note, I'll send you the compendium as it stands. I'll send it both as a LaTeX file (REVTeX actually) and as a PostScript file. I'll attach both to the same email. If you have any trouble opening or reading these files or getting them to compile, let me know and I'll try to find a solution.

As you'll be able to tell, I'm quite in mid-project with this. A lot of material still needs to be added (essentially all the entries marked with a ¶), but also the introduction still has a long ways to go. In particular, with regard to you, you'll notice very few quotations in the Wheeler area. But that is only because I haven't yet gotten them out of the papers and into my scanner. Most of those papers I read more than 10 years ago, long before I started this project. Anyway, I'll be fixing that shortly, i.e., as soon as I get back to New Jersey.

Fordism 1: *Or I could send you a copy of his bibliography (59 pages) for you to eyeball.*

That would be great![32] I appreciate the help. If you can send it electronically, just send it now. If, however, you only have it on paper, please send it to my Bell Labs address below. Beyond that, maybe one of the best ways you could help me would be in helping me obtain copies of some of the papers I haven't been able to find. For instance,

> J. A. Wheeler, "Delayed-Choice Experiments and the Bohr-Einstein Dialogue," in *American Philosophical Society and the Royal Society: Papers Read at a Meeting, June 5, 1980*, (American Philosophical Society, Philadelphia, 1980), pp. 9–40.

seems to be a crucial paper. And there are some ones beyond that.

Fordism 2: *I really have no good ideas about a place to publish it. Maybe it will have to end up on the Web with references to it published in journals and newsletters.*

[32] NOTE: I would have worked to include the bibliography Ken sent me, but using it as a seed, Terry M. Christensen built a significantly more thorough bibliography for his PhD thesis, *John Archibald Wheeler: A Study of Mentoring in Modern Physics*. The bibliography section of the thesis has been conveniently posted by Baruch Garcia here: `http://jawarchive.files.wordpress.com/2012/03/bibliography.pdf`.

Yeah, that's certainly an option. I guess I was half hoping there might be some room in the Wheelerfest volume you're associated with, and if so, that'd give me the incentive to get this finished right away. But, in truth, the paper is already pretty large, and I expect it to maybe double in size by the time I'm finished. So, it's probably way too large for anything like that.

Fordism 3: *I'm sorry that John Wheeler himself has slowed down so much that he is probably no longer able to absorb your work. There was a time when it would have meant a lot to him and when he no doubt would have loved to enter into a colloquy with you.*

How is John's health? Both physical and mental? I haven't talked to him since 1994. I had been thinking about visiting him this summer if was still going in to his office in Princeton. I read an article in the *New York Times* that said he was still going in a couple of times a week. And I thought, if his health is that good, then it might be good to establish contact now that I am in the neighborhood.

OK, the files will come in the next mail, after I go have a cup of coffee.

05-06-02 *Touching the Bound* (to G. Plunk)

I guess the simplest and main question on my mind at the moment is: How does volume of the "state sphere" (i.e., the sphere within the simplex that *surrounds* the full set of quantum states) scale as a fraction of the volume of the full simplex? So, calculate the volume of the sphere in arbitrary dimension, and calculate the volume of the simplex, and take their ratio.

I suspect the volume tends to zero, but it'd be nice to get a formal expression of that.

This would give a formal expression to the idea that, as the size of a system grows, one accepts in quantum mechanics that one can know less and less about it.

06-06-02 *Good News and Not-So-Good News* (to G. Plunk)

Plunkism 3: *In higher dimensions my results say that the n-sphere's volume divided by the n-simplex's volume becomes unbounded(!). This means (a) the n-sphere of required radius does not fit inside the n-simplex and consequently (b) the states trace out only part of the sphere–at most the part that intersects the n-simplex.*

Yeah, that means something's got to be wrong. The sphere, by definition, has to be contained within the (regular) simplex. So, I guess there are two options. Either your original calculation of the radius is wrong (make sure you calculate it from the center of the simplex). Or the formulas you've found for the volumes are off or misapplied.

I presented this picture of quantum mechanics in a talk yesterday at U. Queensland. It went over well, especially with some of the postdocs. I told them also about your explorations. Next week I do the same at Griffiths University.

Main question: Are you having fun with this problem?

Gabe's Preply

> Some good news. I was just thinking a little about the parametrization of pure states in terms of the SICPOVM elements. In the analysis I sent you I decompose using D^2 coefficients. The conditions on the coefficients are that they sum to 1 and the squares sum to 1. In "coefficient space" this is the intersection of a plane and a sphere which

gives a sphere of dimension $D^2 - 1$ which requires $D^2 - 2$ parameters to describe. This is exactly the dimensionality we need for describing the sphere in the simplex. Pure states have dimensionality $D^2 - 2$ and the full set of states has dimensionality $D^2 - 1$.[33] It's even simpler. Creating the "radius" vector in the simplex amounts to a shift and rescaling of the "coefficient vector" (look at $r(\alpha)$ in the proof I sent). The coefficient vectors form a sphere so the radius vectors do also. It looks like we have the *complete* sphere after all. A similar analysis fills the interior of the sphere using the mixed states.

Finding the volume ratio is rough going. For the qubit, my results for the ratio are exactly as you'd expect for a sphere inscribed in a tetrahedron. In higher dimensions my results say that the n-sphere's volume divided by the n-simplex's volume becomes unbounded(!). This means (a) the n-sphere of required radius does not fit inside the n-simplex and consequently (b) the states trace out only part of the sphere—at most the part that intersects the n-simplex. That can't be right (especially given what I said above). But I'm using textbook formulae for the volume of regular n-simplices and n-spheres. I'll attach a Mathematica file of what I've done.

07-06-02 *Spheres and Simplexes on a Saturday Morning* (to G. Plunk)

Plunkism 4: *I'm dumb. I forgot completely about positivity. We don't have the whole sphere, you were right all along. At most we have the intersection of the sphere with the simplex. Maybe that's exactly what we have. Is it obvious? Does the fact that the probabilities are contained in the simplex guarantee that a given ρ is a valid positive density matrix?*

You're not dumb. I know you're smarter than me. But goddamit, start thinking about the sphere from the center of the simplex! That is the one that is of interest. Not the one centered on the origin of the coordinate system. That sphere—the one from the center of the simplex—is automatically contained *within* the simplex.[34]

In other words, the set of valid quantum states will be a subset of that sphere. A proper subset. Nevertheless, even though the sphere's volume will only be an upper bound on the volume of the true set of quantum states, we can still glean some interesting information by studying the sphere. If the ratio of sphere's volume to the simplex's volume goes to zero as the dimension grows—as I suspect—then it will follow that the more interesting ratio (namely that of the volume of the valid quantum states to the simplex) will go to zero too. It'd just be a nice fact to know for sure.

Plunkism 5: *My principle hope is to come out of this with a deeper understanding of quantum mechanics.*

I hope so too. Have you given my paper `quant-ph/0205039` a shot? If you have any questions, I'd be glad to answer. Or why don't you pick up the book *Pragmatism* by William James or the book *Philosophy and Social Hope* by Richard Rorty off my desk? I think, with respect to quantum mechanics, they contain a lot more physics than you might believe.

11-06-02 *Who Is asdf? Who Is jkl?* (to G. Plunk)

Plunkism 6: *So what I'm trying to say is that I've been doing this … and the sphere is still too big. Here's how I resolve the discrepancy:*

---

[33] This sentence and the one previous to it are incorrect, as the pure states have dimensionality $2D - 2$; however I preserve it for historical accuracy.

[34] Clearly, I was the "dumb one" because this is not true except in $D = 2$.

Hmm. This is intriguing. But I have difficulty seeing how it could happen. I guess strictly speaking, what you have really proved is that all the pure states are equidistant from the center of the simplex. Period. And indeed, there is no requirement that the sphere those points sit on need be strictly contained within the simplex. However, I find it difficult to see how that could happen. It seems to me that that would require that the pure states form a set of disconnected sets (one for each element of the SICPOVM). But we know the pure states form a connected set.

I'll be glad when I'm back to there, so I can have a chance to see these things more directly. I get back very late Sunday night. I'll probably spend the night with my friend Jeff and then come back to the house Monday morning. Would you mind hanging out there until then, so that I can get a ride to the repair shop to pick up my mini-van etc.?

Gabe's Preply, "asdf likes jkl;"

> [CAF said:] "goddamit, start thinking about the sphere from the center of the simplex!"

So what I'm trying to say is that I've been doing this ... and the sphere is still too big. Here's how I resolve the discrepancy:

By taking linear combinations of the POVM elements (the construction of ρ in the proof I sent) and requiring trace and trace of the square to be one, we don't necessarily get valid states–they aren't necessarily positive operators though they are hermitian and normalized by construction. I've been banking on these things being actual states. It turns out that some of them give probabilities outside the simplex (i.e. negative probabilities). So those ones definitely can't be states.

The question (which I tried to pose in the last email) is if we take the points on the sphere that are inside of the simplex can we say that all of them correspond to actual, valid states? Most of them certainly. If *all*, then I can attempt calculate the volume of the intersection of the sphere and the simplex and get your bound ....

This is a strange result–the sphere-simplex intersection as the quantal probability space. But I've been so careful checking the math that I think it's right. Just in case you don't believe me (which is understandable given my vacillations) I went ahead and calculated the radius of the largest sphere which could fit in the simplex (the inscribed sphere). Its volume divided by the simplex volume goes to zero as expected.

Gabe's Reply, "Spheres with Holes"

> [CAF said:] "It seems to me that that would require that the pure states form a set of disconnected sets (one for each element of the SICPOVM). But we know the pure states form a connected set.

The picture I have in my head is a connected region with holes. The vertices and edges of the simplex always are further from the center of the simplex than the sphere's radius. Here the sphere is contained in the simplex. It is close to the center of the faces of the simplex (set one probability to zero to get a face) that the sphere emerges from the simplex ($D > 2$). D^2 faces give D^2 holes. That the pure states are a connected set follows from this picture I think.

11-06-02 *Radical Probabilism* (to A. W. Harrow)

http://www.princeton.edu/∼bayesway/

11-06-02 *Act II – Griffith University* (to A. W. Harrow)

1. Tomorrow at 11 seems fine for a seminar, although I am yet to get a room booked. Could you send me a title and abstract, please?

2. Another good question I meant to ask, is how would you translate the following into subjective language? In quantum control, optimal feedback control is based upon using one's knowledge of the system (i.e. its quantum state). However due to practical processing power limitations (shades of the quantum computer problem), one often cannot compute the true quantum state conditioned on the measurement results quickly enough. Instead, one computes an approximation to this, a best-estimate given the limited resources available, and uses that as a basis for feedback control. By simulation, one can determine on average how well this does compared to feedback based on the true state.

3. On the "let's call the whole thing off" theme, if you used some Greek letter other than ρ, it could work really well. For example, "you say beeta, I say bayta, you say eeta and I say ayta ..." Or for pure states it could work: "you say psigh, I say psee, you say phigh, I say phee ...".

12-06-02 *Receipt* (to M. J. Donald)

I got your long note; thanks. I'm going to mull over it for a while before replying. But I will reply.

Donaldism 3: *I also haven't commented much on the points I agree with in the paper, although there are a few of these!*

It would be nice to see what these are. In ways, I'm more interested in where we agree than in where we disagree. A good discussion needs some solid ground somewhere.

Beyond that, it would please me to no end to learn that you might have found a thought or two that you could use in the thing. But if you didn't, you didn't. It's a horrible feeling to think I might be writing nothing for nothing.

Each day, I tell my daughters that they can change the world. I tell them that they can change it to the core. But I never tell them that they can believe anything they want. There is a difference. And you don't see it.

The summary at the end of your note troubles me to no end.

Donaldism 4: *Your know-nothing ism, like de Finetti's irrationalism (Gillies, "Philosophical Theories of Probability", page 86), have the dangers of Bohr's writings on which I would agree with Beller (Physics Today, September 1998, pages 29–34). In particular, by leaving far too much in vagueness, incoherence, and pious hope, you give the religously-minded the official endorsement of the physics establishment that they may believe anything they want, instead of, by example, instructing them that they can believe anything they want as long as it is rational, coherent, tentative, revisable, and compatible with the evidence (and therefore contrary to naive expectations, because if quantum theory, or indeed science in general, tells us anything it is that the world is not how we would have imagined it before we investigated); and they accept that they may be completely wrong.*

I will certainly return.

12-06-02 *Bell Ineqs as Limitations on State Distinguishability* (to A. Peres)

I'm in Australia at the moment, but it won't be too long before I'm able to go home! I'm getting quite homesick. Kiki and the girls are in Munich; they arrive in New Jersey one day after me.

Asherism 24: *I spent two days in Geneva. The first was mostly business, related to Helle's final PhD exam (a public lecture) and the second was relaxing and touring the city. My preceding visit was in 1979, for three weeks, when I was the guest of John Bell.*

Helle's work was on Bell ineqs and cryptography, and relations between the two (you probably remember Gisin's insistence on this point). In an informal discussion, Helle asked me whether Bell ineqs could be reformulated in terms of limitations on state distinguishability. My answer was "QM as QI: there is no God but Chris Fuchs, and Danny Terno is His prophet." Can you be more specific?

I wish I could say more about that! But unfortunately my mind runs dry right now.

16-06-02 *Weddings and Connecting Flights* (to A. Peres)

Thanks for the pleasant note keeping me up-to-date on everyone. We are indeed like one big family. Sam actually invited me to his wedding! But Israel is a bit out of my reach at the moment.

Actually, I'm not home yet. At the moment I am in the American Airlines Lounge in Los Angeles. Still six more hours of flight to go. Kiki and the girls return to New Jersey from Munich on the 18th.

An interesting coincidence happened to me on the flight from Brisbane to Los Angeles. It stopped for an hour in Auckland, New Zealand. To my surprise, one of the passengers who entered there was Andrew Doherty, one of Hideo Mabuchi's postdocs. Moreover, his seat was directly behind mine. He had been in New Zealand on vacation, visiting his family, and was now going back to Caltech. We had some pleasant conversations about the latest results in entanglement.

Take care of yourself.

17-06-02 *The Dreams Stuff Is Made Of* (to T. Rudolph)

Rudolphism 6: *This would be a good title for one of your papers: "Quantum mechanics: The dreams stuff is made of".*

I like the title. Now we just have to figure out a content for it.

18-06-02 *SIC POVMs* (to C. M. Caves)

That result is rather neat. Thanks for sending it. Funny coincidence: at the end of the day yesterday, Gabe and I parted after asking whether there was a simple way to express a quantum state in terms of the SICPOVM probabilities.[35] But I didn't work on the problem after getting home. Instead, I woke up this morning and find that you've sent me the answer! Maybe I'll try the experiment again tonight ...

Carl's Preply

Here's a nice property of SIC POVMs. Let

$$p_\alpha = \mathrm{tr}(\rho E_\alpha)$$

be the measurement probabilities for a SIC POVM

$$E_\alpha = \Pi_\alpha / D\ .$$

Then

$$\rho = \sum_\alpha \left((D+1)p_\alpha - \frac{1}{D} \right) \Pi_\alpha$$

The complete story is in the attached TEX file updating my little document on SIC POVMs.

18-06-02 *SIC POVMs* (to G. Plunk)

Have a look at the document below that I just got from Caves. [See 18-06-02 note "SIC POVMs" to C. M. Caves.][36] The result is rather neat and relates to our conversation at the end of the day yesterday. I'll attach a PS file of the account in case you can't TEX yet. It might be a good exercise to see if you can find a more elementary derivation of the fact.

[35] See 04-06-02 note "Random Questions" to G. Plunk. Gabe had actually already solved this problem, and I was somehow not aware of it.

[36] See 04-06-02 note "Random Questions" to G. Plunk. Gabe had actually already solved this problem, and I was somehow not aware of it.

18-06-02 *Horrible!* (to T. Rudolph)

As I said, horrible (title, that is):

> INSTITUTE FOR QUANTUM INFORMATION SEMINAR
>
> Tuesday, June 18: IQI Seminar
> Quantum steering
> Frank Verstraete, KU Leuven, Belgium
> 3:00 p.m., 74 Jorgensen
>

> Campus map: `http://www.caltech.edu/map/` (Jorgensen is bldg. #80.)

19-06-02 *Classical Essence* (to E. Chisolm)

Thanks for your letter. You ask, "What is the essence of classical physics?" I agree that this is something worth thinking about. I don't have an answer.

Maybe the closest thing I can give you at the moment is to send you to a few passages in my samizdat, `quant-ph/0105039`. First have a look at the passage titled "Genesis and the Quantum" on pages 85–86, and then have a look at the note "The Oyster and the Quantum" on pages 100–103. Finally, have a look at the note "Reality and the Symbol" on pages 233–234.

They will kind of lead you down the path of where I think classical mechanics fits into the scheme of things. As I say, I agree with you that it is worthwhile to try to characterize the essence of classical physics. However, in possible opposition to you, I think trying to do that in isolation, independently of the quantum problem, won't lead to the greatest insight. The difficulty as I see it is that quantum mechanics strikes me much more as a radical departure from classical physics than just a shift in "calculational recipes." For instance, take Newtonian gravity. I would argue that finding its essence gives one little insight into the essence of general relativity ... even though Newton's gravity is one of the limiting cases of general relativity. The underlying ontologies of the two theories are just so very different. Similarly I am thinking of classical versus quantum physics.

Eric's Preply

> I recently read your e-print "Quantum Mechanics as Quantum Information (and only a little more)", and I like your suggestion that our understanding of QM right now is in a state similar to that of physicists trying to understand length contraction et al. before special relativity. I also like your idea (hope?) that there are a few simple physical statements from which the formalism of QM emerges as naturally as special relativity does from Einstein's two postulates, and I want to ask you a few questions related to that idea.
>
> Let me describe how I think about the overall structure of theories in physics. I see classical mechanics and quantum mechanics, understood in their broadest senses to include the corresponding field theories, as basically recipe books: If you want to make a theory of the electromagnetic field, or projectile motion over the surface of the earth, or of the gravitational field, then you come up with a Lagrangian or Hamiltonian and

then either classical or quantum mechanics provides you with a basic set of rules to follow (use the Euler-Lagrange equations in one case or Schrödinger's equation in the other, states are in either a phase space or a Hilbert space, etc.) to get a fully predictive theory. Each one is an outline, so to speak, that tells you how to use a Lagrangian or Hamiltonian to describe the behavior of a system. On the other hand, another question most theories must answer is how they incorporate the principle of relativity, and this can be done in two ways: Galilean invariance or Lorentz invariance. Thus, for example, we can formulate a theory of free body motion classically or quantum mechanically and with Galilei or special relativity. (This is a huge oversimplification, I know; many theories aren't strictly classical or quantum, not every theory has a Lagrangian, for some theories the principle of relativity isn't included at all, etc., but this is a good scheme to think about.)

In this scheme, quantum mechanics and special relativity are not naturally parallel; instead, special relativity is parallel to Galilean relativity and quantum mechanics to classical mechanics. That leads me to ask this question: We know the simple, clear physical statements that lead to special relativity, and we know the same for Galilean relativity (I believe replacing Einstein's postulate about the speed of light with something like "velocities add" would do it); how about classical mechanics? Now an answer to this question would be interesting; surely it would help us understand what to look for as the "essence" of quantum mechanics if we could clearly state the essence of its classical partner. I honestly have no idea what simple physical ideas could serve as the foundation of classical mechanics (broadly understood, including theories like classical electromagnetism and general relativity). Do you?

19-06-02 *Experience* (to W. K. Wootters)

Woottersism 12: *I'm writing just to let you know that I have not ignored or forgotten the excellent questions you've asked. I've been busy with other things, and I still need to do some serious thinking about your questions (i.e., about my earlier statements). I promise a response before long!*

That's no problem, but certainly I'd like to hear your answers. In fact, I'm just back from Australia and Kiki and the kids are back from a month in Munich, so I'll probably be taking a couple of days off from the intellectual life.

Nevertheless, I've picked up my first Whitehead essays to read. Maybe I'll have a chance of better understanding your terminology this way. They're from a book titled *Philosophers of Process: Bergson, Peirce, James, ..., Dewey, ..., Whitehead.* Given my fascination with some of the ideas of James and Dewey, I think that indicates I may have some of the groundwork already within me. We'll see.

20-06-02 *Superadditivity* (to S. L. Braunstein)

Kiki and I got back from almost a month away from home yesterday (in Munich and Brisbane, respectively), and we found the invitation to your wedding in our mail pile. Many congratulations to you and Netta! Kiki and I wish you a long and happy marriage. I wrote this to another friend some time ago—in this hurry to write you something tonight, let me just repeat the words: "Marriage is about stability, happiness, and the kind of leisure that leads to true productivity (which only two people propped against each other can ever hope to negotiate)."

It's hard to imagine you being more productive, Sam, but I suspect we'll see a kind of brilliance from you that we've never seen before.

20-06-02 *Physics without Math* (to U. Mohrhoff)

You may not believe it, but I have been struggling on and off for several months to make some comments on your papers. The writing in each of them is locally beautiful, and it is for that reason to no small extent that I have kept coming back to give them another shot. But tonight, with too many burdens upon me, I have decided I must admit defeat and try to shake this feeling of guilt I have placed upon myself.

Life is short, and one has to make decisions on how to spend it. It is a gamble, it is always a gamble, but if one wants to do something of lasting value, one just has to proceed with dogged determination. I can see in your writings that you are doing that. But you have got to understand, I am doing it too. I may be damned for taking the route I am taking, but I feel I will only be able to know that with hindsight. My game is one of consistency: I want to push the subjective interpretation of the quantum state harder than anyone has ever pushed it before. I do that because I have a gut feeling that this will rattle something loose from quantum mechanics. Something that is wonderful and new. That little nugget—whatever it turns out to be—strikes me as something our community can hope to attain in the near future, and something that may even be revolutionary in a Kuhnian sense.

From your view, this strategy certainly looks like a stupid move. I understand that. I guess what I am writing is that I am willing to live with what you must be thinking of me. I really am sorry that I have not been able to say something sensible and useful about your papers.

I don't quite understand why I have had such difficulty reading your papers. They draw me in and then they push me back out. This may be the most flippant thing I can say, and may reveal a certain artlessness in me, but over and over I find myself asking, where's the meat? Where's the mathematics? Where's something explicit I can point to and either find a logical flaw in or—with greater desire—find some logical satisfaction. In your 14 papers (289 pages) on `quant-ph`, I count only 58 displayed equations. I lose orientation very quickly with a nonmathematical structure like that. Beyond this, in all honesty, for the same reason I find myself losing faith in your program. The gap between the size of your claims and the number of your equations is enormous. My intuition is that that is a symptom of a deeper trouble.

A couple of times, for instance, when you spoke of deriving the quantum probability rule, you wrote, "To find the quantum counterpart to $\mathcal{P}$, all we have to do is make room for nontrivial probabilities, and the obvious way to do this is to replace the subsets of a phase space by the subspaces of a vector space, or by the corresponding projectors." Well, it is not obvious to me; none of these things are obvious to me. (I struggle everyday to see where the vector-space structure of quantum mechanics might come from.) But I could give countless instances beyond that. One of my greatest complaints about Bohr is how he spoke over and over of how the quantum formalism is forced upon us by complementarity. But I never could see that he gave the slightest shred of evidence for that. Instead, I only saw him attempt to demonstrate that his point of view was consistent with the structure of quantum mechanics already given in its abstract axioms. I am sorry to say, but I fear the same for you.

You may indeed have a novel view that allows you to fulfill all your Vedantic wishes, just as I may have a view that will allow me to fulfill all my Jamesian (pluralistic) ones, but I would say we both need more. We both need to know what is it that allows us to have no other view. That is, to be convincing, we need a hard-core derivation of the quantum formalism. I see myself and the community I am trying to stir up as moving in that direction. On that count, however, your papers leave me cold, and I am making the judgment to leave the issue now.

I hope that explains somewhat my obstinacy. I think it probable that I have hurt your feelings, and I apologize for that; I don't wish any harm upon you. It really only boils down to, as I said, that life is short, and we all have to make decisions.

21-06-02 *Semi-Classical Mail* (to K. W. Ford)

I just mailed off my "Activating Observer" document to you. Hopefully it'll reach you in a couple or few days. You called the method "classic mail", but I hope the document is so thoroughly infused with the quantum it would be hard to think of the package as anything but semi-classical ... at the very least!

21-06-02 *Holevo Paper, Etc.* (to G. Plunk)

Well, I guess I don't have the Holevo paper any more after all. Here it is, in case you want to dig it up and make copies for us:

- A. S. Holevo, "Statistical decision theory for quantum systems," *Journal of Multivariate Analysis*, vol. 3, pp. 337–394, 1973.

It contains the most general result.

However, I also remembered a derivation of the result for the more limited case of rank-1 POVMs, as I was tossing and turning in bed. The paper below lays it out essentially, and is a classic in any case. Would you mind copying that for us:

- L. P. Hughston, R. Jozsa, and W. K. Wootters, "A complete classification of quantum ensembles having a given density matrix," *Physics Letters A*, vol. 183, pp. 14–18, 1993.

To get the result we need, we just consider the case where the density operator is proportional to the identity.

23-06-02 *Voice Recognition* (to C. M. Caves & R. Schack)

At the moment, I'm taking a few minutes from a frustrating morning to do a little web-surfing for fun. Reading about new voice-recognition technologies, I ran across the following. Apropos to our present situation, wouldn't you say?

> To understand the problem of speech recognition, one must merely compare written and spoken conversations. In a spoken conversation, we have hundreds of inflections that allow us to "read" further meaning into the words that are actually spoken. Those inflections are instructed by the intelligences at both ends of the conversation, by culture, by environment, by timing, by context, and a myriad other factors. When we write, it often takes many more words to make sure that the meaning is clear. Many times, a two or three sentence conversation can clear up a month's correspondence over some difficult point.

24-06-02 *Points* (to H. M. Wiseman)

You see, I'm catching up on my email finally. Thanks for the Nash pointer and the Aussie WWII statistics.

Wisemanism 11: *4. re. the processing power limitations on quantum states. You could have a look at my paper "Bayesian feedback versus Markovian feedback in a two-level atom" (Phys Rev A 2002, or* `quant-ph`*) to see what language I actually did use (I can't remember). But the point is that the state an experimenter computes on the fly to do feedback control is not necessarily less pure than the "true" state which the experimenter does not know. But the experimenter still wants to know how much his state is likely to be "in error" from the "true state". I guess so the experimenter armed with this knowledge would have a better state estimate, by accounting for the error by making the state more mixed. But in any case, how can you call the "true state" a state of belief or whatever if there is no one who believes it? It is what the experimenter's state of knowledge should be, given what they know. That is, it is their state of knowledge, even if they are too dumb to know it. This is another reason you may use to avoid the phrase "state of knowledge", but the challenge is still how to describe this "true state" in that case, without circumlocuting intolerably.*

What you are asking for is the experimenter to compare his pragmatic gambling commitments under the real world constraints he is living under at a given moment, to the beliefs or commitments he would possess under more ideal conditions (for example, if he had limitless computing power). Just as there is no "true" quantum state, independent of the agent—i.e., for two agents, there might be two quantum states—the same may be the case for a single agent. I like your examples because they help draw that out. I can contemplate how I should bet believing what I believe now and knowing that my feeble mind cannot analyze the full implications of those beliefs, or I can contemplate how I should bet believing what I believe now and imagining a supercomputer that draws out the proper conclusions from those beliefs.

In all cases, whatever the final products of all calculations and all approximations one writes down, those are one's gambling commitments. And *with respect to* that situation, that is one's "quantum state" for a system.

24-06-02 *The World is Under Construction* (to H. M. Wiseman)

Wisemanism 12: *Do you believe that events in the world really are random? Or do you believe they only appear to be random? In the first case, doesn't that mean that you have to believe in objective probabilities? ...*

Or are you saying that the real world is unanalysable, unthinkable even? Everything we say should be couched in terms of gambling commitments. First, that seems to be a cop-out, giving up on any understanding of the Universe. Second, it can't explain anything in the Darwinian way you mentioned, except Dutch-book consistency. It can't explain why it is "bad" to hold a gambling commitment based on the idea that all world cup soccer balls contain bombs that have a 50% chance to blow up every time a goal is scored ... You cannot say anything about animals that would have been likely to have gone extinct because of poor (but consistent) gambling commitments, because that is a statement using the concept of objective probabilities. You cannot <u>explain</u> *anything that is not strictly deterministic without using objective probabilities, it seems to me.*

I trust you understand my motives. I wouldn't bother discussing this with you if I didn't think your ideas were potentially revelational. What does not kill you makes you stronger.

For a couple of days I have been thinking about how to reply to the questions in your 6/14/02 email 'reality', but this morning I found myself significantly revising the response I had started to build. In particular, I decided to hardly reply to your questions at all! This may be a little bit annoying to you, but I think it will benefit our longer term discussion.

Of the three options you gave me for answering your questions (I only quoted the last one of the three above), I suppose if I were forced to choose one, I would align myself with the one you called a "cop-out." However, from my point of view, the language you use builds about the ugliest picture it can for where this effort is going. Indeed, you miss the very point, the very beauty, of the "cop-out." So, what I'd like to do is set that right—right here and right now—before we go much further. As advertised, in that way, I will not reply straightforwardly to your questions.

You see, the very starting point for most of my latest thoughts—the thing I think quantum mechanics gives us the deepest and most thorough hint of—is that there is no such thing as THE universe in any completed and waiting-to-be-discovered sense. The thought I am *testing out* is that the universe as a whole is still under construction. And when I say this, I am not thinking of just bits and pieces of it; I am thinking of the whole shebang, all the way to the roots. Nothing is completed. Not just the playhouse Kiki is building for Emma and Katie, or the evolutionary track of the human species, but even the "very laws" of physics. The idea is that they too are building up in precisely the way—and ever in the same danger of falling down as—individual organic species. That is to say, it's Darwinism all the way down.

So when you ask me if I am "saying that the real world is unanalysable, unthinkable even," the answer in a way is "yes." For it is blatantly impossible to analyze to the last detail the characteristics of a world that has not even been dreamt up (even in its own mind's eye).

But how can I impress this upon you, or even make it seem reasonable as a direction for research? That is a tough call. For, like with beer or single-malt Scotch, it is surely an acquired taste that builds only slowly and with the right company. Of course, I could just send you back to my paper `quant-ph/0204146` and ask you to take it very seriously. But this morning it dawned on me to maybe spend a little time with my scanner to try to IV some thoughts straight into your bloodstream.

At the moment, I can think of no better introductions to the line of thought I'd like to expose you to than three articles by Richard Rorty: "A World without Substances or Essences," "Truth without Correspondence to Reality," and "Thomas Kuhn, Rocks, and the Laws of Physics."[37] (Read them in that order, if you read them.) All three papers can be found in his collection of essays, *Philosophy and Social Hope*. If you absorb these, I think you'll understand completely what I'm up to, and why I so dislike the negative connotations you associate with the radical-Bayesian way of viewing the quantum state. Of course, it may not turn your head the way it turns mine, but at least you'll know where I'm coming from, and from what pool of enthusiasm I derive my strength to eschew the "golden nuggets" of *mere* quantum cosmology, *mere* Bohmianism, and *mere* "dreams of a final theory." The world as I see it is a much bigger place than those stories can tell. And the interpretational issues at the core of quantum mechanics strike me as our first rigorous indication that there is something more to this idea than simply the hopes and desires of an enthusiast.

[37]WARNING: Just because I say I can think of no better introductions to these ideas, it does not mean I endorse every statement in these papers; I may not endorse even half of them. However, I think these papers go in the right direction, even if they go too far ... and even if their arguments are far too weak. But I choose the papers I do because they are easy reading, with beautiful writing, and I suspect these thoughts are so foreign to you that if you can find any sense in *some of them*, then it may be a good start for a dialogue. Moreover, I continue to stress that the best justification yet to pursue this direction of thought—and this is something Rorty does not know—is quantum mechanics itself. So, rather than being the final words on things, these are just the beginning words on things.

For now, let me give you a flavor of the thoughts in these papers, and then leave you on your own in the case that you would like to pursue this further. The following quotes come from "Truth without Correspondence to Reality."

> In this essay I shall focus on Whitman's phrase 'counts ... for her justification and success ... almost entirely upon the future'. As I see it, the link between Whitmanesque Americanism and pragmatist philosophy—both classical and 'neo-'—is a willingness to refer all questions of ultimate justification to the future, to the substance of things hoped for. If there is anything distinctive about pragmatism it is that it substitutes the notion of a better human future for the notions of 'reality', 'reason' and 'nature'. One may say of pragmatism what Novalis said of Romanticism, that it is 'the apotheosis of the future'.
>
> As I read Dewey, what he somewhat awkwardly called 'a new metaphysic of man's relation to nature', was a generalization of the moral of Darwinian biology. The only justification of a mutation, biological or cultural, is its contribution to the existence of a more complex and interesting species somewhere in the future. Justification is always justification from the point of view of the survivors, the victors; there is no point of view more exalted than theirs to assume. This is the truth in the ideas that might makes right and that justice is the interest of the stronger. But these ideas are misleading when they are construed metaphysically, as an assertion that the present status quo, or the victorious side in some current war, stand in some privileged relation to the way things really are. So 'metaphysic' was an unfortunate word to use in describing this generalized Darwinism which is democracy. For that word is associated with an attempt to replace appearance by reality.
>
> Pragmatists—both classical and 'neo-'—do not believe that there is a way things really are. So they want to replace the appearance-reality distinction by that between descriptions of the world and of ourselves which are less useful and those which are more useful. When the question 'useful for what?' is pressed, they have nothing to say except 'useful to create a better future'. When they are asked, 'Better by what criterion?', they have no detailed answer, any more than the first mammals could specify in what respects they were better than the dying dinosaurs. Pragmatists can only say something as vague as: Better in the sense of containing more of what we consider good and less of what we consider bad. When asked, 'And what exactly do you consider good?', pragmatists can only say, with Whitman, 'variety and freedom', or, with Dewey, 'growth'. 'Growth itself,' Dewey said, 'is the only moral end.'
>
> They are limited to such fuzzy and unhelpful answers because what they hope is not that the future will conform to a plan, will fulfil an immanent teleology, but rather that the future will astonish and exhilarate. Just as fans of the avant garde go to art galleries wanting to be astonished rather than hoping to have any particular expectation fulfilled, so the finite and anthropomorphic deity celebrated by James, and later by A. N. Whitehead and Charles Hartshorne, hopes to be surprised and delighted by the latest product of evolution, both biological and cultural. Asking for pragmatism's blueprint of the future is like asking Whitman to sketch what lies at the end of that illimitable democratic vista. The vista, not the endpoint, matters.
>
> So if Whitman and Dewey have anything interesting in common, it is their principled and deliberate fuzziness. For principled fuzziness is the American way of doing what Heidegger called 'getting beyond metaphysics'. As Heidegger uses it, 'metaphysics' is the search for something clear and distinct, something fully present. That means

something that does not trail off into an indefinite future ...

and

So far I have been trying to give an overview of Dewey's place in the intellectual scheme of things by saying something about his relation to Emerson, Whitman, Kant, Hegel and Marx. Now I want to become a bit more technical, and to offer an interpretation of the most famous pragmatist doctrine—the pragmatist theory of truth. I want to show how this doctrine fits into a more general programme: that of replacing Greek and Kantian dualisms between permanent structure and transitory content with the distinction between the past and the future. I shall try to show how the things which James and Dewey said about truth were a way of replacing the task of justifying past custom and tradition by reference to unchanging structure with the task of replacing an unsatisfactory present with a more satisfactory future, thus replacing certainty with hope. This replacement would, they thought, amount to Americanizing philosophy. For they agreed with Whitman that America is the country which counts for its 'reason and justification' upon the future, and *only* upon the future.

Truth is what is supposed to distinguish knowledge from well-grounded opinion—from justified belief. But if the true is, as James said, 'the name of whatever proves itself to be good in the way of belief, and good, too, for definite, assignable, reasons', then it is not clear in what respects a true belief is supposed to differ from one which is merely justified. So pragmatists are often said to confuse truth, which is absolute and eternal, with justification, which is transitory because relative to an audience.

Pragmatists have responded to this criticism in two principal ways. Some, like Peirce, James and Putnam, have said that we can retain an absolute sense of 'true' by identifying it with 'justification in the ideal situation'—the situation which Peirce called 'the end of inquiry'. Others, like Dewey (and, I have argued, Davidson), have suggested that there is little to be said about truth, and that philosophers should explicitly and self-consciously *confine* themselves to justification, to what Dewey called 'warranted assertibility'.

I prefer the latter strategy. Despite the efforts of Putnam and Habermas to clarify the notion of 'ideal epistemic situation', that notion seems to me no more useful than that of 'correspondence to reality', or any of the other notions which philosophers have used to provide an interesting gloss on the word 'true'. Furthermore, I think that any 'absoluteness' which is supposedly ensured by appeal to such notions is equally well ensured if, with Davidson, we insist that human belief cannot swing free of the nonhuman environment and that, as Davidson insists, most of our beliefs (most of *anybody's* beliefs) must be true. For this insistence gives us everything we wanted to get from 'realism' without invoking the slogan that 'the real and the true are "independent of our beliefs" '—a slogan which, Davidson rightly says, it is futile either to accept or to reject.

Davidson's claim that a truth theory for a natural language is nothing more or less than an empirical explanation of the causal relations which hold between features of the environment and the holding true of sentences, seems to me all the guarantee we need that we are, always and everywhere, 'in touch with the world'. If we have such a guarantee, then we have all the insurance we need against 'relativism' and 'arbitrariness'. For Davidson tells us that we can never be more arbitrary than the world lets us be. So even if there is no Way the World Is, even if there is no such thing as 'the intrinsic nature of reality', there are still causal pressures. These pressures will be described in different ways at different times and for different purposes, but they are pressures none the less.

The claim that 'pragmatism is unable to account for the absoluteness of truth' confuses two demands: the demand that we explain the relation between the world and our claims to have true beliefs and the specifically epistemological demand either for present certainty or for a path guaranteed to lead to certainty, if only in the infinitely distant future. The first demand is traditionally met by saying that our beliefs are made true by the world, and that they correspond to the way things are. Davidson denies both claims. He and Dewey agree that we should give up the idea that knowledge is an attempt to *represent* reality. Rather, we should view inquiry as a way of using reality. So the relation between our truth claims and the rest of the world is causal rather than representational. It causes us to hold beliefs, and we continue to hold the beliefs which prove to be reliable guides to getting what we want. Goodman is right to say that there is no one Way the World Is, and so no one way it is to be accurately represented. But there are lots of ways to act so as to realize human hopes of happiness. The attainment of such happiness is not something distinct from the attainment of justified belief; rather, the latter is a special case of the former.

Pragmatists realize that this way of thinking about knowledge and truth makes certainty unlikely. But they think that the quest for certainty—even as a long-term goal—is an attempt to escape from the world. So they interpret the usual hostile reactions to their treatment of truth as an expression of resentment, resentment at being deprived of something which earlier philosophers had mistakenly promised. Dewey urges that the quest for certainty be replaced with the demand for imagination—that philosophy should stop trying to provide reassurance and instead encourage what Emerson called 'self-reliance'. To encourage self-reliance, in this sense, is to encourage the willingness to turn one's back both on the past and on the attempt of 'the classical philosophy of Europe' to ground the past in the eternal. It is to attempt Emersonian self-creation on a communal scale. To say that one should replace knowledge by hope is to say much the same thing: that one should stop worrying about whether what one believes is well grounded and start worrying about whether one has been imaginative enough to think up interesting alternatives to one's present beliefs. As West says, 'For Emerson, the goal of activity is not simply domination, but also provocation; the telos of movement and flux is not solely mastery, but also stimulation.'

and

It may seem strange to say that there is no connection between justification and truth. This is because we are inclined to say that truth is the aim of inquiry. But I think we pragmatists must grasp the nettle and say that this claim is either empty or false. Inquiry and justification have lots of mutual aims, but they do not have an overarching aim called truth. Inquiry and justification are activities we language-users cannot help engaging in; we do not need a goal called 'truth' to help us do so, any more than our digestive organs need a goal called health to set them to work. Language-users can no more help justifying their beliefs and desires to one another than stomachs can help grinding up foodstuff. The agenda for our digestive organs is set by the particular foodstuffs being processed, and the agenda for our justifying activity is provided by the diverse beliefs and desires we encounter in our fellow language-users. There would only be a 'higher' aim of inquiry called 'truth' if there were such a thing as *ultimate* justification—justification before God, or before the tribunal of reason, as opposed to any merely finite human audience.

But, given a Darwinian picture of the world, there can be no such tribunal. For such a tribunal would have to envisage all the alternatives to a given belief, and know everything that was relevant to criticism of every such alternative. Such a tribunal would have to have what Putnam calls a 'God's eye view'—a view which took in not only every feature of the world as described in a given set of terms, but that feature under every other possible description as well. For if it did not, there would remain the possibility that it was as fallible as the tribunal which sat in judgment on Galileo, a tribunal which we condemn for having required justification of new beliefs in old terms. If Darwin is right, we can no more make sense of the idea of such a tribunal than we can make sense of the idea that biological evolution has an aim. Biological evolution produces ever new species, and cultural evolution produces ever new audiences, but there is no such thing as the species which evolution has in view, nor any such thing as the 'aim of inquiry'.

To sum up, my reply to the claim that pragmatists confuse truth and justification is to turn this charge against those who make it. They are the ones who are confused, because they think of truth as something towards which we are moving, something we get closer to the more justification we have. By contrast, pragmatists think that there are a lot of detailed things to be said about justification to any given audience, but nothing to be said about justification in general. That is why there is nothing general to be said about the nature or limits of human knowledge, nor anything to be said about a connection between justification and truth. There is nothing to be said on the latter subject not because truth is atemporal and justification temporal, but because *the* **only** *point in contrasting the true with the merely justified is to contrast a possible future with the actual present.*

I don't have to tell you that I find these ideas tremendously exciting. It is not that nature is hidden from us. It is that it is not all there yet and never will be; 'nature' is being hammered out as we speak. And just like with a good democracy, we all have a nonnegligible input into giving it shape. That is the idea I am <u>*testing*</u> for consistency and utility. On the chance that it will lead somewhere, it seems to me, worth the gamble.

24-06-02 *Five Fuchsian Reasons for Rejecting a Line of Thought* (to H. M. Wiseman)

Wisemanism 13: *Yes, perhaps. But there is another challenge for you. If I understand Chris' latest to me, his response is to dismiss as impoverished the HEP's view of the world, rather than to try to incorporate it.*

I thought you might enjoy this. It is a list Rüdiger distributed during our last days in Brisbane.

Five Fuchsian Reasons for Rejecting a Line of Thought:

1. This question is not part of the foundations of quantum mechanics . . .
2. . . . and has no answer within quantum mechanics.
3. The question is ill-defined anyway . . .
4. . . . and, if formulated properly, would have a trivial answer.

5. And should it have a nontrivial aspect, working on it is a waste of time that really should be spent on proper foundational issues.

25-06-02 *Of Interest* (to G. Plunk)

This may be of some interest to us; I don't know.

> `quant-ph/0206169` [abs, ps, pdf, other]:
> Title: How to mix a density matrix
> Authors: Ingemar Bengtsson, Asa Ericsson
> Comments: 13 pages, 3 figures
>
> A given density matrix may be represented in many ways as a mixture of pure states. We show how any density matrix may be realized as a uniform ensemble. It has been conjectured that one may realize all probability distributions that are majorized by the vector of eigenvalues of the density matrix. We show that this is not true, but a marginally weaker statement may still be true. (70kb)

26-06-02 *The One Boolean Algebra Approach* (to I. Pitowsky)

I might as well let you know: I was one of the referees on your proposal to the ISF to study a Bayesian approach to quantum mechanics. Of course I was flattered by the prominent position you gave some of my papers, but, no matter, it is a good proposal. I wrote about the best report I could; now, all we can do is sit back and keep our fingers crossed that the other referees agree with me.

Let me make one further comment. I too used to think that the PBA approach was the way to go if one wanted to build up a theory along quantum logical lines. But now, I'm not so convinced of it. That is because I am starting to think that quantum mechanics is more analogous to the epistemological theory Richard Jeffrey calls "radical probabilism" than anything else. From that view, there are "probabilities all the way down" with one never getting hold of the truth values of *any* propositions. Rüdiger Schack and I just discovered a wealth of material on Jeffrey's webpage `http://www.princeton.edu/~bayesway/`.

In any case, I think what this leads to is that we ought to be focusing much more on characterizing quantum mechanics solely in terms of the "logic" of POVMs than anything else—these being the structures analogous to what crops up in Jeffrey's "probability kinematics." Thus, if one is looking to characterize PBAs, the best task might be to focus on the kinds of PBAs that POVMs generate, rather than the ones of Kochen and Specker based solely on standard measurements. (This may or may not have some connection to what people are calling "effect algebras" but I don't know.)

Beyond that, I am now of the mind that all one really ever needs for understanding quantum mechanics is a *single* Boolean algebra that is kept safely in the background (solely) for reference. The rest of the theory (and indeed all real-world measurement) is about probability kinematics with respect to that algebra. See Sections 4.2, 6, and 6.1 of my paper `quant-ph/0205039` for details.

Take care, and I'm so happy you find this approach interesting.

27-06-02 *Compatibility Never Ends* (to D. Poulin)

I apologize for taking so long to get back to you. My email box has just been running over lately, and on top of that I've been traveling a lot (just back from Australia, actually).

Poulinism 1: *About your approach: as far as I can see, the main difference (aside from the "vocabulary") between your derivation of the BFM compatibility criterion and theirs is that you are aware that it follows from* strong consistency*.*

No, I think the difference between us and them runs deeper than that. Let me try to express the point in a way that maybe I haven't used before. Concerning the BFM criterion: When BFM call it "necessary and sufficient" and when CFS call it "necessary and sufficient," we mean two very different things. For BFM the "necessary" part is enforced by the supposed existence of a super-observer, Zeno. That is, they mean that their criterion is "necessary" because they suppose a super-observer, Zeno, must exist. (See the final section of their paper.) What we (i.e., CFS) do instead is define a notion of "compatibility" based on the classical notion of "strong consistency" and show that the BFM condition is necessary and sufficient with respect to that. Beyond that, however, we leave the issue open.

That is, with regard to the question, "MUST the quantum states of two observers be compatible?," we make no statement in the paper. That is because, from our view—or at least mine in particular—there is nothing in nature that enforces that states MUST BE compatible. This is quite important if one wants to get a consistent Bayesian view off the ground. (I try to say all this in a lengthier and maybe more complete way in my samizdat *Quantum States: What the Hell Are They?*, pages 116–118, in a note titled "The Spirit of Gandhi." Actually, I think I say it better there; so have a look at that.)

Now, if there is nothing to enforce compatibility in the BFM sense, what would happen if two observers are incompatible with respect to this criterion? That's a fair and decent question, and I think where all the excitement begins. What the W criterion shows is that the two observers can just shake off their incompatibility and go forward (if they are in a congenial mood). That is, they can come to future agreement, not simply by pooling their prior beliefs, but by making an active intervention upon the system their states are about (i.e., by making a measurement). I view this as an extremely interesting property of the quantum world: it allows possibilities for going forward that the classical world does not.

On the other hand, if two observers are not in a congenial mood (i.e., will not perform a measurement of the W variety), then a "crisis" can ensue. What the full implications of that are, we don't know yet. But it may be even more exciting still.

Poulinism 2: *Maybe honesty can be related to strong consistency?*

Yes, you are right, and this is an important point. I discuss this at length in a note titled "The Commitments" on pages 133–138, and again on pages 192–193 in a note titled "More Balking." The upshot is, yes, strong consistency is deeply tied to honesty. The next question is, must one enforce honesty in a Bayesian approach to things? Your note implies that you tend to think, "yes." The pages I refer you to show that I tend to think, "no."

Poulinism 3: *Finally, while you relate the BFM condition to your ES, PP, W, and W', it is fundamentally different in spirit. This distinction is related to what we refer to as "type of knowledge". In our vocabulary, the BFM criterion is appropriate to compare knowledge of the quantum while the other are suited for quantum knowledge (just like quantum fidelity is). To me,* *the most convincing argument is the one of two nonorthogonal pure states: the "measurement criteria" will grant that they are compatible while, as we expressed it "if two observers claim to have complete knowledge of a system, their descriptions had better agree completely." Comparing states of knowledge and measurement outcomes predicted from these states are two different things. We have discussed a similar subtlety by comparing knowledge described by a density matrix and one described by a preparation: these are two different questions which deserve different answers although physically, they cannot be distinguished.*

It's a question of perspective. If one goes the full Bayesian route (which I am starting to do), then it is much better to call a quantum state a "state of belief or judgment," and not a "state of knowledge." For then, one finds that one is never inclined to say "their descriptions had better agree completely." There is nothing to enforce that, except possibly Darwinism. (I'm serious about that statement.) That is to say, when the world rears its head, someone with a firm belief might be wiped out, but in a Bayesian approach (where probabilistic statements always depend upon *subjective* priors), there is nothing to enforce compatibility beforehand. A misjudgment can only be declared a misjudgment after the fact, not before the fact (which in the quantum setting is created by the process of measurement).

27-06-02 *Probabilism All the Way Up* (to H. M. Wiseman)

Wisemanism 14: *Second, my wife, Nadine, wants to know why Kiki was building a playhouse while you indulge yourself in philosophy.*

I'd like to think we both do what we do best. But I suspect there's no philosopher out there who would say I'm doing good philosophy. (Kiki's artistry on the other hand is always a good hit.)

Wisemanism 15: *Now, more seriously, you say that my language "builds about the ugliest picture it can for where this effort is going". As I keep saying, I mean to be provocative. I hope it drives you to new heights in building a beautiful picture in response. Honestly I do see the beauty in your program. And I think the more extreme it becomes, the more beautiful it becomes. I am very interested to see where it ends up.*

Thanks for the compliment. And, indeed, your correspondence does drive me to new heights (of something). But now I worry that I offended you with my phrase "ugliest picture." It probably came off that way, but it wasn't meant to be an emotional statement or a point about you personally. If some emotion did slip into it, it most likely refers to a conversation I had with Harvey Brown, circa September 11 of last year. Harvey kept saying that I wanted to "doom" nature to being "ineffable." But that language carries such a negative connotation. It carries the idea that there is something there that we can never, or should never, attempt to speak of. So, when you said something similar in print, it gave me the opportunity to try to reply in print. (As you know, I try to have my thoughts recorded so I can refer people to them. One of the original ideas was that it would save me time that way; so far, that aspect of it hasn't worked out.) Anyway, as I made clear, I want to combat that with all my strength. In particular, the way that I am thinking about it, it is not a bad thing that there are some things beyond description in nature. Instead, it is just a statement that there are more things to come; it is a way of leaving room for something new.

Wisemanism 16: *As it happens, I don't have much of a taste for beer or single-malt Scotch. Also as it happens, I was reading a critique of Richard Rorty the very morning before I got your* *letter. Otherwise I never would have heard of him. It was a 1997 article by Alex Callinicos "Postmodernism: a critical diagnosis". The most interesting criticism in there was to say that Rorty "presumes what he needs to establish, namely that science and philosophy can be assimilated into literature. ... It is ... very hard in practice when trying to explain why one theory can be said to be more useful than another to avoid at least tacitly appealing to the idea that it captures how things are better than its rival does."*

Perhaps this is one aspect of Rorty you disagree with. But I wonder about your saying that quantum mechanics is the best justification for Rorty's philosophy, as if quantum mechanics is something you accept to be real, an "intrinsic nature of reality", the very idea of which Rorty explicitly rejects.

First, just a technical point. The philosophies I am most attracted to at present are those of James and Dewey and what James says about F. C. S. Schiller (but I haven't read Schiller himself yet). Rorty has donned himself to be the spokesman of those guys—and I don't mind that because he writes so nicely—but his writings also have a good admixture of the postmodernist ideas (of Foucault, Derrida, etc.) thrown into them to boot. This business about science not being more trustworthy or real than literary criticism presently strikes me as going too far.

But to Callinicos' point (give me the reference, by the way, and I'll read it)—"It is ... very hard in practice when trying to explain why one theory can be said to be more useful than another to avoid at least tacitly appealing to the idea that it captures how things are better than its rival does."—I would just reply, "Darwinism." And then, if that didn't sink in, I'd say, "Darwinism." The point is, from this conception, there is very little to say beyond that. Were elephants written into the blueprints of the universe? From the Darwinistic conception, they were not. Yet, the species fills a niche and has had a stability of at least a few million years worth. There is a sense in which an elephant, like a theory, is a "true" component in a description of the world. But that "trueness" only has a finite lifetime, and is largely a result of a conspiracy of things beyond its command (selection pressures). To put it another way, in contrast to Callinicos, the elephant doesn't "capture how things are better than its rival does" in any absolute sense—only in a transitory sense—but that doesn't take away from the functional value of the elephant today. So too, I am trying to imagine with theories.

Henry Folse, by the way, wrote me that there is something of a tradition with this evolutionary idea (beyond Rorty). So I've got a big reading list ahead of me: He tells me Toulmin, Kuhn, Kitcher, and van Fraassen.

Now, to quantum mechanics. You find something contradictory about my liking both quantum mechanics and Rorty. Here is the way I would put it. Presently at least, I am not inclined to accept quantum mechanics "to be real, an 'intrinsic nature of reality'," except insofar as, or to the extent that, it is a "law of thought," much like simple (Bayesian) probability theory. Instead, I view quantum mechanics to be the first *rigorous* hint we have that there might actually be something to James's vision.

I've already told you the history of this, haven't I? I gave a talk in 1999 at Cambridge on the quantum de Finetti theorem, after which Matthew Donald came up to me and bellowed, "You're an American pragmatist!" I didn't know what that meant really, but I kept the thought in the back of my head; I figured one day, I'd figure out what he meant. As it goes, that happened on July 21 of last year. I came across this book of Martin Gardner's of which one of the chapters was titled, "Why I Am Not a Pragmatist." (Part of the story is recorded on page 15 of my little samizdat in a note titled "The Reality of Wives." You might read it for a little laugh.) As I read it, it was like a flash of enlightenment. For every reason Gardner gave for not being a pragmatist, I thought about quantum mechanics and realized that indeed I was one. Donald was right after all; I am an

American pragmatist. And my further study of pragmatism has borne that out to a T.

My point of departure, unlike James's, was not abstract philosophy. It was simply trying to make sense of quantum mechanics, where I think the most reasonable and simplest conclusion one can draw from the Kochen-Specker results and the Bell inequality violations is, as Asher Peres says, "unperformed measurements have no outcomes." The measurement provokes the "truth value" into existence; it doesn't exist beforehand. Now, go off and read about James's and Dewey's theory of truth and you'll find almost exactly the same idea (just without the rigor of quantum mechanics). And similarly with lots of other pieces of the philosophy.

So, I view quantum mechanics as the hint of something much deeper. But the full story is not yet told. That is, quantum mechanics strikes me as being to our community what the Galapagos Islands were to Darwin—just a hint of something bigger.

Wisemanism 17: *You and Rorty I guess would agree that "dreams of a final theory" will never be more than dreams. I guess that idea does not worry me as much as it would some physicists, but it does seem like a defeat. But perhaps that just says something of my personality. How much of a role does personality play in one's preferred philosophy?*

Your question is a good one, and one I worry about a lot. Where your knee-jerk reaction is defeat, mine is one of unlimited possibilities and newfound freedom. On a similar issue, James put it like this:

> The history of philosophy is to a great extent that of a certain clash of human temperaments. Undignified as such a treatment may seem to some of my colleagues, I shall have to take account of this clash and explain a good many of the divergencies of philosophies by it. Of whatever temperament a professional philosopher is, he tries, when philosophizing, to sink the fact of his temperament. Temperament is no conventionally recognized reason, so he urges impersonal reasons only for his conclusions. Yet his temperament really gives him a stronger bias than any of his more strictly objective premises. It loads the evidence for him one way or the other, making a more sentimental or more hard-hearted view of the universe, just as this fact or that principle would. He *trusts* his temperament. Wanting a universe that suits it, he believes in any representation of the universe that does suit it. He feels men of opposite temper to be out of key with the world's character, and in his heart considers them incompetent and 'not in it,' in the philosophic business, even though they may far excel him in dialectical ability.
>
> Yet in the forum he can make no claim, on the bare ground of his temperament, to superior discernment or authority. There arises thus a certain insincerity in our philosophic discussions: the potentest of all our premises is never mentioned. I am sure it would contribute to clearness if in these lectures we should break this rule and mention it, and I accordingly feel free to do so.

But I think the disparity between our views is in better shape than that. I think you're only seeing the program "physics is the ability to win a bet" as a defeat because—even if you don't know it—you're working within a kind of Kantian mindset. That the universe is already formed and there; that there is an "a priori." Anything that can't be said about the universe is then most surely a loss or limitation. But, I think once you see that what the pragmatist is trying to get at is not that, maybe your heart will change. Physics as the ability to win a bet will strike you as something immensely positive. Physics is like that because reality is still forming, and the Darwinistic component (along with the "non-detachedness" of the observer in quantum mechanics) indicates that it may be somewhat malleable. From that point of view, to have "dreams of a final theory" is almost like admitting defeat.

But given what you've said, maybe you're already starting to feel some of this. And that tickles me immensely.

Wisemanism 18: *To conclude, I can (or rather could) accept a lot, or even all, of what you and Rorty are exploring. But I am still not emotionally or intellectually compelled to do so. And I am really not sure whether I want to be compelled in one direction, or whether I want to be able to contain conflicting philosophies. I have this idea that there is an incoherence at the heart of things. Irreconcilable levels of description. Profound truths being the opposite of other profound truths. Incompleteness theorems. That sort of stuff.*

Understood. I know that there's nothing worse than an evangelist knocking at your door on a Saturday morning. Feel free to not reply to this note at all. In the mean time, I'll try to do my best to do what I really ought to be doing: proving theorems, simplifying the quantum axioms, trying to find real-world physics problems for which this view is the most powerful way to tackle it, etc., etc. One thing physicists never deny is a better method for solving a problem.

28-06-02 *To Believe to Know* (to D. Poulin)

Poulinism 4: *Otherwise, you get incompatible statements with which Bayesian theory cannot deal (like computing $p(x|y)$ when y is assigned probability 0).*

It's starting to sound like we mean two different things by Bayesian theory. See, `http://www.princeton.edu/~bayesway/KC.tex.pdf`, slide #12 (on page 13 actually). More seriously, see: `http://cepa.newschool.edu/het/essays/uncert/subjective.htm`, especially the parts on de Finetti and Ramsey.

Poulinism 5: *I think that most of the discussion is based around this distinction: "state of knowledge" and "state of belief". I would say that states of knowledge must be (BFM) compatible while states of belief can be incompatible. How are these two things defined? Well I would say that a state of knowledge is built with the help of an initial state on which everybody agrees, the postulates of quantum mechanics, and "public actions".*

I will agree to your definition of "state of knowledge." But, backtracking from that, an initial state upon which everyone agrees? If one is taking a subjectivist approach (or what I had been calling a "Bayesian approach") to interpreting the quantum state, there is nothing in nature to enforce an initial prior agreement. God does not come down from on high and say to all the agents (i.e., all the observers), "Your starting point shall be the quantum state Ψ." Everyone is left to fend for himself.

That is to say, in the language of the second webpage I sent you to above, in a world where the quantum state is not presupposed to be objective—as had been Mermin's goal when he started this exercise—there is nothing to enforce the "Harsanyi doctrine."

28-06-02 *The Harsanyi Doctrine* (to C. M. Caves & R. Schack)

I just happened to run across the following discussion:

> Finally we should mention that one aspect of Keynes's (1921) propositions has re-emerged in modern economics via the so-called "Harsanyi Doctrine"—also known as the "common prior" assumption (e.g. Harsanyi, 1968). Effectively, this states that if agents all have the same knowledge, then they ought to have the same subjective probability assignments. This assertion, of course, is nowhere implied in subjective probability theory of either the Ramsey / de Finetti or intuitionist camps. The Harsanyi doctrine is largely an outcome of information theory and lies in the background of rational expectations theory—both of which have a rather ambiguous relationship with uncertainty theory anyway. For obvious reasons, information theory cannot embrace subjective probability too closely: its entire purpose is, after all, to set out [an] objective, deterministic relationship between "information" or "knowledge" and agents' choices. This makes it necessary to filter out the personal peculiarities which are permitted in subjective probability theory.

28-06-02 *Who Would Have Thunk?* (to N. D. Mermin)

Who would have guessed that all we were debating in our ill-fated correspondence on the BFM criterion was simply the validity (or maybe the jurisdiction) of the "Harsanyi Doctrine"? Not me! But that's what I found out this morning quite by accident.

If you want to read the story leading up to this, download my mini-samizdat "Quantum States: What the Hell Are They?" and look at the notes to Poulin on pages 215 and 219. I now find this quite interesting actually. Harsanyi won the Nobel prize with Nash, and there seems to be a bit of literature on his doctrine.

By the way, you never responded to (the main content of) my December 10 note "The Spirit of Gandhi." Here's your chance before I close the doors on this chapter of my life. (I.e., I'm going to bind up and close this mini-samizdat by the end of the day. The next one is going to be titled, "Darwinism All the Way Down.")

29-06-02 *Old Boole* (to I. Pitowsky)

Pitowskyism 1: *Anyway, the Bayesian Quantum Probability paper is much better than my research proposal (which was written with some haste, but this is a different story). I'll send you a copy when it's in a reasonable shape. I use projection operators, but have no prejudice against POVM's, only I'm not clear how to use the gambling language with them (we talked a bit about this problem in the Växjö conference).*

You play exactly the same game you did in your proposal, except now that a complete set of mutually exclusive events are identified with the elements in a POVM. I.e., *stop* thinking of POVM elements as non-mutually-exclusive events. (Well, I don't know that you haven't already abandoned that line, but much of the community tends to call them "unsharp" measurements and such. And that just creates the wrong imagery. They are sharp as anything else from this view.) These elements correspond to measurement "clicks" and are thus mutually exclusive. From my standpoint, the "clicks" are the closest we can come to grasping a "truth value." And thus that is the formal role they take on.

Pitowskyism 2: *The slogan "probability all the way down" is great. One should even make a sharp distinction between "probability equals unity" and truth.*

Yes. And that is what the better part of my samizdat "Quantum States: What the Hell Are They?" posted at my website (link below) is about. You might enjoy thumbing through it. In my own view, it leads one along the lines of something like a Jamesian theory of truth … but hopefully with the opportunity to make it more rigorous now.

29-06-02 *Incompatible Beginnings* (to D. Poulin)

Poulinism 6: *Maybe requiring a single description on which everyone agrees is a bit too strong, but something has to be imposed.*

The whole point of the research program I am building up, and the point of most of the 220 pages in *Quantum States: What the Hell Are They?*, and much of the point of my paper `quant-ph/0205039`, is that I don't buy that. Remember the line in the Pink Floyd song, "Mother's going to put all her fears into you."? The point is, none of us are born with "rational" views. We start out in life with whatever our community pumps into us. The mark of "rationality" instead is how we change our views in the light of evidence, and how we gamble based on what we believe. That is what Dutch-book coherence is about, for instance.

So, when I say "agents are left to fend for themselves," I mean it. Every now and then agents start out compatible in one sense or another and then they stay that way, indeed … perhaps with ever more similarities between their distributions as data flows in. But that is not the norm. Instead most of the time, there is some incompatibility in our world views lurking in the background. We can live with that as long as nothing comes to light to challenge our views. But when the opportunity arises, there will be a "crisis," as Rüdiger Schack likes to say.

At that point, as you say, Bayesian theory can't handle things. But the view I am shooting for is that Darwinism can. That is, if you have a firm belief (i.e., a probability 1 ascription) for something, by Dutch-book rules you are willing to bet your whole bank account on the event. If the event doesn't occur, then you have lost your whole bank account, and in a way your life.

The program, as I see it, is to see how rigorous and fruitful on can make that line of thought.

01-07-02 *Nose Jobs* (to T. Rudolph)

Rudolphism 7: *Yah – finished Rorty, I'm actually rereading a bit of the stuff near the beginning and the section on Weinberg/Kuhn etc. I'm not entirely satisfied with the way he answered Weinberg … not that Weinberg's statements were that great, which is the reason I think Rorty could have been stronger.*

Agreed. (Clearly there was some emotion behind it that got out of hand.) But funny, on my own second reading, I liked the reply better.

I posted some stuff in that connection in the form of some letters to Howard Wiseman. You might be interested. They can be found near the end of my "Quantum States: What the Hell Are They?" on my webpage.

One thing I need to understand better (and not just trust Rorty on) is Donald Davidson's theory of truth. But my reading list is a mile high.

05-07-02 *The Physics of Floyd* (to M. J. Donald)

I said I would be back; I apologize for the delay.

Donaldism 5 : *Your know-nothing ism, like de Finetti's irrationalism (Gillies, "Philosophical Theories of Probability", page 86), have the dangers of Bohr's writings on which I would agree with Beller (Physics Today, September 1998, pages 29 - 34). In particular, by leaving far too much in vagueness, incoherence, and pious hope, you give the religiously-minded the official endorsement of the physics establishment that they may believe anything they want, instead of, by example, instructing them that they can believe anything they want as long as it is rational, coherent, tentative, revisable, and compatible with the evidence (and therefore contrary to naive expectations, because if quantum theory, or indeed science in general, tells us anything it is that the world is not how we would have imagined it before we investigated); and they accept that they may be completely wrong.*

In saying this, you demonstrate that you have read Gillies page 86. I'm glad I know that. But, as I tried to convey before, I think you show a deep misconstrual of de Finetti's program (or radical subjectivism, or radical probabilism, or whatever you want to call it, even irrationalism). I never tell my girls that they can believe anything they want. I always try to be as impartial as possible, but in the end, I'm sure all I really teach them is to believe what *I* believe and what the community around me believes. That's where they take their start in life.

And so it is with all of us. Pink Floyd recorded a great lesson with the words, "Mother's going to put all her fears into you." De Finetti's theory of probability is simply a stark recognition of this fact and a stark recognition that there is no getting around it. The point is, none of us are born with "rational" views, and a particular opinion at any one moment is *neither* rational or irrational. The mark of "rationality" is instead in how we change our views in the light of evidence, and how we gamble based on what we believe. This is what "coherence" and Bayesian updating are about. When Mother has put such a bad opinion into us that rationality cannot realign it enough for us to survive, then we won't survive, and that opinion will not propagate.

It is not "anything goes" here any more than it is for the species in the animal kingdom (Darwin). If you see in my writings a hint that anything goes, then it seems to me you are fighting a battle with someone else and hoping I will fill his shoes. The mathematical side of "radical subjectivism" is an attempt to quantify the ideas above and to show their consistency and utility. It is what the 586 pages of Bernardo and Smith's book *Bayesian Theory* is about; example after example that rationality is not in the prior, but in the conditionalization and in the coherence.

Where you think you need a law-driven reality to explain the success of our scientific activity, I think all I need is (something along the lines of) de Finetti and Darwinism. The most important point of distinction between our views is in how we are willing to mark the "badness" of an opinion/belief/judgment. I say it is only possible to mark a judgment as a misjudgment—in any objective way—after the fact, after the event to which it was directed has either occurred or not occurred. Whereas you want to think there is something that defines the badness or goodness of a judgment before the event.

This is the great gulf between us. I say, "unperformed measurements have no outcomes." "The universe is in the making." You say, if I'd just step back far enough—until I'm outside of the universe, actually—I'd see that the universe "is." It's already there. It's already complete and waiting for me to draw a precise picture of its smooth surface. And in the dimples of that smooth surface, I would see which of my actions are right and which of my actions are wrong long before they take place. Indeed, in that timeless ground state, I would see that everything I'm talking about is folly.

There's no denying that there is something about the former picture that piques the lascivious side of my character. But the problem is deeper and more openly communicable than that. A couple of times in your notes, you have said something to the effect,

Donaldism 6 : *I do hold as an article of faith that there is a true view, although I accept that we may not ever know it, let alone ever know that we know it.*

If we may never know it, or even know that we know it, then I cannot see that it plays any normative role whatever in helping us get along in life. Its explanation of the phenomena about us is little more than a hollow promise. The argument is a minor modification of J. S. Mill's argument against substance:

> If there be such a *substratum*, suppose it at this instant miraculously annihilated, and let the sensations continue to occur in the same order, and how would the *substratum* be missed? By what signs should we be able to discover that its existence had terminated? Should we not have as much reason to believe that it still existed as we now have? And if we should not then be warranted in believing it, how can we be so now?

Just change "substratum" to "immutable law."

There, I've said my piece. And I've probably said too much in too condescending a way: For that I apologize (almost). But I wanted to make a point and make it forcefully. My purpose is not to give fuel to the religious fire-burners. It is to change our conception of how the law-like stability we see around us arises, in a way that does justice to what I view as the great lesson of quantum mechanics. Quantum mechanics, that is, as viewed from inside the world, where we actually live, instead of from some Everettic fantasyland (where 1957 stands out as the most atypical year ever, the year man first saw the universe in its entirety and confirmed what the rationalists had suspected for so long: its image is so bleak as to fit within the mind of a single man). The mark of pious hope is in the belief of miracles: I don't believe in miracles or miraculous years.

Is all that I've said vague? Of course it is. But that is why this is a research program rather than a completed product. There is so immensely much to do. Carl Caves instilled in me long ago that the good physicist is the one who poses a problem he can hope to just solve in the span of his lifetime. That's the way I see this program. With sustained determination, some creativity, and the help of a lot of friends, I see it as actually going through (and carrying us to a vista that is almost unimaginable now).

Some of the best help we could probably get would be the mind of Matthew Donald. But that might require a midlife crisis! (And I would hate to think of what that might do to your wife and children.)

Now let me address some of your other comments.

Donaldism 7 : *Actually, it was great fun writing: I've always wanted to be allowed to say "Nope", but I've never got away with it before.*

Are you saying that you find it easier to let your hair down around me than with your Cambridgean/Oxfordian contemporaries? If so, then I will reinstate the image of the romantic and mustachioed revolutionary just for you. What the whole movement needs is a little letting down of the hair; glad to be of service.

Donaldism 8 : *page 9: "the final state itself for B cannot be viewed as more than a reflection of some tricky combination of one's initial information and the knowledge gained through the measurement." To what extent then is the "final state for B" actually "for B" and to what extent is it "for" the observer?*

similarly, on page 12, in the last paragraph of section 3, can we say that the system "has" the state $|\psi\rangle$, or should we say that for Alice the system has the state $|\psi\rangle$?

A later point in your note indicates that you know I would say "for the observer" here. Indeed that is better language. Sometimes it's just hard to make the right rhetorical judgment; sorry if I caused you confusion. My intention instead was to put one foot into the enemy camp, and try to fight on their terms. That is to say, my intention was to draw an absurdity from associating a quantum state with a system rather than with an observer's judgment.

Donaldism 9: *footnote 12: which view gives the most coherent, consistent, plausible explanation of the most phenomena? which view is true?????*

I exasperate you, don't I? The point is, I have my reasons for refraining from that word, and I tried to explain some of them above.

Donaldism 10: *page 22: I'm not sure what to conclude from section 4.2. This is all that comes to mind:*

Somewhere in the classical division of the BIPM is a die testing machine. It is used to throw a die sufficiently many times to provide a reasonable estimate of the probability of each face. It shares with its quantum analogue the features that in general the probability of any face is never zero, and that many trials are needed to provide useful statistics.

If it were a good classical die testing machine—that is, if it really did the same thing each and every time—then the toss would always come out exactly the same. That is to say, there are no good classical die testing machines.

Donaldism 11: *page 24: Are POVM's really "the structure of our potential interventions"? All of our potential interventions? Our most important interventions? The structure of a two-year old child's interventions? Or are they just one particular "very carefully contrived way by which we can sometimes manage to see fairly directly into part of [reality's] deep structure".*

The way I would say it now is this. Our interventions are whatever they are. Even a two-year old's. The concept of our interventions having a structure is something we lay on top of them. To that extent, the use of POVMs as a formal descriptive device is a normative one. I would say the same thing for our general use of probability theory. That is to say, we don't use the probability calculus in making all our decisions, but we ought to. Bernardo and Smith put it this way:

> What is the nature and scope of Bayesian Statistics within this spectrum of activity?
>
> Bayesian Statistics offers a rationalist theory of personalistic beliefs in contexts of uncertainty, with the central aim of characterising how an individual should act in order to avoid certain kinds of undesirable behavioural inconsistencies. The theory establishes that expected utility maximization provides the basis for rational decision making and that Bayes' theorem provides the key to the ways in which beliefs should fit together in the light of changing evidence. The goal, in effect, is to establish rules and procedures for individuals concerned with disciplined uncertainty accounting. The theory is not descriptive, in the sense of claiming to model actual behaviour. Rather, it is prescriptive, in the sense of saying "if you wish to avoid the possibility of these undesirable consequences you must act in the following way."

Similarly I would say of POVMs. If you want to do your best reasoning concerning the consequences of what you've just done (or what you are about to do) then you should use the calculus of quantum mechanics. And that says lay a template down over what you've done (or what you are about to do) that happens to have the shape of a POVM.

Donaldism 12: *page 34: "Quantum measurement is nothing more, and nothing less, than a refinement and a readjustment of one's initial state of belief." But it is something more. It is also the result of a physical process.*

No, I would say, the result of the physical process is something else. It is a creation of sorts. The structure of quantum mechanics, I would say, has something to do with what I can say about that creation ... thus my refinement and readjustment. But concerning the real stuff of the world, the theory hardly goes there. (And that's what I try to say, for better or for worse, in my `quant-ph/0204146`.)

Donaldism 13: *The idea in many-worlds interpretations is to drop von Neumann's process 1 (collapse of the wavefunction). In section 6, it looks as if you're intending to drop process 2 (unitary time propagation). But, the A_{di} in (63), or the Π_d in (65), should be derived from the physics of the measurement; no doubt using environmental decoherence at some point.*

Yes, I do intend to drop process 2 as being something more fundamental than process 1. I keep looking for ways to do that that I find completely convincing. From my view, process 2 is just a special case of process 1, where the POVM is a one-element set. The word "should," you should realize, is little more than a cultural statement ... from a cult that I do not buy into. The phrase "no doubt," on the other hand is a statement of faith. The reasons for your use of that phrase I will leave as an exercise in self-reflection.

Donaldism 14: *Probability theory is only a law of thought in as far as it describes how one should deal with new information. (vN process 1). But physics should also be able to describe how one acquires new information. (vN process 2).*

Ditto.

Donaldism 15: *It is the physical laws and initial conditions which make an agent's beliefs about the forms and the probabilities of possible future experiences either right or wrong given his past experiences.*

I told you that was the gulf between us.

Donaldism 16: *The rational assignment of a POVM to a given experimental device is not a matter of free choice.*

I claim it is; at least initially so. The rationality lies purely in coherence and updating, not in particular assignments. But clearly it's going to take a lot of inculcation into my culture to convince you of that. I know it won't help, but I'll throw this out for evidence's sake that I take your skepticism seriously: Just as there is a de Finetti theorem to make sense of "unknown states," there is a de Finetti theorem to make sense of "unknown measurements." (This is a result Schack, Scudo, and I will be posting soon.)

Donaldism 17: *The strict quantum Bayesian of the Fuchsian persuasion, however, faces the quagmire that physical laws are as subjective as probabilities, so that there is nowhere to start (not even with nothing!).*

Darwinism. Darwinism. Darwinism. Darwinism. It's presently the best nothing I've ever known.

Donaldism 18: *page 51: Hilbert space dimension, of the small integer type you are referring to, is itself only an effective concept, which depends on not looking too closely at the systems studied. For example, D=2 arises when you consider a photon which may hit one of two detectors, and ignore the full (infinite-dimensional) photon-detector space. Therefore D also is state and agent and context dependent and subjective.*

Absolutely. But it is of the harmless type that fixing a classical phase space is: and that's the point. Any classical (real-world) pendulum has more than one degree of freedom, but once the context is set, once the approximation is made, the human interests that set that context and made that approximation can be safely forgotten. This is what I envision for Hilbert-space dimension (but not the quantum state).

Let me thank you also for the other uplifting note you sent me. Despite my own combative reactions (as witnessed above), I do find my conversations with you valuable. And in ways, you are partially responsible for the creation of this monster. (In fact, I recently set to paper the story about your involvement. In case you're interested, I'll narrow the search for you: it's somewhere between page 202 and 221 of the mini-samizdat "Quantum States: What the Hell are They?" posted on my webpage. If you wade through that, you'll get the full impact of the story. By the way, I'll be shutting the doors to that samizdat soon. I'll equip it with an index, etc., like I did with the last one, but I won't post it on `quant-ph` this time, only my webpage. After that, I intend to start constructing a new one titled "Darwinism All the Way Down." The present letter to you will be my first entry.)

Finally, let me end with a long quote that I pulled from Richard Jeffrey's paper, "Reading Probabilismo." You inspired me to copy it into my machine.

> There is a most instructive contrast between de Finetti's "irrationalist" probabilism and Carnap's rationalist positivism.
>
> For Carnap, probabilism was a fallback position from what one might call dogmatic rationalism, i.e., the view that scientific forecasts and universal hypotheses ought to be logically deducible from *Protokollsätze*. Probability theory was to replace deductive logic; dogmatic rationalism would give way to probabilistic rationalism. Rationalism itself was seen as essential to empiricism. The probability $c(h,e)$ of a scientific forecast or hypothesis h relative to a sentence e that reports the totality of one's empirical evidence needed to be independent of who one might be, provided only that one were ideally rational: qua scientist, an ideally rational being would be individuated only by e, the report of that being's total individual experience to date. If c as well as e could vary from scientist to scientist then $c(h,e)$ would represent a subjective judgment. The only scientific basis on which the $c(h,e)$ values might vary must appear in the second argument-place, not in the function c itself, i.e., such a basis must be empirical. Logical empiricism was wedded to that sort of rationalism. *That* sort of rationalism—not the rationalism of the bogeyman who thinks he can predict the future by pure reason, or can prove that space must be euclidian, a priori.
>
> De Finetti's probabilism was "irrationalist" in denying the possibility of an intelligible split between reason, represented by the conditional probability function c, and experience, represented by the total observation-report e. "Anti-rationalist" would have been a less provocative term. But if de Finetti's probabilism was anti-rationalist it was anti-empiricist as well on the same showing, and "anti-empiricist" has the same ring

of madness that "irrationalist" has. The suggestion is that an anti-empiricist opposes observation and experiment, just as an irrationalist is against being reasonable and thinking things through. What's rejected, though, is neither experience nor reason, but the dichotomy underlying logical empiricism, according to which the two can be cleanly separated—say, into e and c. de Finetti rejects as untenable the basic dogma of logical empiricism: the dualism between reason and experience.

05-07-02 *Coherence Everlasting* (to H. M. Wiseman)

Wisemanism 19: *The comment by van Enk and Fuchs on Ref. [1] can be understood as an explicit calculation showing (part of) how a laser beam, without an absolute phase, can function as a clock; how the phase information can be distributed and how there is no harm in regarding the phase as real. This is essentially the same point originally made by Molmer, that laser phase is a "convenient fiction".*

No. Our point was not even remotely the same as Klaus's. Klaus was concerned with an intracavity mode, where I would say there is no reason whatsoever for preferring one decomposition of the density operator over another. This contrasts with the multi-mode system we were concerned with. With respect to that *tensor-product structure*, there is a preferred decomposition, and it involves coherent states. If the modes are believed to be exchangeable, as they standardly are with continuous-wave laser light, then the de Finetti theorem dictates that there is a unique decomposition of the big multi-mode density operator into a probabilistic mixture of pure states, each of which preserves the exchangeability property. Yes, it is a convenient fiction, just like when anytime one has a density-operator description of a system, it is PURELY a fiction to furthermore think of that state as composed of a deeper (more real) set of pure states.

The point of the expansions of a density operator—as I tried to make clear in my lecture at Griffith—is not to talk about "what is there," but rather to tell something about the potential measurements one can perform on a system, and what those measurements will teach us. I.e., what predictive value they will give. Measurements correspond to decompositions. Full stop. There is nothing deeper than that. What is significant about the de Finetti expansion of a laser beam is that it tells you that IF you can measure the phase of one mode, THEN the remainder of the modes will be describable via a simple, pure product state. If one were to think of the multi-mode case as a mixture due to an original mixture of intracavity photon-number states, one would have to work like hell to see that. If that is not a reason to prefer one valid decomposition over another, I don't know what is. One thing is for sure though: It does not endorse the *reality* of any decomposition, number-state, coherent-state, or otherwise.

07-07-02 *And Continuing Consternation* (to H. M. Wiseman)

Wisemanism 20: *Actually I don't think that is so important, if you mean the multimode versus single mode thing. I hope you don't mean they should have written down a statistical mixture, because then I would really disagree with you.*

Yes, that is exactly what I meant. Sargent, Scully, and Lamb, in their Chapter 17, do a perfectly fine calculation, and the result is a mixed-state density operator. It represents the laser operator's state of knowledge about his laser field, given some standardly agreed upon information. To think there is a purer state of affairs—i.e., to think that there is an "unknown state" over and above his mundane description—is to go against the grain of everything I (and Caves and Schack, and Peres, etc.) have been striving for in the interpretational game. Those pure states that lie underneath a density operator are pure artifice from my point of view.

Wisemanism 21: *Well you certainly do not make that clear in your paper. On my reading, you are accepting Rudolph and Sanders' idea that there is such a thing as a real coherent state. That before you measure it, the laser is in a statistical mixture, and after you measure it, it isn't. I am saying there is no need to ever write down a statistical mixture for the laser. The laser can be its own clock, and hence (ignoring phase diffusion) it is in a coherent state.*

Then, you carry a lot of baggage into your reading. (Perhaps as I carried a lot of baggage into my reading of your comment.) A few notes ago, you wrote the following:

Wisemanism 22: *After looking at it with Carl and Rüdiger, I take back what I said to Chris about the paper having sneaked in objective probabilities — I was misled by reading "probability" as "objective probability".*

I would suggest you are doing something similar with my paper with Steven. The idea that "that before you measure it, the laser is in a statistical mixture, and after you measure it, it isn't" is now a foreign concept to me. And it was already a foreign concept by the time Steven and I wrote those two papers.

I just re-read both papers, the PRL and the QIC version, and though they are written in a more neutral way than you usually see from me—Steven did the bulk of the writing—I still find none of the thoughts you thought you saw there.

Wisemanism 23: *An electronic oscillator is no more real than an optical oscillator.*

Agreed. The issue in my mind is one of a chain of inference. Given the previous ascription of a multi-mode mixed state, what pinging of the quantum world (i.e., what measurements) will allow one to refine that ascription to a pure state for some of the remaining (unmeasured) modes? We think we know how to ping the electronic oscillator, and we draw a chain of inference. That's all. But without the electronic oscillator as an intermediary, we are stuck with the mixed state ascription. (Notice, I keep using the word ascription, not description.)

08-07-02 *Short First Reply* (to H. M. Wiseman)

Wisemanism 24: *Hey, I think I do understand the quantum de Finetti theorem. If you have an infinite sequence of systems you are happy to swap around in any way then it is always possible to represent your state of knowledge as being AS IF there is an unknown quantum state common to all of them. It's not that complicated. That's not to say of course that I could reproduce your proof, so to avoid being offended, I could assume that being able to do that is what you mean by "strong understanding". On the other hand, your statement could hardly have been said unless you thought I had demonstrated in the past a weak understanding of the issues (e.g. my not understanding what is so terrible about the idea of an unknown preparation procedure) then my defence would be that I believe I am in quite good company.*

Yes, it is the latter (i.e., being in "quite good company") that I meant. So, I really only mean the points made in the introduction of that paper.

Wisemanism 25: *For an optical experiment the laser is the clock, and therefore it is in a pure coherent state.*

Our agreement lasts for the first part of this sentence. Where we part, is in the "therefore."

Wisemanism 26: *All quantum states are pure artifice, full stop. They are in the observer's head — what can be more artificial. I thought that's what you taught me. If I say a laser is in a pure coherent state, how can you say I'm wrong?*

True enough. My point is only one about consistency. If one *accepts* the standard derivation, say of Sargent, Scully, and Lamb, Chap. 17, then one has NO RIGHT TO GO FURTHER and say, "well, there's really a coherent state there after all, and I just don't know it." One is simply not being internally consistent. If, on the other hand, one wants to believe that the field should be described by a pure coherent state, that is fine by me, but then one should know what that state is (otherwise, to my post-1999 ears, they are speaking nonsense).

Wisemanism 27: *What other possible meaning can be taken from this quote: "This measurement would create an optical coherent state from a standard laser source for the first time."*

> **create** (krê-ât') verb, transitive
> created, creating, creates
> 1. To cause to exist; bring into being.
> 2. To give rise to; produce.
> 3. To invest with an office or title; appoint.
> 4. To produce through artistic or imaginative effort.

13-07-02 *The Fabric of Sexuality* (to A. Plotnitsky)

Plotnitskyism 3: *As I was reading your Växjö piece, indeed already as I started to read it at Cornell, one impression it made on me was a bit peculiar. The very concept and terminology of "quantum states" appeared to me (in part because of an appeal to a "state") to be a remnant of a more conventional ontological view, and your argument seemed to have difficulty to adjust the concept to the view advanced by you in your article and elsewhere. Almost immediately, however, I recalled the discussion in "Quantum States," where you speak, I think rightly, of the quantum state as a state of belief rather than knowledge, although "state of expectation" or "probabilistic estimates" may even be more precise. (I agree that "knowledge" is better suited to refer to the outcomes of measurements already performed, even though, at least in my view, both knowledge and expectation concerns only what is manifest in measuring instruments, never anything pertaining to quantum objects themselves.)*

Yes, I see your point and I agree with it. It is a remnant. But so far, I've had no stroke of inspiration for a better term.

Plotnitskyism 4: *It seems to me, however, that, rather than of QUANTUM STATES, it would be more accurate to speak of the STATE VECTORS (the ket-vectors defined by the psi-function in a corresponding Hilbert space) as representing or reflecting the state of expectation. I do not think one could speak of states vectors themselves as states of expectation, but only as a mathematical device representing information related to our expectations concerning the outcomes of certain possible experiments or events. One might in fact call them "EXPECTATION VECTORS."*

And actually this one doesn't do it for me either. It's hard to pinpoint why, but I guess mostly I would be searching for a more philosophically evocative term. Secondary to that, you use the word "vector," and it is crucial to my point of view that there is nothing more fundamental about a pure state (i.e., a state vector) than a general density operator. Thus, perhaps, "expectation operator" might be more to my taste, but along the point I just made, I really would like something more evocative than that.

Right now, "belief" still does the most for me—because I am so taken with William James's essay "The Sentiment of Rationality"—quantum states are, in part, those things that he talks about there—but I agree with you that the terminology ought to go, once something better comes along.

Plotnitskyism 5: *With these qualifications in mind, however, "quantum state" may be a possible conception and perhaps even a necessary one (especially in the EPR-type situations), insofar as it indicates an independent existence of "quantum objects." That includes their capacity to enter interactions with our measuring instruments or other classical and quantum entities with which they can interact, and various occasions of what you would call "Zinc!" that may arise as a result.*

Here I think I disagree with you: the *ascription* of a Hilbert space (and with it a dimension) already strikes me as up to the job. Thus, in a sense, the Hilbert space—but none of the vectors in it—is the proper mode for expressing an individuality or independent existence.

And by the way, it's "Zing!" dammit. (Howard Barnum wrote a paper recently, where he made slight fun of the term, and called his version of it "Voom!") "It don't mean a thing, if it ain't got that zing."

Plotnitskyism 6: *Now (this is perhaps a tad less banal) it appears to me that, at least on this view, it is in this and only in this that one could speak of an UNKNOWN quantum state (the locution one sometimes find in, among others, your writings). This "state," however, could, on this view, never be represented by a state vector, which indeed reflects the state of expectation, or by any other mathematics.*

I believe I understand where you are going here. But precisely because of the last sentence, I would be reluctant to call what you are talking about a state. The way I imagine it, quantum systems have little to no properties in and of themselves ... and thus no "states." To the extent that they have any properties at all, they are born in a sexual act, so to speak. What is most real of a quantum system is what comes out of two of them going bump in the night.

Right now, I'm about two hours into my flight toward Madrid. As you can see, I've been filling my time writing a little email. But also I am forcing myself during this trip to finally read David Deutsch's book *The Fabric of Reality*. I figure I ought to do this since I might get a chance to talk to him at the QCMC meeting at MIT. Before setting off to write you, I finished the first chapter, and have been finding it just as detestable as I had suspected. God save me this week if I get all the way through the thing.

13-07-02 *Yestopher* (to A. Plotnitsky)

Plotnitskyism 7: *I would only reiterate that all our knowledge (already obtained in measurements) or predictive estimates only concern classical effects of the interactions between quantum objects and measuring instruments upon the latter, but not quantum objects themselves, although these effects would not of course be possible without the existence of quantum objects. I am not saying "reality," since there is no concept of reality I know or can think of applicable to such "objects,"* *while it seems to be possible to think of existence as a capacity to produce effects, in a classical-like (as in classical physics) or in a nonclassical fashion (as in quantum mechanics).*

Yes, I definitely like this statement. But let me think more about the rest of your letter (for maybe a couple of days) before commenting further. It might prod me to finally write down some thoughts about a divergence that I think is starting to develop between Bohr and me.

BTW, you don't mean "orthogonal" in this passage:

Plotnitskyism 8 : *Indeed, once we perform a momentum measurement on the first system we completely cut ourselves from any possibility of making prediction concerning the [position] measurements on the second system. I suppose this point is linked in some ways to Mermin's observation to the effect that once a given system is [in] a given state (in the sense of psi-function) it cannot be in the state orthogonal to it. This language does not altogether satisfy me, however, since, as I said in my previous email, ket-vectors in a Hilbert space do not describe actual physical states. One could say (in a more cumbersome but more accurate way) that the possibilities of predictions defined by orthogonal state vectors (expectation vectors) are always mutually exclusive, which is of course to say, rigorously complementarity in Bohr's sense, since they also entail mutually exclusive experimental arrangements.*

Position and momentum eigenstates are not really orthogonal in the sense that Mermin is speaking of here. Rather they are "complementary" (as Zeilinger would say) or "mutually unbiased" (as Bill Wootters would say). That is, two vectors in a D-dimensional space are "mutually unbiased" when their inner product is $1/\sqrt{D}$ in magnitude. It just so happens with position and momentum eigenstates that $D = \infty$, (and thus they are strictly speaking orthogonal), but that is a secondary concept or property. Mermin's trouble with orthogonality arises, even in a D-dimensional space, when the inner product is zero.

29-07-02 *20 More Minutes* (to B. W. Schumacher)

I was intrigued by your comment of, "If you would have just had about 20 more minutes, I might have been convinced by your talk." Seriously, could I get you to tabulate your most serious objections to a Bayesian approach to quantum mechanics? It would certainly help to orient me and the other boys: sometimes it hard to see the biggest leaks in a ship from the inside. We need this kind of criticism if the point of view is going to hope to survive.

On another subject, I'm afraid you haven't lifted your pen yet to write up your doubting-Everett argument. The original deadline has just about slipped past, and I really would like to have your paper. There are some stories that only you can tell. What can I do to help you, or help keep you on course? Seriously; I'll be at your service if you need me. (And if that doesn't work, remember the guilt thing. Once upon a time you said, "I owe you this paper.")

Ben's Reply

> Oh, I guess my basic worry is that the wave function is a bit too peculiar to be an "a priori" object — probabilities seem inescapable, but who ordered the quantum? So a program of thinking of quantum mechanics as a rational calculus of inferences seems to be lacking some ingredient. Wish I knew what it was. (Is it the Zing?) But until I have an inkling, the project seems a little doubtful.
>
> I wish you could see just how much I'm hanging my head in abject shame. (It makes it hard to type.) I'm leaving for sabbatical tomorrow, and will take two weeks to drive

across the country. I'll be in Los Alamos for a day next week. Anyway, I'm taking my Everett stuff, with the intention of trying to write the danged thing on the way. I'll be in touch and let you know how it goes. I will *not* be on e-mail every day.

I suppose my basic problem is that I feel such a paper should be couched as a massive and authoritative review of the conceptual issues in the Everett interpretation. This of course is madness. I will ignore this instinct and write only what I really have to say.

It was amazingly good to see you at MIT and I am really looking forward to visiting Montréal.

29-07-02 *Complimentarity* (to A. Plotnitsky)

OK, the title is probably a bad pun. But I thought I might tell you something nice I heard Asher Peres say of you while we were in Spain. "That Plotnitsky is a wise man." He was quite impressed by your understanding of Bohr.

Here's another piece of complimentarity: While I was in Cambridge last week, I picked up a copy of your book *Reconfigurations*. It's in beautiful shape and I got it for a great bargain, only $11.75.

How much longer will you be in NYC? I might drop in one day soon if you've got some free time.

29-07-02 *Coordinate Systems, 1* (to W. K. Wootters)

This is a small note to let you know that after a little thought I decided I really liked your question at the end of my talk Wednesday. Setting the standard quantum measurement device is more like setting a coordinate system than merely setting a length or time scale. Now I'm not sure how to take that any further, but I'll keep you up to date as the thoughts arise.

Did you and Robin make any progress with the SIC-POVM? If there's still some work left to be done, then Gabe and I will likely plunge back into the water as the week goes by.

30-07-02 *Coordinate Systems, 2* (to W. K. Wootters)

Woottersism 13: *PS. Have you seen the following concept in classical probability theory? Consider a probability distribution P over n variables. Now consider all the $(n-1)$-variable marginal distributions derived from P. Let $\tilde{P}$ be the n-variable distribution that agrees with P in all its marginals but otherwise maximizes the entropy. Then the difference in entropy between $\tilde{P}$ and P can be taken as a measure of the amount of information in P that is not in its marginals.*

Have you seen that idea anywhere? Noah Linden, Sandu Popescu and I are doing the same thing for quantum states, and I'm wondering what's been done classically along these lines. Thanks.

I meant to tell you, by the way, that that's a really beautiful idea. I don't think I have ever seen it before, so there's not much I can tell you. Presumably—in analogy to what you showed for the quantum case in your talk—in the bipartite setting it reduces to simply the standard mutual information. (Well of course it does; I started to see it as I wrote that sentence.) I'll ask around to some of the information theorists here.

By the way—now this is a completely different subject, but the memory was jogged by your question—here's a historical tidbit that might interest you. In the mid 1850s, George Boole was also interested in the marginals a posited joint probability distribution could produce. In fact he studied the inverse problem, given a set of potential marginals, under what conditions can there exist a joint distribution giving rise to them? Those conditions are now called Bell inequalities, but Boole had expressions for some of them even in the 1850s. Here's a great little article to read along those lines:

- I. Pitowsky, "George Boole's 'Conditions of Possible Experience' and the Quantum Puzzle," Brit. J. Phil. Sci. **45**, 95–125 (1994).

30-07-02 *Copenhagen Visit* (to F. Topsøe & P. Harremoës)

A friend and I will be visiting Copenhagen September 12–17, partially as a vacation, but partially for some work. (He will be there because of a conference Sept 8–12 on laser physics; and I will be there because of an obligation in Växjö, Sweden during the same time.) Also while in Copenhagen, I thought I might do a little work, either visiting you and/or doing a little historical digging at the Niels Bohr Institute.

Do either of you have any suggestions for how this friend and I might make the trip affordable but still pleasant? For instance, do either of your universities have any visitor housing? Or could you recommend any affordable, but pleasant, hotels in an interesting part of town (with cafés, bars, etc., nearby)?

We're just fielding suggestions at this point. Please tell me anything you can?

30-07-02 *20 More Minutes, 2* (to B. W. Schumacher)

Schumacherism 7: *I suppose my basic problem is that I feel such a paper should be couched as a massive and authoritative review of the conceptual issues in the Everett interpretation. This of course is madness. I will ignore this instinct and write only what I really have to say.*

Yes, that would be madness. Just think over and over, "Transcribe my talk. Transcribe my talk. Transcribe my talk. Capture the atmosphere of my talk." And when you need some filler, say something about information being relative, say something about what quantum information holds for quantum foundations studies. Say what you feel, and everything will be OK. If you need references, I'll dig them up.

Have a safe trip … but make it your best mental writing experience ever.

01-08-02 *Research Problem* (to M. Raginsky)

Maxim's Maxim 1: *I must say that I thoroughly enjoy reading your papers on the foundations of quantum theory. However, I came of late to take any "Quantum Theory as Information" manifesto with a grain of salt. Is it just me, or are people insisting on an information-theoretic revision of quantum theory simply because the field is so, shall we say, "trendy?" Certainly we may demand an "information-theoretic reason" for the fact, say, that a pure state of a quantum-mechanical system is a ray in a complex Hilbert space, and that is fine as far as that goes, but what about the good ol' classical information theory? Why doesn't anyone clamor for an "information-theoretic reason" for the mathematical formalism of classical mechanics, with its symplectic manifolds and Hamiltonian flows and the like? Perhaps the answer is this: the modern mathematical machinery of classical mechanics is, after all, a fancy way to express the belief in the ultimate determinism of the classical world. So, insofar as there is no "spooky" artifact of this formalism, no one could give a damn* *about any "information-theoretic reason." It is only when our macroscopic intuition gets blown to smithereens by the microworld (entanglement, anyone?), do we suddenly demand a paradigm overhaul. What I mean to say, so loquaciously, is that the "classical" (Shannon) information theory is far from being a physical theory the way quantum information theory is shaping out to be. Any thoughts on this?*

I promised you that I'd tell you what I said to Ulrich Mohrhoff when he said what you said (but in a meaner way). It's pasted below. [See 04-07-01 note "Carts and Horses" to U. Mohrhoff.]

But that aside, I think your question is a good one, and it leads immediately to a research problem that might interest you. Indeed I do think it is worthwhile to try to give information theoretic reasons for some aspects of classical physics—Hamiltonian flow being precisely one of them. Go to my samizdat, `quant-ph/0105039`, and have a look at the following notes:

- page 408, "Andrei"
- page 283, "End of Day"
- page 284, "Wigner"
- page 285, "contra-Koopman"
- page 165, "The Evolution of Thought"
- page 166, "On the Mark"
- page 167, "More Linearity"
- page 168, "Three References"

I think they explain what I'm talking about in pretty good detail.

It was good meeting you at MIT, and I'm looking forward to studying your channel papers if I ever get an ounce of time. If you have any good ideas along the lines above, I'd love to hear them.

01-08-02 *Manuscript* (to C. King)

Dear Math-Chris,

Kingism 1: *I have one observation about your multiplicativity problem: if you replace the "maximum eigenvalue" operation (aka the operator norm) by the entropy function (you have to normalize the states first, and put the normalization factors outside, so you have a weighted average of entropies) then the corresponding minimal entropy quantity is additive. Any interest?*

That sounds intriguing, but I can't quite visualize which expression you're talking about. If you can, just TEX in a quick equation. What would the interpretation of that quantity be (within the cluster of ideas that the paper is about)?

All the best,

Philo-Chris

01-08-02 *Notes* (to C. King)

Aha! Thanks for the notes. I don't think I had ever thought of the set of states as defining a doubly-stochastic channel before. So, at least I understand your notation. Very good. And neat result of yours. Does it lead to any insight on how to solve the original problem? And here's another question: Does $G(\Phi)$ define an interesting channel characteristic in general? Have you ever seen it before in that kind of context?

02-08-02 *Baby* (to C. H. Bennett & T. M. Bennett)

Beautiful pictures, but more importantly beautiful babies. Congratulations to everyone in the family. Busy days ahead. Charlie knows I get philosophical when I think about life and all the possibility it opens up in the universe—possibility that wasn't even there before. These babies are part of that. Wonderful creations. Please give our best to George and Martha.

05-08-02 *The Spirit that Breathes Life* (to G. L. Comer)

"The divinity that breathes life into nature cannot be represented."

Thanks for your note of August 1. It gave me food for thought; free will saved another life. Indeed, I think the divinity that breathes the whole of life into nature is just that: free will, the essence of making a choice.

I don't think I ever told you this, but 132 years ago, the realization that free will is key saved the life of another great man. It was William James, and the realization is attributed not only to saving his life—he had been in deep depression for some time, with the accounts saying he was on the brink of suicide—but in turning his philosophy and all his thought around. The full road to recovery took several years, but that moment was the starting point.

Let me paste in a passage from his diary for you.

> April 30, 1870
>
> I think that yesterday was a crisis in my life. I finished the first part of Renouvier's second "Essais" and see no reason why his definition of Free Will—"the sustaining of a thought because I choose to when I might have other thoughts"—need be the definition of an illusion. At any rate, I will assume for the present—until next year—that it is no illusion. My first act of free will shall be to believe in free will. For the remainder of the year, I will abstain from the mere speculation and contemplative *Grüblei* in which my nature takes most delight, and voluntarily cultivate the feeling of moral freedom, by reading books favorable to it, as well as by acting. After the first of January, my callow skin being somewhat fledged, I may perhaps return to metaphysical study and skepticism without danger to my powers of action. For the present then remember: care little for speculation; much for the form of my action; recollect that only when habits of order are formed can we advance to really interesting fields of action—and consequently accumulate grain on grain of willful choice like a very miser; never forgetting how one link dropped undoes an indefinite number. *Principiis obsta*—Today has furnished the exceptionally passionate initiative which Bain posits as needful for the acquisition of habits. I will see to the sequel. Not in maxims, not in *Anschauungen*, but in accumulated acts of thought lies salvation. *Passer outre*. Hitherto, when I have felt like taking a free initiative, like daring to act originally, without carefully waiting for contemplation of the

external world to determine all for me, suicide seemed the most manly form to put my daring into; now, I will go a step further with my will, not only act with it, but believe as well; believe in my individual reality and creative power. My belief, to be sure, can't be optimistic—but I will posit life (the real, the good) in the self-governing resistance of the ego to the world. Life shall [be built in] doing and suffering and creating.

06-08-02 *SHPMP Quantum Information Issue* (to the SHPMP participants)

Dear friends,

I have to open up this note with some sad news. Rob Clifton the editor-in-chief of *Studies in History and Philosophy of Modern Physics* and the main instigator of our special issue, died sometime late last week, succumbing to cancer. He was a young man in the prime of his life and leaves behind a wife and two young children. You can find out a little about Rob, his life, and his love for quantum mechanics at his webpage `http://www.pitt.edu/ rclifton/index.html`.

With that, I should get to the formal task of this note, our special issue on quantum information. The original deadline for all papers was to be August 1. Jeff Bub and I have talked to many of you privately about your progress, but especially in light of this tragedy, we think it is time to get serious. With that, we propose to extend the deadline to October 1, but to make that one hard and fast. It is important that we get the papers to the journal with plenty of time for refereeing and copy editing before the special issue's appearance.

I hope that you will all reconfirm your participation, and that we can count on you for a quality issue. Please let us know your status as soon as possible. Below, I list the proposed papers (forgive me if I didn't quite get your title right), and further below that I paste in the original invitation with details.

Best regards,

Chris (and Jeff)

Contents:

- H. Barnum
  "Quantum Information and Quantum Logic: Toward Mutual Illumination"
- C. H. Bennett and J. A. Smolin

- R. Jozsa
  "Quantum Computation and Quantum Foundations"
- N. D. Mermin
  "Philosophical Ruminations on Deutsch's Problem"
- I. Pitowsky
  "Betting on the Outcomes of Measurements: A Bayesian Theory of Quantum Probability"

- J. Preskill,
  "Defending Everett"

- B. Schumacher,
  "Doubting Everett"

07-08-02 *Trouble Man* (to N. D. Mermin)

Merminition 93: *I completely forgot about this and have no idea what I was thinking of when I sent you that title. Better count me out. I have too many other things I'm supposed to do in the next two months.*

Is there none of that college spirit left in you? No loyalty to the editorial board (of which you are a member)?

Honestly, is there really nothing you would find worthy to write up? I remember loving the last line in this paragraph from your "teaching" paper:

> There are nevertheless some who believe that all the amplitudes α_x have acquired the status of objective physical quantities, inaccessible though those quantities may be. Such people then wonder how that vast number of high-precision calculations (10^{30} different amplitudes if you have 100 Qbits) could all have been physically implemented. Those who ask such questions like to provide sensational but fundamentally silly answers involving vast numbers of parallel universes, invoking a point of view known as the *many worlds* interpretation of quantum mechanics. My own opinion is that, imaginative as this vision may appear, it is symptomatic of a lack of a much more subtle kind of imagination, which can grasp the exquisite distinction between quantum states and objective physical properties that quantum physics has forced upon us.

Surely, that sentence could be turned into a whole paper, at least under my pen.

I remember the first time I met you—in Montréal—I heard you say, "Quantum computation is the biggest sham in the industry. The government gives you all this money to crack codes, and what you're really doing is quantum foundations." Couldn't you find some way to flesh that out and say it in print? It would benefit you and it would benefit the community.

07-08-02 *Books and Notes* (to A. S. Holevo)

Thank you for the Humboldt book; I very much enjoy reading things like that. And I will surely distribute copies of your own book to Ruskai, Schumacher, Caves, etc. I will be seeing all of them in the month of October.

In sorting through your things yesterday, I put all of your handwritten notes into a single pile. I also placed all the papers by other people on which you had written some notes into the same pile. It really would be no problem for me to mail that to you. If you will just give me an appropriate address, I will do it.

By the way, it was a surprise to see that you had started a draft titled "A Remark on Conjecture of Bennett, Fuchs and Smolin." Too bad you were never able to complete it! Regardless of the result, with a title like that it would have certainly helped my career. Few people today associate me with that question, even though to my knowledge, Bennett and I were the first to ever bring it up (at a meeting in Torino in 1996).

08-08-02 *The Recalcitrant P's* (to A. Peres)

I almost titled this note "Two Recalcitrant Positivists," remembering something you had called us long ago. But then thinking of how I am more closely aligned with the pragmatists now (James, Dewey, Rorty, etc.) than with the positivists, I decided to be more careful. We're just two recalcitrant P's, and I'll leave it at that.

I'm glad to hear that you and Aviva are home safely.

09-08-02 *Conspiracy Theory* (to J. W. Nicholson)

By the way, have a look at my conspiracy theorist article:

`http://www.pcmag.com/article2/0,4149,440168,00.asp`.

09-08-02 *Conspiracy Theory, 2* (to J. W. Nicholson)

Nicholsonism 7: *Did you really say, "I'm sure that the government is already using quantum cryptography systems for real applications."??*

That line really scares me, because he put quotes around it. I can't imagine that I would have said it. But on the other hand, I'm sure reporters know how to cover their asses. I've been thinking about what to write this guy to lodge a complaint. Maybe it was really said in a context that took some of the edge off it? I don't know. I can imagine that I would have said "developing" ... but he bases the whole story on the word "using".

13-08-02 *Variola* (to R. W. Spekkens)

Spekkensism 10: *A quick question for you regarding POVMs. It seems to me that there is an interesting distinction between, on the one hand, POVMs that can be obtained by convex combinations of coarse-grainings or convolutions of PVMs, and, on the other, those that can only arise by restriction of a PVM on a larger Hilbert space. An example of a POVM in the latter category would be one with rank 1 elements numbering greater than the dimensionality of the Hilbert space. Has this distinction been noted and studied anywhere?*

Yes, this distinction was first noted by Holevo: A. S. Holevo, "Information-Theoretical Aspects of Quantum Measurement," *Problemy Peredachi Informatsii*, **9**(2), 31–42 (1973); also listed as A. S. Kholevo, *Problems of Information Transmission*, **9**, 110–118 (1973).

Beyond that, a most interesting distinction has to do with thinking of the POVMs as a convex set. The extreme points of that set have the character you mention, except that all the operators in the POVM must be linearly independent. You can read about that in: A. Fujiwara and H. Nagaoka, IEEE Trans. Inf. Theory **44**, 1071–1086 (1998).

14-08-02 *Empty Head* (to J. W. Nicholson)

I loved the Maureen Dowd "empty-headed" comment today. Just sayin.

By the way, I've thought a little bit about the ethics of killing cattle and the culture of the "compassionate cattle raiser/killer." Interesting issues with, shall we say, quantum implications. I'm honing the thoughts for a (thoughtful) conversation in the near future.

20-08-02 *Old Note to Rolf* (to C. H. Bennett)

Your remark last night about "Gilles's idea" to derive quantum mechanics took me by surprise. The surprise came from the way you continue to associate my efforts with a kind of religion, rather than with an honest effort to get at some different ways of looking at quantum mechanics (by deriving it from information theoretic structures, etc.)—i.e., you don't even see that this is what I am always talking about. I'd like to think some of my latest papers represent progress in that direction, and I guess I'd also like to think the pressures I put on the people around me (Hardy is a good example) have been part of the reason for their own good work in that direction. Religion without theorems, or a dream to prove them, is just religion. But religion that gives rise to some solid results in return is usually called science.

Anyway, thinking of the history of this, I came across a little passage I wrote to Rolf Landauer in July of 1998 which I thought was cute. I'll paste it below. It puts a lot of weight on your shoulders Atlas.

With my usual love, Chris

> The [speculated] information-processing limitation has to do with a funny property of the world we happen to live in. It is this: *my* information gathering about a given physical system will generally disturb *your* description and predictions for that self-same system. Nonetheless we, as communicating beings, must come to a consistent description of what we see and know about that physical system. This, I ever more firmly believe, is the essence of the quantum mechanical formalism. Quantum theory is nothing more than Bayesian-like reasoning in a world with such a funny property. (This I see as a large chunk of my personal research program: clarifying, delineating, and searching for holes in this point of view.) Perhaps ... to put it in a more amusing way ... what I am saying is that I wouldn't be surprised if the whole edifice of quantum theory couldn't be constructed from the singular fact that "quantum cryptography exists." That is to say, Hilbert spaces, the inner product rule, entanglement, and unitary evolution all from that clean, simple idea Bennett and Brassard were the first to make some currency of.

21-08-02 *Way in the Back* (to D. Gottesman)

Gottesmanism 1: *Yes, I was wondering if I should suggest you as a recruit. Some of the Perimeter recruiting is in Foundations of QM rather than quantum computing proper; I guess Lucien is the first real hire in that area.*

Thank you; I'm flattered. I guess I don't have to advertise to you the depth of my faith that a beautiful spark will eventually fly out of rubbing those two fields together.

Charlie Bennett and I are sitting at the back of this enormous room in the OpryLand Hotel [at the ARO conference in Nashville] acting like it's our office. He's reading science fiction from his laptop, and I'm writing email. There seems to be a speaker saying something from way up in the front.

27-08-02 *Dimensionality* (to P. J. Reynolds)

Reynoldsism 1: *Thanks for the e-mail. I love your web page! I'll have to make some time and look at those PowerPoint talks.*

Sorry for the long delay in my reply: Any man who says he loves my webpage certainly deserves a prompt, if not immediate, reply!! But I finagled my way into the ARO review meeting last week, and that ended up commandeering all my attention … I'm just recovering now.

Reynoldsism 2: *I justify the small amount still in my program as benefiting metrology, clocks, and time transfer. Is the Hilbert space "resource" different (versus "more fundamental than") entanglement? In other words, does it enable different things than the things we attribute to entanglement? If so, then (depending on what those things might be) we might have an "in" for you.*

What I am thinking of here is seeking ways to quantify the extent to which the dimensionality D of a quantum system's Hilbert space signifies that quantum system's "sensitivity to the touch." If you have a look at some of my more foundational writings, in fact, you'll see I'm starting to view this "sensitivity to the touch" as the most fundamental property there is for a quantum system—i.e., the most significant feature that sets quantum stuff apart from classical stuff is its potential to be perturbed. From this point of view, quantum entanglement is a secondary effect, and has more to do with how this sensitivity scales with the number of quantum systems than anything else. The more important question is what does D tell us, and what can we do with it?

With regard to your program, I can foresee at least a couple of directions with which to take this idea.

1) In an upcoming paper with Masahide Sasaki—I can supply the manuscript-under-construction if you'd like—we try to quantify the "quantumness of a Hilbert space" by a system's ability to sniff out whether it is being sent through a classical channel or a quantum channel. In fact, we view this ability as a Bureau of Weights and Measures kind of thing: Lucent Technologies says it is supplying you with a good quantum channel. How can you tell that it really is?

2) Good "sensitivity to the touch" signifies some potential for good antennas. Here I'm thinking of things like LIGO in particular (though in a more abstract setting). What does Hilbert-space dimensionality buy you with respect to the ability to distinguish weak signals? I've got some of this captured in my Caltech lecture notes "Viewing LIGO through Schwarz Colored Glasses," which I can send you. Also you can find some hints of the ideas in a paper by Childs, Preskill, and Renes, "Quantum Information and Precision Measurement" (`quant-ph/9904021`), of which I played some part.

Anyway, that's the sort of stuff I'm thinking about. If I were to put this down in a proposal I could beef it up pretty significantly, and hit the theme from still a couple more directions.

I hope that builds a little clearer picture for you.

30-08-02 *Transformations of This and That* (to G. L. Comer)

Thanks for the enjoyable note.

Comerism 2: *Why did this passage interest me? Because of the problem of the dictionary: How can one "understand" language? It seems to me that even when we native English speakers speak English, all we are doing is using rules of translation. Into what? I don't know. Interestingly enough, when I think of relativity, I see a big similarity. For me, relativity is not only about gravity as a manifestation of the curvature of spacetime, but also about how two observers can communicate the results of their experiments in such a way that they can agree that they have witnessed the "same" event. As an example, in order to determine the energy of the cosmic microwave background, one observer with unit four-velocity u_1^μ will say the energy is $u_1^\mu p_\mu$, where p_μ is the momentum of the radiation, but another observer with four-velocity u_2^μ will say the energy is $u_2^\mu p_\mu$. Even if the* *observers are at the same place, at the same time, when they make their measurement, they will in general not record the same energy because their motions will in general be different. So how can they ever agree on anything? Relativity tells them how to "translate" one measurement into the other so that a consistent description results. What is objective about the energy? Nothing. Its value depends on the motion of the observer. Where is the objectivity? Only in the rules of translation. The only objective thing to me seems to be the how one object is to be compared with another.*

Did you ever read my "Anti-Växjö Interpretation of Quantum Mechanics" paper? (If not, you can download it from my webpage; link below. It should be super-easy reading; no equations at all.) If I'm not mistaken I play up a similar point there, in the context of noncommuting observables.

But I kind of like something about your twist. Spacetime is the dictionary. And, like the dictionary, the "divinity that breathes life" into its connections is its user, the active agent. Without the agent it is a snake that bites its tail.

I'm in Los Alamos at the moment, being forced by the scenery to remember some of my own transformations. It has been two years since I've been here; the first time I've been back since the fire. The mountainside is still full of these toothpicks that used to be trees; I guess it'll be like that for at least 20 more years or so, fading slowly. Yesterday I drove to the street where our house (and all my material possessions) used to be. A new house is finally being constructed in its place. Funny, I found myself thinking mostly about the ground underneath it; I guess like a burial place.

05-09-02 *Copenhagen Visit* (to O. C. Ulfbeck)

My name is Chris Fuchs. We have a mutual friend in David Mermin, and he has suggested that I contact you. For a quick introduction to me and my work, you can read David's foreword to my pseudo-book posted on the Los Alamos archive; here is a quick link to it: `http://xxx.lanl.gov/abs/quant-ph/0105039`. Alternatively, for a technical introduction to the sorts of things on my mind, see my paper "Quantum Mechanics as Quantum Information (and only a little more)": `http://xxx.lanl.gov/abs/ quant-ph/0205039`. (It is a coincidence that the two papers have almost identical locator numbers.)

In any case, I will be visiting Copenhagen September 12 through 17, and I would very much like to talk to you and/or Prof. Bohr about your quantum-foundations paper on genuine fortuitousness. I would also like to spend some time in the Niels Bohr Archive if it is possible and I can figure out how to make an appointment there, etc. Would you like to get together?

If so, there is a chance I will be able to maintain email contact within Denmark; so perhaps I can be reached that way. Also, however, I will be staying at a guest room of the university, and should be findable by some means there. Here is the information I have on it: [...] Finally I should be reachable through my hosts Peter Harremoës and Flemming Topsøe: [...]

If you have the time, I would love to hear from you.

PS. I will also be giving two talks while in residence:

- 13/9 13.15-14.00 On Unknown Quantum States: The Quantum de Finetti Representation Theorem
- 16/9 9.15-10.00 Quantum Mechanics as Quantum Information (and only a little more)

I'm not sure where they will be yet and there is some possibility that the order will be reversed, but those are their dates and times. I would be flattered if you could attend either one; I will place the abstracts below.

Quantum Mechanics as Quantum Information (and only a little more)

I say no interpretation of quantum mechanics is worth its salt unless it raises as many technical questions as it answers philosophical ones. In this talk, I hope to convey the essence of a salty, if not downright briny, point of view about quantum theory: The deepest truth of quantum information and computing is that our world is wildly sensitive to the touch. When we irritate it in the right way, the result is a pearl. The speculation is that this sensitivity alone gives rise to the whole show, with the quantum calculus portraying the best shot we can take at making predictions in such a world. True to form, I ask more questions than I know how to answer. However, along the way, I give a variant of Gleason's theorem that works even for rational and two-dimensional Hilbert spaces, give another variant of Gleason's theorem that gives rise to the tensor-product rule for combining quantum systems, and finally derive a new form for expressing how quantum states change upon the action of a measurement.

On Unknown Quantum States: The Quantum de Finetti Representation Theorem

There is hardly a paper in the field of quantum information theory that does not make use of the idea of an "unknown quantum state." Unknown quantum states can be protected with quantum error correcting codes. They can be teleported. They can be used to check whether an eavesdropper is listening in on a communication channel. But what does the term "unknown state" mean? In this talk, I will make sense of the term in a way that breaks with the vernacular: an unknown quantum state can always be viewed as a known state—albeit a mixed state—on a larger "multi-trial" Hilbert space. The technical result is a quantum mechanical version of the de Finetti representation theorem for exchangeable sequences in probability theory. Interestingly, this theorem fails for real and quaternionic Hilbert spaces. The implications of this theorem for the point of view that quantum states represent states of knowledge, rather than states of nature, will be discussed.

05-09-02 *Everett Quote* (to N. D. Mermin)

I just want to make sure I have this quote archived. An easy way for me to do that is to send it to you. It comes from a footnote in Hugh Everett's original relative-state paper.

> Note added in proof. — In reply to a preprint of this article some correspondents have raised the question of the "transition from possible to actual," arguing that in "reality" there is—as our experience testifies—no such splitting of observer states, so that only one branch can ever actually exist. Since this point may occur to other readers the following is offered in explanation.
>
> The whole issue of the transition from "possible" to "actual" is taken care of in the theory in a very simple way—there is no such transition, nor is such a transition necessary for the theory to be in accord with our experience. From the viewpoint of the theory *all* elements of a superposition (all "branches") are "actual," none any more "real" than the rest. It is unnecessary to suppose that all but one are somehow destroyed, since all the separate elements of a superposition individually obey the wave equation with complete indifference to the presence or absence ("actuality" or not) of any other elements. This total lack of effect of one branch on another also implies that no observer will ever be aware of any "splitting" process.

08-09-02 *Commune '02* (to the Communards)

Quantum Foundations in the Light of Quantum Information II Montréal, Canada October 13, 2002 – November 2, 2002

Chers communards,

Gilles and I are making final plans for the October Montréal quantum foundations commune. I think the meeting promises to be a lot of fun and more importantly promises to be the site of some good physics.

Below is the latest tabulation of attendees. If your dates are still marked with an X or a ?, please make a final confirmation as soon as possible. Alternatively if you cannot ultimately attend the meeting, please let us know that too. (In the coming days, we hope to populate the remaining spots with friends in the waiting list. Recall, we have room for about 15 attendees at any one time, so that everyone will have a desk.)

Beyond that, the main thing we need from you now is to make your flight plans and living arrangements. (Because of the late date of this letter, this is something that should be taken care of rather urgently.) Concerning the former, please try to include a Saturday stay in your plans so as to keep the airline fees down. Concerning the latter, the procedure is the following. Have a look at the following webpage, and decide which option looks best for you: `http://www.crm.umontreal.ca/en/niveau2/index_vis_sug.html`. After that, write an email to Luc St-Pierre (`stpierre@CRM.Umontreal.Ca`) at CRM telling him which option you would like reserved and what your precise dates will be. Gilles and I would suggest the Chateau Versailles Hotel as the best option for most of you: it is the most pleasant hotel and only a short, straightforward bus ride from the university. If you prefer no busses, Hotel Terrasse Royale is a small walk from the university, but—be warned—it's not nearly as pleasant a place to live.

The format of the meeting will be relaxed and mainly devoted to work, conversation, and collaboration time. We will, however, schedule one to two talks per day; so everyone should come prepared for that eventuality. Also—and this is a key component to the meeting—we ask that everyone compile and share a list of concrete problems whose solution, they believe, will tell us something novel about quantum foundations.

Key:

`X` – dates proposed by Fuchs (based on request and/or guesswork)
`O` – dates confirmed by participant
`?` – additional dates participant is contemplating and/or requesting
`-` – means person is not in attendance on that date

(Saturdays and Sundays are signified by an `S`.)

08-09-02 *Y'all Come* (to C. H. Bennett)

You will have noticed that I included you in the latest announcement for the Montreal Commune. I do hope you'll come for some of it, and I mean that from the bottom of my heart. I'm spending a week in Sweden presently, and I'm typing this letter from the hotel lobby where John Smolin, Lucien Hardy, and I had so many pleasant conversations at the last quantum foundations meeting I put together. John, as I've told you before, turned out to be one of the most useful and interesting participants of the meeting—that took me by surprise because I never imagined he would have any interest in this subject. Nothing could be better than for you to surprise me the same way!

Looking forward to your response.

08-09-02 *Information is Physical* (to A. Peres)

Asherism 25: *I am looking for references that will appear in my RMP with Danny. Ben Schumacher confirmed that he invented "qubit", and Gilles found the father of Alice and Bob (Blum, 1981) after I found Savitt 1982. I remember that Rolf Landauer used to say "information is physical" but I can't find a written record. Would you know one?*

I'm in Sweden with a bad connection, so I'll be brief.

The following comes from page 192 of my samizdat, `quant-ph/0105039`.

> **08 October 1998, to Rolf Landauer, "Info is Physical"**
>
> I have room in a very tight conference proceedings paper that I'm writing to make one citation to your phrase, "Information is Physical." Do you have a favorite paper that I should cite? Should I make the citation to your earliest mention of the phrase? Or should I make the citation to what you think is the clearest statement of it? Please

make the decision for me and send me the correct reference. My paper is going off to the editors tomorrow, so if you could send me a quick note that'd be great!

Rolf's Reply

The concept, but not that phrase, first appeared in R. L. *IEEE Spectrum* vol 4, issue #9, pgs. 105–109 (1967). (Like for *Physics Today*, the page numbering restarts with every issue.) The exact wording PROBABLY first showed up in my 1991 *Physics Today* paper. But it seems best to cite an early or a very recent paper. Two are on their way into print. One that is likely to appear within a few weeks: R. L. in *Feynman on Computation 2*, ed. by A. J. G. Hey, Addison Wesley, Reading (1998?). The title of that one "Information is Inevitably Physical". About 11 days ago at a session in Helsinki I complained to my audience: I have gotten a fair amount of acceptance for that phrase, but not for the message attached to it. But thanks for checking.

P.S. I'll mail both papers, even though they will arrive too late. But if you take an instant dislike to the one you used, you can scratch it at galley proof time.

09-09-02 *Information Carriers are Physical* (to A. Peres)

Asherism 26: *I could not understand your answer, but there is nothing urgent. What I would like is the exact wording, and a reference that ordinary readers can easily access (*Physics Today *is fine, or some conference).*

I was just demonstrating that my samizdat can be a resource for historical questions. The words below are Rolf's words himself:

> The concept, but not that phrase, first appeared in R. L. *IEEE Spectrum* vol 4, issue #9, pgs. 105–109 (1967). (Like for *Physics Today*, the page numbering restarts with every issue.) The exact wording PROBABLY first showed up in my 1991 *Physics Today* paper. But it seems best to cite an early or a very recent paper. Two are on their way into print. One that is likely to appear within a few weeks: R. L. in *Feynman on Computation 2*, ed. by A. J. G. Hey, Addison Wesley, Reading (1998?). The title of that one "Information is Inevitably Physical". About 11 days ago at a session in Helsinki I complained to my audience: I have gotten a fair amount of acceptance for that phrase, but not for the message attached to it. But thanks for checking.

Thus you should cite either the *IEEE Spectrum* and/or the *Physics Today* articles of his. I don't know the exact sentences in those papers; for that you should probably get Danny to go to the library.

By the way, I really wish Rolf had said "information carriers are physical" instead of "information is physical" ... but I never got a chance to tell him that while he was alive.

09-09-02 *Dates and Talks* (to W. K. Wootters)

I think, it is best to assume that people will be trickling in on the 13th, and the events will start on the morning of the 14th. Let me make an executive decision: Events will start on the morning of the 14th. There.

I would like to reserve dinner with you, or you and Ben, for Oct. 13. Do you think we could do that? (I sure wish you had the time to stay longer.) I'd really like to get a chance to corner you on some of these Whitehead things.

On top of that, though, would you be willing to give the first talk of the meeting? Well, the first technical talk; Gilles or I will probably give some procedural talk/s before that. I would be particularly pleased if you would talk about your "private world within entanglement" ideas. And beyond that, I'd also be pleased if you would add a smattering of discussion about the Whitehead stuff. Even if you don't feel that these things are science yet—maybe just ideas for ideas—I think it would still be immensely useful for setting a tone for the meeting.

Moreover, can you dream up any concrete problems to share that are motivated by these points of view? That's your challenge.

10-09-02 *Tentative Talk Schedule for Commune* (to the Communards)

Chers Communards,

Below is a tentative schedule for talks at the commune. Not having an official title from any of you yet—you can't be blamed, I haven't asked for one—I decided to make up some titles of my own. Mostly the titles are a little whimsical, but they do reflect what I've found interesting in my conversations with you. (Thus, I guess I have a secret wish that you'll talk about these things.) But do feel free to talk about anything you want. Please send me a better title as you get a chance.

Also, further below you'll find the latest tabulation of attendance. If I've gotten anything wrong please let me know.

Soon I will send more detailed instructions for how to get from the hotels to the meeting site.

Looking forward to seeing you all soon.

Quantum Foundations in the Light of Quantum Information II
Montréal, Canada
October 13, 2002 – November 3, 2002

<u>Monday, Oct 14</u>

a) Gilles Brassard and/or Chris Fuchs
"Opening Remarks"
"Moment of Silence for the Paris Commune 1871"
"The Spirit of the Commune"

b) Bill Wootters
"Speculative Physics from Speculative Philosophy"

<u>Tuesday, Oct 15</u>

a) Nicolas Gisin
"Why Correlation?"

b) Dominic Mayers
"The Foundational Significance of Bit-Commitment and Coin-Tossing No-Go Theorems"

<u>Wednesday, Oct 16</u>

a) Charles Bennett
"Why I Feel It Important to Always Defend Many Worlds in Private, but Never in Public"

b) Patrick Hayden
"A Paper I Wrote Long, Long Ago with David Deutsch – Pro and Con"

<u>Thursday, Oct 17</u>

a) Hans Briegel
"The Quantum-Foundational Significance of Measurement-Based Models of Quantum Computation"

b) David Poulin
"What Do You Mean 'Simulating a Quantum Computation?"'

<u>Friday, Oct 18</u>

a) Stefan Wolf
"Intrinsic Information and Classical Analogs to Entanglement"

b) Problem session, roundtable, festival of outlandish ideas.

<u>Monday, Oct 21</u>

a) Chris Fuchs, 10:30 AM
"The End of the World as We Know It: Doing Quantum States and Quantum Time Evolutions on a Simplex"

b) Gilles Brassard, 3:15 PM
"Quantum Computing without Entanglement"

<u>Tuesday, Oct 22</u>

a) Rob Spekkens, 10:30 AM "In Defense of the View that Quantum States Are States of Knowledge"

b) Adán Cabello, 3:30 PM
"All the Latest on Kochen-Specker, and Why It's Important"

<u>Wednesday, Oct 23</u>

a) Rüdiger Schack, 10:30 AM
"Exorzismus der objektiven Quantenoperationen"

b) Howard Barnum, 3:30 PM
"Quantum Information Processing and Quantum Logic, Toward Mutual Illumination, … or How I Became a (Closed, Convex, Pointed) Conehead"

<u>Thursday, Oct 24</u>

a) Jeffrey Bub, 10:00 AM
"Characterizing Quantum Theory in Terms of Information-Theoretic Constraints"

b) John Smolin, 1:35 PM
"Another Excuse to Say 'Lock Box'"

c) Ben Schumacher, 3:30 PM, departmental colloquium
"Reversible Computation and Demonic Thermodynamics"

Friday, Oct 25

a) Claude Crepeau, 10:30 AM
"Quantum Authentication and Codes Correcting more than N/4 Arbitrary Errors: A Possible Key to Quantum Foundations"

b) Ernesto Galvao, 3:35 PM
"What a Single Qubit Gives Us"

c) José, 4:20 PM
"A Result in Quaternionic Quantum Mechanics"

Monday, Oct 28

a) Lucien Hardy, 10:30 AM
"The Classical and Quantum State Change Rules are the Same"

b) Roberto Floreanini, 3:05 PM, just after coffee
"Entanglement and Complete Positivity in Open System Dynamics"

Tuesday, Oct 29

a) Carlton Caves, 10:30 AM
"The Point Fuchs Keeps Failing to Appreciate"

b) Marcus Appleby, 3:05 PM, just after coffee
"The Man Who Mistook His Wife for a Hat, or Nullification of the Nullification"

Wednesday, Oct 30

a) Chris Timpson, 10:30 AM
"Claude Shannon Was Smarter Than You Might Think: Quantum Mechanics Can't Stop His Information Measure"

b) Fotini Markopoulou, 3:30 PM
"What Can Quantum Information Do for Quantum Gravity and Quantum Cosmology, and What Can They Do for Quantum Information?"

Thursday, Oct 31

a) David Mermin, 10:00 AM
"Poetry without Poetata"

b) Ben Schumacher, 3:05 PM
"Checklist of What I DO NOT Find Compelling in any Quantum Interpretations To Date"

Friday, Nov 1

a) Problem session, roundtable, workshop of outlandish ideas.

10-09-02 *Don't Forget Your Problem Sets* (to the Communards)

Chers Communards,

This time I am writing briefly to remind you that Gilles and I would like you to dream up a set of concrete problems to share with everyone at the meeting. It would be so nice to see everyone playing, having fun, and perhaps a few collaborations spark up in the process. By my count, the problems from the last Montréal meeting led to at least four published papers.

To give you a feel for the sorts of things we are thinking of—the level of difficulty, etc.—below I place a write-up of the problems I myself presented at the last meeting. (Some of them are still unsolved.)

Let's make this a great meeting! It's mostly in your hands.

"Problems Based on Information-Disturbance Foundation Quest," 15 May 2000

I hope you've had a chance to think about the request Gilles and I made in our invitation letter: namely, to compile a list of concrete problems whose solutions might shed some light on the foundations of quantum theory. What we were thinking in particular is that no point of view about quantum foundations is worth its salt if, at this stage, it doesn't raise as many questions as it answers. Why should we buy into a point of view if it doesn't lead to more fun or, at the very least, something more concrete than a stale philosophical satisfaction?

With that in mind, I've decided to grease the gears a bit by giving you a preview of some of the problems motivated by my particular ish-ism. If you haven't yet created a set of your own problems (based on your ish-ism of course), I hope this will give you a flavor of what we were thinking when we made our request. Certainly the more varied the sets of problems everyone brings, the greater the chance we have for making some real progress!

The point of view I'm likely to represent at our meeting is, I think, best captured (though perhaps a little flamboyantly) by a manifesto I wrote a couple of years ago. Let me reproduce that here as an introduction and motivation to the problems that follow.

Genesis and the Quantum

> In the beginning God created the heaven and the earth. And the earth was without form, and void; and darkness was upon the face of the deep. And the Spirit of God moved upon the face of the waters. And God said, Let there be light: and there was light. And God saw the light, that it was good; and God divided the light from the darkness. And God called the light Day and the darkness he called Night. And the evening and the morning were the first day. ... [And so on through the next five days until finally ...] And God saw everything that he had made, and behold, it was very good. And there was evening and there was morning, a sixth day. Thus the heavens and the earth were finished, and all the host of them.

But in all the host of them, there was no science. The scientific world could not help but *still* be without form, and void. For science is a creation of man, a project not yet finished (and perhaps never finishable)—it is the expression of man's attempt to be less surprised by this God-given world with each succeeding day.

So, upon creation, the society of man set out to discover and form physical laws. Eventually an undeniable fact came to light: information gathering about the world is not without a cost. Our experimentation on the world is not without consequence. When *I* learn something about an object, *you* are forced to revise (toward the direction of more ignorance) what you could have said of it. It is a world so "sensitive to the touch" that—with that knowledge—one might have been tempted to turn the tables, to suspect a priori that there could be no science at all. Yet undeniably, distilled from the process of our comparing our notes with those of the larger community—each expressing a give and take of someone's information gain and someone else's consequent loss—we have been able to construct a scientific theory of much that we see. The world is volatile to our information gathering, but not so volatile that we have not been able to construct a successful theory of it. How else could we, "Be fruitful, and multiply, and replenish the earth, and subdue it?" The most basic, low-level piece of that understanding is quantum theory.

The *speculation* is that quantum theory is the unique expression of this happy circumstance: it is the best we can say in a world where *my* information gathering and *your* information loss go hand in hand.[38] It is an expression of the "laws of thought" best molded to our lot in life. What we cannot do anymore is suppose a physical theory that is a direct reflection of the mechanism underneath it all: that mechanism is hidden to the point of our not even being able to speculate about it (in a scientific way). We must instead find comfort in a physical theory that gives us the means for describing what we can *know* and how that *knowledge* can change (quantum states and unitary evolution). The task of physics has changed from aspiring to be a static portrait of "what is" to being "the ability to win a bet."

This speculation defines the larger part of my present research program.

A. Some Concrete Problems

Problem #1: Pre-Gleason, or Why Orthogonality?

Andrew Gleason's 1957 theorem is an extremely powerful result for the foundations of quantum theory. This is because it indicates the extent to which the Born probability rule and even the state-space structure of density operators are *dependent* upon the theory's other postulates. Quantum mechanics is a tighter package than one might have first thought.

The formal statement of the theorem runs as follows. Let $\mathcal{H}_d$ be a (complex or real) Hilbert space of dimension $d \geq 3$, and let $\mathcal{S}(\mathcal{H}_d)$ denote the set of one-dimensional projectors onto $\mathcal{H}_d$. We shall suppose that whatever a "quantum measurement" is, it always corresponds to some complete orthogonal subset of $\mathcal{S}(\mathcal{H}_d)$. Particularly, within each such orthogonal set, the individual projectors are the theoretical expressions for the possible outcomes of the measurement associated with it.

Assume now that it is the task of the theory to assign probabilities to the outcomes of all conceivable measurements. Suppose all that we know of the way it does this is the following: There exists a function

$$p : \mathcal{S}(\mathcal{H}_d) \longrightarrow [0,1] \tag{30}$$

such that

$$\sum_{i=1}^{d} p(\Pi_i) = 1 \tag{31}$$

whenever the projectors Π_i form a complete orthonormal set. It might seem a priori that there should be loads of functions p satisfying such a minimal set of properties.

[38] Why is that a happy circumstance? Because it implies in part that the book of Nature may not yet be a written product. "The world can be moved."

But there isn't. Gleason's result is that for any such p, there exists a density operator ρ such that

$$p(\Pi) = \mathrm{tr}(\rho\Pi) \ . \tag{32}$$

In words, Gleason's theorem derives the standard Born probability rule *and*, in the process, identifies the quantum state-space structure to be the density operators over $\mathcal{H}_d$. Moreover, he gets this from assumptions that are ostensibly much weaker than either of the end results. This theorem is quite remarkable in that it requires no further conditions on the class of allowed functions p beyond those already stated. In particular, there is not even an assumption of continuity on the functions p.

A question on my mind is to what extent, if any, does the structure of this theorem support an information-disturbance foundation for quantum mechanics? I think this might be fruitfully explored by thinking in the following way. The assumptions behind Gleason's theorem naturally split into two pieces. (A) The questions that can be asked of a quantum system *only* correspond to orthogonal projectors onto $\mathcal{H}_d$. A consequence of this is that there is no good notion of measuring two distinct questions simultaneously—that is, there is no good notion of an AND operation for two measurements. And (B), it is the task of physical theory to give probabilities for the outcomes of these questions, and we can say at least this much about the probabilities: They are *noncontextual* in the sense that, for a given outcome, it does not matter which physical question (i.e., which orthogonal set) we've associated it with. This is the content of the assumption that the probability rule is of the form of a "frame function" (a function satisfying Eqs. (30) and (31)).

It seems to me that the first assumption to some extent captures the idea that information gathering is invasive. If you gather some information and I gather some other information, there is no guarantee that we can put the two pieces of information into a consistent picture: my information gathering has disturbed the relevance of the information you've already gathered. The second assumption, however, appears to be more of the flavor that nevertheless such information gathering is not *too* invasive. For otherwise one might imagine the probabilities for a measurement's outcomes to depend upon the full specification of the orthogonal set used in its definition. The Born probability rule clearly has a much weaker dependence on the measurement than it might have had.

A question whose answer could bolster (or discourage) this point of view is the following. Why is the invasiveness of quantum measurement specifically captured by identifying measurement outcomes with orthogonal sets of projectors? Hilbert space has a lot of structure; why single out precisely the orthogonal projectors for defining the notion of measurement? To get a handle on this, we could try to see how it might have been otherwise.

As a wild example, consider an imaginary world where quantum measurements are not only associated with orthogonal projectors, but with the projectors onto *any* complete linearly independent set of vectors. This would be a notion of measurement that made use solely of the linear structure of $\mathcal{H}_d$, eschewing any concern for its inner product. What kinds of probability rules can arise for such a notion of measurement? In particular, can one have an interesting "noncontextual" probability rule in the spirit of Gleason's theorem? More precisely, what kind of functions p can satisfy Eqs. (30) and (31) but with the summation in the latter equation satisfied for any linearly independent set?

Well, it's not hard to see that the only noncontextual probability rule that works for all "measurements" of this kind would have to be the trivial probability assignment of $1/d$ for each outcome, no matter what the measurement. To give an example of how to see this, visualize three linearly independent unit vectors v_1, v_2, and v_3 in R^3 and imagine assigning them probabilities p_1, p_2, and p_3. Hold v_1 and v_2 fixed and rotate the third vector whichever way you wish. As long as it doesn't fall on the two lines spanned by v_1 and v_2, then the projector associated with it must always be assigned the same probability, namely p_3. Now do the same thing with vector v_2, holding v_1 and v_3 fixed. This will make almost all vectors on the unit sphere associated with projectors of probability p_2, proving that $p_2 = p_3$. Finally, one does the same trick with v_1, proving that $p_1 = p_2 = p_3 = 1/3$.

The lesson is simple: if every linearly independent complete set of vectors in $\mathcal{H}_d$ constituted a measurement, one could not hope to retain a noncontextual probability assignment for measurement outcomes without making the world an awfully dull place!

But maybe this version of the game is just too dumb. So, let's try to spice it up a bit by explicitly using the inner product structure of $\mathcal{H}_d$, but in a nonstandard way. Again consider R^3, the smallest Hilbert space on which Gleason's standard theorem can be proved. Suppose now that a "measurement" corresponds to any three vectors with a fixed angle relation between themselves. What I'm thinking of here is to start with three vectors v_1, v_2, and v_3 whose angles (moving around them cyclically) are α, β, and γ. Now rigidly rotate that structure in all possible ways to generate all possible measurements. Are there any interesting *noncontextual* probability rules—again in the spirit of Gleason—that one can associate with this notion of "measurement?"

Here I don't know the answer. But I do know of some special cases where one again gets only the trivial assignment $p_1 = p_2 = p_3 = 1/3$. For instance, take the cases where $\alpha = \beta = \gamma$ and α is such that if we rotate around v_1, v_2 will fall back upon itself after an odd number of "clicks"—what I mean by a click here is rotating v_2 into v_3 and so on ... click, click, click. What happens if we run through such a "clicking" process? Well, v_1 must be constantly associated with the same probability value p_1 by the assumption of noncontextuality. But then by that same assumption, as v_2 rotates into the old v_3, it must pick up the probability p_3. And so on it will fluctuate up and down: p_2, p_3, p_2, p_3 ... until it finally falls upon its original position. If this happens in an odd number of clicks, then it will have to be the case that $p_2 = p_3$ or the assumption of noncontextuality would be broken. Similarly we can see that the whole circle generated by rotating v_2 and v_3 around v_1 must be "colored" with the same probability value. Finally, run through the same process but by rotating about the vector v_2. This will generate a second circle that intersects with the first. From that and the assumption of noncontextuality, it follows that $p_1 = p_2 = p_3 = 1/3$ and this will be true of any triad by the very same argumentation.

Another case where one can see the same effect is in the single qubit Hilbert space C^2. There the game would be that any two vectors with a fixed angle α between them would constitute a measurement. Thinking about the Bloch-sphere representation of C^2, one can use the argument similar to the one above to see that whenever $\alpha \neq 90°$ the only possible noncontextual probability assignment is $p_1 = p_2 = 1/2$ for all possible measurements.

Conjecture 1: *In the case of R^3, whenever one of the angles α, β, or γ is not identically $90°$, then the only possible noncontextual probability assignment for measurements* *outcomes will be the trivial one* $p_1 = p_2 = p_3 = 1/3$.

How to tackle such a problem? I think it may not be too hard actually, especially if one assumes that the noncontextual probability assignments, whatever they are, must be continuous functions. The starting point would be to try to trace through Asher Peres's derivation of the standard Gleason theorem in his textbook. There, something will surely fail when one looks at the expansion of the proposed "frame functions" in terms of spherical harmonics. (I hope someone will bring Asher's book with them to the meeting: I would bring mine, but I don't have it anymore.)

What's to be learned from this problem? I'm not quite sure, but I think mostly it will help reinforce the idea that our standard notion of quantum measurement is not simply an arbitrary structure. It's there for a reason, a reason we still need to ferret out.

Problem #2: Wootters Revamped with POVMs.

Bill Wootters in his Ph.D. thesis explored an alternative derivation of the quantum probability rule. His work was based on the hope that it could be obtained via an extremization principle much in the spirit of the principle of least action in classical mechanics. (I believe he may talk about this very problem at the meeting.) The quantity extremized was the Shannon information a measurement reveals about a system's preparation, under the assumption that one has many copies of the system all with identical measurements.

Specifically the scenario was this. Consider a *real* Hilbert spaced of dimension d and a fixed orthogonal basis within that space. One imagines that one has possession of N copies of a quantum system with that Hilbert space, all with precisely the same quantum state $|\psi\rangle$. Which quantum state? One drawn randomly with respect to the unique unitarily invariant measure on the rays of $\mathcal{H}_d$, only one doesn't know which. The fixed orthogonal basis represents a measurement that one will perform on the separate copies in an attempt to ascertain the unknown preparation.

[**NOTE:** *Here, through the remainder of this problem set, the words were thrown together hurriedly after the fire.*]

Anyway, Bill's attempt of a derivation didn't really work so nicely for complex Hilbert spaces. The question here is, can we make it work after all, if we start thinking of POVMs as a primitive notion of measurement in its own right.

Specifically, the first thing we must ask is does there always exist an informationally complete set of rank-one POVM elements all of equal weighting on $\mathcal{H}_d$. And it might be even nicer if that set could taken to have precisely d^2 elements. That is, for each d, does there exist a set of d^2 projectors $|b\rangle\langle b|$ and a positive number g such that

$$g \sum_{b=1}^{d^2} |b\rangle\langle b| = I \ ? \tag{33}$$

We know that there does exist such a set if $d = 2$ or $d = 3$. When $d = 2$, just take any four states corresponding to the vertices of a regular tetrahedron on the Bloch sphere. For the case $d = 3$, Bill has explicitly worked out an example that perhaps he can remind us of. Also I remember some vague murmurings by Armin Uhlmann that "of course" they exist in all dimensions. But still, we should treat the existence in all d as an open question—I'm not sure how much of Armin's talk was statement of known fact, how much was conjecture, and how much was faith.

If such a set exists always, then we can ask of it precisely the same question that Bill did in his thesis. Assume we don't yet know the quantum probability law: we only know that there is some function f for which the probability p_b is given by

$$p_b = f(|\langle\psi|b\rangle|^2) \tag{34}$$

when the system's "unknown" preparation is $|\psi\rangle$. What function f extremizes the information we gain about $|\psi\rangle$ when we have only one copy of the system available? What function f extremizes the information when we have a very large number of copies available?

What does this have to do with my manifesto? Perhaps nothing. But I have always felt that Bill's attempt at derivation was missing something in that nowhere in it did it make use of the idea that quantum measurements are invasive beasts: it talked about information, but it didn't talk about disturbance. If Bill's derivation does turn out to work nicely by the addition of POVMs, then maybe that will be some motivation for me to rethink my ish-ism.

Problem #3: Post-Gleason, or Should I Think von Neumann Is Special?

For a long time, I have disliked the tyranny of thinking of von Neumann measurements as more fundamental than other POVMs. Here's a question that might break some of that orthodoxy.

Suppose such a set of informationally complete POVMs as described in the last problem exists. Let us think of the class of all "primitive" measurements on $\mathcal{H}_d$ as those that can be gotten from acting the unitary group on that set. For instance, for a single qubit, the primitive measurements would correspond to all possible regular tetrahedra draw on the Bloch sphere.

Let us now imagine a notion of "frame function" as in Problem #1 for these kinds of measurements.

Question 1: Is there a Gleason-like theorem for these structures? And in, particular does the extra freedom of having d^2 outcomes to play with simply the proof of Gleason's result?

Question 2: By use of the Church of the Larger Hilbert space, can we construct an arbitrary POVM with this notion of primitive measurement. That is, is there a kind of Neumark extension theorem for this notion of measurement?

Problem #4: Where Did Bayes Go?

From my point of view, quantum states are best interpreted as states of knowledge, not states of nature. Quantum mechanics is **mostly** a "law of thought" in that it provides a firm method of reasoning and making probabilistic estimates in light of the fundamental **physical** situation that the world is "sensitive to our touch."

With that in mind, I have to ask myself why doesn't wavefunction collapse look more like Bayes' rule for updating probabilities under the acquisition of new information. Recall Bayes' rule for when we acquire some data D about a hypothesis H:

$$P(H|D) = \frac{P(H)P(D|H)}{P(D)}\ . \tag{35}$$

On the other hand, when we perform an efficient POVM $\{E_b\}$ and find outcome b, we should update our quantum state ρ according to

$$\rho \longrightarrow \tilde{\rho}_b = \frac{1}{p_b} U_b E_b^{1/2} \rho E_b^{1/2} U_b^\dagger \;, \tag{36}$$

where U_b is some unitary operator and $p_b = \mathrm{tr}\rho E_b$.

Forgetting about the unitary U_b for the present discussion, notice the difference in expression of these two "collapse" rules. Bayes' rule involves states of knowledge alone: it is constructed solely of probabilities. Quantum collapse, on the other hand, appears to involve two distinct kinds of entities: density operators and POVMs. Can we put it into a form more reminiscent of Bayes' rule and perhaps learn something in the process.

Here's one way that I think might be fruitful. For each density operator ρ and each POVM $\{E_b\}$, we can construct a canonical decomposition or refinement of ρ: just multiply the equation $I = \sum E_b$ from the left and the right by $\rho^{1/2}$. We get,

$$\rho = \sum_b p_b \rho_b \;, \tag{37}$$

where

$$\rho_b = \frac{1}{p_b} \rho^{1/2} E_b \rho^{1/2} \;. \tag{38}$$

Note that with this, and just a little bit of algebra, we can rewrite the collapse rule (again forgetting about the U_b) to be

$$\tilde{\rho}_b = \rho^{-1/2} \left(\rho^{1/2} \sqrt{\rho^{-1/2} \rho_b \rho^{-1/2}} \rho^{1/2} \right)^2 \rho^{-1/2} \tag{39}$$

This expression is, I think, quite intriguing. This is because it turns that the quantity in the large parentheses above,

$$G(\rho_b, \rho) \equiv \rho^{1/2} \sqrt{\rho^{-1/2} \rho_b \rho^{-1/2}} \rho^{1/2} \tag{40}$$

has been characterized independently in the mathematical literature before. It appears to be the most natural generalization of the notion of "geometric mean" from positive numbers to positive operators. Here are some references:

1. W. Pusz and S. L. Woronowicz, "Functional Calculus for Sesquilinear Forms and the Purification Map," Rep. Math. Phys. **8**, 159–170 (1975).
2. T. Ando, "Concavity of Certain Maps on Positive Definite Matrices and Applications to Hadamard Products," Lin. Alg. App. **26**, 203–241 (1979).
3. F. Kubo and T. Ando, "Means of Positive Linear Operators," Mathematische Annalen **246**, 205–224 (1980).
4. M. Fiedler and V. Pták, "A New Positive Definite Geometric Mean of Two Positive Definite Matrices," Lin. Alg. App. **251**, 1–20 (1997).

Can someone bring these references? As you know, my copies don't exist anymore. (If you only have time to copy one, perhaps the last one is best ... as it gives a large summary of all things known. Jozsa may be most interested in the first reference by Pusz and Woronowicz. Kubo and Ando would be the third most useful.)

Something fun to do is to rewrite the classical Bayes' rule in a similar form as this revamped quantum rule. Indeed the standard geometric mean crops up in precisely this way. Now try to further the analogy if you can.

One possible fact I seem to recall is that the operator geometric mean can be characterized in the following way. Start with ρ_b and ρ and consider the following matrix, where X is also a positive semidefinite matrix:

$$\begin{pmatrix} \rho & X \\ X & \rho_b \end{pmatrix} \tag{41}$$

Then $X = G(\rho_b, \rho)$ is the matrix that maximizes the above matrix in the sense of making it as large as it can be in the standard matrix ordering sense.

Can we learn something about why the collapse rule takes the form it does from this exercise. (Perhaps Jeff Bub can give us an introduction to his other characterization of the Lüders collapse rule.)

B. Some Not-So Concrete Problems

Proto-Problem #1: Computing Power vs. Error Correctability.

We know (suspect) that quantum computing gives us a speed up over classical computing. But we also know that we have to strain slightly harder to get error correction and fault tolerance for it. Imagine now the set of all computational models (whatever that might mean). Within that set will be both classical computing and quantum computing, but also a lot of other things. Could it be the case that quantum computing hits some kind of happy medium, the one where the ratio of speed-up to error correction resources is best? (You can see that this is directly motivated by my parable: could the speed-up of quantum computing be due to this world's wonderful sensitivity to our touch?)

Proto-Problem #2: Entanglement Monogamy and Schrödinger's Insight.

Can we think of a way of viewing quantum entanglement as a secondary effect? The primary effect being information disturbance tradeoff. Let me just cut and paste an old email here. [See the note to Todd Brun, titled "Information Theoretic Entanglement," dated 8 June 1999, and the note to Howard Barnum, titled "It's All About Schmoz," dated 30 August 1999.]

Proto-Problem #3: Down with Beables, Up with Dingables.

Quantum logicians (and presumably Jeff Bub), like to think that quantum mechanics is about "what is," i.e., beables not observables (a phrase coined by Bell). The only way they can do that is by introducing a kind of logic about the "facts of the world" that is different from our usual logic of AND, OR, and NOT. I, on the other hand, like to think that that kind of change of logic is a strong indicator that we just can't get a notion of a "free-standing reality" within physics.

So the question on my mind is what kind of algebraic structure (if any) does my parable indicate/motivate for a purely algebraic approach. I've already said, I don't think AND makes any sense at all in such a world. Do the other notions from standard logic still make sense though?

I realize, I've left too much vague in this question. Talk to me at the meeting.

Proto-Problem #4: Intrinsic Characterization of Complete Positivity.

I really don't like the Church of the Larger Hilbert space. Let's see how far we can get toward CPMs and POVMs without ever having to assume it. Is there a physically motivated criterion for CPMs that makes no reference to the Church.

Proto-Problem #5: Doing Gleason with Algebraic Numbers.

Problem motivated by Bennett remark. Recently Pitowsky and Meyer have raised some interesting questions about Gleason's theorem when the number field of quantum mechanics is restricted to the rationals. It might be useful for our understanding of QM to ferret out what is essential and what is not in its formulation. Cabello and Peres completely discount Pitowsky and Meyer because their world has no superposition principle. But who cares? Well, maybe if Gleason still works in the minimal world with a superposition principle (i.e., algebraic number fields), we should think harder about the meaning of the "superposition principle."

Proto-Problem #6: Challenge to Everettistas.

- Would your interpretation still work if the number field of $\mathcal{H}_d$ were the reals instead of the complexes? If it were the rationals instead?
- Would your interpretation still work if the time evolution of the universe as a whole were nonlinear instead of unitary?
- Would your interpretation still work if the collapse rule of QM were anything different from the standard one?
- Would your interpretation still work if _______? [You fill in the blank, challenge yourself.]

I understand that I'm being belligerent, but I *suspect* your answers to each of these will be "yes." Cf. Any of David Lewis philosophical works on the modal logics and the plurality of worlds, or Max Tegmark's paper `gr-qc/9704009`, "Is the 'theory of everything' merely the ultimate ensemble theory?" The tentative conclusion I draw from this is that the Everettista has a contentless interpretation.

12-09-02 *The Copenhagen Interpretation* (to C. King)

I'm in Copenhagen at the moment and will be here until next Tuesday. I'm giving two talks in the Math department—one tomorrow and one Monday—and then I've got an appointment at the Niels Bohr Institute Monday afternoon. With some luck, there's a chance I'll get to talk to Niels Bohr's son Aage (Nobel prize sometime in the 1950s or 60s). He's recently turned his attention to quantum foundations. In any case, I'm definitely talking with his collaborator Ole Ulfbeck. If the Bohr thing comes through, I'll call this my best vacation ever!

17-09-02 *Wow!* (to G. Brassard)

Wow, read this introduction to Appleby's paper!!!! You've just got to tell me that we can have him at the meeting (and pay his way if need be)! (I feel like a kid in a toy store, screaming, "Daddy, daddy, I've just got to have that toy!")

Introduction

The stimulus for this talk came from a number of conversations with Chris Fuchs about his information-theoretic approach to the interpretation of quantum mechanics (include references).

Fuchs starts from the position that the quantum state simply is a probability distribution[39]: that, and nothing more whatever. He also takes a radically Bayesian approach to the interpretation of probability[40]. According to him the quantum state has a *purely* subjective significance: it simply represents one's expectations (or beliefs, or gambling commitments) regarding the outcome of a measurement. On these assumptions the collapse of the wave-function is no more remarkable than the collapse of a classical probability distribution when new information is acquired—no more remarkable than, for example, the probability of a coin landing heads being 1/2 before the toss, but either 1 or 0 afterwards.

Of course, this proposition, that the wave-function should not be interpreted as an objectively real entity, is the starting point of the Copenhagen Interpretation. So it might appear from the above that Fuchs is proposing nothing very new. However, I think that that would be wrong. It seems to me that Fuchs's programme is best described as an attempt to reinvigorate the Copenhagen Interpretation. To breathe new life into the old bones. The qualification is crucial. If Fuchs's hopes were fulfilled—indeed, if his hopes were only half-fulfilled—the consequences would, I think, be revolutionary.

The term "Copenhagen Interpretation" , as it has previously been understood, is not very sharply defined. To begin with, it isn't really a single interpretation at all. Rather it is a family of interpretations, held together by certain common features. Moreover, even if one focuses on a particular variant, one finds numerous obscurities. The writings of Bohr, in particular, are notoriously difficult to follow.

If I have understood him correctly Fuchs would argue that what is contained in the work of the Copenhagen school is, not so much a completed interpretation, more a project: a direction of thought which, if pursued with sufficient determination, might eventually *lead* to a satisfactory understanding of what quantum mechanics is really telling us. Unfortunately, the programme which they initiated, during the heroic age of the subject, has languished ever since.

Fuchs suggests that if we were really to follow through on the basic insights of the Copenhagen school it might have major implications, not just for our philosophical understanding, but on an empirical level. As he puts it

> I have this "madly optimistic" (Mermin called it) feeling that Bohrian-Paulian ideas will lead us to the next stage of physics. That is, that thinking about quantum foundations from their point of view will be the beginning of a new path, not the end of an old one. (samizdat, p. 173)

I find these ideas deeply interesting. I share Fuchs's feeling that the present situation in quantum foundations is one of "impasse". His programme excites in me the hope that this could be a way to break out of the sterile circle.

[39]Specifically: it is the probability distribution for the outcomes of an informationally complete (generalized) measurement.

[40]The interpretation of probability gives rise to almost as many conflicting views as does the interpretation of quantum mechanics. So saying that the wave-function simply is a probability distribution is not yet a complete answer. It is also necessary to say what a probability distribution is—which is not so easy (at least, it does not seem easy to me).

Before becoming acquainted with Fuchs's ideas I was definitely not an adherent of the Copenhagen philosophy[41]. It was not so much that I disagreed with the Copenhagen Interpretation. I could not get as far as that. I felt that it was not sufficiently clear for me to be able to tell whether I agreed or disagreed. In other words, I took the same view as Bell: the Copenhagen philosophy struck me as "unprofessionally vague and ambiguous" (*Speakable*, p. 173). The degree of vagueness and ambiguity is, in places, such that agreeing to these propositions would be like signing a blank cheque: you might be committing yourself to almost anything (I think Beller scores some palpable hits in this respect).

However, Fuchs's ideas have caused me to revise this assessment. It is not, let me hasten to say, that, where I formerly saw vagueness and ambiguity, I now see sharpness and rigorous exactitude. On the contrary: the Copenhagen Interpretation remains, in my view, as obscure as ever it was. And I continue to think that this means it cannot be seen, in the way Bohr and others wanted it to be seen, as the terminus of all intelligible thought on the subject. If, however, one looks at it from the standpoint Fuchs suggests, not as a *finish*, but as a *start*—not as a completed interpretation, but as a project—then the ideas of the Copenhagen School appear much more interesting. What I had not properly appreciated, before reading Fuchs, was the extent to which my rejection depended on the claim to complete finality. If one subtracts this claim—if, instead of regarding Bohr as the voice of unimpeachable authority[42], one merely sees him as someone groping toward ideas which he himself did not adequately comprehend—then I think one can easily acknowledge, without doing any damage to one's logical conscience, that there is much in Bohr's writings which is deeply suggestive. Seen in this light the obscurities in Bohr's account may appear, less as grounds for rejection, more as a challenge. One may be stimulated to think that, concealed among the obscurities, there could be the germs of something cogent, which it might be worth one's while to try to ferret out.

Reading Fuchs has not persuaded me of the basic correctness of the Copenhagen philosophy. It has not even persuaded me of the correctness of a kind of neo- or revitalized Copenhagenism. Such a statement of belief would, in the circumstances, be premature. In any case, it seems to me that, if history shows anything, it shows that we ought to be extremely cautious about making unreserved commitments at the level of basic concepts. Like Fuchs, I do not believe in final theories.

However, what I am persuaded of is that Fuchs has opened up an extremely interesting line of thought, which deserves to pursued very seriously. I do not know where his programme will lead. But even if it does not lead in precisely the direction he now envisages, I feel it promises to take us significantly further forward.

17-09-02 *No-Cloning* (to S. L. Braunstein)

Not only does he miss the full result, but there is a line in there where he actually gets it wrong. For the full story, see page 451 of my samizdat, `quant-ph/0105039`.

I'm in Heathrow at the moment, heading home from my first trip to Copenhagen. What a

[41]This is not to say that I preferred some other interpretation. I belonged to the school of the frankly perplexed, which does not pretend to know how quantum mechanics should be interpreted.

[42]Which, it would seem, is how he all too often was regarded, in the past. For a discussion of the "overpowering, almost disabling, impact of Bohr's authority", see Beller [add reference].

wonderful place! Copenhagen, that is.

17-09-02 *Wigner* (to S. L. Braunstein)

You still don't get it: Wigner actually gets it WRONG. There is a line in the paper where he says, (essentially) "all linear superpositions of living states must also be living states." That cannot be; that's the point of the no-cloning theorem. But he didn't even realize that he made a mistake.

19-09-02 *Chris's Blurb* (to R. Pike)

Steven van Enk is indeed a physicist. I don't know what I am: physicists tend to call me a mathematician, while mathematicians generally call me a physicist. Information theorists call me a philosopher. But I practice quantum information. Predominantly I have been interested in formalizing and quantifying the idea that information gathering causes a disturbance when it comes to quantum phenomena. That idea has steered me to several problems in the field, including: developing criteria for successful quantum teleportation, calculations in quantum channel capacity theory, work in quantifying quantum entanglement, and exploring novel notions of quantum nonlocality.

19-09-02 *Unsurprising Fact* (to N. D. Mermin)

Merminition 94: *Did you know that Bob Griffiths believes that within each and every one of his frameworks there is a "history that actually occurs"?*

Yes, I did. He says so quite explicitly in the *Scientific American* article (or was it *Physics Today*?) he wrote with Omnès. I talked with Omnès at length about it at the NATO meeting in Greece you sent me to a couple of years ago, picking particularly on this point.

I'm not sure whether I've told you this in the past, but I am convinced that the consistent historians do nothing beyond what (some interpretations) of Bohr already do. Focus for the moment on a SINGLE standard observable. If one considers that observable in isolation—i.e., without consideration of all other possible observables—then there is absolutely nothing to stop one from acting AS IF one of the values of the observable obtains and all the others don't. Where one runs into trouble (via Kochen-Specker, etc.) is if one tries to hold that view for all observables simultaneously. Now, what do the consistent historians do? Instead of playing the game above for a single standard observable they do it for a single so-called "consistent set of histories." But from my point of view, all a consistent set of histories is, is an arbitrarily singled-out kind of multi-indexed POVM. The point being, woop-ti-do! You give me *any* POVM, and there is nothing to stop me from acting *as if* one of its values obtain and all the others don't. I would only run into trouble (through KS, etc.) if I were to try to play this game for various noncommuting POVMs simultaneously. When Griffiths and company command that one cannot consider distinct sets of consistent histories simultaneously, all they are doing is what I could already have done with *any* POVM. There is nothing deep there.

19-09-02 *Black Sheep* (to A. Kent)

Kentism 4: *I think there's lots of interest to talk about in quantum foundations, and of course in quantum information, but I'm not at all sure that quantum information actually sheds any new light on the deeper problems of quantum foundations. Is this heresy tolerable?!?*

Tolerable, and in fact, maybe welcome. That can be your theme for the week and the subject of your talk. If you can defend it well, that'll surely lead to some good discussions.

20-09-02 *How's It Look?* (to R. Pike)

I just threw thing below together. I'm going to lunch now, but when I get back I'll put the finishing touches on (if there are finishing touches to put). Tell me what you think.

Employee Report on Activities and Accomplishments
Oct. 2001 – Sep. 2002

> This year has been another good one for science. I had eight articles going to press, all of them confirming the thread of thought that has become so important to me: the predominant structure of quantum information is automatically and deeply connected to the structure of Bayesian probability theory. Where the two structures differ is where one should look for the power of quantum information as an information-processing and communication resource. On the practical side, this has implications for understanding quantum information experiments performed with standard laser light, such as the quantum teleportation experiment performed at Caltech and more recently at the Australian National University.
>
> I consider two results my better ones of the year. The first had to do with the settling of a long drawn-out debate in the literature concerning the compatibility of quantum-state assignments made by different experimentalists with differing amounts or kinds of information about a single quantum phenomena. (This work is soon to appear in Physical Review A, co-authored with C. M. Caves and R. Schack.) The second had to do with the precise form of the quantum-state change rule under the gathering of experimental data. This phenomenon is normally mentioned in conjunction with the "von Neumann collapse postulate." Using a little-observed fact from linear algebra, I was able to express the collapse in a way that makes it look *almost* identical to standard probabilistic Bayesian conditionalization. This I believe sheds significant light on the process of quantum-state-change-through-measurement, and, consequently, as already alluded to, points toward the key ingredient in the power of quantum information processing. The evidence that the quantum information community also sees these efforts as shedding light can be found in the number of invitations to speak I have been given this year.
>
> I count having given 14 external invited talks this year. These talks have carried me to Japan, Ireland, Australia, Spain, Sweden, and Denmark, all at zero cost to Lucent. On the official-recognition side of things, I was awarded an (international) E. T. S. Walton Visitor Award by the Science Foundation Ireland, which would translate into a 20% increase in salary and substantial equipment and travel funds, if accepted. (Presently the award is being renegotiated into a small series of small visits.) I made three media appearances, via short interviews in *PC Magazine*, *PC Magazine Online*, and the book *The Best American Science Writing 2002*.
>
> Concerning general service to the physics community, I served as an Associate Editor for the Rinton Press journal *Quantum Information and Computation*, as a member of the Advisory Board for the International Center for Mathematical Modeling in Physics, Engineering and Cognitive Sciences at Växjö University, Sweden, and as a member of the Advisory and Award Committee for the Sixth International Conference on Quantum Communication, Measurement and Computing (QCMC'02). I co-organized an

international meeting *Workshop on Quantum Foundations in the Light of Quantum Information*, to be held at University of Montréal, October 13 – November 3 this year, co-edited a special issue of the journal *Studies in History and Philosophy of Modern Physics* devoted to quantum information and quantum computation, and mentored two visiting graduate students for DIMACS for six weeks this year.

As internal service goes, I mentored a summer intern for the SRP program, I gave two talks for Lucent customers, France Telecom and SBC, and attended the Army Research Office annual review of funding for quantum computation and quantum information to strengthen the ties between Bell Labs and government funding sources. Finally, I played a significant part in a lively visitor program of quantum information scientists of all walks to present their research to the Bell Labs community.

23-09-02 *Genuine Fortuitousness* (to H. J. Folse)

I haven't talked to you in a while. I was in Copenhagen last week, and I got a chance to meet with Ole Ulfbeck, who has recently written a quantum foundational paper with Aage Bohr titled "Genuine Fortuitousness: Where Did That Click Come From?" Have you seen it? If not, you can find it in Foundations of Physics **31**, 757–774 (2001).

In it, young Bohr makes a quite sharp turn around from his father's position. It's kind of a shame, and as I understand it all, not a system worked out to any great extent. Just wondering if you've got any opinions.

By the way, I noticed that you never submitted you Växjö paper to the `quant-ph` archive. I think you ought to do that since it is already written in LaTeX. If the concept frightens you, I could submit it for you; it's a rather easy procedure and would only take about 10 minutes of my time. (Though, of course it would be best if you did it, so as to retain control, etc.)

Henry's Reply

Right now Isidore is bearing down on New Orleans, so they've canceled classes and I have time to catch up on email. Sorry I didn't know you were in Copenhagen, I would be glad to provide an introduction to Jan Faye at Kobenhavns Universitetet, whose work you know. I've also been corresponding recently with Erik Rudinger who is teaching a course on Bohr, I presume at NBI, and who edited a lot of the Archives. He is a mine of Bohr information and I'd be glad to provide an introduction there as well.

Yes, I did have that Ulfbeck and A. Bohr article called to my attention. [...]

It definitely appears to me that this view rejects a big portion of Father Bohr's commitment to the reality of atoms and embraces an extreme anti-realist attitude which I, for one, do not attribute to Niels Bohr, though of course many others have indeed taken to be his view. But at the same time I do see a lot of bits of the father's ways of thinking poking through the mix. Niels constantly reflected on the theme of the limits of "space-time description" and in the period from 1913 to 1925 he wrote repeated bits and pieces with the title "Space-time Description" ("Rum-tids Beskrivelse," in Danish). In the end, i.e. by Como, he concluded it stood in a complementary relation to "the claims of causality." I think this period is very revealing precisely because there was then no formalism to reason from, and one had to think out experimental interactions (observations) physically, so to speak, without any mathematical algorithm to help (or worry about). Already in his 1913 model Niels *knew* that the electrons in an atom couldn't be considered as "real particles" in the classical sense. Talk about the electrons "orbiting" the nucleus was thus already then not to be taken in a classical realist sense. The discontinuity in change of state of atomic systems in an interaction between, as he put it, "radiation and matter" implied it was meaningless to ask whether the electron in one orbit before the "jump" was the same as the electron in a new "orbit" after the jump, and of course the attempt to trace the electron's spatio-temporal career through this interaction is explicitly forbidden. So Bohr concluded that talk about elementary particles as though they were the sorts of things that traced classical trajectories was used solely for its instrumental value in "interpreting" the interaction as a "measurement" determining some property of the "object" system. The interpretation of elder Bohr that I have defended is that he rejects regarding the citizens of the microdomain as realistically represented by "particle" or "wave" "pictures" (the "accustomed demands for visualizability"), but that he nonetheless regards such entities as *real* (not as instrumental fictions) because they are one of the interactors in the "indivisible" interaction with the observing instruments which provide the empirical evidence for the theory. Electrons, in short, are *real*, but they're not *really* particles (or waves, either).

Now U&B clearly reject the reality of particles in a more uncompromising way. I think this is a version of the class of interpretations you have categorized as "correlations without correlata," and they of course do refer to Mermin's article. (What did he think about U&B?) In philosophical jargon we would say it is a macrorealism combined with a micro anti-realism. "Clicks" are real; but electrons are just, as it were, "the set of all electron clicks." Of course they're able to dispense with any commitment to a microreality only by paying a very high price in insisting that the occurrence of such clicks is "genuinely fortuitous." Immediately after defining this phrase, they write: "What makes the click 'irrational' is seen to be that the variable, which manifests itself by the click, never enters spacetime." (p. 762) (The reference 'irrational' struck me because Father Bohr was fond of saying "the quantum postulate with its inherent irrationality" which a lot of people completely misunderstood in a positively perverse way.) Now this seems to me to be a very strange way of speaking; indeed, I get the feeling that their "genuine" fortuitousness, isn't so genuine after all.

We are supposed to undercut any problems with crossing the bridge from the formalism to the physics because "matrix variables" never "enter spacetime." However, when they "manifest themselves" in spacetime, they do so with good old fashioned classical single valued measured outcomes. It all sounds quite ghostly: if I am told "poltergeists never enter spacetime but they manifest themselves by making noises and making doors creak open" then I understand this to mean they are non-physical (out of spacetime) *causes* for physical (empirically observable) effects. Thus it seems to me that they're really just *saying* the "click" is "genuinely fortuitous" but at the same time talking about how it is "caused" by the "manifestation" of a "matrix variable" when it "enters" spacetime. Talk of "variables" of course originally was a way of talking about *properties* of macrophysical real entities which were functions of time. Now it seems that matrix variables are a way of talking about properties of outside-of-spacetime entities (aka "atomic systems" or "systems in quantum mechanical states"). If clicks are real, they are the "manifest*ed*," but if the manifest*ed* are real, that implies the reality of a manifest*or*, the thing being "manifest*ed*" when it "enters" spacetime. So what began as an anti-realist ontological minimalism (only click events are real) blossoms into a whole 'nother "reality" which is characterized by "matrix variables" in a way somehow analogous to the way old time classical reality was characterized by single valued variables. We see only the surface of the pond, but the bubbles and eddies on its surface are the manifestations of the doings of submerged beings beneath that spacetime surface. I expect U&B would reject that, and say that's only a way of speaking to say that "clicks" are such "manifestations," but the point is that it is damn hard to do physics when you stop talking about "causes," and the temptation always lurks to simply paper over the problem with an alternative locution. [Kant for example, forbad any application of the category of "causality" transcending the phenomenal, empirical world. But at the same time, in order to cling to realism and not cave into idealism, he wanted to see these phenomena as the "manifestations" of "things-in-themselves" not experienced but necessarily "posited" by the cognizing subject. He realized, of course, he couldn't say "noumena *cause* phenomena" so instead he started talking about the noumenon as the "ground" of the phenomenon. But everyone saw this as a transparent ploy to circumvent the strictures on "causality," and in point of fact in history philosophy did cave in to idealism.]

The same things happens when U&B talk about "associating" one set of "source clicks" with another set of "measurement clicks" in the case of alpha decay of uranium. (They also use expressions like "give rise to," etc.) The phenomenon of "alpha decay" manifested in our macro-surface-of-the-pond world of spacetime refers to, we are told, a certain distribution of clicks. With that phenomenon we *associate* another set of macro clicks which we refer to as the phenomenon of "a lump of pure uranium turning into half thorium after half-life t." But if "causes" is treated as "constant conjunction in time" we have in effect just said the uranium's transmutation into thorium is the cause of the alpha radiation. Moreover, we must still make use of particle pictures in designing the "clicker" as a detector of the sort of "particles" we are looking for, a fact which the elder Bohr certainly would have stressed in his talk about interaction. We can know of causal connections quite independently of knowing anything about the mechanism by which such connections are affected, or indeed if there be any mechanisms at all. We knew sexual intercourse causes babies long before we knew any biology. All U&B have really professed here seems to me to be that uranium decay causes emission of alpha particles, but we don't know the mechanism by which it is accomplished, and we do know whatever it might be it isn't a classical one capable of being predicted deterministically. Instead we speak of these processes using the language of "manifesting," "entering spacetime," "giving rise to," etc. So it seems, when all is said and done, quantum mysteries abide. If this be demystification, it seems more like demystification by *fiat*, rather than one earned by explaining the mysteries. Not that this does not happen in the history of physics.

You might be interested to learn that the biennial meeting of the Philosophy of Science Association this coming November features no less than two sections on Bohr and the Copenhagen Interpretation, one of which is chaired by Jeff Bub, whom you know, of course. The other is devoted to Mara Beller's inflammatory *Quantum Dialogues*. So it seems that interest in Bohr is heating up again. The program is at: `http://www.pitt.edu/~psa2002/`. It would no doubt be as weird to you as Växjö was to me, but it'd be fun if you could come.

To change subject abruptly: I obviously do not keep up with the `quant-ph` archive and am only dimly aware of it through your references. I would greatly appreciate your posting the paper there. What do you need me to do?

BTW, in connection with the Proceedings of the Växjö conference I got an email from Andrei in June saying that "Soon we sill be able to send you copies of this volume." I have never received any copy. Did they actually send them? Did I miss my copy?

Oh, also, did you ever get together with van Fraassen, and what happened if and when you did?

23-09-02 *Appleby Confirmed* (to G. Brassard)

So, Appleby is confirmed for the last week of the meeting. Thus, basically, the end of the meeting is full now. The issue now is what is going to happen at the front of it? It looks like we've got loads of room there. (Though I still wait to hear from you how many people we can really house.)

If I don't hear from you as the day passes, I'll probably be calling you!

23-09-02 *Your Future* (to R. W. Spekkens)

Spekkensism 11: *The more I think about quantum foundations, the more I become sure that you are on the right track. For a variety of reasons, I am now absolutely convinced that the quantum state represents information, and that we are on the verge of major advances in our understanding of quantum mechanics. So, what's the news on funding?*

You know, even if it weren't obvious that you were pulling my strings, I'd still want you as a postdoc. But reality is not completely shaped by wants. Tell me about your back-up plans. [. . .]

I'll be in Waterloo, Oct 2-8, giving talk at Perimeter Oct 4 and a talk at IQC Oct 7. Is there a chance I could visit with you then? Are you very far down the road? I'll probably have a lot of time on the weekend (the 6th in particular).

23-09-02 *Let Me Count the Ways . . .* (to R. W. Spekkens)

Spekkensism 12: *First of all, I am not simply pulling your strings. I am absolutely sincere about my conviction that the state vector is a representation of information. (I'm not about to follow you in your attitudes on realism though.)*

How many times (and how many ways) do I have to say I'm a realist?!?! I'm just a more subtle realist than most. (Read the anti-Växjö interpretation paper again.)

24-09-02 *Title and Abstract* (to D. Poulin)

Does this sound like the sort of thing you guys might want to hear? If not, I could probably put together a new talk on an information function Sasaki and I have been studying. But the present talk has the advantage for me that half of it has already been prepared!

> **Title:** Exchangeable Quantum States / Exchangeable Quantum Operations
>
> **Abstract:** There is hardly a paper in quantum information that does not make use of the idea of an unknown quantum state. Unknown quantum states are protected with quantum error correction, teleported, and used to check for quantum eavesdropping. But what does the term "unknown state" mean? In this talk, I focus on quantum-state tomography and make sense of the term in a way that breaks with the vernacular: An unknown quantum state can always be viewed as a known state—albeit a mixed state—on a larger multi-trial Hilbert space. The technical result is a quantum mechanical

version of the de Finetti representation theorem from classical probability. Interestingly, the theorem fails for real and quaternionic Hilbert spaces, and this teaches us something new about entanglement. Furthermore, a variation of the theorem applies to quantum operations, where it tells us something about the nature of complete positivity. The implications of both theorems for the point of view that quantum states represent states of knowledge, rather than states of nature, may be discussed briefly, time permitting.

24-09-02 *Carriers of the Torch* (to A. Peres)

Asherism 27: *Have you seen my* `quant-ph/0209114`*? It has no relation to* `quant-ph`*. I had tried to put it in* `hep-th`*, but the* `arXiv` *manager thought it was a joke and refused to publish it. After lengthy negotiations, with the help of Mermin, I was told to put it in* `quant-ph`*, whose readers know my name. If I am not concerned about my good reputation with* `quant-ph`*, I'll be able to cross reference it in* `hep-th` *(so I did, also* `gr-qc` *and* `astro-ph`*).*

I just had a read of it; thank you for pointing it out. I'll think about the point you make.

25-09-02 *Ulfbeck and Bohr* (to N. D. Mermin)

Merminition 95: *While I don't think they're [Ulfbeck and Bohr] foolish by any means, I was not terribly excited by what they had to say. If you were, by all means invite them.*

I'm finally getting a chance to clean up my mailbox. Sorry for the long absence.

After writing you the note referred to above, I got a chance to actually read the Ulfbeck/Bohr paper. Before that, I had only had discussions with Ulfbeck. Here's what really surprised me. In talking to him, I got the impression that he was giving me something of a précis of their views, and that I would find the heart and the details in their paper. But I didn't! In fact, as far as I could tell, I didn't find anything more in their paper that I didn't already find in our short conversation ... only said six times over in paper form. "The older view did not adequately account for the genuine fortuitousness of the measurement click."

I know I've complained about Father Bohr's lack of detail when asserting the origin of the quantum formalism, but I think they force my complaints to a new level.

There is, however, one idea in the paper that I am inclined to keep or, at least to me, seems worth trying to develop. I say this predominantly because of its William Jamesian feel. Here it is, deleting the words of theirs that I don't like or don't agree with,

> The click with its onset is seen to be an event entirely beyond law. ... [I]t is a unique event that never repeats ... The uniqueness of the click, as an integral part of genuine fortuitousness, refers to the click in its entirety, with all the complexity required for a break-through onto the spacetime scene. ... [T]he very occurrence of laws governing the clicks is contingent on a lowered resolution.

You see, from the Jamesian viewpoint of "radical pluralism," every piece of the universe, every crumb of its existence, is a unique entity unto itself. Here's a little quote in that direction from his essay "Abstractionism and 'Relativismus' ":

> Let me give the name of 'vicious abstractionism' to a way of using concepts which may be thus described: We conceive a concrete situation by singling out some salient or important feature in it, and classing it under that; then, instead of adding to its previous

> characters all the positive consequences which the new way of conceiving it may bring, we proceed to use our concept privatively; reducing the originally rich phenomenon to the naked suggestions of that name abstractly taken, treating it as a case of 'nothing but' that, concept, and acting as if all the other characters from out of which the concept is abstracted were expunged. Abstraction, functioning in this way, becomes a means of arrest far more than a means of advance in thought. It mutilates things; it creates difficulties and finds impossibilities; and more than half the trouble that metaphysicians and logicians give themselves over the paradoxes and dialectic puzzles of the universe may, I am convinced, be traced to this relatively simple source. *The viciously privative employment of abstract characters and class names* is, I am persuaded, one of the great original sins of the rationalistic mind.

I wish I could find a better quote than that—I have memories of reading the idea expressed in much greater detail and so much more eloquently—but this morning, try as I might, I can't find it.

So I'll end this little note with another note I wrote a few months ago—it carries the sentiment, if not the eloquence. [See note to Greg Comer titled "Music in the Musician," dated 23 April 2002.] It's pasted below. Maybe I should have titled the present article, "A Click is but a Click Not: it is so much more." For the same holds with "clicks" as with "atoms."

26-09-02 *More Ulfbeck and Bohr* (to H. J. Folse)

I hope things are going well for you in spite of Isidore. I see from the weather channel that it made an early-morning landfall in Louisiana.

Thanks for your long assessment of the Ulfbeck/Bohr paper. I enjoyed reading it, and think I agree with many (all, possibly) of the things you said. You asked what was Mermin's reaction to it. The only record I have (other than that he called their ideas "very Mohrhoffian," referring to Ulrich Mohrhoff) is contained in the note below. [See 25-09-02 note "Ulfbeck and Bohr" to N. D. Mermin and 23-04-02 note "Music in the Musician" to G. L. Comer.]

Unfortunately, I think it is going to be almost impossible for me to attend the Pittsburgh meeting. I'll be in Montreal Oct 13–Nov 3 running an extended workshop on "Quantum Foundations in the Light of Quantum Information"—I've got about 30 people coming on and off this time—and there are limits to how far I can push my family. But, boy, I sure would like to be at those Bohr sessions.

Henry's Reply

Folsesm 8: *Quoting Chris Fuchs:*

> There is, however, one idea in the paper that I am inclined to keep or, at least to me, seems worth trying to develop. I say this predominantly because of its William Jamesian feel. Here it is, deleting the words of theirs that I don't like or don't agree with,
>
> > "The click with its onset is seen to be an event entirely beyond law. ... [I]t is a unique event that never repeats ... The uniqueness of the click, as an integral part of genuine fortuitousness, refers to the click in its entirety, with all the complexity required for a break-through onto the spacetime scene. ... [T]he very occurrence of laws governing the clicks is contingent on a lowered resolution."

This part of Aage's view is consistent with his father's. In a recent discussion of this, Erik Rudinger gave me a bunch of quotes from Niels: As a collector of quotes, I thought you might like these:

> "In this connection, it is also essential to remember that all unambiguous information concerning atomic objects is derived from permanent marks -such as a spot on a photographic plate, caused by the impact of an electron- left on the bodies which define the experimental conditions. Far from involving any special intricacy, the irreversible amplification effects on which the recording of the presence of atomic objects rests rather remind us of the essential irreversibility inherent in the very concept of observation. The description of atomic phenomena has in these respects a perfectly objective character, in the sense that no explicit reference is made to any individual observer and that therefore, with proper regard to relativistic exigencies, no ambiguity is involved in the communication of information." — (Mid-Century, p. 310 – BCW 7, p. [390])
>
> "... the emphasis on permanent recordings under well-defined experimental conditions" — (Mid-Century, p. 313 – BCW 7, p. [393])
>
> "Moreover, the circumstance that all such observations involve processes of essentially irreversible character lends to each phenomenon just that inherent feature of completion which is demanded for its well-defined interpretation within the framework of quantum mechanics." — (Dialectica, p. 317 – BCW 7, p. [335])
>
> "It may also be added that it obviously can make no difference as regards observable effects obtainable by a definite experimental arrangement, whether our plans of constructing or handling the instruments are fixed beforehand or whether we prefer to postpone the completion of our planning until a later moment when the particle is already on its way from one instrument to another." — (Einstein Paper, p. 230 – BCW 7, p. [370])

27-09-02 *Email* (to R. W. Spekkens)

Concerning the epiphany, you tease me: I don't want to see the research fruits at the moment; I just want to see a psychological description of their originator. You've got to know by now, I find even the emotional aspects of quantum mechanics extremely interesting. Concerning my publishing your words publicly, you can always ask that a given thing you write not be repeated: Plenty of people do that with me, and I always abide.

27-09-02 *A Pearl!* (to A. Peres)

Asherism 28 : *Here is part of a letter I received from an old lady who was a pretty student in 1974 and forced me to learn Bell's theorem. She is now unemployed and has plenty of time to work on physics. She even intends to publish her first paper.*

> What makes me read papers is to make sure that I am original. I have to tell you that I covered quite a material. There were three things that I liked, I don't have enough

words. One is a paper of Chris Fuchs, a PEARL, another one is Mermin's "Ithaca Interpretation" and the third is Gordon Baym's book.

That made my day!

27-09-02 *Commune of the Incorrigibles* (to C. H. Bennett)

Communard Charles,

You're incorrigible. (And you should not read that as merely reflecting a fear of mine about your foundational fetish.) I've marked you for October 15 through 17. It's looking like we're going to have plenty of extra space the first week; I think I'm going to try to see if Reinhard Werner can come then.

If you'd like to stay in a hotel follow the instructions below, post haste. Alternatively, if you want to save Gilles some money, you can stay at the Rockledge Apartments with me: I've got an empty second room during that time. (But whichever way, let me know for accounting purposes.)

Communard Chris

28-09-02 *Better Editing* (to H. J. Folse)

That's it, I think. You should check over the result, making any further changes you want, and then send it back to me. I'll send it to `quant-ph` as time permits (though I'll be in Canada Oct 2–8, so it probably won't get done until after I'm back). [The final result was `http://arxiv.org/abs/quant-ph/0210075`.]

Concerning the content of the paper, I believe I absorbed that pretty well too. This time, however,—you know I've read all but one of your papers—I was struck more than ever for the need of a translation table to mediate between some of your choices (or Bohr's choices) of words and the more modern, more common quantumspeak that present-day practitioners of the field use. I hope to get a chance to write you about this in detail while I'm at the Montreal commune (Oct 13 – Nov 3). There is the seed of something good in your "ontological lesson" section, but I am afraid it will be obscured to most in our field because of the point above.

28-09-02 *Substances and Properties* (to H. J. Folse)

I'm back again. As I said, (hopefully) I'll write in more detail about the content of your paper when I'm in Montréal. In the meantime, let me forward you some letters I wrote contra taking the quantum state (in the usual sense of a $|\psi\rangle$) as a *property* of a quantum system. [See 25-04-02 note "Short Thoughtful Reply" to C. H. Bennett, 14-05-02 note "Qubit and Teleportation Are Words" to C. H. Bennett and others, 14-05-02 note "Chris's World" to J. A. Smolin and others, and 16-05-02 note "King Broccoli" to J. A. Smolin and others.] You made me think of this because of your talk of substances and properties in the "ontological lesson." The letters below were spurred by a discussion about the words "qubit," "entanglement," and "quantum teleportation" soon appearing in English dictionaries. (Charlie Bennett, in particular, was seeking better definitions than had been proposed by some lexicographer. He wanted something that didn't confuse the reader into thinking that quantum teleportation involves instantaneous action at a distance. *Yet*, he still wanted to call a quantum state a property. I found these two demands inconsistent.)

You might enjoy the letters, for what they're worth.

06-10-02 *Ed's Book* (to A. Plotnitsky)

Plotnitskyism 9: *I have a question. Rüdiger in his piece refers to Jaynes' 2003 book on probability. Would you recommended it? I'd like to revisit probability.*

In fact, I wouldn't be able to think of a better place for you to start. Jaynes' book—never finished before his death—is really the very best Bayesian-tilted book to start off with. (It doesn't go as radically Bayesian as I am now going, but that is a minor blemish in comparison to the good it does.)

I see, looking in Rüdiger's paper, that he has cited the soon to be published posthumous version. At the moment, you can nevertheless download it at the website: `http://bayes.wustl.edu/`.

Beyond that though, a good book to understand the more philosophical issues around Bayesianism, have a look at the Kyburg and Smokler book he cites in reference 1.

08-10-02 *FYI Comments on Recent Papers* (to M. B. Ruskai & B. J. Hiley)

Thank you both for sharing your correspondence with me. I very much enjoyed reading them on my flight from Toronto to Boston this morning. There are substantial issues here and it is pleasant to read about them in an evenhanded way.

I got a nice snicker in reading Basil's comment,

Hileyism 1: *In my own study of quantum theory I have often reached the stage when I am led to wonder why a particular author has come out so strongly for a certain point of view and against all others when there is no observational evidence one way or the other. My own long experience of being associated with Bohm's work has brought me directly and forcefully into contact with such questions. For example I have been greeted with the phrase "You're a Bohmian aren't you?" I would like to feel flattered by such a comment but it is often meant as a reference to someone who is regarded as belonging to the complement of sane!*

I certainly feel that social and cultural factors strongly influence these choices. As I have already remarked above they are very implicit and very difficult to bring to the surface, partially because it is universally held that such factors should not have any role to play. Yet why does the debate about the interpretations of quantum theory generate such deep emotions if these questions do not touch the very depths of what we believe lies at the heart of nature and even our very being? There are only two other areas where I have experienced the same passion and energy and that is in politics and religion.

thinking about the pleasant breakfast we had together in Växjö last year and the talk he gave soon after that: "Chris Fuchs bounded up to me this morning and said, 'Are you a Bohmian?!?"' Well, it's good to know a true Bohmian, and to know the distinctions between him and a Goldsteinian.

10-10-02 *Infinitesimal Comments* (to H. J. Folse)

Let me just make some infinitesimal comments on your comments of my comments on van Fraassen's comments.

Folsesm 9: *I interpret this to mean that the justification for your holding that subjective judgment is its success in predicting the POVM's which are themselves objective.*

Predicting the *outcomes* of POVMs, yes. (A POVM—i.e., a *set* of operators with a certain property—is the theoretical expression of a (physical) measurement.) The operators within the POVM express the possible outcomes of the measurement.

Folsesm 10 : *The updating is in a subjective belief, but the cause of the updating is something presumably as objective as a "click"?*

Yes.

Folsesm 11 : *Here it seems to me that the "about the world" part is the objective part. Consider two odds-makers for horse races who give different odds for the same races. Clearly one is rational to "accept" the odds made by the guy who, betting on those odds, wins the most money. So if somebody asks me why do I go by these odds, I answer because of the outcomes. It's all about what I'm justified in believing regarding how to bet. But then if I ask why does one guy succeed over the other, and I discover the successful one has a lot more information about the horses, jockeys, conditions, etc., isn't this "objective" and has nothing to do with what I believe?*

I'm shooting for a Darwinian conception of success here. Success is only defined with hindsight. There is no objective state of affairs that predetermines a "degree of success" for one's future gambles. In that sense, there are no objective probabilities, past gambling success or not.

10-10-02 *Your First Quant-ph* (to H. J. Folse)

OK, the dirty deed is done: You've now had your first `quant-ph` submission. I've checked it and everything appears to be OK; it downloads fine and looks just like it was supposed to.

You once wrote me this:

Folsesm 12 : *Actually I've had at the back of my mind the project of collecting a subset of these papers and trying to get them published as a book. If you do read thru them all, I'd appreciate your telling me what you think of the worthiness of such a project.*

I do indeed think that would be a worthy project; your papers certainly opened my eyes. I'll pledge this: If you ever decide to do it, if you're interested I'd volunteer to write a foreword to the book — I bet you couldn't find a more enthusiastic foreword-writer than me. In particular, I'd love nothing more than to see the quantum information community get a good healthy dose of Bohr. The extent to which I can contribute to making that happen is bound to help me get a little closer to heaven.

13-10-02 *Quantum Foundations Commune* (to L. Hardy and Perimeter Institute generally)

Partially because of the size of the auditorium we ended up with and partially because of our desire to keep the sparks flying, Gilles Brassard and I decided to selectively open the doors for attendance to our quantum foundations commune. Thus, if anyone at Perimeter is interested in audience participation and general discussions, they are more than welcome to come. There are no more official talk slots open at the moment, but that shouldn't stop anyone from giving an impromptu talk on the subject if they'd like to. (Unfortunately though, there are no more travel funds. And if there's any desk space in the offices, we'll probably dole it out on a rotating basis.)

If you wouldn't mind, please help spread the word by forwarding this note to anyone at Perimeter who might be interested. (Presently, I'm cc'ing the note to those of you at Perimeter who are in my address book.)

Below, I'll place four items of information:

a) The tentative talk schedule and attendance table.

b) Part of the original meeting announcement.

c) Instructions for how to obtain a hotel.

d) Directions to the meeting.

Please join us if you can.

26-10-02 *Classical Measurement* (to K. Jacobs)

Jacobsism 2: *You know that classical measurement can just be written as quantum measurements, so long as all the POVM elements and the density matrix commute. But do you know of a paper that actually states this (other than my paper on pooling knowledge). I would like to reference somebody other than myself.*

Sorry to take so long to reply to you. I've been tied up for two weeks with a workshop in Montreal that Gilles Brassard and I organized, and I've hardly gotten a spot of email done in that time.

I don't recall any papers that have discussed the issue explicitly, but I think it is implicit in my discussion of Section 6 of my paper:

- C. A. Fuchs, "Quantum Mechanics as Quantum Information (and only a little more)," in *Quantum Theory: Reconsideration of Foundations*, edited by A. Khrennikov (Växjö University Press, Växjö, Sweden, 2002), pp. 463–543. `quant-ph/0205039`.

Have a look at that and let me know if it's appropriate.

27-10-02 *A Crowded Placetime* (to G. L. Comer)

Thanks for sending your poem about the solitary place. I especially liked the penultimate paragraph.

> My choices are radioactive remedies
> That rot the roots, spin down the spirals,
> Snip the snares, and dampen the dark.
> Something much larger than the universe,
> With all that space and time and matter.

You make me want to quote William James again. This one comes from a letter in his collection (of letters):

> All I can tell you is the thought that with me outlasts all others, and onto which, like a rock, I find myself washed up when the waves of doubt are weltering over all the rest of the world; and that is the thought of my having a will, and of my belonging to a

brotherhood of men possessed of a capacity for pleasure and pains of different kinds. ... And if we have to give up all hope of seeing into the purposes of God, or to give up theoretically the idea of final causes, ... we can, by our will, make the enjoyment of our brothers stand us in the stead of a final cause ...

27-10-02 *Technical Question Minus* (to H. M. Wiseman)

Sorry to take so long to reply to you. I've been inundated with the duties of organizing this meeting in Montreal I'm involved in ("Quantum Foundations in the Light of Quantum Information II"). Luckily, however, I had to fly home this weekend for pumpkin picking, and so I've got a little time on the flights to get some email done.

Wisemanism 28: *He was preparing a section on q. tomography, but I was not happy with it as it did not address the question of how many different projective measurements are necessary to fully characterize a state. I thought this would be well known, but the answer does not seem to be in any tomography papers Gerard can find. My hypothesis is that the answer is $N+1$, where N is the Hilbert space dimension. Michael Nielsen suggested you would be the person to ask about where to find this result (or whatever the relevant result is), as there was a time when you cared about things less general than POVMs. Can you help?*

To my knowledge, the first guys to give that answer were Band and Park. Here are some references:

- W. Band and J. L. Park, "The empirical determination of quantum states," *Foundations of Physics*, vol. 1(2), pp. 133–144, 1970.
- J. L. Park and W. Band, "A general method of empirical state determination in quantum physics: Part I," *Foundations of Physics*, vol. 1(3), pp. 211–226, 1971.
- W. Band and J. L. Park, "A general method of empirical state determination in quantum physics: Part II," *Foundations of Physics*, vol. 1(4), pp. 339–357, 1971.
- W. Band and J. L. Park, "Quantum state determination: Quorum for a particle in one dimension," *American Journal of Physics*, vol. 47(2), pp. 188–191, 1979.

A paper showing that something goes wrong with tomography in real Hilbert-space quantum mechanics is:

- W. K. Wootters, "Local accessibility of quantum states," in *Complexity, Entropy and the Physics of Information* (W. H. Zurek, ed.), (Redwood City, CA), pp. 39–46, Addison-Wesley, 1990.

To my knowledge, the first people to talk about doing tomography with a single (minimal informationally complete POVM) were Caves, Schack, and I:

- C. M. Caves, C. A. Fuchs and R. Schack, "Unknown Quantum States: The Quantum de Finetti Representation," *Journal of Mathematical Physics*, vol. 43(9), pp. 4537–4559 (2002). [Reprinted in *Virtual Journal of Quantum Information* **2**(9).] `quant-ph/0104088`.

Wisemanism 29: *Now, moving swiftly into the metaphysical plane, given that you profess to believe in a real world (apart from your state of belief about it, which is a quantum state) ...*

No, my states of belief are in general captured by probability distributions. In some special cases, those probability distributions have the character of quantum states. As I'm presently toying with the idea, the world is a much more varied place than I would ever use quantum mechanics to describe in toto. It is just I think that quantum mechanics hints at something particularly deep about how we (as active agents) are wired to the world.

Wisemanism 30: *Another question: if your state of belief is your odds for future occurrences (on which you can either win or lose money), what is your state of belief about events after you are dead? You can't win or lose any money on them, so how can rational behaviour help? To put it another way, how do you justify having life assurance? I haven't read your tracts lately, so my point of view is [wandering?] all over the place again.*

I don't understand the question. But maybe that's just because I'm giving this reply a rush job.

Wisemanism 31: *A simpler question: have you read Carlo Rovelli's work "Relational Quantum Mechanics". He says quantum states are about information, but I'm not sure if you'd agree with his approach.*

Aha! You haven't actually read either of my papers `quant-ph/0205039` or `quant-ph/0106166`. I caught you. In both those papers, I wrote:

> "But what nonsense is this," you must be asking. "Where else could they start?" The main issue is this, and no one has said it more clearly than Carlo Rovelli. Where present-day quantum-foundation studies have stagnated in the stream of history is not so unlike where the physics of length contraction and time dilation stood before Einstein's 1905 paper on special relativity.

But, yes, though I really liked Rovelli's motivational sermon ... and even something of the flavor of his two principles, I think he floundered pretty badly when it came time to put some meat on the bones.

28-10-02 *Blather, Lather, and Rinse* (to J. Bub)

The following is a note I started to construct for you several weeks ago. Unfortunately, I never got a chance to finish it, but it seems appropriate to send you the note as it stands nevertheless ... if for nothing else as a starting point for this week's discussions. The note was to be titled "Blather, Lather, and Rinse." I had wanted to polish it better and add some more detail, but maybe this will get the ball rolling.

> Pilate was probably not the first to ask what truth is, and he was by no means the last. Those who ask it seek something deeper than disquotation, which was the valid residue of the correspondence theory of truth.
>
> — W. V. Quine

I apologize for taking so long to reply to your several letters, but I wanted to read Quine's little book *Pursuit of Truth* (revised edition) before doing so.

I want to defend my position that there is some good stuff in Marcus's manuscript. At the very least, there are things that I needed to read about and be exposed to. One man's blather is another man's rinse, I suppose. But I think it is more than that. There were three things that caught my attention.

a) The strategy of taking the Bohmian and Everettista's strong desire to find a "designatable reality term" within quantum theory to take as its anchor and turning that against them. The point he was trying to make could be more polished and intensified, but it was one that I found to be a keeper to be developed.

b) I found the discussion of the "primitive theories" that underlie our developed theories quite well done, and I think it is an important point that has yet to sink in to most of our mentalities. I just loved some of his lines in that section. Here was one that particularly struck me:

> My second point was that the function of a formal physical theory is to extend the primitive theory. And, indeed, modern physical theories extend it to a degree which may seem almost miraculous (which, to a Palaeolithic hunter, and perhaps even to an Elizabethan savant, might really have seemed miraculous). But, however striking the advance, we are never in a position actually to dispense with the primitive theory. No matter how sophisticated the fighter aircraft, the pilot still controls it in the time-honoured Palaeolithic manner, using hands and feet. Similarly here: if you want to confirm the theory, or to apply the theory, then you must have recourse to your Palaeolithic sensory organs, and your Palaeolithic sensory cortex. No matter how marvellous the theory, if you want to relate it to the world it is supposed to concern, you have to go through these Palaeolithic channels. Which means the theory can have no commerce with the world it is about except through the mediacy—the good offices, as it were—of the primitive theory. There is no escaping it: it's the way we're wired.

I think this is the proper way to understand (or at the very least build upon) what Bohr was talking about when he kept referring to the necessity of a classical description for making sense of quantum phenomena. You can see this mimicked (but in much less developed form) in my Samizdat: p. 260, "Foods for Thought [sic]," p. 464, "Always One Theory Behind," and in footnote 18 of my `quant-ph/0205039`.

In particular I found Marcus's discussion of this point extremely relevant to an ongoing debate I've been having with Mermin, Caves and Schack for some time. From where comes the judgment that a beamsplitter is a beamsplitter (and not some other kind of device)? Those fellows want to think that it somehow—in a way yet to be explained!—comes out of quantum theory itself. But I don't buy it. The path I'm traveling indicates that that judgment will never come out of quantum theory. The judgment that a beamsplitter is a beamsplitter is, in proper Bayesian terms, the assumption of a "prior". And where an ultimate prior comes from, Bayesian theory is silent. One must seek an answer from somewhere else, if from anywhere at all. In fact, I would say this is the ultimate meaning of my slogan "Quantum Mechanics is a Law of Thought" (at those times when I hold to it).

c) Finally, I rather liked the discussion of "reality as a logical requirement" at the very end of his draft. I mimic some loosely related thoughts at the beginning of Section 4 of my `quant-ph/0205039`, and flesh it out a little more fully in Section 5 of my `quant-ph/0204146`. The reason to draw a distinction between the "state space" and the "sample space" is not because the "sample space" captures the idea that there is a representative that is "really there" and we are just ignorant of it, but because it captures the idea of a spur on which we revise our beliefs.

The things in Marcus's draft that seemed to capture your attention were those (small) things that fall within the frame of usual (nonpragmatic) philosophical debate. I'm thinking here of your remark on disquotation. But I think he and I both have bigger bones to pick. The deeper issue is to do away altogether with a correspondence notion of truth, and to put into its place something akin to a pragmatic account (where "truth" is made by the process of "measurement intervention"). The old pragmatists, as I see it, had a glimpse of something that quantum mechanics gives us a much stronger reason to take seriously. [I was going to write much more here, but now no time.]

30-10-02 *Time to Make a Difference* (to R. W. Spekkens)

I've been thinking about it on and off all night, and I wonder if I can convince you to do a rush job on the paper you proposed writing (when we were talking in Waterloo). Namely, putting down in paper form the talk you gave here last week. What I'm thinking is that I would really love to have it in the special issue of *Studies in History and Philosophy of Modern Physics* that Jeff Bub and I are co-editing. We've already got more than enough stuff for the issue, but I'd like to squeeze you in . . . if I can convince you to take on the project.

Your talk struck a chord with me as being the right way to wham people over the head (if done right). And I'm now pretty sure you can polish it to that point. Moreover I think with this special issue we've got the right opportunity to be convincing to a lot of (the right) people, all at once.

So I hope you'll think seriously about this. If I can get a relatively final draft from you in one month—but not a week over that—then I think I'll be able to squeeze you in. But I've got to be absolutely hard about the deadline. I know you'll very likely have to seriously rearrange your schedule to pull this off, but I think this could be a grand opportunity for you (and for me vicariously) to make a difference in the community.

Let me list below the papers we've now got in hand to show you that you'll be in some respectable company.

- Howard Barnum, "Quantum Information Processing, Operational Quantum Logic, Convexity, and the Foundations of Physics"
- Charles Bennett, "Notes on Landauer's Principle, Reversible Computation, and Maxwell's Demon"
- Armond Duwell, "Quantum Information Does Not Exist"
- Itamar Pitowsky, "Betting on the Outcomes of Measurements: A Bayesian Theory of Quantum Probability"
- Chris Timpson, "On the Supposed Conceptual Inadequacy of the Shannon Information"
- David Wallace, "Quantum Probability and Decision Theory, Revisited"
- Andrew Steane, "A Quantum Computer Only Needs One Universe"

Talk to you later today or tomorrow.

02-11-02 *Technical Question Minus, 2* (to H. M. Wiseman)

Wisemanism 32: *Let me try again. It makes no sense to have a bet on an event that will happen after you are dead, as you can never benefit from it. So if your state of belief is just your betting* *odds for future events, logically you can have no state of belief about events after you are dead. So why have life assurance for the benefit of your family, for instance?*

I think it was Henry VIII that first said, I am England.

Howard's Reply

I've never heard that about Henry VIII. Does "I am England" mean something different from "England is me"? (cf. Louis XIV "L'état? C'est moi.")

I understand (I think) what you are saying, but I don't buy it.

03-11-02 *Visionlessness* (to R. W. Spekkens)

Spekkensism 13: *Admittedly, I am feeling these days that the hidden variable program envisioned by Einstein was never really pursued seriously and thus may have been abandoned too quickly.*

Your note struck a fear in me that I'm having a hard time shaking. In coming to Bell Labs, it looks like you might be wasting a year of your time. But worse than that, I fear you're going to waste a year of my short life.

I have little to no tolerance for this. The way I see it, the quantum conundrum—after 75 years of waste—is only going to be broken by a leap of faith and imagination. It needs something creative. And, most importantly, it needs a vision of simplicity. The thought you express above is neither of those.

Rob's Reply

Perhaps you are reading more into my comments than was intended. Your reaction reminded of the following Emo Philips joke:

> I was walking across a bridge one day, and I saw a man standing on the edge, about to jump off. So I ran over and said "Stop! Don't do it!" "Why shouldn't I?" he said. I said, "Well, there's so much to live for!" He said, "Like what?" I said, "Well … are you religious or atheist?" He said, "Religious." I said, "Me too! Are you christian or buddhist?" He said, "Christian." I said, "Me too! Are you catholic or protestant?" He said, "Protestant." I said, "Me too! Are you episcopalian or baptist?" He said, "Baptist!" I said,"Wow! Me too! Are you baptist church of god or baptist church of the lord?" He said, "Baptist church of god!" I said, "Me too! Are you original baptist church of god, or are you reformed baptist church of god?" He said,"Reformed Baptist church of god!" I said, "Me too! Are you reformed baptist church of god, reformation of 1879, or reformed baptist church of god, reformation of 1915?" He said, "Reformed baptist church of god, reformation of 1915!" I said, "Die, heretic scum", and pushed him off.
>
> — Emo Philips

In the spectrum of views on quantum foundations, ours are not so dissimilar.

04-11-02 *Yoo-Hoo* (to J. W. Nicholson)

I've been spreading the word with van Enk and my management that I'm still in Canada ... and will be through Wednesday ... but the truth of the matter is I'm exhausted (at home) and need to get a load of housework done or I'll go insane.

Also I had an epiphany on the plane yesterday—something I thought to be exceedingly deep—and I struggled much of last night to get it written up.

Shall we have lunch Friday?

04-11-02 *Got It!* (to R. Schack, C. M. Caves & N. D. Mermin)

> **WARNING! WARNING! WARNING! WARNING! WARNING!**
>
> Subsections 2 and 3 of the present note are UTTER RUBBISH, and I entirely withdraw the ideas put forth there. (I still agree with subsections 1 and 4, however.) See the notes "Utter Rubbish and Internal Consistency, Parts I and II" of 27 and 28 June 2003 for an explanation. I nevertheless leave the ill-fated sections in this collection because, despite their embarrassment for me, I deem them crucial for understanding the surer path we all explored later.
>
> **WARNING! WARNING! WARNING! WARNING! WARNING!**

It finally sank in completely and whammed me over the head! It's beautiful; it's compelling; it was implicit the whole time. It's trivial even, and I am so excited! There is absolutely no mystery in the Penrose example, and there is absolutely no mystery in the Einstein-Podolsky-Rosen example once one has accepted that POVM ascriptions have the same non-ontic character as the state vector itself. Since my first note to you on my "Identity Crisis" in August of last year—("Quantum States: WHAT?", page 35)—the solution has been staring us in the face. In fact, the examples above now appear as hardly worthy of ever having been called conundrums or paradoxes in the first place.

I guess this is what Rüdiger was trying to get across to me (and to David?) on Friday before he left. Let me put the story in my own words.

I'll break the note below into four sections for clarity:

1. A general exegesis on how to think about POVMs
2. The Penrose example
3. The EPR example
4. Forward-looking thoughts on POVMs and a pluralistic universe

1) The POVM as a function from raw data to meaning

We generally write a POVM as an indexed set of operators, E_d. Here is how I would denote the referents of those symbols. The index d should be taken to stand for the raw data that can enter our attention when a quantum measurement is performed. The whole object E_d should be construed as the "meaning" we propose to ascribe to that piece of data when/if it comes to our attention. It is important here to recognize the logical distinction between these two roles. The symbol d stands for something beyond our control, something that enters into us from the world outside our head. The ascription of a particular value d is not up to us, by definition. The *function* E_d, however, is of a completely different flavor. It is set by our history, by our education, by whatever incidental factors that have led us to believe whatever it is that we believe when we walk into the laboratory to elicit some data. That is to say, E_d has much the character of a subjective probability assignment. It is a judgment.

I have tried to say this in various ways before. Maybe the first place in "Quantum States: WHAT?" is in the note "Note on Terminology," pages 49–50, or in more detail in "Replies to a Conglomeration," page 92. Maybe there are still better shots at it, but I didn't look further. (I guess I also give another variation on the matter on page 42 of `quant-ph/0205039`). You can have a look at those if you think it'll help, but I think the paragraph above says it as well as anything. And I know that at least Rüdiger is on board with all this. Carl probably is too, but I'm not as sure.

2) The Penrose example

Here's one of the passages I recorded [from Penrose's book] in the Samizdat, pages 402–404,

> One of the most powerful reasons for rejecting such a subjective viewpoint concerning the reality of $|\psi\rangle$ comes from the fact that whatever $|\psi\rangle$ might be, there is always—in principle, at least—a *primitive measurement* whose **YES** space consists of the Hilbert-space ray determined by $|\psi\rangle$. The point is that the physical state $|\psi\rangle$ (determined by the ray of complex multiples of $|\psi\rangle$) is *uniquely* determined by the fact that the outcome **YES**, for this state, is *certain.* No other physical state has this property. For any other state, there would merely be some probability, short of certainty, that the outcome will be **YES**, and an outcome of **NO** might occur. Thus, although there is no measurement which will tell us what $|\psi\rangle$ actually *is*, the physical state $|\psi\rangle$ is uniquely determined by what it asserts must be the result of a measurement that *might* be performed on it.

Let's think about this from our perspective. From our point of view, both the state $|\psi\rangle$ and the measurement Penrose speaks of are subjective judgments. They both count as priors. In principle, they are distinct subjective judgments, but in this case they happen to coincide in a meaningful sense. Here's the meaningful sense. When accepting quantum mechanics as a theory for reasoning, we are, among other things, accepting the consequences of Gleason's theorem. And with that comes the coordinated states and measurements Penrose speaks of. WHEN the state, THEN the given measurement outcome with probability one.

But what does that mean? It means little more than that, no matter what the objective character of the raw data we find, we *ascribe* to it a meaning appropriately associated with the given state. That is, the **YES** boils down to essentially a convention. The meaning we ascribe to the raw data has no choice but to be labeled **YES**.

And that, I think, is the whole story. I'll add some more metaphysics to this in a minute, but first let me move on to the EPR situation before going further.

3) The EPR example

To illustrate this one, consider a bipartite set of qubits in a maximally entangled state and suppose one measures the same von Neumann measurement on each. In this case, we can't predict the outcome of either measurement, but we can predict that the two will match identically. Is there anything mysterious about this? Nicolas Gisin tells me there is. For he says, "I'll grant you that at least one of the results is a sort of free creation or birth—i.e., it does not arise because of a local hidden-variable theory—but then how does the other creation in the pair know how to go the same way?" "That simply can't happen unless there is some kind of superluminal communication going on or, even more radically, spacetime itself is meaningless."

Well, what do we have here but little more than an extension of the situation above? Now, there are simply three priors rather than two. And those priors command us to interpret the two pieces of raw data (coming from the two separated parts of the experiment) as having the same meaning. That is to say, in analogy to our solution to the Penrose conundrum, it is simply a convention that the clicks are the same in the two wings of the experiment.

And that too is the end of the story. It is just a triviality that the measurements come out perfectly correlated. They came out that way because WE labeled them that way with the choice of our priors.

4) POVMs and radical pluralism

Now let me go into a bit of the metaphysics of this. Here's a point of view that I'm finding myself more and more attracted to lately.

I think it is safe to say that the following idea is pretty commonplace in quantum mechanical practice. Suppose I measure a single POVM twice—maybe on the same system or two different systems, I don't care—and just happen to get the same outcome in both cases. Namely, a single operator E_d. The common idea, and one I've held onto for years, is that there is an objective sense in which those two events are identical copies of each other. They are like identical atoms ... or something like the spacetime equivalent of atoms. But now I think we have no warrant to think that. Rather, I would say the two outcomes are identical only because we have (subjectively) chosen to ignore almost all of their structure.

That is to say, I now count myself not so far from the opinion of Ulfbeck and Bohr, when they write:

> The click ... is seen to be an event entirely beyond law. ... [I]t is a unique event that never repeats ... The uniqueness of the click, as an integral part of genuine fortuitousness, refers to the click in its entirety .... [T]he very occurrence of laws governing the clicks is contingent on a lowered resolution.

For though I have made a logical distinction between the role of the d's and the E_d's above, one should not forget the very theory-ladenness of the set of possible d's. What I think is going on here is that it takes (a lot of) theory to get us to even recognize the raw data, much less ascribe it some meaning. In Marcus Appleby's terms, all that stuff resides in the "primitive theory" (or perhaps some extension of it), which is a level well below quantum mechanics. What quantum mechanics is about is a little froth on the top of a much deeper sea. Once that deeper sea is set, then it makes sense to make a distinction between the inside and the outside of the agent—i.e., the subjective and the objective—as we did above. For even in this froth on the top of a deeper sea, we still find things we cannot control once our basic beliefs—i.e., our theory—are set.

Without the potential d's we could not even speak of the possibility of experiment. Yet like the cardinality of the set of colors in the rainbow—Newton said seven, Aristotle said three or four—a subjective judgment had to be made (within the wide community) before we could get to that level. If this is so, then it should not strike us as so strange that the raw data d in our quantum mechanical experience will ultimately be ascribed with a meaning E_d that is subjectively given. (I expressed some of this a little better in a note I wrote to David last month; I'll place it below as a supplement.) More particularly, with respect to the EPR example above, it should not strike us as odd that the phenomenon comes about solely because of an interpretive convention we set: All quantum measurement outcomes are unique and incomparable at the ontic level. At least that's the idea I'm toying with.

I think that's enough for tonight. I now intend to sleep for at least 14 hours! (It was a long three weeks.)

David's Reply

Thanks cc'ing me the latest epiphany. I've only had a chance to glance at it and am still torn between whether my response is "that was how I understood your position to be all week" or "what utter rubbish" so I will take a little time before responding. (I have to go to Germany for a week in a week so it may be a couple of weeks.)

Rüdiger's Reply

I am happy with your section 1) on the POVM as a function from raw data to meaning. But I don't get the point you are making in section 2). I would say that the sentence "a σ_x measurement of a particle in the state $|+\rangle$ gives the outcome YES with certainty" is saying exactly the following: If our states of belief about the POVM and the state are expressed by σ_x and $|+\rangle$, then consistency requires us to assign probability 1 to the outcome YES. It's a statement about consistent application of the formalism. To say about a particular experiment that it performs a σ_x measurement of a particle in the state $|+\rangle$ is a subjective judgment. So far we are in agreement.

But then you write

> But what does that mean? It means little more than that, no matter what the objective character of the raw data we find, we *ascribe* to it a meaning appropriately associated with the given state. That is, the **YES** boils down to essentially a convention. The meaning we ascribe to the raw data has no choice but to be labeled **YES**.

I probably just misunderstand this paragraph. It seems to me that once we have ascribed the state (the pair σ_x, $|+\rangle$), we are making a very strong statement. We have identified two possible outcomes, YES and NO, and we make a commitment to accepting bets on YES with arbitrarily unfavorable odds. It is logically possible that the outcome will be NO. If the outcome is NO, there will be a crisis. Ruin. Your paragraph suggests that in this case we just relabel the raw data. If that's what you mean, then I agree with David's "what utter rubbish". But I probably misunderstand you here. (In a year's time, you'll write "I never said it better than in my note headed 'Got It!' from 3 November 2002" :-)

I agree that for the purpose of this discussion, the EPR scenario does not add much. But you get me worried again in section 3):

> That is to say, in analogy to our solution to the Penrose conundrum, it is simply a convention that the clicks are the same in the two wings of the experiment.

Either I don't get it, or it's utter rubbish.

Section 4), I like. It highlights the chasm that exists between our approach and the many-worlders and decoherence people. We all agree that a click is not an elementary phenomenon. They want to reduce it to something more fundamental. We say it's irreducible (which does not mean that we cannot analyze a measurement apparatus or decoherence of a quantum register in as much depth and detail as anybody else). Your metaphysical bit is nice in that it makes clear that "irreducible" is not the same thing as "elementary". As you say it,

> All quantum measurement outcomes are unique and incomparable at the ontic level.

I hope you got your 14 hours of sleep. My best night so far has been 5 hours long.

04-11-02 *Carts and Horses, 2* (to A. Kent)

Kentism 5: *There's a long tradition of physicists becoming over-enthused with current technology as a source of metaphors and even fundamental explanations for physics. ... I wonder if there's maybe a danger of your program falling into the same class.*

Ulrich Mohrhoff once wrote something similar in sentiment. It's a good thing you're one of my friends, and I would never treat you like I treated him. [See 04-07-01 note "Carts and Horses" to U. Mohrhoff.]

04-11-02 *One Day* (to A. Kent)

Kentism 6: *I take the point that you were interested in information-theoretic aspects of quantum theory before quantum information became popular, and this earns you several cosmic brownie points for originality (which are not dispensed lightly). Still, for me, the fundamental worry stands: so much of physics doesn't look reducible to information theory that I wonder if any of it is.*

You're right about GR not looking like anything to do with information. Nor would any physics whose main task is to set a Lagrangian, like QCD say. However, quantum theory (as a principle theory in Bub's sense) stands out like a sore thumb to me. I see so many problems melt away with an epistemic view of the quantum state, with no new problems coming back to haunt in its stead. The task, as I see it, is to see how many further terms and rules in the theory (quantum operations, the Born rule, the tensor-product rule, the Hamiltonian, etc.) can also be taken to be epistemic in a fruitful way. The ones that can't, finally with a little breathing space around them, will be able to scream out their ontic significance loudly and clearly. We'll hear it, and, I'll bank money, know what to do with it for that next step in physics beyond flat quantum mechanics.

14-11-02 *Probabilismo!* (to D. M. Appleby)

I'm sorry, I forgot to send you those references, didn't I? Let me dig them up.

- B. de Finetti, "Probabilism," Erkenntnis **31**, 169–223 (1989).
- R. Jeffrey, "Reading *Probabilismo*," Erkenntnis **31**, 225–237 (1989).

Also, I think that whole issue of Erkenntnis is worth perusing. I think there is an article on de Finetti's approach to the "problem" of induction in there that Dick Jeffrey recommends ... unfortunately, I can't remember the author at the moment. It might have been von Plato or Zabell.

Applebyism 1: *I hope my niggling doubts weren't too exasperating.*

Not at all; I very much enjoy your company. And I appreciate your worries, even if I am only now learning how to respond to them adequately … and, indeed, only now recognizing some of the weaknesses in what I spout. (Though the latter is an ongoing thing with me.)

I hope one day you'll post a version of your "Elements of a Prolegomenon" to `quant-ph`. Rüdiger and I, at least, found parts of it very, very helpful. And, self-servingly, I can't imagine a more flattering appraisal of the foundations program I'm trying to define than the one in your introductory section. Inspiring words can help recruit a workforce, and you know I'm all for that!

Let me end this note by pasting in part of another note that I wrote soon after the Montréal meeting. (I'll paste in the part I still trust; parts of it, I think need to be redone now.) [See 04-11-02 note "Got It!" to R. Schack, C. M. Caves & N. D. Mermin.] Anyway, it leans heavily on explanatory modes that I developed while talking to you.

17-11-02 *Växjö* (to J. Finkelstein)

Good to hear from you. You haven't seen any details on the meeting because none have been worked out yet. Thus, I was a little surprised to see Andrei's announcement of the meeting in Y. S. Kim's conference listing; he probably just wanted to get something announced fast (for administrative purposes). The last time we had talked, we were thinking hard (and I thought it had already been agreed to) about giving the meeting the slant: Quantum Information meets Quantum Logic. The idea being to get predominantly quantum information people who had some interest in learning about the quantum logic community's results and quantum logic people who were interested in learning about the results of quantum information. And so on. That, by the way, is Howard Barnum's predominant research theme at the moment.

We're definitely going to have to get geared up over the holidays to get the planning settled.

In any case, I think it'd be great if you'd come. It'd be nice to meet you finally. The last meeting was pretty successful, and I think once we put in some work, this one will probably come out the same. I think there's a good chance we'll have Hardy, John Smolin, and Jeff Bub there. And from the quantum logic and convex structures side, we're going to try to attract Dave Foulis, Alex Wilce, Dick Greechie, Paul Busch, and Reinhard Werner. Clearly some in that list have already taken part in a cross-culturation. Also, I guess there'll be the people that Andrei has already listed in his announcement. Some of those, too, like Holevo, have done the same thing.

Would you need any funding, or would you be able to make it on your own travel grants. We'll have some small amount of money, but I want to use it as advantageously as possible so that we'll be able to get the maximum number of interesting people there.

17-11-02 *Fertilization?* (to J. Finkelstein)

Well I just discovered that "culturation" doesn't seem to be a word. Maybe you understood what I was trying to get at anyway.

19-11-02 *Ridiculous Interpretation* (to S. L. Braunstein)

Braunsteinism 1: *Hi! Do you recall an odd interpretation about how the quantum information gets across in quantum teleportation? It suggested the quantum info goes backwards in time from Alice's Bell measurement to the point of creation of the entanglement and then forward in time to Bob. Do you recall where this odd idea came from? Or would you have any idea whether it actually appears in print somewhere?*

Yes, you can find that in the original quantum teleportation paper itself. It was an idea of Ben Schumacher's.

Personally, I hate the idea and think it is misleading. For it gives the image that a quantum state is an objective property of something, and that that objective property just travels along a wire (and through time) in the process of quantum teleportation. Whereas I would say, the only thing that travels backwards then forwards in time is our *chain of inference*. Then, once it is realized to be inference, you don't need to talk about traveling at all: Quantum teleportation is just a case of taking some prior information, gathering some data, and updating to a posterior. See my description of teleportation in Section 3 of `quant-ph/0205039`. (And note footnotes 14 and 15.)

03-12-02 *Poetry, Subjectivity, Mirroring and Algorithms* (to D. M. Appleby)

This is just to let you know that I got your email a while ago, and even read it once, but I've had almost no time to get philosophical for a while. (Rather serious business concerns.) What I'm trying to do at the moment is just clean out my email box before I go crazy.

So, please accept my apologies, but I'm not going to be able to reply in detail for still a while further.

Let me just comment on one key piece, for which much seems to hinge for you:

Applebyism 2: *It is worth noting, incidentally, that you do ascribe objective status to the dimension d, and to the bound on the volume of that shape in the probability simplex. This means you are still playing the same game as Caves: trying to find something in our heads which genuinely is the reflection of something real out there. It is just that you are much harder to please than Caves.*

I don't think you have me right on that count. Please reread my paper `quant-ph/0204146`—especially the part written to Wootters—and tell me whether you still think what you said above syncs with me.

06-12-02 *SHPMP Issue on Quantum Information* (to the SHPMP participants)

We are now in the very final stages of collecting manuscripts from contributors to the special quantum information issue of *Studies in the History and Philosophy of Modern Physics*. The issue will contain the following papers:

1. Howard Barnum: 'Quantum information processing, operational quantum logic, convexity, and the foundations of physics'

2. Armond Duwell: 'Quantum information does not exist'

3. Lucien Hardy: 'Probability theories in general and quantum theory in particular'

4. David Mermin: 'Teaching computer scientists quantum mechanics, or how I discovered the Copenhagen interpretation'

5. Itamar Pitowsky: 'Betting on the outcomes of measurements: a Bayesian theory of quantum probability'

6. Andrew Steane: 'A quantum computer only needs one universe'
7. Chris Timpson: 'On the supposed conceptual inadequacy of the Shannon information'
8. David Wallace: 'Quantum probability and decision theory revisited'

The special issue is scheduled for publication as the September, 2003 issue of SHPMP. To avoid being bounced to a later issue, we absolutely *must* have the final version of your manuscript before the end of December. So please send (or re-send) us a LaTeX file of your paper, prepared in accordance with the journal's guidelines below, by December 20.

We are excited about this project and we look forward to hearing from you shortly.

Jeffrey Bub and Chris Fuchs

06-12-02 *Call Me, Let Me Call You* (to C. H. Bennett)

When we were in Montréal together, I remember one sleepy 4:00 AM conversation when you said that Jeff Bub and I could use your paper `physics/0210005`, "Notes on Landauer's Principle, Reversible Computation and Maxwell's Demon," for our special issue of *Studies in History and Philosophy of Modern Physics*.

Is the paper still up for grabs? If it is, we would really, really, really love to have it. It would be perfect for the issue. I'll put the issue announcement below, so that you can see who you're potential neighbors would be. They're all really good papers.

All you'd have to do is say *yes* ... and I'd even format the paper properly for you. I'll just take it directly off the archive. You couldn't find a better bargain in Filene's Basement.

Just let us know as soon as possible (i.e., as soon as you read this note). Also, you could either call me, or I could call you tomorrow/today. Where will you be?

06-12-02 *From the Real Chris* (to C. H. Bennett)

Bennettism 19: *The subject line of your email almost motivated me to throw it into the junk bin. I expected that someone had hijacked your From: address and was about to continue with, "Nice lady wants to meet you." I would be glad to have you publish* `physics/02010005` *but I am currently working on version 2, which will be much better, and will address more critics of Landauer's principle. I prepared version 1 in a hurry so as to get an archive number in time for Rex and Leff to cite in their new edition of the Maxwell's Demon book.*

The paper is already great as it stands (by our standards). But, if you could finish the new version before December 20—at the absolute, absolute, absolute latest (see explanation below)—we could still accept that.

Don't forget, by the way, that Earman and Norton, Shenker, and Bub have all published their papers on the same subject in the same journal. So, this really is the appropriate place (and the appropriate time) for your paper.

You want me to give you a call? Where are you?

You encourage me!

06-12-02 *Enjoyed* (to D. M. Greenberger)

I enjoyed listening to you talk about an evolutionary approach to quantum mechanics the other day. When we get together next time please tell me more! You've got my ear on this subject.

Below I'll place some notes I've written on things to do with Darwinism and quantum mechanics ... and their connections. The notes come from my samizdat, *Quantum States: What the Hell Are They?* [See 18-02-02 note "Psychology 101" to J. Preskill, 25-02-02 note "A Wonderful Life' to W. K. Wootters, and 24-06-02 note "The World is Under Construction" to H. M. Wiseman.]

Danny's Reply, "Tiny Answer to Large Questions"

> Your emails, like your papers, are quite prolix, lots to read (not meant as a criticism, only as an excuse for having not had time to digest it yet), and so I can only tell you where I am at on a few issues. I will have to reread most of the comments in the email and ruminate upon them.
>
> But I strongly believe in Darwinism as the mechanism that drives science. In fact I define science by saying that man is always reacting to the environment presented to him, in order to better adapt to it, and science is his conscious effort to maximize this adaptation. So I strongly believe that we frame the theories that we do because we perceive the world the way we do. Our senses and conceptualizations are partly built in and are partly a response to what is out there, and we build theories and instruments to help us better interact with it. But if our senses and brain structure were different, we would have evolved a different response.
>
> For example, if like a snake we could sense infrared, our whole world view would be different. The snake sticks out his forked tongue and says, "ah, a mouse passed this way a while ago, and it is hotter to the left than to the right, so I can track him to his lair." The mouse and his infra-red image aren't very separable.
>
> Now we see objects in visible light, of short wavelength, and so we see sharp images. So we develop rules that give things sharp boundaries, and we say two things can't occupy the same place at the same time. This in turn leads us to think that the integers are important, and that enumerating things is important. Our whole counting system and mathematics is based on it. If we perceived things like a snake, nothing would be sharp, and I suspect the integers would be way down on our list of what's important in mathematics. We would think a continuum approach would be much more intuitive.
>
> So you see, I don't even think mathematics is god-given. I think it is part of our response to our environment, based on our senses. And when people tell me, as almost all mathematicians do, that mathematics is objective, and corresponds to a Platonic something "out there", my answer is that "The reason you believe that two plus two equals four, is because those of your ancestors who also believed that, ate the ones who believed that two plus two equals five." There was survival value in it for us as we are. But that might not have been the case if we were different. It's not necessary, it's Darwinism.
>
> And so science evolves in a manner reminiscent of the man who looks for things under the lamppost, on a dark night, because the light there is better. We do the experiments we can do, with the equipment we have, because otherwise we couldn't do anything. But we end up with a very skewed view of the world. One of the things Darwinism gave us was an insatiable curiosity, and so it is good to dream of final theories, but the

dream is rationally a silly one. Every time we open a new window on nature we see all sorts of things we never dreamed of. We are under a lamppost somewhere in the middle of nowhere, and most of creation is totally unknown to us. Topics like consciousness and ESP, etc, we ban from science, because we can't begin to get a handle on them. But that doesn't make them unimportant. They are actually the essence of things for us. Our lamppost just doesn't throw any light in those directions.

About a real theory of everything, I always tell people that I wouldn't want to live in a universe where I could understand everything. Or even the important things. And I don't think there's any danger of that.

So you see, I think the search for knowledge is a wonderful dream, but it's a romantic, even Quixotic one. I think we'll learn a lot about controlling the small part of nature that we see. But truly understanding anything deep, when we aren't even aware of most of what's out there? Not very likely.

I'm afraid I can't even take science seriously at some level, although I thrill to its beauty, and am willing to dedicate my life to the search. But it's hubris to expect too much, because any reality we can perceive now, can only pertain to where we are now on the evolutionary ladder. I think that when we die, and go to heaven, and ask God how things really work, he will look at us and smile, and say, "first you need a brain transplant."

As for my views on quantum theory, I'll tell you sometime when we're drunk. Anyway, thanks for coming, I enjoyed it very much. And I very much would like to come down and see you soon.

06-12-02 *Quantum Information Does Not Exist* (to A. Duwell)

Jeff Bub passed on a copy of Appendix B to your PhD thesis to me, and I've got to tell you, I just love it. And I love the title: I don't know if you know it, but it is a wonderful play on the words Bruno de Finetti wrote in boldface in the preface to his book on probability theory:

> My thesis, paradoxically, and a little provocatively, but nonetheless genuinely, is simply this:
>
> PROBABILITY DOES NOT EXIST.
>
> The abandonment of superstitious beliefs about the existence of Phlogiston, the Cosmic Ether, Absolute Space and Time, . . . , or Fairies and Witches, was an essential step along the road to scientific thinking. Probability, too, if regarded as something endowed with some kind of objective existence, is no less a misleading conception, an illusory attempt to exteriorize or materialize our true probabilistic beliefs.

I think you make a sound point in your paper and an important point, and I am behind you 100%. Indeed I have tried to make the same point many times over to my friends (like Jozsa), but I've never done it so clearly or thoroughly as you have done it in this document. (As points of reference, you can have a look at the note titled "Colleague", on page 132 of my samizdat *Quantum States: What the Hell Are They?* posted on my webpage (link below), or look at the "Swedish Bikini Team" and "More Swedish Bikini Team" stories on page 34 of my `quant-ph/0105039`.) The point is, Landauer has caused a lot of trouble with his slogan "information is physical." The real issue is that "information carriers are physical," and by studying the information carrying properties and capabilities of those carriers we may get a new, more insightful way of expressing their very essence.

Anyway because of this respect for your work, Jeff Bub and I would like to invite you to include a copy of your paper in a special issue of *Studies in History and Philosophy of Modern Physics* devoted to issues to do with quantum information that we are co-editing. This is extremely short notice to give you because, essentially, we will have to have a final version of the paper by the end of next week. But still, we hope you will say yes. Let me exhibit a list of the confirmed papers (imaginatively including yours), so that you can get a feel for the gist of the issue.

1. Howard Barnum: 'Quantum information processing, operational quantum logic, convexity, and the foundations of physics'
2. Armond Duwell: 'Quantum information does not exist'
3. Lucien Hardy: 'Probability theories in general and quantum theory in particular'
4. David Mermin: 'Teaching computer scientists quantum mechanics, or how I discovered the Copenhagen interpretation'
5. Itamar Pitowsky: 'Betting on the outcomes of measurements: a Bayesian theory of quantum probability'
6. Andrew Steane: 'A quantum computer only needs one universe'
7. Chris Timpson: 'On the supposed conceptual inadequacy of the Shannon information'
8. David Wallace: 'Quantum probability and decision theory revisited'

As I said above, we realize we are asking this on very short notice. But I have read your paper twice now, and I would say that we can accept it almost exactly as it presently is … and hope that that will be extra incentive for you to say yes.

Below, I'll just list a few (very minor) points that caught my eye, and suggest that you fix those things up if you do submit it for the special issue. The scheme will be the following: In a separate email, I'll send you the original manuscript that Jeff had sent me (in the form of a pdf file) for the purpose of knowing which pages I am talking about. (I figure you might have changed things, or used a different format, since the time of the draft that I read.)

Hoping to hear from you soon (almost immediately actually),

Chris Fuchs

PS. You might also enjoy the notes "Short Thoughtful Reply," "Qubit and Teleportation Are Words," "Chris's World," and "King Broccoli," on pages 175, 184, 185, and 187, respectively, of my *Quantum States: What the Hell Are They?* These notes also connect somewhat—though not directly—to the points you make in your paper.

Notes on "Appendix B: Quantum Information Does Not Exist"

1) p. 3, just a comment, not a request for change. You write, "… it seems that Jozsa thinks that quantum information is somehow real." I can confirm that. We've argued this over far more times than I care to remember!

2) p. 5, footnote 2. You give Brukner and Zeilinger more credit than they deserve on this. That property goes back to Faddeev in the 1950s. I think you can find a reference in the Timpson paper listed above (it can be found on quant-ph). If you can't find it there, I'll dig harder.

7) p. 15, bottom sentence. I'm not sure I get this sentence. Even epistemic entities or, if you like, classical information, can have qualities. $H(X:Y)$, for instance, is bounded above by $H(X)$—that is a quality mutual information possesses. But you must mean something more specific to the context here; so maybe just strive to say it a little better.

9) p. 20, bottom paragraph. You call $H(X:Y)$ the "accessible information," but that is not the common usage. Accessible information, as the term was coined by Schumacher in his PhD thesis, is defined as $\max H(X:Y)$ where the maximization is taken over all POVMs that can be performed at the destination.

10) p. 20, bottom paragraph. Also, the Holevo bound actually tells you very little in detail about the accessible information, in distinction to what you seem to indicate. For instance, take a pure state ensemble whose density matrix is I/d (the identity operator divided by the dimension). If the ensemble happens to consist of orthogonal states, then the accessible information will equal the Holevo bound and be given by $\log d$. On the other hand if the ensemble is the "Scrooge ensemble" that Jozsa, Robb, and Wootters talk about [Phys Rev A, **49** (1994), p. 668], then the accessible information will never exceed 0.61 bits, regardless of d.

11) p. 21, first sentence, second paragraph. I didn't like your phrase, "one member of the singlet state." It seems that all too often I find people in the field of quantum information—for some reason that is mysterious to me—using the words "system" and "state" synonymously. You might think that slip doesn't cause much trouble, but I think it causes a lot of damage. (Especially if you are someone like me who tries to think of quantum mechanics as consisting of both ontic and epistemic terms, and seeing the interpretive task as classifying which is which. For me, the system is ontic in nature, whereas the state is epistemic.) Anyway, I might have said something like, "Alice and Bob each possess a system drawn from a pair of systems prepared in the singlet state."

12) p. 21, last sentence, second paragraph. Just a remark. What is remarkable is that local operations alone can transform the initial state to states that live with the full span of the Hilbert space. But I think you make this point somewhere later in the paper.

13) p. 22, second paragraph. I didn't like at all the part where you write, "[S]he can establish correlations nonlocally. This is not a perplexing property of information, but rather a well-known fact about quantum states." But I won't bother you about that.

14) p. 23, first sentence in Section 8. Again the system/state distinction problem. Actually read the note "Short Thoughtful Reply" that I mentioned above, and you'll see more clearly why I'm bothered by this.

24) p. 33. You write, "It is possible that given some ensemble which describes the information source, the number of qubits required for q-reliable communication can be less than the number of cbits required for reliable communication." It is not only possible, it is always true. In the language Caves and I used in the 1996

paper of ours that you cite, "The preparation information is always greater than or equal to the von Neumann entropy." I think we prove it there.

25) p. 34, the part below the displayed equation. On my first reading of this, I thought you had just got it wrong. I thought you were suggesting that the encoder in a Schumacher compression scheme could just throw away the qubits that were given to him and generate some new qubits prepared in an eigenstate of ρ (doing so with the appropriate probabilities) and send those on. But on second pass I realized you were not saying that. The thing that saved you was the phrase "formally equivalent." Still, I think it might be useful for your readers to make the distinction between this formal equivalence, and what is really done in the physical process of Schumacher compression.

28) I would appreciate it very much if you would cite my samizdats (maybe the specific parts I listed above) in connection to the main thesis of your paper ... rather than just citing Caves and Fuchs, 1996. A good place for that might be your sentence on page 3, "In fact, I will defend the position that quantum information theory is properly about properties of classical information in quantum systems and that no new concept of information is needed." The more readers I can draw into those samizdats, the more I can hope to have an impact on the community.

07-12-02 *The Holiday Season* (to T. A. Brun)

Brunism 8: *If you do go to the Republic of Ireland for this QI-fest, were you planning on following up on the sort of stuff you talked about in your "Quantum Mechanics as Quantum Information" paper? I don't mean to sound like a broken record (and how long before no one remembers what that simile refers to?), but I really did enjoy that paper; it's one of the most interesting I've read in a long time, and I'm keen to see where you go with it. For instance, can you relate your information-based approach to the physical process of gathering information in an intuitive way? You made a start at that, I think, with your Bayes-rule-plus-disturbance formulation, but it seemed like more might be possible along those lines. That sort of thing interests me very much.*

Thanks for the encouraging note; I'm flattered. Let me apologize for taking so long to reply. I haven't had a chance to write nearly so much email in the last few months as I'd like to (and need to).

Concerning your first question, in fact that's all I plan to do in Ireland! There's just so much to be done before this Bayesian picture can have any real substance.

The main lines I'd like to develop (or see developed) fall into two categories. The first has to do with the shape of the restricted region in Figure 1. Depending upon which measurement device is taken to be the "standard quantum measurement device," that region will have various different shapes. In particular, the volume of the region can be arbitrarily small. It cannot, however, be arbitrarily large. There is a supremal volume, and I'd like to know it. For a qubit, the supremal volume is just the shape of a sphere. In higher dimensions, unfortunately, it gets more complicated. But I think finding a bound on the biggest volume could already be interesting. In particular, I'd like to know how the ratio of sup region volume to full simplex volume scales with dimension. Does it go to zero? I suspect it does, but that's based on philosophy.

Beyond that, though, just the more we can say about the region, the better. For instance, for a supremal-volume region, how many edges of the simplex will the region touch? How many faces? Etc. What is for sure is that if we can get a characterization of these regions without having first started with POVMs, then we will have a new characterization of the state spaces of quantum mechanics.

The second line I'd like to see developed is the business I started in Section 7 of the paper. Namely, giving some substance to the slogan, "A quantum operation is just a density operator in disguise." Or more accurately, just as a quantum state can be viewed as nothing more than a probability distribution $P(x)$ restricted to a certain region of the simplex, a quantum operation should be viewable as nothing more than a conditional probability distribution $P(y|x)$ restricted to a certain region of the appropriate enveloping space. Then, all the questions above arise again, but within this new regime.

I've shored up the ideas (and the arguments for them) in that Section pretty significantly since first writing it ... and also since writing the stuff on the subject in my samizdat *Quantum States: What the Hell Are They?* posted on my webpage. I'd like to get all that into a paper; it's just finding the time to do it. If God will grace me, maybe I'll get it done in January after the holiday season passes. In any case, some statement of it will definitely come out in the near future in the introduction and conclusions to the paper Rüdiger, Petra Scudo and I are writing on a de Finetti theorem for quantum operations. Since Rüdiger is in charge of completing the draft that'll probably get done in short order.

Anyway, as I said above, I'm flattered that you find some of this stuff interesting. And I'll be even more flattered if you find some of the answers to these questions! If you get any good ideas, do let me know. And if you'd like to collaborate on anything, let me know that too: I'm hoping that after mid-January, I'll be able to regain my identity as a scientist again.

07-12-02 *Prolix Boy* (to D. M. Greenberger)

Thanks for the great note! I especially liked the snake example. I didn't realize before that we are so in synch with each other.

For fun, let me send you a PART of one my stories. This one comes from page 237 of my samizdat, `quant-ph/0105039`. It was originally written for Mermin. By "Firing Line," I really meant "Reference Frame"—that always annoys him.

Why don't you come to Bell Labs some time in January. You ought to give us a talk.

09-12-02 *No Jack Kennedy* (to C. M. Caves)

"Senator, I served with Jack Kennedy, I knew Jack Kennedy, Jack Kennedy was a friend of mine. Senator, you are no Jack Kennedy."

I did tell you that Dick Slusher is my supervisor now, didn't I? Well, he started reading my fat paper "Quantum Mechanics as Quantum Information," today, and he came into my office for a while this afternoon to make a few comments on it. In the course of that he also told me how he was concurrently reading the paper you wrote for a 1991/92 Spain meeting. Apparently he has some interest in quantum chaos now. I said, "You shouldn't start with that; I think some of his more mature works were much better." He insisted that he needed to start at the beginning, saying, "Carl writes so clearly and methodically." I said—referring back to the part of the conversation about my own paper—"You know that's what I strive for too; Carl's been my model since the beginning." Dick was just about to walk out, but before he went, he looked me straight in the eye and said, "Yeah, and you've got some way to go."

I couldn't help but think of that Lloyd Bentsen debate with Dan Quayle.

13-12-02 *More Addenda* (to A. Peres)

Concerning Cabello, I find him just wonderful. He gave a talk at our meeting in Montreal on various KS things, but there was a part of it on MKC in particular. I learned a lot in that section. The main thing being, that just because *a* KS coloring exists, it does not mean that an *arbitrary* coloring exists. Of course, that logical point should have been obvious, but it didn't strike me so much until Adán's presentation.

I had a funny conversation with David Meyer in Nashville this summer. He told me, "I had known about the Godsil and Zaks result for years, but didn't realize it was useful for anything until you asked me about the existence of KS theorems for rational vector spaces at an AMS meeting." It dawned on me then that I had indeed first asked that question, to Itamar Pitowsky, David Meyer, and probably to a few others, but I didn't recall ever having been thanked in the literature. (All this raced through my head in a flash as I was talking to him.) I said somewhat smilingly, "Well, did you thank me for the question in your paper?" He must have caught on, because his reply was, "I don't know, did I?" Since leaving the lobby and going back to my room that night, the smile turned into a little bit of a frown. See pages 448 and 449 in my samizdat.

19-12-02 *Which One Really?* (to G. L. Comer)

Great new little poem. Here, the lines that took me were: "The freedom to choose! The source of chance." Often someone will say to me, as Howard Barnum did,

Barnumism 3: *Here's a caricature, so feel free to object: Bell's worry about the foundations of QM has been: that we have "measurement" as an "unanalyzed primitive" of the theory. Everett shows us how to get around that. You don't like Everett's resolution because you* want *to have an unanalyzed primitive around so it can be the locus of free will.*

And I say it is not that. The universe has within its categories two species, one is chance, and one is free will. Free will does not rely on chance as its source. Instead, it's only through the intercourse of the two that we get a real birth.

Gotta run to a big division meeting. Such things are always scary to me.

20-12-02 *Oh Haight Ashbury* (to N. D. Mermin)

Merminition 96: *Footnote 13 repeats without acknowledgment a point that you, Carl, and Rüdiger love to make. More disturbingly, it promulgates a joke that arose (for me) in the course of an email exchange with you that I can no longer find. For the life of me I can't remember whether I made the joke or you did. Googling on +"go ask Alice" +"entangled state" produces nothing. Feel free to delete footnote 13 if you think I'm stealing your line.*

Funny you can't remember the origin of the "Go Ask Alice" line. We had a conversation about it the moment I arrived at your MerminFest. Since it didn't sink in then, I'll tell you the story again. At 6:56 PM that morning, I sent off a note to my old friend Greg Comer titled "Go Ask Alice"—I'll place the first part of it below. After the part I quote here, however, the letter becomes quite personal.

So, you can imagine the shock when at 12:15 PM I receive a note to you titled "Go Ask Alice"!!! I have always had a fear of getting a note written and then, by accident, sending it to the wrong person! I thought, "Oh my God, I finally did it." However, reading your note, I quickly realized that there was no connection at all . . . (other than a Jungian synchronicity).

Merminition 97: *I don't see what your teleportation example (pages 11, 12) adds to ordinary EPR. Aren't all the issues exactly the same if Alice "in her laboratory prepares" the single qubit in (1) that she possesses by an appropriate measurement (to be sure, she can't control which outcome she'll get, but that doesn't seem to be central to your point, or is it?) after which she and only she knows what the outcome of the corresponding yes-no measurement on Bob's qubit will be.*

But this, of course, has been debated in the EPR context for generations, and I don't see the force of your argument that the would-be informationist should not be weak in the knees. Everybody agrees that Alice is the only one who can do the trick. There's no problem if she only does it once. Bob says the YES was random and only Alice knows that it had to be YES. Bob can think she has delusions of grandeur. But if she does it right 10,000 times, then on run 10,001 Bob would be a fool if a certain confidence that Alice can call it every time should start to enter his mind too.

So to find out what the qubit will do you do indeed have to go ask Alice. (Isn't that an old Jefferson Airplane (pre-starship) song?) You ask her; you don't ask the qubit (as you guys like to say). But by run 10,001 everybody who has been paying attention (except confirmed Humeans) will be fairly sure that "the system [is] prepared to reveal" whatever answer Alice has sent over in a lock-box.

I'm not saying I agree with Penrose on this. Just that I don't see that you've helped very much in relieving the queasiness one is left with when one denies the psi-ness.

On 5/29/02 I finally replied at length in a note titled "I Think She'll Know." The opening lines of the note were, "Remember what the dormouse said; feed your head."

But back to your question: I think beyond a doubt, for the present context, you were the inventor of the phrase "Go Ask Alice." It's a nice way to put it. (But only people of our generation are gonna get it.)

But the importance of the point in our little group, as far as I can remember, was first brought out clearly by Carl. It's always been Carl's favorite "argument" for the subjectivity of the wave function. This piqued my own curiosity to see where we first put it in print. I could find a trace of the idea in Footnote 44 of our paper `quant-ph/9601025`. Also I could see it shining through just after equation 4.105 on page 120 of my `quant-ph/9601020`.

If you think `quant-ph/9601025` gets sufficiently close to the mark, it might be nice if you'd cite it.

24-12-02 *Give Us a Pluriverse* (to G. L. Comer)

Comerism 3: *I've been fiddling around with the idea, though, that chance is a result of the intercourse between free-willed entities.*

Yes, I think I like that better. I had played with still a different turn for a while. One that I might sloganize like this: Chance is what you call "it" when viewed from the outside; free will is what you call "it" when viewed from the inside. What I wrote you in the last note, was a small attempt to get away from the monism of that slogan. But what you said above, I think, might now appeal to me even more.

Merry Christmas.

28-12-02 *Two Things* (to J. W. Nicholson)

Just reading a NYTimes article on cloning in which I read:

> Senator Bill Frist, the Tennessee Republican who was just chosen Senate majority leader and who favors a ban on all forms of cloning, called Friday's announcement "disturbing" and added: "While its validity is unclear, it should serve as a chilling reminder that individuals are still trying to clone human beings. These actions offend our sensibilities and undermine fundamental respect for the decency of human life."

Now, tell me how could someone say that if he didn't believe that the genetic makeup IS the person ... rather than predominantly the watermark? (Recall our conversation on the way to lunch one Friday.)

29-12-02 *Erratum?* (to A. Peres)

I just noticed that Conway (of the Conway-Kochen noncolorability result) makes no appearance in the Author Index of your book. Maybe that is an erratum, or maybe I don't properly understand your criteria for admission into that index. Either way, cheers!

Asher's Reply

> I did not include Conway in the author index because there was no reference to cite. Recently he and Kochen published a paper
>
> - J. H. Conway and S. Kochen, "The geometry of the quantum paradoxes", in R. A. Bertlmann and A. Zeilinger (eds.), *Quantum [un]speakables: From Bell to quantum information (Vienna, 2000)*, Springer-Verlag, Berlin, 2002, pp. 257–269,
>
> but these are mostly anecdotes. The only proof I know of their construction is the one in my book.

02-01-03 *Foundations Site?* (to P. Busch)

Thanks for the inclusion of a link on your webpage. The more people I can draw into my "quantum dreams" page, the more people I can hope to take the bait of thinking about quantum mechanics as the hint of something deeper and more wonderful. And the more people I can hope to start applying their brain pulp to the project! So, thanks again.

Congratulations on your promotion. When I look at your research record I guess I would have thought you to have become a full professor long, long ago! Certainly this is overdue.

I will be on a sabbatical from Bell Labs in Dublin in the coming year, so maybe I'll get a chance to drop by Hull for a visit.

Speaking of seeing you, Howard Barnum and I are organizing a session for one of Andrei Khrennikov's meetings in Sweden this summer. (I think it is in the early part of June.) Our plan is to give it the theme "quantum information meets quantum logic" and we're trying to figure out how to stretch the money we've been given to get as many interesting people there as possible. Some of the people we're thinking about trying to attract are you, Jeff Bub, Lucien Hardy, Dave Foulis, Alex Wilce, Dick Greechie, and maybe a few others. a) Would you be interested, and b) if so, would you need travel funding to get there?

02-01-03 *Glory Days* (to A. Peres)

Asherism 29: *Yesterday the Dept Chairman informed me that it was impossible to extend by one more year my professorial position, because of the dismal financial situation of Technion (well, the whole country is bankrupt). ...*

I am not unhappy to "retire" this fall. I won't have to teach or bother with administrative duties, and I'll have more time for research.

Congratulations on your new career move! You should think of yourself as being a postdoc again, and what glorious days you will have!

Here: I'll give you your first postdoctoral research project! I learned predominantly from you that the proper analog to the quantum state in classical physics is the Liouville distribution. However, I learned from Wigner that the only time evolutions for quantum states that are overlap preserving are (up to phase equivalence) the unitary evolutions:

- V. Bargmann, "Note on Wigner's Theorem on Symmetry Operations," J. Math. Phys. **5**, 862–868 (1964).
- C. S. Sharma and D. F. Almeida, "A Direct Proof of Wigner's Theorem on Maps Which Preserve Transition Probabilities between Pure States of Quantum Systems," Ann. Phys. **197**, 300-309 (1990).
- U. Uhlhorn, "Representation of Symmetry Transformations in Quantum Mechanics," Arkiv För Fysik **23**, 307–340 (1963).

My question is, what are the complete set of time evolutions on a classical phase space that are overlap preserving for Liouville distributions. As far as I can tell, this question has never been tackled in the literature.

02-01-03 *The Quantum Shirt* (to A. Cabello)

Yesterday morning, New Year's Day, as I went to get my wife's newspaper, I discovered that the previous day's mail had been accidentally delivered to my front door, rather than to the usual mailbox in the back. Anyway, in it, there was a package from Spain. Thanks so much for the shirt! I showed it off to my whole family and the friends that came to our afternoon celebration.

You are a great friend, and I am flattered.

03-01-03 *Growing Old* (to L. Hardy)

The last few days I've been editing my big samizdat—mostly just working on completing the name index—and what a task it has been! (The index is now almost 10 pages long all by itself.) But maybe one interesting thing (to me anyway) has come from the project: I'm starting to realize just how little the broad outline of my program has changed over the years. I don't know if that's good or bad, but it seems true. Apparently things started to gel in me somewhere around 1995/1996, and I've been trying to make the thought more precise ever since.

For instance, in my `quant-ph/0205039` this year, I write in a footnote:

> It is at this point that the present account of quantum mechanics differs most crucially from Refs. [Hardy01a] and [Hardy01b]. Hardy sees quantum mechanics as a generalization and extension of classical probability theory, whereas quantum mechanics is

> depicted here as a restriction to probability theory. It is a restriction that takes into account how we ought to think and gamble in light of a certain physical fact—a fact we are working like crazy to identify.

and I had thought that this characterization of what I'm shooting for arose only after reading your papers. But just a few minutes ago, I found this old note to Sam Braunstein:

> **19 July 1996, to Sam Braunstein, "The Prior"**
>
> While in Torino, you really got me interested in the old Cox Box question again. I noticed in this version of the book that Jaynes makes some points about how there are still quite a few questions about how to set priors when you don't even know how many outcomes there are to a given experiment, i.e., you don't even know the cardinality of your sample space. That, it seems to me, has something of the flavor of quantum mechanics ... where you have an extra freedom not even imagined in classical probability. The states of knowledge are now quantum states instead of probability distributions; and one reason for this is that the sample space is not fixed—any POVM corresponds to a valid question of the system. The number of outcomes of the experiment can be as small as two or, instead, as large as you want.
>
> However I don't think there's anything interesting to be gained from *simply* trying to redo the Coxian "plausibility" argument but with complex numbers. It seems to me that it'll more necessarily be something along the lines of: "When you ask me, "Where do all the quantum mechanical outcomes come from?" I must reply, "There is no where there." (with apologies to [Gertrude Stein] again!) That is to say, my favorite "happy" thought is that when we know how to properly take into account the piece of prior information that "there is no where there" concerning the origin of quantum mechanical measurement outcomes, then we will be left with "plausibility spaces" that are so restricted as to be isomorphic to Hilbert spaces. But that's just thinking my fantasies out loud.

Maybe it's just evidence of hardening of the arteries.

By the way, when are you going to send us the final version of your SHPMP paper, with references added? I hope you'll read this sentence and say, "Now."

03-01-03 *QM with Finite Fields* (to J. M. Renes and C. M. Caves)

I just came across a paper title that might interest some combination of us three:

- J. P. Eckmann and Ph. Ch. Zabey, "Impossibility of quantum mechanics in a Hilbert space over a finite field," Helvetica Physica Acta **42**, 420–424 (1969).

I have no clue what the actual content of the paper is, but it might be worth a look one day. In particular, does it connect any with the fact that the POVM-version of Gleason probably breaks down when the vector spaces are over a finite field? Or does it?

05-01-03 *ForAsher.tex* (to A. Peres)

Asherism 30: *Thank you for telling me that I'll be like a postdoc. It's so true. Now this will be my way of telling it to friends. Only one thing will be missing: a good adviser for my research (my first adviser in 1961 was Wheeler, although I was formally the postdoc of Misner). Will you be willing to play that role?*

Those are awfully big shoes, and I wouldn't dare to fill them. Nor would I even dare to the presumption of being your advisor! You have been my teacher since before we met, and my teacher you remain. (I think I first read one of your papers in 1989.)

Asherism 31 : *You already asked:*

> What are the complete set of time evolutions on a classical phase space that are overlap preserving for Liouville distributions?

All I can think of is Koopman's theorem (my book, pp. 317–318). The phase space evolution is also a unitary evolution. The overlap of two Liouville functions is constant in time in any Hamiltonian evolution.

Yes, that's right. And what I'm asking is whether there is a converse to this. If the converse were true, then it would mean that the sum content of Hamiltonian evolution is overlap preservation for Liouville distributions. I think that would be pretty if it's true. Also, if it is true, I don't think it is a completely trivial consequence of the usual Wigner theorem. I say this because I am asking for the preservation of Liouville overlaps only, not necessarily the preservation of overlaps between arbitrary functions on the phase space.

Asherism 32 : *Have you seen* `0301001`*, the first* `quant-ph` *of the year? It's by Grangier, who participated in the first Aspect experiment, and now writes some "foundational" papers. I like the expression "quantum holism" instead of "nonlocality." But there are many errors in that paper.*

No I haven't seen that one. I'll try to have a look at it eventually. Philippe and I have had several discussions on quantum foundations, to no great avail.

Asherism 33 : *I searched* `quant-ph` *for the string "unknown" and I found your* `0104088`*. Where was this published? Now I also found Mermin's "Whose knowledge?"* `0107151`*. Probably these two references are enough for my purpose.*

Yes, I think that will do. Here's my full reference on it:

- C. M. Caves, C. A. Fuchs and R. Schack, "Unknown Quantum States: The Quantum de Finetti Representation," *Journal of Mathematical Physics* **43**(9), 4537–4559 (2002). [Reprinted in *Virtual Journal of Quantum Information* **2**(9).] `quant-ph/0104088`.

The package of things I put together for you is concerned with some discussions I had with Charlie Bennett, John Smolin, and Philippe Grangier about the perils of thinking of quantum states as "properties" of the systems they refer to. I think that gets singularly in the way of Charlie's public expositions of what quantum teleportation is about. Putting together a package seemed a little relevant since you said you'd be giving a lecture on the subject: I don't think you will learn anything from the content, but you may enjoy some of the turns of phrase.

I'll place the code of my file "ForAsher.tex" below. [See 25-04-02 note "Short Thoughtful Reply" to C. H. Bennett, 14-05-02 note "Qubit and Teleportation Are Words" to C. H. Bennett and others, 14-05-02 note "Chris's World" to J. A. Smolin and others, 16-05-02 note "King Broccoli" to J. A. Smolin and others, and 01-06-02 note "High Dispute" to P. Grangier.]

06-01-03 *Pedagogy* (to N. D. Mermin)

Now I'd like to use your patient ear as an excuse to think out loud. This is what I was referring to when I wrote you yesterday, "Much more soon."

Today, I've got to spend part of the day preparing a talk to give at Bell Labs tomorrow. Here's the title and abstract I sent in for it:

> Title: Representing Quantum Mechanics on the Probability Simplex
>
> Abstract: Classical information theory is about input probability distributions, output probability distributions, and the transition functions that connect them. Quantum mechanics and so far quantum information theory, on the other hand, have been traditionally formulated in terms of linear operators on a complex vector space and the linear superoperators that connect them. To automate a comparison between the two theories, a means for expressing the newer theory in a way that leans toward the older, more established one ought to be sought. It can be done. This talk is about a small part of that project and a couple of mathematical questions it poses.

In substance, the talk will focus predominantly on the stuff I presented to you (privately) in Montréal, but will give a little more emphasis to the stuff about symmetric POVMs that Gabe looked at this summer.

However, I'd like to give the beginning of the talk a little different slant than I had previously. Here it is. (Here's the part where I'm thinking out loud.)

Everybody has their favorite speculation about what powers quantum information and computing. Some say it is the superposition principle, some say it is the parallel computation of many worlds, some say it is the mysteries of quantum entanglement, some say it is the exponential growth of computational space due to the tensor product. For my own part though, my favorite speculation is that it is Newton's Third Law: For every action, there is an equal and opposite reaction. Indeed I sometimes wonder if the very essence of quantum mechanics isn't just this principle, only carried through far more consistently than Newton could have envisioned. That is to say, absolutely NOTHING is exempt from it.

What do I mean by this? What might have been exempt from the principle in the first place? To give an answer, let me note an equivalent formulation of old Newton. For every REACTION, there is an equal and opposite ACTION. Strange sounding, but there's nothing wrong with it, and more importantly, this formulation allows for the possibility of an immediate connection to information theory. In particular, we should not forget how information gathering is represented in the Shannon theory. An agent has gathered information—by the very definition of the process—when something in his environment has caused him to REACT by way of revising a prior expectation $p(h)$ (for some phenomenon) to a posterior expectation $p(h|d)$ (for the same phenomenon).

When information is gathered, it is because we are reacting to the stimulation of something external to us. The great lesson of quantum mechanics may just be that information gathering is physical. Even something so seemingly unimportant to the rest of the universe as the reactions that cause the revisions of our expectations are not exempt from Newton's Third Law. When we react to the world's stimulations upon us, it too must react to our stimulations upon it.

The question is, how might we envision a world with this property—i.e., with such a serious accounting of Newton's law—but in a way that does not make a priori use of the information gathering agent himself? If the question can be answered at all, the task of finding an answer will be some tall order. For never before in science have we encountered a situation where the theorizing scientist is so inextricably bound up with what he is trying to theorize about in the first place.

It's almost a paradoxical situation. On the one hand we'd like to step outside the world and get a clear view of what it looks like without the scientist necessarily in the picture. But on the other hand, to even pose the question we have to imagine an information gathering agent set in the middle of it all. You see, neither Shannon nor any of modern information theory has given us a way to talk about the concept of information gain without first introducing the agent-centered concept of an expectation $p(h)$.

So, how to make progress? What we do know is that we actually are in the middle of the world thinking about it. Maybe our strategy ought to be to use that very vantage point to get as close as we can to the goal. That is, though we may not know what the world looks like without the information gathering agent in it, we certainly do know something about what it looks like with him in: We know, for instance, that he ought to use the formal structure of quantum mechanics when thinking about physical systems. Beyond that, we know of an imaginary world where Newton's Third Law was never taken so seriously: It is the standard world of classical physics and Bayesian probability.

Thus, maybe the thing to do first is to look inward, before looking outward. About ourselves, at the very least, we can ask how has the formal structure of our *behavior* changed since moving from what we thought to be a classical Bayesian world to what we now believe to be a quantum world? In that DIFFERENTIAL—the speculation is—we may just find the cleanest statement yet of what the quantum world is all about. For it is in that differential, that the world without us surely rears its head.

To do this, we must first express quantum mechanics in a way that it can be directly compared to classical Bayesian theory, where the information-gathering agent was detached from the world. That is what this lecture is about ...

As I say, just thinking out loud. Thanks for the imaginary ear.

07-01-03 *Newton's Third Law* (to R. E. Slusher)

By the way, here's the set of notes I wrote for myself before giving the talk Monday. Since the business about quantum mechanics being an expression of something like Newton's third law, but much deeper, seems to strike a resonance with something you were groping for one day in one of our discussions—i.e., when you were saying things like "you can't leave anything out in the quantum world"—I thought might enjoy reading this. [See 06-01-03 note "Pedagogy" to N. D. Mermin.]

08-01-03 *Your Note to Grangier* (to N. D. Mermin)

I haven't read the Grangier paper outside of the sentence he quoted from me, but I did read your letter. I think you do me pretty good justice, and I rather liked your explanation.

Merminition 98: *At the beginning of section II of* `quant-ph/0301001`*, I believe you miss Chris Fuchs's point. He is not talking about Bell's theorem; he is talking about something rather like pre-Bell EPR. After you have made a measurement on subsystem A, the information you acquire permits you to assign a quantum state (as defined by your second paragraph [in boldface type]) to subsystem B. Before the measurement on subsystem A, subsystem B had no quantum state.*

Fuchs uses this to argue that the quantum state of a system (or subsystem) — when it has one — cannot be an objective property of that system since statehood can (under EPR conditions) be conferred on a system from afar.

You want to have it both ways — denying action at a distance, yet maintaining the objectivity of the quantum state. I believe you can do it, but only if you acknowledge that the objective state of subsystem B after subsystem A has been measured (so B does indeed have a state) is not a local property of subsystem B.

I would say that the state of subsystem B is a compact way of summarizing (1) the preparation of the A-B system that resulted in the original EPR state, (2) the fact that nothing further was done to B, (3) the fact that a measurement was performed on A, and (4) the outcome of that measurement. Because (1)-(4) are all objective facts (Fuchs would disagree about this) the state of B can be said to be objective. But it would be dangerously misleading to call it an objective property of B, because this suggests something residing in B, whereas (1)-(4) are statements about both A and B and their earlier history.

True enough. But then here's my challenge to you. It's something I should have challenged to you too long ago. Once you have that a state can be said to be objective, and once you have that a measurement specification can said to be objective, then through the Born rule you have that the probabilities generated by the measurement can be said to be objective too. If so, then you must be able to give me a definition of what it means to be a particular probability value q in a way that 1) is not circular, and 2) makes no necessary use of a gambler. (For after all, invoking a gambler is just another way of invoking the agent/observer/experimentalist once again.)

10-01-03 *Filth Under the Rug* (to N. D. Mermin)

Merminition 99: *What's wrong with the old frequentist definition? If N different sets of qubits are subject to those same objective conditions the fraction of final measurements giving the outcome x gets very close $p(x)$ when N is large.*

Granted you need more probabilistic statements to say what you mean by "gets very close" (is that what you meant by circular?) but surely that's an issue for any non-Bayesian view of statistics and not peculiar to the interpretation of QM.

Now it is MY turn to be shocked by the triviality of YOUR reply. I almost feel like it is 1996 again, and we haven't made a bit of progress in our discussions. That bugs the hell out of me. What have I been wasting my time on all these years? You might as well still be writing papers that say, "If all quantum puzzles can indeed be reduced to the single puzzle of interpreting objective probabilities, I would count that as progress."

If what you're still shooting for is to sweep the issues of quantum mechanics under THAT rug—and there's every indication you are—you're just going to find more filth and dirt there. What a shame really. I thought you had been slowly absorbing the Bayesian point all this time. I guess I had just not expected you to fail my challenge in this facile way ... and I'm taken aback.

I'm fairly confident I understand (from your notes to Philippe and Rüdiger and also your newest paper) your latest view of what the quantum state is about. And it might as well be the same view as expressed in Asher's paper "What is a State Vector?" [AJP, 1984, p. 644]. What he calls a "procedure" or an "instruction set" you call a "history," but that's essentially where the difference ends. And just as that paper led Asher to no deeper or more convincing insight for 15 years, so too it will be with you if you continue down this ... I almost said "path," but maybe I should say "dead end."

Let me pick up on your last sentence above:

Merminition 100 : *Granted you need more probabilistic statements to say what you mean by "gets very close" (is that what you meant by circular?) but surely that's an issue for any non-Bayesian view of statistics and not peculiar to the interpretation of QM.*

You get this completely backwards. The great insight Ed Jaynes had, and that Carl and Rüdiger and I have slowly been reckoning with, is that because quantum mechanics is so intimately tied up with probability, one cannot hope to disentangle the troubles of quantum mechanics without FIRST clearing up what the formal structure of probability theory is actually about. And on that first count, we think the Bayesians are the winners.

Once that is accepted—clearly you haven't accepted it yet, but that is no matter for the argument I want to make—then the task is to ask, what are the IMPLICATIONS of that acceptance for our understanding of quantum mechanics? What my debates with you, and to a lesser extent Carl, and to a still lesser extent Rüdiger, have been about since the beginning of your BFM murmurs is just this: What are the implications?

My starting point has been the unbending acceptance that probabilities are of the (de Finettian) subjective caste. What are the IMPLICATIONS of this? Well, the first thing one gets is that the quantum state is of the same subjective caste. But then—and I don't know why it was so hard to stumble across this, except possibly for sheer prejudice—the next thing one gets is that at least some quantum operations are also of the same subjective caste. For beauty's sake, I then go further than Carl and Rüdiger are presently willing to go, and say, "If so be it for SOME quantum operations, then so be it for ALL quantum operations." But the main point is that the first three steps of this paragraph are pure implication.

You called it poetry at the Montréal meeting—yes, it did hurt a little—but it is logic just as clean as you can get it. And it's of the most elementary sort. (That's what made your remark hurt.) The only thing that makes it appear to be poetry to you is some deep resistance and, I suspect, fear of where it leads.

So, I have implications that run FROM interpretation of probability TO quantum mechanics. So what? If it just stays at you saying objective every time I say subjective, then this is a worthless exercise and a waste of time. There had better be more to it. And I claim there is.

For, I would say the implications above lead me down a mathematical path. Whereas your hope to retain the word objective for these structures leads you nowhere.

1. My point of view COMPELS me to ask whether there is a way to think of a quantum state as a (single) probability distribution, plain and simple. With a little toil, I find there is.

2. My point of view COMPELS me to seek out the analogies between Bayes' rule and quantum collapse. With a little toil, I find an analogy that's never been found before.

3. My point of view COMPELS me to ask why the notion of quantum measurement is anything other than the refinement of one's belief, i.e., exactly what classical (Bayesian) measurement is about. With a little toil, I find that it is precisely that after all ... just that in the quantum case there is an extra little kick given to my final state of belief.

4. Here, I think this is the most important one: My point of view COMPELS me to ask, if a quantum operation is as subjective as a quantum state, then why are the two mathematical structures not formally identical? And we are led back to Jamiołkowski's and Choi's old insight: A quantum operation IS a density operator. With a little reflection, one sees that that had to be ... in the same way that *prior* probabilities $p(h)$ and *conditional* probabilities $p(h|d)$ are both probabilities nevertheless.

I would dare say that your point of view—where probability theory is, at very best, secondary to, or at very worst, absolutely detached from the deeper issues of quantum mechanics—would leave all of these things as little more than coincidences. "There is a way to map quantum operations and unitary operators to density operators? Who cares? It's just as mysterious as the structure of quantum mechanics to begin with."

But as long as there are coincidences in the structure of the theory, that structure will always be a mystery. What I think Bayesian probability theory does for us is COMPEL us to view as natural the connections we see within the axioms of quantum theory, rather than as miracles plain and simple.

So you see, you have depressed me. If I can't make any headway with my best and most sympathetic friends—you're one of them—I don't see how I'm going to make any headway in the wider world. Even YOU had not realized that all this talk about Bayesian stuff was meant to LEAD us, and not just be an afterthought tacked on for NOTHING BUT philosophical reasons.

Have you read Carl's document "Resource material for promoting the Bayesian view of everything" posted at his website `http://info.phys.unm.edu/∼caves/`? It would do you some good. It's about time you took a course in Bayesian Ideas 101. "What's wrong with the old frequentist definition?"—that about knocked me over!!

If after reading this note, you don't think it is too offensive, I may forward it to Carl and Rüdiger. I'll bet they too will be shocked—though much more polite in reaction than me—by this dangerous frequentist tendency you're starting to reveal.

I thought I was going to write a little report on your Copenhagen Computation today, but I knew I couldn't touch it until I got this off my chest. Sorry about that. I won't be able to write you a report until Sunday now. (I'll be in NYC tomorrow.)

In friendship, disappointment, and enduring hope, ...

13-01-03 *Ouch* (to N. D. Mermin)

I told Kiki the other night, "Well, I probably lost a friend today." In an ominous voice she replied, "What'd you do?" I said, "I wrote David Mermin a scathing note about some stuff in quantum mechanics." In a scolding tone, she said, "Why do you always do that?" I said, "I just couldn't take it. This guy hasn't hardly absorbed a thing in our six years of discussion!" She said, "Why do you get so upset? You know your work's never going to be done: Churches never go out of business, do they?"

Ouch.

13-01-03 *Der Kopenhagener Geist* (to N. D. Mermin)

I actually don't have much to say in the capacity of a referee.

First, a couple of typos: [...]

Finally, a little technical point: [...]

Now, let me tell you the thoughts you provoked as I was reading the paper.

Merminition 101: *The state of n Qbits has no meaning going beyond the abstract state vector itself, together with the rules for how it can be constructed and the computational uses to which it can be put. We return to this below, merely noting for now that although we shall speak often, as everybody does, of "the state of n Qbits" the terminology is potentially misleading. It must not be taken to imply that the state characterizes a property possessed by and directly inferable from* *those Qbits, as it does for Cbits. A better, but clumsier usage, would be always to say "the state associated with n Qbits".*

For my own part, I would say, "the state ascribed to n Qbits." "Ascribed to" is not a hell of a lot clumsier than "of," and it has the advantage that it makes clear and serves as a constant reminder that the origin of the "state" is not in the system itself, but in a system external to it—namely, the agent.

Merminition 102: *The fact that the generic multi-Qbit state is incompatible with associating states with the individual Qbits is already an indication that Qbit states have a much more abstract character than the states of Cbits, which are always products of one-Cbit states.*

Nice sentence. I like it. That's the way everyone ought to view the issue.

Merminition 103: *The state associated with the Qbits is merely an extremely convenient way of recording the potential consequences of the past actions of the computer on those Qbits. The consequences of those past actions can become accessible in only one way, and this way is the only way to extract information from n Qbits: one can measure them.*

There's something about this that I don't quite like, but I'm having trouble putting my finger on it. Probably has something to do with your using the word "consequences" in a way that I wouldn't endorse. See glossary on page 49 of my *Quantum States: W.H.A.T.?*

Merminition 104: *The Born rule contains, as a special case, a quantum imitation of the unproblematic (and therefore usually unremarked upon) process of extracting information from Cbits. ... The statistical, state-altering character of the outcome of a measurement of n Qbits in a general state becomes the deterministic, state-preserving, unproblematic classical extraction of information when the state is one of the* 2^n *classical-basis states. (page 7)*

and

Merminition 105: *The view of quantum mechanics I gave my computer scientists relies on a primitive notion of measurement, without which the computation has neither a beginning nor an end. A measurement gate is a black box whose interaction with the n Qbits results in an unambiguous output on a display, whose reading is as unproblematic as reading the display of an ordinary classical computer. Measurement is where the quantum-computational process starts, by permitting the association of an initial state with the Qbits, and finishes, by producing an unambiguous digital output. Quantum computer science delves no more deeply into how information is actually extracted from a measurement than does classical computer science, where the preparation of the initial state of the Cbits and the reading of their final state are steps too trivial to warrant explicit theoretical attention, though they are certainly of concern to the engineers who design the computer. (page 9)*

I like these lines. But ask a philosopher if this is unproblematic. The reason the physicist finds it unproblematic is the same reason he finds the independence or nonindependence of the continuum hypothesis unproblematic in transfinite set theory: He never thinks about it. But philosophical lives have come and gone on the question. (Probably, the question first came to life for me in reading William James's little book, *Pragmatism*.)

Anyway, I view your lines above as the greatest contribution of the present paper. That is, because they sort of soften up the western front for a (one-day-in-the-future) full-fledged assault. To the extent that you can find yourself willing to do that, I'm happy.

The way I would emphasize the issue, though, is to say that quantum measurement is either as *problematic* or as *unproblematic* as classical measurement, take your pick. The main point is that it is not MORE problematic.

Here's the way I put it in my `quant-ph/0205039`:

> As far as Bayesian probability theory is concerned, a "classical measurement" is simply any *I-know-not-what* that induces an application of Bayes' rule. It is not the task of probability theory (nor is it solvable within probability theory) to explain how the transition Bayes' rule signifies comes about within the mind of the agent.

And here's the way Rocco Duvenhage put it in another paper in `quant-ph`:

> In classical mechanics a measurement is nothing strange. It is merely an event where the observer obtains information about some physical system. A measurement therefore changes the observer's information regarding the system. One can then ask: What does the change in the observer's information mean? What causes it? And so on. These questions correspond to the questions above, but now they seem tautological rather than mysterious, since our intuitive idea of information tells us that the change in the observer's information simply means that he has received new information, and that the change is caused by the reception of the new information. We will see that the quantum case is no different.

The reason I say you are softening up the western front is because, though you seem to admit this for a single, particular quantum measurement—the computational basis—you haven't yet had the heart to admit it for ALL quantum measurements.

The only things, it seems to me, that set the quantum case of measurement apart from the classical case is A) what we do with the information we gather, and B) what we concede the information is about. In the classical case, we enact "Bayes' rule full stop" with the information we've just gathered. In the quantum case, we generally do something more (unless we are confident that the system we are talking about was not touched physically by our measuring device). Concerning B), we had gotten in the habit classically of thinking that the information we've just gathered is about "what is" or "what was." Quantum mechanics instead teaches us to look to the future. The information is about "what will be." (I use the measurement device LOCKED AWAY in the bureau of standards to make it dramatic.)

So, the action, the excitement, of quantum mechanics is not in the measurement, but in what it is that we're presupposing about the world that causes us to process our data differently than we would have classically.

Merminition 106: *A state can be associated with the Qbits only if their prior history is of a certain special form. The state can then be constructed out of the particular features of that history: the outcome of the initial measurement and the particular sequence of unitary gates subsequently applied to the Qbits prior to the moment at which one associates the state with the Qbits. But there is no way to determine that state if one is simply presented with the Qbits; only those who know this history know what state to assign to the Qbits. The state does not reside on the Qbits; it is a concise encapsulation of those features of their history, back to the initial measurement, that are relevant to the outcome statistics of a subsequent measurement.*

and

Mermინition 107: *But to describe this as a collapse of the state of the Qbits and to regard it as a second kind of time dependence that Qbits can have in addition to their unitary evolution, is to ignore the whole point of the state vector and its unitary evolution, and, of course, to confuse the Qbits themselves with the state vector that compactly summarizes the statistical implications of their past history for future measurement outcomes.*

Beside these two passages, I wrote in the margin, "Asher's 'What Is a State Vector?'." It's interesting that you (in your note Friday evening) called this accusation to be that of a "regress." This is because I think an infinite regress is all this view is gonna get you. That is to say, ultimately you're going to have to admit that the quantum state "compactly summarizes the statistical implications of [the] past history" of the entire universe.

Look at the discussion around Eq. (14) in my `quant-ph/0205039`. What you would call a measurement is always determined by a further quantum state for the apparatus. And off to infinity (or the boundaries of the universe) it goes.

Merminition 108: *Indeed, the generalized Born rule demonstrates that their state cannot be regarded as a property carried by the Qbits, since it provides an indirect method for associating a state with n Qbits that share an entangled state with an additional Qbit, and therefore cannot initially be associated with any state of their own. By measuring only the additional Qbit, one disentangles the $(n+1)$-Qbit state and is able to assign a state to the n Qbits, even though nothing interacts with them during or after the one-Qbit measurement. This is only possible because the association of all $n+1$ Qbits with an entangled state prior to the measurement requires the additional Qbit to interact with the n of interest at some time before it is measured. If one knows enough about that past interaction to determine the original $(n+1)$-Qbit entangled state assignment, then it is not surprising that the outcome of the measurement on the single Qbit can provide enough additional information to permit the assignment of a state to the n Qbits. This newly assigned state cannot be a property inherent to the n Qbits, because nothing interacts with them during the process that takes them from stateless and externally entangled to having a state of their own.*

Tell this to Philippe Grangier a thousand times and tell me whether you've made any more progress than I have. I think it is just silly to say "a state is a property" or "a state is a reality," and then say "some systems have no properties" (when they are entangled). The realization he should have is rather, systems have whatever properties they have, it is just that "the" quantum state is not one of them.

Finally,

Merminition 109: *[I]n our description of nature the purpose is not to disclose the real essence of the phenomena but only to track down, so far as it is possible, relations between the manifold aspects of our experience. — Bohr (1934)*

I don't like this quote, precisely because it is going to cause people to accuse you of what they always (unjustly) accuse me of: BANNING a set of questions that every physicist in his right mind ought to be asking. What is the real essence of the phenomena?

I have a pretty good reply to that now. I'll attach it (`ForSlusher.pdf`) for your midnight reading.

14-01-03 *Impact Analysis* (to L. Hardy)

As I was driving in to the office yesterday, I heard that January 13 is officially designated "Make Your Dreams Come True Day." That seemed apropos, as I was using the long drive to tumble some things over in my head about Perimeter.

I do have a dream, and it is simple and obvious and just about written on my forehead: It is to get at the heart of quantum mechanics (or help the friends around me to do it), and then turn that understanding toward the next big phase of physics. I do not think I am fooling myself by believing so strongly that we are within arm's reach of this goal. It is just a question of concentrated, right-headed thinking with a smidgen of creativity ... and probably the main issue is simply amassing enough intellectual resources in one place for a final resonance.

15-01-03 *Vanity, Sayeth the Preacher* (to J. W. Nicholson)

Nicholsonism 8: *Is everyone in quantum foundations as verbose as you?*

No one else in science is as verbose as me.

15-01-03 *The Ability to Write* (to N. D. Mermin)

I got a critique of one of my email expositions from a friend this morning, and he said:

Nicholsonism 9: *... the tone is probably appropriate. [But] it's about twice as long as (I thought) it needs to be. Is everyone in quantum foundations as verbose as you?*

He's got a grain of truth there. But I find it so hard to rope myself in sometimes. I guess the best writer says what needs to be said and little more. I've got to work on the demons inside me.

15-01-03 *Memory Lane* (to O. Cohen)

Pasted below is a letter I started to write to you in early December but never finished because of the holidays and some personal things that got in the way. ...

It seems I have email contact with you only about every three years. I hope things are going well. Where are you now, and what are you doing professionally? The last I remember, I recommended you seek a postdoc position with Carl Caves in New Mexico; I guess that never materialized.

Anyway, I'm writing you because I've been reading your paper "Classical Teleportation of Quantum States" this week. It's a nice paper, and I very much like the simplicity of your scheme and the point you make with it. I am in complete agreement.

In fact it took me a little down memory lane. You see, Asher Peres and I had used teleportation as an example in our March 2000 *Physics Today* article, "Quantum Theory Needs No 'Interpretation'," precisely to illustrate the sensibility of the conception of a quantum state as a "state of knowledge, rather than a state of nature". When the paragraph peaked in clarity (i.e., before the editor's knife), it went like this:

> The peculiar nature of a quantum state as representing information is strikingly illustrated by the quantum teleportation process. In order to teleport a quantum state from one photon to another, the sender (Alice) and the receiver (Bob) need a pair of photons in a standard entangled state. The experiment starts when Alice receives another photon whose polarization state is unknown to her, though known to some preparer in the background. She performs a measurement on her two photons, and then sends Bob a classical message of only two bits, instructing him how to reproduce the unknown state on his photon. This economy of transmission appears remarkable

> because to completely specify the state of a photon, namely one point in the Poincaré sphere, we need an infinity of bits. However, the disparity is merely apparent. The two bits of classical information serve only to transfer the preparer's information, i.e., his *state*, to be from describing the original photon to describing the one in Bob's possession. This can happen precisely because of the previously established correlation between Alice and Bob.

At the time I was basing my opinion predominantly on the result of Cerf, Gisin, and Massar (`quant-ph/9906105`, "Classical Teleportation of a Quantum Bit") along with the long heartfelt conviction that the idea of a quantum state as a state of knowledge gave the most sensible and constructive point of view about quantum mechanics. Sometime after that though, Steven van Enk and I—to the best of my recollection—worked out a scheme pretty similar to your own at the chalkboard at Bell Labs. We never wrote it down however.

But that doesn't take away from your discovery. It's a very clean example, isn't it? The conclusion you draw, I think, is particularly important: the phenomenon of quantum teleportation only looks surprising and remarkable if one takes an ontic view of the quantum state. In fact, in the past, I have accused some of my friends (some of whom were authors on the original teleportation paper) of sticking with an ontic interpretation of the quantum state precisely because it is the only way to keep the phenomenon surprising and newsworthy. You might enjoy reading some of my correspondence with them on the subject: Have a look at pages 175–176 and 184–189 of my samizdat *Quantum States: What the Hell Are They?*. The said accusation comes on page 189. That correspondence occurred, by the way, as they were debating about how a dictionary definition of "quantum teleportation" should be written. (To get a copy of this samizdat, you can download the pdf file for it at my webpage; there's a link to the webpage below in my 'signature'.)

If you are interested in seeing the struggle Asher and I had in constructing the paragraph above (and the reasoning and cues behind it at the time), have a look at the discussions in my other samizdat, *Notes on a Paulian Idea*, `quant-ph/0105039` (or you can download a better indexed version of it from my webpage). The pages to look at are 312, 316, 319-320, 322, 326, 327-330. I have pages 326, 328, and 329 marked as the most interesting in my notebook (can't quite remember exactly in what way though). Maybe the main lesson in those discussions is how difficult it is to give up an objectivist language when using quantum states, even for a recalcitrant positivist like Asher, and even in an example intended to be illustrative of why quantum states should be viewed as states of knowledge, rather than states of nature. (The philosophy being: if quantum mechanics looks too very mysterious, then you're probably being wrong-headed about it. Case in point: if teleportation looks mysterious, then you're probably being wrong-headed about it too.)

The sense I get from your paper is that you are much more neutral about the lesson than I am. You say simply: "[O]ur classical version of teleportation is just as impressive as the original protocol, if we think of quantum states as representing states of knowledge. . . . If, on the other hand, we think of a quantum state as having ontological content, . . . , then our classical version of teleportation is not equivalent to the quantum case," and leave it at that. However, there is a spate of evidence starting to come out that a significant fraction of some of the most 'remarkable' phenomena in quantum information theory can be mocked up with classical toy models just as your own. The only requirement for seeing it is that one must focus on the epistemic states (i.e., the states of knowledge) in such models rather than the ontic states (like the actual H or T in your own model). For instance, Rob Spekkens has a toy model which he has presented in several conferences and which he is writing up presently as a paper, "In Defense of the Epistemic View of Quantum States: A Toy Theory," in which he can reproduce the following quantum mechanical and quantum information-theoretic type phenomena in a pretty NONremarkable way:

the noncommutativity of measurements, interference, a no-cloning theorem, a no information-gain-without-disturbance principle, the multiplicity of pure state decompositions of a mixed state, the distinction between two-way and intrinsic three-way entanglement, the monogamy of entanglement, superdense coding, mutually unbiased bases, locally immeasurable product bases (i.e., what we originally called 'nonlocality without entanglement'), unextendible product bases, the possibility of secure key distribution, the impossibility of bit commitment, and many others. (In particular, he gets teleportation too, just like you do.) As Rob puts it in his abstract:

> Because the theory is, by construction, local and non-contextual, it does not reproduce quantum theory. Nonetheless, a wide variety of quantum phenomena have analogues within the toy theory that admit simple and intuitive explanations. ... The diversity and quality of these analogies provides compelling evidence for the view that quantum states are states of knowledge rather than states of reality, and that maximal knowledge is incomplete knowledge. A consideration of the phenomena that the toy theory fails to reproduce, notably, violations of Bell inequalities and the existence of a Kochen-Specker theorem, provides clues for how to proceed with a research program wherein the quantum state being a state of knowledge is the idea upon which one never compromises.

So, given that your paper is an independent and particularly notable link in that, and as opposed to his paper, your result is not buried within over 70 pages (and counting) of text, I very much endorse it. I think the lesson is this: A good lot of quantum information theory is simply regular probability theory and information theory applied in ways that had not been deemed interesting before. What is interesting and unique to the quantum itself, thus, must be something else.

In my paper `quant-ph/0205039`, "Quantum Mechanics as Quantum Information (and only a little more)," I tried to give the community to a call to arms by saying this:

> This, I see as the line of attack we should pursue with relentless consistency: The quantum system represents something real and independent of us; the quantum state represents a collection of subjective degrees of belief about *something* to do with that system (even if only in connection with our experimental kicks to it). The structure called quantum mechanics is about the interplay of these two things—the subjective and the objective. The task before us is to separate the wheat from the chaff. If the quantum state represents subjective information, then how much of its mathematical support structure might be of that same character? Some of it, maybe most of it, but surely not all of it.
>
> Our foremost task should be to go to each and every axiom of quantum theory and give it an information theoretic justification if we can. Only when we are finished picking off all the terms (or combinations of terms) that can be interpreted as subjective information will we be in a position to make real progress in quantum foundations. The raw distillate left behind—minuscule though it may be with respect to the full-blown theory—will be our first glimpse of what quantum mechanics is trying to tell us about nature itself.

What your work and Spekkens' work does, from my perspective, is give the best illumination yet of what I was hoping for when I was speaking of "combinations of terms" in that passage. Teleportation—being a certain combination of uses of the axioms of quantum mechanics—is nevertheless a purely probabilistic or information-theoretic effect. As such, it tells us very little about the ontology behind quantum mechanics.

My own view—and the thrust of my research program presently—is that these examples help us to realize that what is unique in quantum mechanics is not the probabilities (i.e., the quantum states) but what the probabilities are applied to. There, I think, lies the essence of quantum mechanics: It is localized in the Kochen-Specker theorem. "Unperformed measurements have no outcomes," as Asher Peres likes to say. That is to say, where quantum mechanics gets its uniqueness is from breaking with the old idea that a probability (as a subjective state of knowledge) must be knowledge about a pre-existent reality. Instead, probabilities can just as fruitfully be applied to capturing one's knowledge of "what will come about due to one's actions." The predominant issue becomes how to formalize the difference between probability theory as applied to pre-existent facts and probability theory as applied to "creatables" (for want of a better word).

There are some lines for tackling this idea buried within Sections 6.0 and 6.1 of my `quant-ph/0205039` ...

16-01-03 *A Footnote* (to H. J. Folse)

I've been reading William James's book *Essays in Radical Empiricism* and I came across a footnote in "How Two Minds Can Know One Thing" to do with something Harald Høffding said. It just piqued my interest because I know from your papers (and some other things) that there is an interest in the extent to which William James may have influenced Bohr via the conduit of Høffding. What I have never seen any talk of is the extent to which Høffding may have influenced James. Do you know of any works in that regard?

On a related point, now that I've started to take such an interest in James's theory of truth and what I perceive as its similarity to the stance Asher Peres and I have taken on quantum mechanics, I've started to wonder why there has been so little scholarly work on this before. In Henry Stapp's 1972 paper "The Copenhagen Interpretation" there is a decently extensive discussion on pragmatism, but I don't think I've seen anything really beyond that. Could it be that there's a big gap in my canvassing of the literature? Do you have any leads? Or is it just, unfortunately, a subject that has been overlooked heretofore?

Henry's Reply

> There's no doubt that Høffding was very excited by James' radical empiricism, and I think that it is reasonable to say something like they were "on the same wavelength" but that they had arrived at their views more or less independently. Both men were psychologist-philosophers in a time when psychology was just beginning its break away from the womb of philosophy. Both were empiricists, and both took the "enemy" to be the then dominant force of idealism. H's interest in the question of free will was no doubt stimulated by his interest in Kierkegaard, but surely resounded strongly with James central interest in that same issue. H's *History of Modern Philosophy* which was published in 1895 makes no mention of James. So I suspect his admiration for James only began sometime between 1895 and 1904. He was one year younger than James, when they met in 1904 James would have been 62 and H 61, so I think that their outlooks were pretty well already formulated by that point. In the spring of 1905, right after his visit to James in the fall of 04, H gave a series of lectures on "the psychology of free will" which definitely featured James (he also lectured on Renouvier, whom James admired, and Boutroux, both of whom Jammer has pegged as expressing the same theme that experience can never be completely captured by any conceptual scheme). It was also in 1904-05 that James wrote and put in an envelope marked "essays in radical

empiricism" most of the articles which Perry later posthumously published as *Essays in Radical Empiricism*. Also, right after his return from America in 1905 H published an English translation of his 1902 Danish book called *Philosophical Problems* which included a preface by James himself. We're not certain, but there is a good bit of circumstantial evidence that Bohr attended at least some of H's 1905 lectures. Even if he didn't, it seems to me that it is inconceivable that he never discussed James with Høffding. So clearly J can be said to have "influenced" H, but perhaps it would be best put by saying J's influence was one of underscoring themes that were already present in H's thinking before he visited James.

As to whether or not H "influenced" J, I am not sufficiently familiar with the James materials to venture more than a speculation. However, I do know who probably could answer that. He is John J. McDermott, who's at Texas A&M and has edited a lot of James materials. When he visited Loyola 15 years or so ago I talked with him about James and Høffding, but I was of course primarily interested in both of their influences on Bohr, not on each other. James had only 6 years left after he met H, and I doubt if he had read any of H's works earlier. So there would not have been a lot of time for any great amount of influence, though James's work continued to evolve right up to the end, so one can't rule it out. Of course most of H's writings were in Danish, which James would not have known, but he did know German, and I believe H had published his Kierkegaard book in German. It is just possible that J could have read that, but I think what brought the two men together was more likely to have been the common interest in psychology. In 1906 H published an English translation of his book on *Philosophy of Religion*; I would imagine he very probably sent James a copy, and that surely would have interested James, but I think that H was a good deal less tender minded when it came to religion than was James. So I would think that if there were any influence from H to J, it would have most likely had to come through their conversations in the fall of 04 and the subsequent correspondence that must have been concerned with the publication of James's Preface to H's English translation of his book. As I recall, McDermott had definitely read this correspondence (I imagine it's at Harvard?) but as I said, I didn't ask about any influence of H on J. I also recall one of my old mentors, Andy Reck at Tulane, who wrote a book on James for the French, knowing something about Høffding and James, so I'll ask the next time I see him, but I would think McDermott would be a better bet.

> On a related point, now that I've started to take such an interest in James's theory of truth and what I perceive as its similarity to the stance Asher Peres and I have taken on quantum mechanics, I've started to wonder why there has been so little scholarly work on this before. In Henry Stapp's 1972 paper "The Copenhagen Interpretation" there is a decently extensive discussion on pragmatism, but I don't think I've seen anything really beyond that. Could it be that there's a big gap in my canvassing of the literature? Do you have any leads? Or is it just, unfortunately, a subject that has been overlooked heretofore?

I think that you're right if by pragmatism you mean particularly William James, and/or the so called "classical" pragmatists Peirce and Dewey. But in a larger sense pragmatism has seeped into a great amount of American philosophy and can be said to be a major element in the thought of people like van Fraassen (BTW, I had a very brief conversation with him about you last November) and Arthur Fine. Certainly I would say my own interpretation of Bohr reflects a lot of pragmatist themes, and you could reasonably say I characterize Bohr as a "pragmatic realist." (There is a different anti-realist branch of pragmatism which is represented by vF and Fine.) If I had to name a pragmatist to affiliate this view with, I'd say it is close to C. I. Lewis. In my years of discussion of Bohr with my colleague Jan Faye, I've always pushed Bohr closer to pragmatism, while Jan pushes him closer to positivism. Indeed I would say that a lot of what people see as "positivist" about Bohr, are really the themes that positivism shares in common with pragmatism, namely a hard nosed empiricism.

Have you looked at Max Jammer's two books? I'm quite certain he discusses Bohr and James, but I don't own copies of his books. Gerald Holton also does the James-Bohr issue in his well known article in *Thematic Origins of Scientific Thought* but there's nothing you'll learn there that isn't in my book, and I think he caves in too easily to Rosenfeld's "authority" on the James/Bohr influence. Jan doesn't discuss pragmatism per se but he does discuss James a fair bit in his book on Bohr and Høffding. You ought to just take a look at his book, *Niels Bohr: His Heritage and Legacy*, for its exposition of Høffding in Chap IV, which is without doubt the most detailed exposition of H available in English.

Now that you bring it up, I think one thing is that a lot of those who've written about the history of QM are Europeans and therefore perhaps less likely to emphasize pragmatism or see pragmatism at work in the quantum revolution than would Americans. Most of the younger generation of philosopher physicists writing these days are not so interested in historical kinds of questions, but just take off from the formalism (you're exceptional in that you seem to be going in the reverse direction). Another thing is that the only classical pragmatist to live long enough to actually write on QM was Dewey, and he got uncertainty all messed up as a disturbance caused by elephants trying to measure grains of sand. So that would hardly be likely to enthuse people to look for insights into QM from Dewey. But apart from stupid things he might have said about QM, there are in Dewey's vast corpus a lot of interesting insights about the scientific description of nature which could possibly be useful to someone looking to make sense of quantum mysteries. The same thing might be said about Peirce who saw "truth" as what an ideal rational body of inquirers would reach given an infinite amount of time. Rather than explain the process in terms of the end goal, he explained the goal in terms of the end of the process, and that's really a very profound notion. But if you're looking for contemporary pragmatists, there's no doubt that the leading "pragmatist" expositor on QM these days is none other than van Fraassen in your own backyard. He's of course a pragmatic anti-realist, but one who oddly retains a realist correspondence notion of truth that pragmatists would typically reject. It's just that he thinks this realist notion of truth has nothing to do with "acceptance" of scientific theory which is done solely on the basis of its empirical adequacy and supplementing pragmatic virtues.

I'll let you know if I think of anything else.

18-01-03 *The Quantum Principle, whatever it might be* (to L. E. Ballentine)

Somehow I've been spared from the Volovich, Khrennikov, etc., distribution list on "What is Quantum Mechanics?" ... and I'd like it to stay that way! But this morning David Mermin forwarded me one of your notes (pasted below), which I did enjoy. The point you make is an important one, and I think the whole nub of the matter.

I try to express something similar in my paper "Quantum Mechanics as Quantum Information (and only a little more)", `quant-ph/0205039`. I'd like to think that paper makes a little progress toward your goal, but, if so, there is still a long, long way to go. In any case, I think you might enjoy the paper because of some things I remember reading in your papers and your book several years ago and also because of some discussions I've had with your student Joe Emerson. In particular, playing up the analogy between the quantum state and the Liouville distribution for all it is worth is, I think, the most important move for getting the whole project off the ground.

If you have any comments on the project set forth in that paper (and expanded at my website, link below), and in particular on how we might go further, I'd certainly love to hear them.

Ballentine's Entry in the Discussion

I think that this question is best interpreted as, "What are the principles of Quantum Mechanics?". (Indeed, Igor Volovich referred us to his Seven Principles ....)

The first two principles are usually given as:

(a) Observables are represented by self-adjoint operators on a Hilbert space;

(b) Pure (mixed) states are represented by vectors (statistical operators) in Hilbert space.

What, if any, is the physical content of these postulates? They contrast most unfavorably with Einstein's two postulates, from which all of Special Relativity can be derived:

(1) Equivalence of all uniformly moving frames of reference;

(2) Invariance of the speed of light, c.

These are physical postulates. At least (1) has strong intuitive appeal. Both can be directly tested by experiment. And all of SR follows from these two postulates.

Return now to postulates (a) and (b) of QM. They lack any intuitive appeal. They cannot be directly tested. They are insufficient to solve even one real problem in QM.

By itself, (a) seems to impose no physical restriction, since the spectrum of an operator may contain any possible range of discrete and continuous values. The Indeterminacy Principle is permitted, but not implied, since the observables might, at this stage, be commutative or not. Perhaps (b) together with (a) imposes some physical restrictions, but that is far from obvious. And Gleason's theorem seems to make (b) inevitable after (a).

The specific content of the theory (needed in order to solve any physical problems) enters when we specify which particular operators correspond to which particular observables. Although this is sometimes done by means of extra postulates, in fact the most important operators can be derived by requiring invariance under the space-time symmetries (displacements, rotation, and Galilean transformations). [See my book, *Quantum Mechanics – a Modern Development*, World Scientific, 1998.] In particular, the commutation relation between position and momentum, and hence the Indeterminacy Principle, now follows.

But the same space-time symmetries hold in Classical Mechanics, where there is no Indeterminacy Principle. So postulates (a) and (b) must have imposed some restrictions on the physical contents of the theory, in spite of the appearance that they only defined a general mathematical form without specific physical content.

So my questions are:

- What are the *physical* principles of Quantum Mechanics?
- Can they be expressed in a more transparent form?
- To what extent do the usual postulates (a) and (b) restrict the physical content (not merely the form) of Quantum Mechanics?

20-01-03 *Munificence* (to S. Aaronson)

Thanks for teaching me the word munificence. I'll try to incorporate it into my vocabulary!

Aaronsonism 3: *How far would you take your famed battle cry, "Give an information-theoretic justification if possible"? In particular, venturing beyond QM, would you want/expect an information theoretic justification for why space has 3 visible dimensions, or why the cosmological constant is positive? Both things have been worrying me a lot lately.*

Unfortunately, I don't know how to answer that yet. My feeling is that eventually the battle cry ought to stop. But where, I don't have a strong feeling of yet. I try to lay out the philosophical underpinning of this idea in my `quant-ph/0204146`, where I talk about the "core" of a theory—i.e., a part that at some level likely does not have an agent-centered information-theoretic reason.

I also try to say it somewhat differently in a recent essay I wrote; I'll paste it below. [See 06-01-03 note "Pedagogy" to N. D. Mermin.]

Aaronsonism 4: *I've gotten increasingly annoyed with people who whine, "We need more algorithms! Shor's and Grover's are not enough!" I'm starting to suspect that large-scale quantum computers would be incredibly useful, but for entirely different reasons than the ones that excite us computer scientists. Is that reasonable? I.e. am I mistaken to think that in whole areas of chemistry and high-energy physics, the biggest bottleneck right now is the lack of a quantum computer (to do things like perturbation sums)?*

Yeah, I think that's probably true. But now a question to you. To what extent has it been proven *rigorously* that quantum computers are efficient at performing simulations to do with interesting questions about *other* quantum systems?

20-01-03 *And Believing Simulations* (to D. Poulin)

You're going to be ashamed of me—or maybe you always expected it!—but I've only now read (in detail) the note you sent me December 20!

I liked your phrase "objectivity distillation."

Poulinism 7: *I came across a very simple problem lately which forced me to choose an interpretation for the wave function. It is a little bit hard to explain in an email but I'll gave it a shot.*

I did gather that your note is a specific—and, as opposed to what my lazy butt was willing to do, actually worked out—instance of the sort of thing I talked about a lot in my file *Quantum States: What the Hell Are They?* I.e., of a program I spelled out to Brun-Finkelstein-Mermin in a 7 August 2001 note in this way:

I have the feeling that if quantum mechanics is really about knowledge and only knowledge—or better, belief convergence and *only* belief convergence—then FOR ANY GIVEN METHOD OF GATHERING INFORMATION, there *should* be a way to ferret out of quantum mechanics the necessary and sufficient conditions on two observers' initial state assignments, so that the gathered information leaves them in a better agreement than they started out with.

But I missed this: Which interpretation were you forced to choose!?!? (I'm keeping my fingers crossed we'll see each other in heaven!) Seriously, does this example cause you to lean more toward the epistemic interpretation of the wavefunction or further away? And why? I didn't understand your reasoning on that.

David's Reply

Yes, my note was definitely in this spirit. When I tried to find a way of simulating this system, it was screaming out for an epistemic interpretation for the wave function. But I don't have a complete understanding of it. In its current formulation (which I would call hybrid epistemic-ontic), the monte-carlo simulation will inevitably be observer dependent. What I would like to do is to formulate it in a purely epistemic way, just like you guys did with the tomography problem. Thus, my goal would be to run a monte-carlo which simulates the measurements performed by the observers but whose branching probability is not observer-dependent. This would allow them to dilute objectivity in the sense that I have tried to explained in my previous message. In fact, whether the observers come to an agreement or not (a sort of agreement measure) will also be observer dependent in this simple model which is quite strange!!!

I could tell you many strange things about this simple model but there are probably things you have already thought about ... and they are quite easy to discover when you think of how you would go and numerically simulate this system.

By the way, one of the Montréal talks has really influenced me ... my own! I am taking this physics simulation business quite seriously. In an attempt to show that there is no fundamental (i.e. sub-polynomial) advantage at using a Q-computer to simulate a physical system, I am looking into information processing at the Planck scale. That's right!

20-01-03 *More Pragmatism* (to H. J. Folse)

Thanks for the detailed note. Let me go through it sequentially and make just a few comments.

Folsesm 13: *Also, right after his return from America in 1905 H published an English translation of his 1902 Danish book called* Philosophical Problems *which included a preface by James himself.*

I'll try to dig up a copy of that. That sounds interesting to me.

Folsesm 14: *He is John J. McDermott, who's at Texas A&M and has edited a lot of James materials.*

In fact, I have a massive collection that he put together—*The Writings of William James: A Comprehensive Edition*. It was one of the first things I bought when I took an interest in James. However, I soon discovered that I preferred the original (little) books; they're much easier to carry around in a coat pocket. I'll have a look in the index to that book when I get home. Also, though, I had planned on visiting Marlan Scully and Ed Fry at Texas A&M sometime this year; so maybe I'll try to work up a visit with him too.

Folsesm 15: *Well, I don't remember being much impressed by the exposition of "pragmatism" in Stapp's paper, though it was ages ago that I read it.*

Yep, don't get me wrong: I wasn't particularly impressed with it either. I was only trying to imply that that is the only thing I know of along those lines.

Folsesm 16: *I think that you're right if by pragmatism you mean particularly William James, and/or the so called "classical" pragmatists Peirce and Dewey.*

Yes, that is exactly what I meant.

Folsesm 17: *But in a larger sense pragmatism has seeped into a great amount of American philosophy and can be said to be a major element in the thought of people like van Fraassen (BTW, I had a very brief conversation with him about you last November).*

Aha, that might explain why I got an email from him November 21 that started out like this:

> I know I have not been very communicative recently, but I thought in any case I'd let you know about this bit of Bayesianism ...

I have wondered a little bit about whether I've rubbed him raw, since I didn't hear too much from him after his fairly enthusiastic introduction.

Folsesm 18: *Have you looked at Max Jammer's two books? I'm quite certain he discusses Bohr and James, but I don't own copies of his books.*

Yes, I have read them both (years ago). And more recently I have noted the relevant material in them on this subject. But it's not deep enough for my tastes.

Folsesm 19: *Jan doesn't discuss pragmatism per se but he does discuss James a fair bit in his book on Bohr and Høffding. You ought to just take a look at his book.*

I read it too, about 10 years ago. I remember there were parts in it that I absolutely loved. But then I remember there were parts (like his discussion of Bell inequalities) that I absolutely hated—I thought he went way off the mark. I should reread the book from start to finish, to see how it affects me now. I have certainly changed a lot in my opinions about quantum mechanics since those days. In fact, maybe I'll try to see if I can buy the book.

Folsesm 20: *Another thing is that the only classical pragmatist to live long enough to actually write on QM was Dewey, and he got uncertainty all messed up as a disturbance caused by elephants trying to measure grains of sand. So that would hardly be likely to enthuse people to look for insights into QM from Dewey.*

Yep, that's sad. The insights I'm looking for have to do with a) James's theory of truth, b) James's pluralism, c) and the lovely idea that the universe is still under construction.

Let me attach a couple of essays I've written in connection to this cluster of issues.

1) To contrast myself to the Deweyian thing you mention above, I'll attach a note titled "Pedagogy." [See 06-01-03 note "Pedagogy" to N. D. Mermin.]

2) To expand on the pluralism thing, I'll attach part of a note titled "Probabilismo!" It builds on some previous stuff that I had sent you about Ulfbeck and Bohr the younger. [See 14-11-02 note "Probabilismo!" to D. M. Appleby.]

3) Finally, concerning c) above, now that you can download my files, why don't you have a look at two notes I wrote Howard Wiseman in the collection "Quantum States: What the Hell Are They?" The titles are "The World is Under Construction" and "Probabilism All the Way Up" and start on pages 210 and 217, respectively. This is where pragmatism strikes me the most.

21-01-03 *Høffding and James* (to H. J. Folse)

I did manage to find the following by looking through Ralph Barton Perry's *The Thought and Character of William James*. (I had previously read the condensed one volume version, but just last week in Manhattan I picked up the full two volume version for $30. Høffding was not mentioned in the condensed version. Now I'm chompin' at the bit to read the full thing—it has loads more stuff about Boutroux, etc.)

The first mention of Høffding recorded there is in a letter from James to John Dewey dated 17 October 1903:

> It rejoices me greatly that your School (I mean your philosophic school) at the University of Chicago is, after this long gestation, bringing its fruits to birth in a way that will demonstrate its great unity and vitality, and be a revelation to many people, of American scholarship. I wish now that you would make a collection of your scattered articles, especially on "ethical" subjects. It is only books that tell. They seem to have a penetrating power which the same content in the shape of scattered articles wholly lacks. But the articles prepare buyers for the books. My own book, rather absurdly cackled about before it is hatched, is hardly begun, and with my slow rate of work will take long to finish. A little thing by Harald Høffding, called *Philosophische Probleme*, which I have just read ... is quite a *multum in parvo* and puts many things exactly as I should put them. I am sure of a great affinity between your own "monism," since you call it, and my "pluralism." Ever gratefully and faithfully yours,

The second comes from a 1910 article in *Nation* titled "A Great French Philosopher at Harvard." James writes:

> The great originality of M. Boutroux throughout all these years has been his firm grasp of the principle of interpreting the whole of nature in the light of that part of it with which we are most fully acquainted, namely, our own personal experience. ... Those readers who know something of present-day philosophy will recognize in my account the same call to return to fullness of concrete experience, with which the names of Peirce, Dewey, Schiller, Høffding, Bergson, and of many minor lights are associated. It is the real empiricism, the real evolutionism, the real pluralism; and Boutroux (after Renouvier) was its earliest, as he is now its latest, prophet.

21-01-03 *Choice Quotes* (to G. J. Milburn)

I just canvassed all the book reviews in QIC, in preparation for the one I've got to write on Holevo's new book. I just loved a couple of choice quotes from your article in QIC **1**, p. 89.

> [N]o one has seen a 'probability' in the same way we see a coin land heads up or a pointer deflection on an instrument.

That one was fun because I had just had a conversation with Steven van Enk a week ago, in which he asked, "How would you explain that we never experience a superposition?" I replied, "Have you ever experienced a probability distribution?" A few days later, he came in and told me that that single line had made a big effect on him. He also suggested that I should write a paper of single-liners (maybe in question and answer format): He thinks that my usual papers are far too long, and that I'd get the message out more effectively if I'd trim them so that people can see what the point is! If I ever do follow through, I'll make sure to cite your book review.

> There is no consensus view on why quantum mechanics offers a bonus, if any, in computational efficiency. The allusions to the many-worlds-interpretation of quantum mechanics in the chapter introducing quantum computation, provide an indication of how desperate the situation is. The many-worlds-interpretation provides most certainly not a consensus view of quantum mechanics and, while seductive, it seems to me little more than the last desperate refuge of the classically minded. As far as I am aware photons do not interact with each other in this universe, let alone with photons in other putative universes.

That is great!! It's somewhat like another line that I love, that you might enjoy too. It comes from David Mermin's pedagogical paper, `quant-ph/0207118`. He writes,

> There are nevertheless some who believe that all the amplitudes … have acquired the status of objective physical quantities, inaccessible though those quantities may be. Such people then wonder how that vast number of high-precision calculations (10^{30} different amplitudes if you have 100 Qbits) could all have been physically implemented. Those who ask such questions like to provide sensational but fundamentally silly answers involving vast numbers of parallel universes, invoking a point of view known as the many worlds interpretation of quantum mechanics. My own opinion is that, imaginative as this vision may appear, it is symptomatic of a lack of a much more subtle kind of imagination, which can grasp the exquisite distinction between quantum states and objective physical properties that quantum physics has forced upon us.

Anyway, as usual, I just wanted to get this stuff into my computer and I used you as the sounding board. Thanks for the opportunity. I'll repay you with a little essay I wrote the other day (on the subject matter of 2 above); I'll paste it below. [See 06-01-03 note "Pedagogy" to N. D. Mermin.]

21-01-03 *The Thawing Heart of David Poulin* (to D. Poulin)

Your notes are warming my heart! To see you embrace this distillation idea (and develop it from your own perspective) so keenly, and to see you actually do something with it, is just great.

Poulinism 8: *In fact, whether the observers come to an agreement or not (a sort of agreement measure) will also be observer dependent in this simple model which is quite strange!!!*

No, I think that's quite marvelous and something that one shouldn't loose sight of. I'm guessing it's a general feature of all models that do this problem correctly. See my attempt to formalize the issue on pages 23 and 24 of my *Quantum States: What the Hell Are They?* on my webpage. You'll see I accounted for the potentiality of that feature too.

Poulinism 9: *By the way, one of the Montreal talks has really influenced me ... my own!*

I'm glad you got something out of one talk!

21-01-03 *Peeling Away the Agent* (to S. Aaronson)

Aaronsonism 5: *I loved your diatribe to Preskill. But I realized we have different ideas of what it means for a fact to have an "information-theoretic justification." For you, it means the fact is observer-dependent, and therefore we should "peel it away" if we want to uncover a theory's true physical content (as in your general relativity example).*

For me, the fact could be as observer-independent as anything we know – e.g., the dimensionality of space. Giving an "information-theoretic justification" means you show 3 things:

(1) The fact in question has some implication for the computational complexity, communication cost, etc. of some problem. (That is, anything that would interest a computer scientist.)

(2) If the fact were different, the implication would change.

(3) We (or at least I) have strong intuitions regarding computation: for example, NP-complete problems should not be solvable efficiently. Changing the fact would violate these intuitions – thus yielding an "information-theoretic justification" for why the fact is the way it is.

The ground for a disagreement with that, actually, is maybe the biggest thing I took away from Timpson's thesis. And I guess that's why I liked it. In particular, I had not appreciated so much before the very human-centeredness of the Turing-machine concept. That is, a mathematical model for what is humanly computable.

Also, just focus on the phrase "communication cost." When it comes time to quantify that, a probability distribution is going to be introduced somewhere. At that point, I say, you may not realize it but an agent has been invoked. For, probability ultimately only makes sense as a gambling commitment an agent would be willing to make—i.e., probability only makes sense in the Bayesian sense.

Below, I'll paste a (part of a) note I wrote to Ari Duwell and I'll attach a copy of the paper he's putting in the special issue of *Studies in History and Philosophy of Modern Physics* that Jeff Bub and I are editing. [See 06-12-02 note "Quantum Information Does Not Exist" to A. Duwell.] Between the two of them (including the references I put in the note), I hope it better explains this viewpoint I'm building up.

Aaronsonism 6: *Cases where I think the program has already been carried out include "why is quantum mechanics linear?" and "why is there a minimum length scale (i.e. the Planck scale)?" Also, your de Finetti paper goes some way toward carrying it out for "why are amplitudes complex rather than real or quaternionic?"*

And I'd like to think that Sections 4.2 and 6 of my paper `quant-ph/0205039` get at "information-theoretic reasons" for why the structure of quantum measurements takes on that of the POVMs and, also, why the state-change rule (for what happens upon the completion of a measurement) is what it is.

Finally, let me comment on something that I missed in your last note.

Aaronsonism 7: *PS. I remember you talked about William James in the samizdat . . . Have you read the* Principles of Psychology*? I'm working through it now. I've decided to recommend it to people as "the most up-to-date, state-of-the-art book about consciousness" (without telling them the publication date).*

Is that really true? Do you really believe that? In any case, the comment warms my heart, as I have turned into a huge fan of William James since my first samizdat. I only sort of knew him cursorily when I wrote that stuff. But now he is splattered all over the place in the new samizdat, "Quantum States: What the Hell Are They?"

You might enjoy the stories of my real discovery of him recorded therein. Take a look at "The Reality of Wives" on page 15 (sent to Landahl and Preskill) and the bottom of page 218 in the note "Probabilism All the Way Up." The document is posted at my website.

I haven't read *Principles of Psychology* yet, but I have read *Pragmatism*, *The Meaning of Truth*, *Some Problems in Philosophy*, *Essays in Radical Empiricism*, and a few other scattered articles like "The Sentiment of Rationality." Also—though not written by James—I've read *The Cambridge Companion to William James* and a couple of other second source books. Finally, Ralph Barton Perry's book, *The Thought and Character of William James (Briefer Version)*, is just wonderful. And it's chock full of great letters. Just last week in Manhattan I finally found a copy of the full version, in two volumes, and I'm chompin' at the bit to get at it.

22-01-03 *Another Footnote* (to H. J. Folse)

This one I dug up from somewhere on the web.

> The classic discussion of the "stream of thought" is, of course, to be found in James, W. (1890). *The Principles of Psychology* (2 vols.). New York: Henry Holt; for a discussion of James's view on the "stream of thought," see the essay on James in this volume. While there are only two references to Høffding in James's *Principles*, one having to do with Høffding's theory of recognition memory, a second with Høffding's position on the role of bodily sensation vs. "spiritual affection" in emotion, and both are mildly critical, James nonetheless goes out of his way to indicate a general approval of Høffding's work, in one instance referring to "his excellent treatise on Psychology" (James, op. cit., Vol. 2, p. 455) and in the other professing his "respect for him as a psychologist" (ibid., Vol. 1, p. 674).

29-01-03 *Elegance* (to A. Peres)

Elegance is always in the eye of the beholder.

I just ran across `quant-ph/0212062`, where the last sentence of the abstract reads, "Thus we recover Fuchs and Peres' formula in an elegant manner."

Still, it would be interesting if they have developed a powerful formalism.

05-02-03 *Accuracy (Urgent)* (to J. M. Renes)

I'm hurriedly writing the last section of a long overdue paper on a measure of quantumness for ensembles of states, and I mention symmetric informationally complete POVMs there. Could you take a look at my footnote on page 23 and check it for accuracy? (I mention the business about the long overdue paper to hopefully give you a sense of my urgency!) In particular, I have heard of some other people involved in the SICPOVM project—for instance, the guy who constructed the $d = 4$ case—and I know I should mention them too if I'm going to mention anyone. But I don't know who they are. I'll attach the paper as a PDF file.

06-02-03 *Midnight Oil* (to M. Sasaki)

Do you want a house in America? Ours just showed up in the real estate listings today: [...]

I am going to miss the place. Do you see the rightmost section of the house, with two windows toward the front, and three windows on the side? There are also two windows on the backside that you cannot see. That is the section of the house that I used as my study. I surrounded myself with sunlight and the philosophy of William James in there. Too bad I never got a chance to invite you over for a stay.

But the science will be good for me in Ireland. And that is always what keeps my heart beating. John Lewis (of Davies and Lewis) will be my boss. Also I will have a significant overlap with Chris King and Mary Beth Ruskai, who will themselves be visiting there for something like 2 and 4 months respectively. My plan is to greatly develop the ideas of Section 7 in my paper `quant-ph/0205039`. This will require that I much better understand the structure of the set of completely positive maps. I think I have a set of questions in that regard that no one has ever explored before. Basically, I want to develop the slogan, "A quantum operation is nothing but a quantum state in disguise." Lately I am taken with the idea that the Jamiołkowski representation theorem—equation 116 in my paper—is one of the deepest statements in all of physics ... second only to Einstein's principle of equivalence! (I am only joking a little!)

Anyway, I want to very much apologize to you again for causing such a great delay in getting our paper into the public eye. Deep inside I am a very selfish and undisciplined person, and it can hurt my friends and associates. It is a shame that you got caught up in that.

06-02-03 *Looking at the List Again* (to N. D. Mermin)

Merminition 110 :

> [CAF wrote:] I'm particularly keen to see the reaction Spekkens gets. (Did he give you a private version of his talk in Montréal as I had asked him to?)

He may have talked to me in Montréal. In my usual irresponsible muddle-headed way, I can't remember who he is or who I talked with.

He has a talk on about 27 reasons why you ought to think that the quantum state is epistemic in nature:

1. You can't clone a quantum state. Guess what? You can't clone a Liouville distribution either.

2. You can change a quantum state from afar by gathering information nearby. Guess what? You can do the same with classical joint probability distributions.

3. … and so the list goes.

Moral: You can believe the quantum state to be ontic in character if you want. But then you've got to create an ad hoc reason for justifying each and every one of the effects above. Wouldn't it be so much simpler and more natural to accept the epistemic hypothesis and follow out its consequences?

06-02-03 *The Minimum Maximally Sensitive Set of States* (to J. W. Nicholson)

… or something like that will be our title. Now that we've got a title, we've got to write a paper.

06-02-03 *No It Doesn't [AJP 53(3), 70 (2000)]* (to D. Poulin)

Now the last note of yours was even sweeter music to my ears! Sorry I haven't replied, but I've been trying to get a paper ready to get on quant-ph next week, and I was quickly losing all face with my Japanese coauthor. But maybe I've also gained face with you in the process: In contrast to my paper `quant-ph/0204146`, this paper has 135 equations. (Have a look at the abstract on quant-ph and you'll see what I mean.)

And speaking of `quant-ph/0204146`,

Poulinism 10: *Last night, I went through the first 20 pages or so and found a recurrent theme: if reality was deterministic, there wouldn't be any distinction between dreams and awareness. I am not sure I fully understand the deep meaning of this but I sure like it. Basically, you are saying that nondeterminism is a proof that there is something out there, right?*

I don't know if I'd go as far as saying "proof", but, yes, that is basically the idea. I think the place where I give the fullest account of what's on my mind about that—though definitely my opinion is still forming on the subject—and say it all the most clearly is in `quant-ph/0204146`, actually. The sections to read are the last two, devoted to Preskill and Wootters. If you read them, please let me know if you get anything out of them. I got a great compliment from Michael Berry, who told me he really liked the paper. But Rüdiger told me he couldn't understand a thing of it; and Carl Caves said something like "it's sickening trash." It's important that you first rent and watch the movie *It's a Wonderful Life* if you haven't ever seen it before. (Too bad it's not Christmastime.)

Anyway, you helped ease my depression with your note. If confident, young David Poulin will invest the time to read 20 pages in my samizdats, maybe just maybe I'm not writing for nothing. And maybe just maybe our community will pool its strength enough to conquer this quantum beast. I'm serious: It made me happy that you took me seriously, and I know I'm gonna sleep better for it tonight.

David's Preply, "Quantum Mechanics Needs an Interpretation"

> How are you? Have you had a chance to look at the problem I send you? And if you did, were you able to understand anything? I believe that this problem and the compatibility problem are both quite interesting because they are well defined mathematical problems for which any solution forces you to give the wave function a meaning. For me, it went the other way around with compatibility. When I wrote the paper with

Robin, it seemed clear that the solution was in the lines set by BFM. It is only later that I realized that underlying this solution was an interpretation of the wave function: a mixed state "can be" a derived product due to lack of knowledge while pure states are really out there. I have put "can be" in quotes since they could also be fundamental when entanglement is present: the adepts of the Church of the Enlarged Hilbert Space would see no difference between these two cases. As you probably suspect, I am no longer so much sympathetical with this point of view. Nevertheless, I find it exciting that there are mathematical problems which require an interpretation to be solved.

I think that the day I can find a satisfactory answer to both these problems will be the day I have made up my mind on the correct interpretation. Of course, this raises the problem of what is a satisfactory answer. My only hope is that it will be like pornography: I'll know it when I'll see it.

The last few emails you have send me contain something like "of course, this is in my notes…". I have glimpsed through your notes before but never had the time (or motivation) to go through the entire thing. I am attempting it now. It will be hard since I am so busy with my two classes and learning spin foams … but it is quite entertaining. Last night, I went through the first 20 pages or so and found a recurrent theme: if reality was deterministic, there wouldn't be any distinction between dreams and awareness. I am not sure I fully understand the deep meaning of this but I sure like it. Basically, you are saying that nondeterminism is a proof that there is something out there, right?

08-02-03 *Is Is* (to M. Sasaki)

I was just reading the *New York Times* (my usual newspaper on the web), and I thought of you when I read the following paragraph:

> "The question is, is this about American power, or is it about democracy?" Mr. Asmus asks. "If it's about democracy, we'll have a broader base of support at home and more friends abroad. The great presidents of the last century — F.D.R., Wilson, Truman — all tried to articulate America's purpose in a way that other parts of the world could buy into. Bush hasn't done that yet." Before long, we'll find out if he cares to.

Actually, you had me worried about the "is, is" construction last week. Your change caused me to reflect that, actually, I was not sure if the thing was proper after all. I'm still not sure. But I do see that others use it too.

We now have three offers on our house! We have decided that we will accept the highest as of noon Monday. I will probably be able to put our paper on `quant-ph` Tuesday.

12-02-03 *Your Recent* `quant-ph` *Posting* (to C. M. Caves)

Let me emphasize the possible connections between this quantumness stuff and some of your more recent work. Maybe the thing that intrigues me the most at present is the conjectured connection between A) symmetric informationally complete POVMs and B) the minimum-cardinality maximally-sensitive quantum alphabet.

What is the deeper meaning of that? The main thing (maybe the only thing) that intrigues me about the SIC-POVMs is that they have got to give A) the prettiest region on the simplex (in the spirit of my National Bureau of Standards stuff that I keep drawing in my lectures) and

B) the maximal-volume region on the simplex. Both these are ingredients that one might think makes quantum mechanics look as close to simple Bayesianism as it can be. Yet, that happens for a "maximally quantum alphabet." Why?

I don't have a clue what the connection is, but my religion tells me there is one.

13-02-03 *Your Schedule* (to K. R. Duffy)

Quantum theory—I predict it will ultimately turn out—is nothing *but* control theory ... when the components have a wonderful sensitivity to the touch (more slippery than the classical kind). So, you've been doing the right thing.

13-02-03 *Doubting Our Coherence* (to C. M. Caves)

See page 5 of `quant-ph/0110107` by Halvorson and Clifton.

19-02-03 *Irish Dates* (to C. King)

My main research plan for my time in Dublin is to get a better handle on the structure of CPMs. What I'd like to get are some characterization theorems in line with my foundational ideas. In particular, I'm thinking of the main issues in Section 7 of my `quant-ph/0205039` and also the samizdat *Quantum States: What the Hell Are They?* on my webpage. That is, I want to put some mathematical meat on my slogan, "A quantum operation is truly and only a density operator in disguise."

20-02-03 *OK* (to C. M. Caves & J. M. Renes)

OK, I desist. Each day and each evening, I tell myself, "Tomorrow I'll really get to that paper," and each morning following something transpires against me. I'll give you what I have: It's only a minor variation of what you originally sent me all those months ago. Do with it what you please: I know that I should be shot for my behavior.

Let me just tell you what I wish were strengthened, in case you decide to be better citizens than me: [...]

One point of philosophy. I don't buy for a minute statements like, "Properties of physical systems, though useful if they help in this task, are ultimately irrelevant." That kind of positivism has never been my guide (though it does fit Asher Peres quite well). My only point has been that one should not mistake the quantum state for a property. The foundational task, as I view it, is precisely to uncover what can be called a property of a quantum system and what cannot. To that task, I see this paper as making a sound contribution.

20-02-03 *Intro Draft* (to J. Bub)

The more times I read over your draft for the intro, the more I like it. I'll send you a very mildly revised version this afternoon.

Possibly the only delicate point will be how I might de-emphasize the role of entanglement enough to suit me, while still pleasing you. A lot of quantum information does not depend upon entanglement at all (most quantum key distribution schemes, for instance, but also quantum non-locality without entanglement, incompleteable product bases, etc.) Or look at the present debate on the power of unentangled states for quantum computation (cf Gilles' talk at the commune). Finally, you ought to know by now that my own opinion is that entanglement is likely to be a red herring in the deeper vision of things: I see it as subordinate to the structure of measurements. Derived and secondary.

20-02-03 *New Draft, Only a Drop More of Poetry* (to J. Bub)

Attached are my modifications to your draft.

I debated for a long time toning down the theme on entanglement, but in the end gave up. I know that I compromise my beliefs somewhat with some of the phrasings, but, very probably, only *I* know that ... and, in the end, I may be able to make an easier connection to the entanglement stampede this way. (My role has always been that of a mole.)

Just some notes for your reference, so that you'll know what I did and what I thought: [...]

2) I inserted "they thought" between "which" and "spelled" in "could exist in certain states which spelled trouble for the Copenhagen interpretation" (second sentence, first paragraph). I did this to leave a window open for the possibility that EPR were on the wrong track with their argument. From my view, the only thing they demonstrated ultimately is that the quantum state is epistemic in character. If Bohr had known that word—epistemic—I think he would have agreed with them up to that point. He would have only disagreed that a more complete epistemic characterization could be given.

3) Second paragraph, fourth sentence: "That is, depending on what measurement Alice chooses to perform ... and the outcome of the measurement, Bob's system will be left in one of the states of some mixture ..." I'll just note this as a sentence that I would not normally write anymore, even though I left it intact. The trouble with it is that it conveys the image that the "state" is something possessed and inherent in the system—i.e., that it is a "property" of the system. Instead, I view the state in question as a property of Alice's head—i.e., her information about the system—and would normally use language appropriate to convey that idea. Since, however, we are contrasting things on Schr̈odinger's understanding, I can be OK with usage in this instance. [...]

10) Last paragraph. Added one small drop of poetry.

22-02-03 *Lorentz Chair* (to J. Preskill)

By the way, what was it like to sit at Lorentz's desk? If you give me a good anecdote, I'll record it for posterity.

24-02-03 *Born and Toeplitz* (to A. Peres)

Asherism 34: *Do you know of an autobiography of Max Born? Danny told me that he saw it (in Russian translation?) and that Born wrote that when he was a student, he was a baby-sitter for the daughter of Prof. Toeplitz in Gottingen. The reason I ask is that the daughter later came to Israel, and recently passed away. She was a cellist in Lydia's orchestra. Her father was an amateur photographer, and she had pictures of all the great men, Hilbert, etc. Lydia borrowed them to show to the Dean of Maths, who had a shock, and asked permission to display some of the pictures in the hallways of his building.*

I think there are two books that could be reasonably counted as autobiographies of Born: 1) *My Life and My Views*, and 2) *Physics in My Generation*. (I just looked them up in my list of burnt books.) I don't remember if there was any overlap in the essays there—I seem to recall that there may have been—but I read them both 10 or more years ago. I do remember enjoying them. (I actually read the Born-Einstein letters twice, but that's a different subject.)

Interesting to hear about Toeplitz. I hadn't noticed his name until last year. I used facts about Toeplitz matrices to calculate Eq. (40) in my `quant-ph/0205039`.

24-02-03 *Fall Calendar and Symmetry* (to W. E. Lawrence)

Lawrencesm 1: *I personally have gotten interested in two directions — unbiased basis sets and related operator sets (and the question of why nobody has found a proof that these exist other than for power-of-prime dimension). Is this just number theory, or is it Physics that I don't understand yet?*

I'll bet that's a number theory reason, rather than a physics reason ... but you never know. Still, though, I'm glad you're interested in the question. I've been interested in quite a similar one: the one of the existence of "symmetric informationally complete POVMs." You can find these things defined on page 23 of my new paper `quant-ph/0302092`. They are much like a complete set of mutually unbiased bases, but even more symmetric. In contrast to the MUB question, though, we do know (numerically) that they exist in, at least, all dimensions from $d = 2$ to $d = 14$. Mostly I'm interested in them on three counts:

1. I think they will give the most beautiful definition for the "standard quantum measurement device" in Section 4.2 of my `quant-ph/0205039`. The prettier I can make the region in Figures 1 and 2—the latter on page 38—the more insight I think we'll be able to glean from such a representation of quantum mechanics.

2. Also, in connection to that, I suspect that the symmetric POVMs define the largest such region possible. Thus, thinking of quantum mechanics as a modification of usual Bayesian reasoning (which makes use of the full probability simplex, not just a restricted piece of it), such a measurement defines a venue in which our reasoning can be as close to Bayesian as possible. That is to say, if you're looking for the minimal change quantum mechanics makes to our methods of probabilistic reasoning, it will be there.

3. Finally, referring to page 23 of `quant-ph/0302092` again, there's something quite interesting about these POVMs that I've just come to realize. There appears to be a sense in which the elements in that set are just as quantum as they can be with respect to quantum eavesdropping. (Since posting that paper, by the way, I have proven that the accessible fidelity for such an ensemble really is $2/(d+1)$, after all.)

So, now I wonder what is the deeper connection between all these statements.

25-02-03 *Book Review* (to A. S. Holevo)

I don't know whether you are able to get the journal QIC (*Quantum Information and Computation*) at your institute, so I will send the file attached directly to you. It is a small (very small) review of your new book that I wrote for the journal. I hope you enjoy it, and that it does not offend you too much (via my greed of always wanting a deeper and deeper explanation of quantum mechanics).

I have distributed copies of your book to Caves and Bennett so far. Friday, when I see Peter Shor, I will give him a copy too. Unfortunately, I forgot to give one to Schumacher the last time I saw him in November (even though I had packed one up for him). I will, though, give him a copy when I see him in May at the Bennett 60th-Birthday Symposium.

25-02-03 *9909073* (to P. Busch)

Carl Caves's student Joe Renes has finally put together our work on Gleason-like theorems for POVMs into a manuscript, with special emphasis on 2-D Hilbert spaces (where one can restrict the class of POVMs and still get the result). We need to cite you. Has `quant-ph/9909073` still not been published?!?!?! I just looked at your webpage and see no update of it. We're hoping to post the manuscript this week.

26-02-03 *Distribution List* (to A. S. Holevo)

By the way, I count that I have three copies of your book left, beside my own. (QIC had also sent me a copy since I was a reviewer.) Who would you like me most to distribute them to? Below is a list of people that I will either see on or before the Bennett-fest.

M. Gell-Mann
E. Fredkin
T. Toffolli
S. Wiesner
G. Brassard
N. D. Mermin
W. Wootters
A. Peres
R. Jozsa
P. Shor
B. Schumacher
J. Smolin
S. Popescu
R. Horodecki
A. Zeilinger
M. B. Ruskai
C. King
J. Lewis
O. Hirota

05-03-03 *Quantum Anti-War Petition: Need Exponential Growth* (to 58 people)

Dear friends and quantum colleagues, (i.e., this really is Chris), If you are as disturbed about the prospect of war in Iraq as I am, the world-wide destabilization it may cause, and the trashing of the United Nations it indicates, I hope you will consider signing the petition at:

`http://www.moveon.org/emergency/`

As far as I can tell, `MoveOn.org` is a serious, significant organization and one to be taken seriously. The petition seems to be at least 300,000 signatures strong presently, but I hope it will grow exponentially before its delivery to the United Nations tomorrow (March 6). You can read about the organization's legitimacy by having a look at:

`http://www.moveon.org/moveonpress.html`

I apologize if this note is an intrusion on your politics, but I tried to be selective in my distribution list, based on conversations I've had with each of you in the past. (I hope I have remembered correctly.) Most importantly, I hope you will pass on this note, or a similar one, to your own friends before tomorrow's deadline.

07-03-03 *Quantum Anti-War Petition: Need Exponential Growth* (to A. Plotnitsky)

You're probably right about the fatalism—that things have progressed too far to be turned around—but there is still time to sign the petition today. The number of signatures has now reached over 550,000. It's one of the very largest petitions in history. They're now aiming for 750,000 signatures. So, I hope you will spread the word.

24-03-03 *Har Har* (to J. M. Renes)

Renesism 8: *Read any good papers on Gleason's theorem lately?*

Point well taken, and I assure you I was already feeling guilty before I got your note. It's just that this darned move and house sale has been pretty much all-consuming. I will, however, be in Ireland away from the family (on my house-hunting trip) for the full week this week. I am hoping to get quite a bit of work done with this opportunity. Your paper is at the top of the list.

27-03-03 *Crypto Scheme* (to B. Yurke)

Here's a simple crypto scheme for these states.[43] It's a little BB84 and a little B92. Alice sends one of the d^2 states drawn at random. After Bob receives the signal, but before he performs a measurement, Alice reveals that the state she sent belongs to a set X of d linearly independent states (X being a subset of the original set of d^2 states). Bob then performs an unambiguous state-discrimination measurement appropriate for the set X. In this way, through a pre-agreed numbering of the states within each set X, Alice and Bob should share a key on the successful outcomes.

The questions are a) how secure is this system, and b) how efficient is it? Clearly it is more efficient in the limit of large d. But that should also be the limit in which it is the most secure … unless I'm missing something. In any case, to do this right is going to take some analysis.

[43] As stated here the crypto scheme is incorrect, but easily modified into something workable.

21-04-03 *A Question of Condensation and Time* (to J. I. Rosado)

Thank you for your interest in my paper. Have we met before? Perhaps in Oviedo? Anyway, I apologize for taking so long to reply to you, but for over a month now I have been scrambling with the details of relocating my family to Dublin. Finally that task is coming to an end, and I hope to be able to turn my attention back to science soon.

Rosado-ism 1: *In section 3 you give an argument, EPR+teleportation, to support the idea that a quantum state is a state of beliefs, so that they have nothing to do with real properties of the real physical state. At the same time, I think, your argument also implies that the outcome of a measurement doesn't reveal a preexisting property of the physical system, inclusive for pure states, inclusive of the case of a measurement of an observable that has that pure state as eigenstate. Do you think that this conclusion is true? If true why don't you have stressed it? I think it is very important to be explicit in this conclusion because in the vast majority of the quantum literature we can find phrases like: "quantum measurement, with very few exceptions, cannot be claimed to reveal a property of the individual quantum system existing before the measurement is performed." so that the vast majority of the scientific community thinks that if we can predict with certainty the outcome of a measurement then this is so because we know a real property of the individual quantum system.*

Yes, that is true. I have tried to stress it very significantly to many of my friends, but unfortunately I may not have yet carried the point through as clearly as possible in my papers. It is a question of time, finding the right phrases, and biting the bullet for a big job. What I mean by the latter is condensing the notes in my document "Quantum States: What the Hell Are They?" into a proper paper. If you are not familiar with that document, I would encourage you to try to follow some of the arguments there, starting around page 35. The content of the samizdat follows the format of email messages, but often they are self-contained. (You can download the samizdat from my webpage; there is a link for it below.) I have it as a goal to try to write a real paper on the subject before the end of the year, but we shall have to see if that really materializes.

Rosado-ism 2: *My conclusion, after I have read your paper, is that if we know with certainty that a measurement will obtain a particular outcome we cannot conclude that this implies a preexisting property of the individual quantum system, only that if we perform that measurement in that physical system we will obtain that outcome with certainty.*

Yes, and I think this realization has the potential to lead us down a profound path. (But that is only a dream at the moment; it is not science yet.) Anyway, it has in part led to my newfound attraction to the philosophy of William James, which you can also read about in the same document. Maybe the best notes are the ones to Wiseman, starting on page 210.

There is much to do to put some technical flesh on these little observations and to follow their implications unflinchingly wherever they lead. I am flattered that you have taken an interest in these ideas, and I hope you'll help carry the torch in your own work.

23-04-03 *The Rumor Mill* (to S. J. van Enk)

van Enkism 3: *But I read several chapters in Dennett's book* Freedom Evolves*.*

I have read parts of his (early) book *Elbow Room* (also on free will), in which I suspect he makes the same argument. He certainly tried to draw the same conclusion. But I should read this other book; I've never heard of it before. Dennett is always good to read. And he's an impressive speaker too.

25-04-03 *Infinity* (to S. J. van Enk)

"Jesus love me, this I know, because the Bible tells me so."

"Separable Hilbert space only so, because von Neumann told me so."

There's probably a deeper answer, but I don't know it. It probably just means that the mathematicians had too many counter-examples to what they wanted to be true in nonseparable Hilbert spaces. Physicists, never worrying about such matters, then just fell in line.

And yes, the answer to 2) is the same as the answer to 1).

I know that's of little help, but I'm in an airport again.

Steven's Preply

> I have 2 questions about infinite Hilbert spaces: I hope you find some time to answer my no doubt simple questions:
>
> 1) I remember that you once said that one always assumes Hilbert spaces to be separable, which if I remember correctly for infinite Hilbert spaces means their dimension is countably infinite. Is that so? Why does one assume that?
>
> 2) For our laser paper we made use of a trick from a paper by Blow and Loudon et al.: starting from a continuum of modes, characterized by a continuous frequency ω, one goes to a discrete set of modes by first defining a complete discrete set of functions of time (or frequency), and subsequently constructing a discrete set of modes. That always looked convincing to me, but why is that allowed? Why doesn't it matter that we go from an uncountable to a countable set of modes? [Maybe this has the same answer as 1)!]

26-04-03 *Vancouver Books* (to P. C. E. Stamp)

Are you serious, "Vancouver has no good used bookstores downtown"?!?! I had a field day! I'm still downtown, in fact, having a pint. Let me tell you what I found:

- Arcanum Books, 317A Cambie St.

  Tom Burke, *Dewey's New Logic: A Reply to Russell*, $12.00.

- Albion Books, 523 Richards St.

  Paul Feyerabend, *Killing Time: The Autobiography of Paul Feyerabend*, $10.00.

- MacLeod's Books, 455 West Pender St.

  W. V. Quine, *Ontological Relativity and Other Essays*, $8.00.

  Michel Foucault, *The Archeology of Knowledge*, $15.00.

  William James, *The Letters of William James*, 1926 edition, $25.00.

  and the real catch of the day

  William James, *The Correspondence of William James, Volume 7: 1890–1894*, $45.00.

That amounts the best book-buying day I've had in a while. (You can see I like to record things.)

Thanks again for inviting me to this meeting. I think much did come out of it for my quantum foundations program, and I am grateful.

27-04-03 *Bull by the Horns* (to R. W. Spekkens)

I just wanted to tell you again how excited your letter has gotten me. This sounds like a real progress in our understanding! Have a look at the note I wrote Sam Braunstein in 1996 [*Samizdat*, page 434] ... or better the 24 April 1998 letter to Rüdiger Schack on page 390. [I think I also put some words like that in `quant-ph/9601025` ... Aha, yes I did; see page 25 of it.] I may have sloganized the idea, but you took the bull by the horns! I must say, *I am jealous*!! But I am also proud of you in this regard: You should have rightly been my postdoc this year, not Perimeter's!

Let me go through a few points of your letter for clarification and a couple of suggestions.

Spekkensism 14: *I've been busily trying to finish up a bunch of projects, and get settled in here. In my spare time, I've been working on a toy theory (Lucien has also been looking at something very similar) that I think strengthens the argument for the epistemic view. Basically, it's classical probability theory with an additional constraint: that the amount one knows about a system must always equal the amount one doesn't know about the system when one is in a state of maximal knowledge. Basically, one demands a balance between certainty and uncertainty.*

Mostly I'm wondering how to interpret this precisely. Presumably, you're starting off with a fixed probability simplex over some number, K, of outcomes. Are you explicitly taking K to be a perfect square as it would be in quantum mechanics? Alternatively, if you're not: I wonder what special properties a perfect square has in this regard?

More importantly though, it sounds like the arena for your considerations is that the "states" ought to correspond to a convex region within the simplex. The states of maximal knowledge are then the region's extreme points. Is that right, or do you mean something else? For instance, I could imagine that you might be thinking of the boundary rather than the extreme points ... though that is less likely.

Now, what is the nature of the constraint that defines your states of maximal knowledge? Are you saying that for an event space of size K, the Shannon entropy of a state of maximal knowledge ought to be $\log \frac{K}{2}$ bits? Or do you have a different way to quantify the idea.

In either case, let me tell you about the move I would make at this point. The tack is look back at quantum mechanics, see what it says about states of maximal information in this language, and then try to make sense of it as a very simple statement, like in your toy model. What I'm thinking of in particular, is to think of the allowed region on the simplex as generated by a "standard quantum measurement" of the SIC-POVM variety, i.e., the symmetric informationally complete POVMs. You recall these from Montréal, right? In case not, I'll attach a note from another collaboration of mine that gives some relevant definitions.

What is most interesting about that POVM in this context, is that it causes all the pure states to live on a sphere surrounding the center of the simplex (the maximally mixed state). By this, I mean in terms of usual Euclidean distance. You'll see this in Eq. (13) of the document I'm sending you.

In particular, it is not the case that all pure states have an equal Shannon entropy in this representation (if that indeed is the assumption of your toy model). Rather they have constant, but not maximal, distance from the state of maximal ignorance. What is the meaning of that? I don't know in any detail, but clearly it is one possible statement that maximal information cannot be complete.

Anyway, question: Making the assumption of "constant distance from center" rather than your assumption of "balance between certainty and uncertainty", how much closer still (if any) does one get to the full theory of quantum mechanics?

I know that it will not go the whole way to quantum mechanics, either. This is simply because true pure quantum states do not make completely fill the surface of the sphere that they live on. So, we're still missing something.

But mostly I'm intrigued in what you've already found with the following:

Spekkensism 15: *such as the impossibility of achieving disturbance-free information gain about non-orthogonal states with certainty, [...] The toy theory includes all these phenomena.*

My immediate reaction when reading your note was that this could not be right, but upon a little thought, I might be willing to buy it. The point is, there can be no absolutely clean probes in such a theory. Eve has to always have a kind of ignorance about her probe when it is quantum too. Following the algebra of the assumption (i.e., that system+probe state must also be a state of maximal information) must always leave both states more mixed (with respect to the standard quantum measurement) than they started off being. Is that the sort of thing you're finding?

Spekkensism 16: *I'm far from done, but I'm sending you a tiny section that addresses Penrose's argument against the epistemic view. I suspect that you will disagree with my response, but, if so, I'd like to hear your objections.*

Yeah, you're right: I enjoyed half the argument. I was trying to capture something similar at the meeting in Montréal, in that I kept trying to dream of a way in which a von Neumann measurement could always be viewed as a "coarse-grained measurement" (the words I was using then) rather than the fine-grained variety everyone always assumes it to be. But I could never quite pull the analogy together in a satisfactory way. What you are talking about here is something of the same flavor ... right before you fall into the quagmire of "ontic significance."

Anyway, you're doing great work. Can't wait to see you in Maryland.

Rob's Preply

> I've been busily trying to finish up a bunch of projects, and get settled in here. In my spare time, I've been working on a toy theory (Lucien has also been looking at something very similar) that I think strengthens the argument for the epistemic view. Basically, it's classical probability theory with an additional constraint: that the amount one knows about a system must always equal the amount one doesn't know about the system when one is in a state of maximal knowledge. Basically, one demands a balance between certainty and uncertainty. As you know, classical probability theory includes a whole bunch of phenomena typically deemed quantum, such as no-cloning, steering, no exponential divergence of states under chaotic evolution, and all the others from my checklist in Montréal, but excludes many other phenomena, such as the impossibility of achieving disturbance-free information gain about non-orthogonal states with certainty, the existence of sets of states that cannot be broadcast, the impossibility of multi-party steering (a.k.a. the monogamy of entanglement), the fact that there are many extremal convex decompositions of a state, the non-commutativity of measurements, the existence of interference, the impossibility of teleporting non-orthogonal states with

certainty in the absence of perfect correlation, the existence of locally immeasurable product bases, the existence of unextendible product bases, and, of course, all the quantum information processing tasks that can be built on these. The toy theory includes all these phenomena. The phenomena that don't arise in the toy theory are things like contextuality, Bell correlations, the fact that there are POVMs that are not convex combinations of PVMs, the gap between the probability of discriminating non-orthogonal states using an optimal measurement and using an optimal unambiguous measurement, and the fact that 2 levels of a 3 level system behave like a 2 level system. (These lists aren't meant to be exhaustive – they only include some of the things I've had a chance to look at) So, it seems to me that the toy theory makes about half of the mysteries of quantum mechanics intuitive. I'm hoping that there is an additional constraint that can be imposed that gets the rest of it. I have some ideas on that, but it's all very speculative.

I'll be talking about it in Washington. Will you be there? I'm also trying to write it all up. I'm far from done, but I'm sending you a tiny section that addresses Penrose's argument against the epistemic view. I suspect that you will disagree with my response, but, if so, I'd like to hear your objections.

27-04-03 *Delighted to Meet You* (to G. Valente)

Thank you for your kind letter. It is always very flattering to know that someone is reading your papers, but it's absolutely dazzling to know that someone is enjoying and, perhaps, getting something useful from them!

Concerning your query about whether I can enter into an extended discussion: Unfortunately, you've hit me at a moment of almost complete correspondence blackout. With all the stresses added by my recent move to Ireland, several of my collaborators beating down on me to finish our incomplete papers, and a very busy travel schedule at the moment, I have had to essentially shut down my email production. (Believe me, that is a very painful thing!) Of course, please feel free to write me anything you wish, but it may be quite some time before I am able to reply in detail.

However, I have two suggestions for a substitute:

1) Chris Timpson, a recent graduate of Harvey Brown, understands the quantum foundations program I'm pushing quite well. If you don't know him already, he'd be excellent to talk to.

2) I very much encourage you to attend a meeting on quantum foundations in Sweden that I am co-organizing this Spring. The dates are June 1–6, I believe, and you can find information about it here:

`http://web.archive.org/web/20030425003339/http://www.msi.vxu.se/aktuellt/konferens/`.

Beyond the attendees listed on that page, Barnum and I are also organizing a separate session on "Quantum Logic meets Quantum Information" which will be attended by:

Scott Aaronson	(U. California at Berkeley, USA)
Paul Busch	(U. Nottingham, UK)
Bob Coecke	(Oxford U., UK)

Richard Greechie	(Louisiana Tech U., USA)
Hans Halvorson	(Princeton U., USA)
Lucien Hardy	(Perimeter Inst., Canada)
Rüdiger Schack	(Royal Hollaway, UK)
John Smolin	(IBM Research, USA)
Alexander Wilce	(Susquehanna U., USA)
Guido Bacciagaluppi	(U. California at Berkeley, USA)
Rob Spekkens	(Perimeter Inst., Canada)

Thus you will have plenty of interesting people to talk to, some of which have tendencies in our same direction, but also I will have plenty of time to talk to you when Barnum, Hardy, Smolin and I inevitably go to the pubs in the evening. (It is a usual thing; and, within that, usually a very philosophical time.)

Giovanni's Preply, "Touchable and Untouchable in QM"

I'm an Italian student from Padua University. My field of work is philosophy of physics and nowadays I'm in Oxford to write my dissertation. In particular I'm dealing with the question (maybe a bad question, in a Wittgensteinian sense) of realism in Quantum Mechanics. I share a skeptical point of view about the possibility to directly touch or to understand an ontological level and I also consider the probabilistic structure of QM as impossible to disregard. Thus, after our first discussion, Dr. Harvey Brown, my supervisor here, asked me if I knew Chris Fuchs' works and I professed my ignorance of it (I'm sorry, sir…): he really looked amused by my convergence at something unknown (for me). Following his advices, I started reading your papers ("Quantum Mechanics as Quantum Information (and only a little more)") and "eavesdropping" your private correspondence ("Quantum States: What the Hell Are They?"). I found your approach very deep, consistent and, most importantly, completely *immanent* to QM. I think we can't forget we are *disentangling* a physical theory; our aim is a reflection over the foundations of quantum mechanics. If one adds further elements (and nothing prevents to do this!), one must be aware of the fact that one is no more doing QM or philosophy *of* QM (but something else!). Physics can be regarded as a linguistic game (Wittgenstein): a tangle of mathematical, experimental, syntactical and hypothetical ropes, where the empirically successful is the premise and the goal at the same time. Our task should be to see deeply *inside* the theory and clarify *its* nature. Philosophy is "only": to play this game with the consciousness that it is a game. Science could be just a working fiction, why not? I deem your works are very eye-opening in this sense, especially for QM. I'd like to explore this track and I hope you'll agree to answer me about some specific doubts I have.

In any case I've been appreciating your perspective and your way of reasoning. Furthermore, I find quite amazing (and sometimes annoying) to discover such a similarity between my still raw view and your articulate and solid plan. I must reveal that sometimes I feel frightened. For example. I woke up thinking about our alchemistic touch to the nature yesterday morning. As soon as I started studying, I read the same idea (alchemy) in your first statement about Pauli. I closed my books and I run away to phone my mum in Vicenza …

Thank you very much for your willingness

P.S. I love Arthur Schopenhauer, too. He is a very deep philosopher. I think his thought was splendidly understood and embodied by Ettore Majorana. In fact he mystically (more than mysteriously) disappeared ...

30-04-03 *Screed* (to A. Wilce)

screed:
noun,
1. long usually tiresome letter or harangue.
2. layer of cement etc. applied to level a surface.

Glad to hear you'll be in Sweden! And can't wait to hear about test spaces! (But finite dimensional ones, please ... if that concept applies.)

01-05-03 *Screed Again* (to H. Barnum)

I'm finally reading Hacking's book *Representing and Intervening*, per your, and Chris Timpson's, and Rob Spekkens's, and Steven Savitt's suggestions. It reads like eating candy; very nice. Just in the interstices of today's flight when I wasn't working on the present paper with Renes and Co., I managed to read 67 pages. That's a phenomenal amount for me! I generally read much slower than that.

05-05-03 *Pitowsky* (to T. Rudolph)

Rudolphism 8: *Did you ever ask Itamar about your "shape of the q-states within the simplex" problem?*

I just remembered that when I first met him at ESI all those years ago (back when we both were still young) he told me he was working on some aspects of a problem to do with parameterising the shape of the convex set of q-states (though not on the same simplex you are I don't think).

He also knows a lot of the math literature, so could probably guide you to anything that has been done ...

No, I haven't. That's a good idea, and I'll follow through with it. I know which convex set you're talking about with earlier work, and, you're right, it's not the same one I'm thinking about. But he'd definitely be a good source of techniques that may be relevant for the present problem.

I decided not to come to Bell Labs today. I'm just too exhausted; maybe a day's recuperation is what I need most. I'll probably be in tomorrow. I very much enjoyed this weekend's discussions, by the way.

05-05-03 *On Bohr and Realism-X* (to R. W. Spekkens)

Attached is my compendium-under-construction, "The Activating Observer: Resource Material for a Paulian-Wheelerish Conception of Nature." To find the best reading on Bohr's particular flavor of realism, look at the Barad and Folse areas of the compendium.

I have read Bohr thoroughly, and I have read Folse thoroughly, and I think no one does a better job of rationally explicating Bohr than Folse. Tell me if you disagree.

10-05-03 *Departing for Ireland* (to C. H. Bennett)

A small note to tell you that the information I ate for lunch was just great! You ought to try the place; it's a nice little cafe outside the Aer Lingus lounge in JFK. The lunchtime special was "all you can eat, $5.99." They brought out the NY Times for desert, but I was absolutely stuffed by then.

Happy birthday again!

17-05-03 *Good News, Bad News* (to J. W. Nicholson)

Thanks for the good news; too bad about the bad news. The good news got me percolating ... since I watched an episode of *Scrubs* the other night, and they explained what *always* happens on a third date! If you can't trust TV, who can you trust?

About the bad news, for some reason it took my mind to a story I once heard from John Wheeler about a physicist who was to be executed—I can't remember—either sometime in WWII or during the Stalinist purge. Anyway, the fellow was put in a death-row cell one evening, with the execution scheduled for the next morning. When morning time came, for whatever reason he was set free. Years later, Wheeler asked him how he survived the night. How could he manage with that horrible dread all night long? The man told him, "I found myself thinking over and over about Hamilton's beautiful equations. It set my mind at ease."

I suppose everyone has to have a Hail Mary in some form or another.

22-05-03 *Your Paper, Hope You Can Come* (to P. G. L. Mana)

Chris King pointed out your paper `quant-ph/0305117` to me, and I downloaded it today. It looks quite nice. I have a significant interest in characterizing quantum mechanical state spaces as portions of a probability simplex (or simplexes), and I'd like to see the prettiest way to do that. It's my hope that your paper will shed some light on the problem.

As for my own efforts in that direction, please let me recommend Sections 4.2 and 6 in my paper, "Quantum Mechanics as Quantum Information (and only a little more)", `quant-ph/0205039`. There I don't use a table, but a vector representation for the outcomes of a single, sufficiently rich measurement. So, the representation is different, but some of the ideas are the same. Ultimately what I would like to do is divorce the representation away from quantum mechanics, and then start over (in the manner of Hardy and you) and recover the quantum formalism as the result of further physically-significant requirements ... but that is a project still in the making.

Anyway, I write to you mostly because I would love to get the chance to talk to you in person and, reciprocally, give you an opportunity to work with several people interested in problems of this ilk. I am one of the organizers of a meeting in Växjö, Sweden, to be held June 1 through 6, on quantum foundations. You can find out information about the meeting at this website:

`http://web.archive.org/web/20050427164645/http://www.msi.vxu.se/aktuellt/konferens/`.

As I say, there will be several people there that I know will be interested in your work. I'm thinking in particular of Howard Barnum, Lucien Hardy, Joe Renes, Rüdiger Schack, and Rob Spekkens. It would be wonderful if you could come. Seeing that you are stationed so close at the KTH, perhaps our chances are better than zero to meet you!

24-05-03 *Mechanica Quantica Lex Cogitationis Est* (to H. Barnum)

Barnumism 4: *Do you know the original source of the words "quantum mechanics is a law of thought?" Is it you, JAW, or someone else?*

It was me. I guess I started using the phrase early in 1996. You can find the story on pages 247 and 370–371 of my samizdat *Notes on a Paulian Idea*.

24-05-03 *Maybe Do Give a Talk ...* (to J. M. Renes)

I just got the note below from Andrei. It got me thinking about your talk again. Maybe it would be a good idea for you to give a talk after all. I told Andrei to go ahead and set aside the time. I think it would be good to talk about the trine and the Platonic solids in relation to Gleason. It could be good to refresh everyone's memory on this. Also you could speculate on what might be the higher dimensional analogues of this. Maybe your talk would prod others to think about these issues and — even if we're not going to work on it — induce them to do something interesting in that direction.

Have you ever thought about how a POVM-version of Gleason where the frame functions are only defined on the extreme points of the POVMs. That strikes me as an interesting arena of investigation. Since such generalized frame functions include the ones from the standard Gleason theorem, the project has to work. But I wonder to what extent the proof might get simplified in this way? Also, the skeptics would not be able to claim that we're overtly assuming the linear structure by going into the interior of the convex set. You might also propose something like this in a talk.

26-05-03 *Practice?* (to P. G. L. Mana)

Thanks for the invitation to Stockholm. However, at the present time my travel schedule is already over-crowded, and I will be flying, both literally and figuratively, in and out of the meeting. Maybe I could visit sometime in the coming year, when I am making my way to Växjö again. I have also wanted to meet Göran Lindblad for many years.

It's great to hear that you'll be at our meeting next week. You've probably already guessed that we won't be able to provide any further support for participants ... but I wonder if you would be interested in giving a talk on your paper nevertheless? One of the speakers from Barnum's and my part of the meeting (Hans Halvorson) had to drop out because his wife had her baby early; so we've got a little extra space for a speaker. If you're interested, let me know immediately. I cannot promise that the time will not already be gobbled up, but the sooner you let me know, the better chance you'll have if you're interested.

If you're a first year graduate student, it could be good practice. Just remember to keep it simple, focusing more on the ideas and motivation, and far, far less on any derivations. Less is always more in a talk. Also it would be quite interesting to see the contrast between your ideas and Hardy's.

27-05-03 *Popper Seminar, with a Side of Oxford* (to S. Hartmann & J. Butterfield)

Thank you both for the invitations. I would be delighted to come give talks at LSE and Oxford. Presently my schedule is completely open in February. So why don't you two decide when you want me, and for how long you want me, and I will put the dates on my calendar.

The papa Bayesian of our group—Rüdiger Schack—by the way, was a student of Schenzle too.

27-05-03 *Got It: Thanks!* (to O. Hirota)

Thanks so much for sending a copy of the book *The Foundation of Quantum Information Science*!! Are you the author of the whole book? Or is it a compilation of many contributions? In any case, it looks very impressive.

I found my picture on page 214, as you had suggested. Now, please translate what it says! Do the four characters below my picture signify the word "Fuchs"? (Or fox, since fuchs means fox in German?)

It was an interesting coincidence that I would get your book today. Just this morning, the secretary in Sweden told me that she mailed off several copies of my samizdat *Notes on a Paulian Idea*. You were in the list of recipients. So it should be arriving soon.

Things are going well for quantumness here in Ireland. Chris King and Koenraad Audenaert were able to prove that the accessible fidelity is a multiplicative function over tensor product ensembles. They are presently writing a paper on the subject. This had been one of the open questions Sasaki and I listed at the end of our paper. What is especially pleasing about this new result is that it shows a very deep connection between quantumness and capacity questions for entanglement breaking channels.

29-05-03 *See You Soon* (to A. Wilce)

10.35–11.15. Alexander Wilce (Susquehanna Univ., USA)
Compactness and Symmetry in Quantum Logic
plus up to ten minutes for questions.

See you soon.

09-06-03 *Quantumness* (to P. Busch)

Thanks for coming to the conference! Your presence really made a difference, especially for Rüdiger and me.

Let me give you a pointer to the background of the problem I mentioned on the last day. It is:

- C. A. Fuchs and M. Sasaki, "Squeezing Quantum Information through a Classical Channel: Measuring the 'Quantumness' of a Set of Quantum States," *Quantum Information and Computation* **3**(5), 377–404 (2003). `quant-ph/0302092`.

After some massaging, the quantity in Eq. (16) there can be turned into the quantity I showed you, i.e., the $\inf \mathrm{tr} X$. Of the open questions in the back, numbers 1, 2, and 6 have now been solved. Koenraad Audenaert, Chris King, Peter Shor, and I will be writing up all that soon. Question 6 especially required some nontrivial mathematics, and led to the expression I showed you.

The biggest problem on my mind at the moment is to show (or find a counterexample) that an ensemble of at least of d^2 states is required to achieve the quantumness of a Hilbert space. That is, if an ensemble consists of $d^2 - 1$ states, then the quantumness of that ensemble is always bounded away from the quantumness of the Hilbert space. King and I mostly, are working on that at the moment, but if you have any insight I'd love to hear it. With you being a B, and he and I being a K and an F, you'd be assured to be first author on the paper!

10-06-03 *Quantum Information* (to T. Siegfried)

We met briefly years ago at a meeting on quantum information and computing, but I doubt you remember me particularly. Anyway, I've been meaning to write you for some time to tell you about a neat little coincidence I ran across as I was proofreading my samizdat *Notes on a Paulian Idea: Foundational, Historical, Anecdotal & Forward-Looking Thoughts on the Quantum* for a slightly more official publication by Växjö University Press.

In the foreword to the book David Mermin writes, "If Chris Fuchs (rhymes with 'books') did not exist ...". On the other hand, in your book *The Bit and the Pendulum*, there is some point where you write, "Chris Fuchs (rhymes with books) applied Landauer's principle ...". In fact I actually report your line in my samizdat, but I doubt David was aware of it, as even I had forgotten of its existence until the final editing. (I guess I say "Fuchs rhymes with books" to a lot of people.)

In any case, all this brings to mind that maybe you'd like a copy of the book. Here and there you might find a story in it that you'd enjoy. If you'd like, I can send you a copy: Just give me your snail-mail address. You can also find the book in PDF format at my webpage (link below), but you wouldn't want to actually print it out. (That version is about 500 pages.) Have a browse of the document, and if you think you'd enjoy a hard copy, I'll have the VUP secretary send you one.

10-06-03 *Too Late, but Sympathetic* (to R. D. Gill)

I wanted to apologize to you for not getting my act together in time to write a few words about your paper "On Quantum Statistical Inference" with Barndorff-Nielsen and Jupp for the Royal Statistical Society. (They had invited me to, but gave a deadline of June 4; now I am away to conferences again until June 14.)

I wanted to particularly endorse your statement in Section 7, "As statisticians, we would like to argue (tongue in cheek) that quantum probability is merely a special case of classical statistics," and write a few comments thereabouts. I think one shouldn't be so tongue in cheek about this.

Anyway, as I say, I'm sorry I passed the deadline.

Too bad you didn't come to the Växjö meeting: I think you would have found it quite a bit more productive than last year's. Several of the talks, in fact, addressed your tongue-in-cheek comment above: Guido Bacciagaluppi, Paul Busch, Lucien Hardy, Luca Mana, Rüdiger Schack, Rob Spekkens, and also my own—all in quite a direct way.

10-06-03 *Orthomodular Lattices* (to S. L. Braunstein)

Maybe suggest to your friend R. I. G. Hughes's book *The Structure and Interpretation of Quantum Mechanics*. It talks quite a bit about quantum logic from several perspectives, and it also will give him loads of references if he wants to dig deeper.

10-06-03 *Notes on a Paulian Idea* (to C. P. Enz)

I don't know if you remember me: You had very kindly sent and then re-sent me copies of all your quantum foundational papers—the latter after my house burnt down in the Los Alamos fires three years ago.

In any case, I'm writing to tell you that my book *Notes on a Paulian Idea: Foundational, Historical, Anecdotal & Forward-Looking Thoughts on the Quantum* has just been published by Växjö University Press. The book is very strongly laced with the influence of Wolfgang Pauli's ideas (to which the title refers), and is legitimized a little with a foreword by N. David Mermin. If you have an interest in reading (parts of) it, I will send you a copy. All I need is your mailing address.

If you are dubious, before making a decision, you may also have a browse through the book by downloading a copy from my website (link below). Also there, you can find various of my other writings along with a Curriculum Vitae.

Another project that I am working very hard to complete this year is a large document to be titled "The Activating Observer: Resource Material for a Paulian/Wheelerish Conception of Nature". Basically it is a compilation of quite a large number of references, along with extensive quotations from most. Presently it stands at 109 printed pages, with 443 references. By the time the project is complete, I expect it to run about 250 pages: I still have a significant amount of material to put into place and have decided to enlist a good scanner along with optical character recognition software to help me in the project. That document is not ready to be downloaded from the website, but you can read its abstract there. If you would like a preview of the project, I could mail that to you directly and perhaps you could give me a few pointers for things I've missed. For instance, I just learned last week that you yourself have just published a biography of Pauli! I look forward to reading that as soon as I can purchase a copy.

11-06-03 *Getting the Word Out* (to R. W. Spekkens)

You know sir, I continue to be excited by your toy model even if we differ in our ultimate goals. I had a conversation with John Preskill about it today, showing him the main ideas, etc. He seemed intrigued. In fact, intrigued to the point that he wants to invite you to Caltech to talk about it. I think this would be a great opportunity. I told John to just try to pick a time that I could make it too. So, a) I hope you'll go, and b) I'd like to be there so that I don't miss a thing. Can we coordinate? I've always gauged the value of the program by the caliber of the people who start out skeptical about it, but then ultimately take note. Early on I singled out both Mermin and Preskill on this count, i.e., as markers of progress. Mermin yielded quickly, but Preskill has been a bit of a holdout. So I'm particularly keen to see if we, through our combined efforts, can finally tip the scales.

While I'm on it, let me tell you about another strategical point that's been on my mind lately. When I first contacted Luca Mana about liking his paper, he wrote me back the following:

Manalogue 1: *Thank you so much for your letter, and for the words of appreciation for my paper. It is just a little more than a draft, and so its form is far from being nice, and many are the missing references. I already knew "Quantum Mechanics as Quantum Information (and only a little more)"; indeed, your idea, expressed there, that time evolution could be a density operator, stimulated (via Rodriguez' "Unreal probabilities",* `physics/9808010`*) some of the research that led to my paper. ...*

(So I hope you understand how honoured, and a little embarrassed, I feel for having received your letter!)

Yet one doesn't find a citation to any of my papers there. It could be that he was just being nice and not quite meaning it. However, if there really was an influence on his work, then his lack of a citation is a bit harmful. If I am going to be able to keep getting funding for conferences and drawing attention to our collective efforts, it'd certainly help if the larger community sees that my attempts to write and communicate and inspire are part of the active process leading to the (significantly more substantial) results of you younger fellows.

I guess all I am saying is, if it influenced you at all toward your toy model, I hope you will not forget to cite `quant-ph/9601025` and `quant-ph/0205039` in your write-up. (Sample below.)

From `quant-ph/9601025`:

> Formally, one says that in classical physics, maximal information is complete, but in quantum physics, it is not. What should we demand of a physical theory in which maximal information is not complete? Maximal information is a state of knowledge; the Bayesian view says that one must assign probabilities based on the maximal information. Classical physics is an example of the special case in which all the resulting probabilities predict unique measurement results; i.e., maximal information is complete. In a theory where maximal information is not complete, the probabilities one assigns on the basis of maximal information are probabilities for answers to questions one might address to the system, but whose outcomes are not necessarily predictable (some outcomes must be unpredictable, else the maximal information becomes complete). This implies that the possible outcomes cannot correspond to actualities, existing objectively prior to asking the question; otherwise, how could one be said to have maximal information? Furthermore, the theory must provide a rule for assigning probabilities to *all* such questions; otherwise, how could the theory itself be complete? Quantum physics is consistent with these demands. A more ambitious program would investigate whether the quantum rule is the *unique* rule for assigning probabilities in situations where maximal information is not complete. You won't be surprised to learn that we don't know how to make progress on this ambitious program.

16-06-03 *Exhaustion, Depression, Stagnation, Integration* (to G. L. Comer)

The world is a big world. And our lives are ever such a small part of it. And ever such a big part of it. But regardless, there are limits. I feel I'm not prepared for this. I tell Emma all the time that she is destined for greatness; she will do important things.

18-06-03 *Spiders, Ants, and Honey Bees* (to P. W. Shor)

I'll match your Morris Kline with a Francis Bacon:

> The men of experiment are like the ant; they only collect and use; the reasoners resemble spiders, who make cobwebs out of their own substance. But the bee takes a middle course; it gathers material from the flowers of the garden and the field, but transforms and digests it by a power of its own. Not unlike this is the true business of philosophy for it neither relies solely or chiefly on the powers of the mind, nor does it take the

> matter which it gathers from natural history and mechanical experiments and lay it up in the memory whole, as it finds it; but lays it up in the understanding altered and digested.

For better or for worse, this is the way I see this sensation I'm trying to instill into our community, "quantum foundations in the light of quantum information": I see it as a honey bee.

Peter's Preply

I just googled it.

> The developments in this century bearing on the foundations of mathematics are best summarized in a story. On the banks of the Rhine, a beautiful castle has been standing for centuries. In the cellar of the castle, an intricate network of webbing had been constructed by industrious spiders who lived there. One day a strong wind sprung up and destroyed the web. Frantically the spiders worked to repair the damage. They thought it was their webbing that was holding up the castle.

Reference given: Morris Kline, *Mathematics: the Laws of Certainty*, Oxford Univ. Press, NY, 1984.
It seems to me that this also applies to the philosophy of the foundations of physics.

19-06-03 *Lurch* (to J. M. Renes)

Renesism 9: *PS in regards to some quantum operations are subjective, is the subjectivity simply the case of assigning a state to the measurement apparatus? This is how Carl put it, and it clears up a lot of the confusion in my mind, but perhaps this isn't precisely the case.*

No. That way of putting it trivializes the point. For it makes it look as if *all* the subjectivity (in the Bayesian sense) is in the state assignment to the joint system of object + measuring device — a concept almost straight from the Tibetan Book of the Larger Hilbert Space. Then one can go around blithely thinking of the interaction Hamiltonian (+ preferred basis, so that the Hamiltonian cannot be transformed away) as objective components of the theory, well protected from the nasty subjectivity of the state. I.e., one can think of these things as classical matters of fact, independent of any agent's belief.

What I want is to go beyond that: And Carl knows that. All operations are subjective, I say, including the unitary derived from the interaction Hamiltonian above. I give fifteen arguments for this, none of which is conclusive, but in sum weighty enough for me to be willing to take the leap. Quantum foundations needs more leaps than baby steps, it seems to me, if we're going to see any real progress in our lifetimes.

19-06-03 *Guidelines* (to M. Pérez-Suárez)

From the last letter you know about my final decision with regard to Benasque. Just a word of warning: If you are allowed to attend, and you give a talk, do it on a technical subject and keep the philosophical remarks to a minimum. We will—with these ideas that you and I are attracted to—change the world. But one has to choose one's battles wisely, and there is something to be said for easing the community into the mindset at a rate slow enough for the resistance to be smaller rather than larger. The community attending the Benasque conference, for the most part, only cares about technical meat: If a foundational program makes no impact on that hunger, then it will be seen as no program at all.

Pérez-Suárezism 1: *Well, I have been to the [Niels Bohr Archive] and, of course, I asked about the William James story. I saw the transcripts of that last interview and I can tell you that things went as I remembered from my readings some years ago. There is no indication of any technical problem during the interview and Bohr's answers seem to have been completely tape-recorded with no remark in the transcript of any disturbance. You can find the content of the answers in several well-known books. Although I haven't consulted my references yet, if you want me to tell you where you can find it, I have no problem to do some research in my library (it is not as big as Howard's, I guess). By the way, I think that perhaps it can be found in Folse's book on Bohr's notion of Complementarity.*

Then the transcripts must be missing the nuance. Here is what Henry Folse himself told me:

Folsesm 21: *As you know, Bohr died after the 6th interview; 20 were originally projected. Jordan's are in German, and a few others; de Broglie in French, of course. However, there are holes in the transcripts where the transcriber couldn't make the tapes out clearly enough. (the tapes in Copenhagen are old reel to reel tapes and require an old machine to play; I don't know if the American centers have them on cassettes). Actually one such occurs when Bohr was talking about his admiration for William James. Just at that moment the noon air raid siren blew, more or less obliterating about 30 seconds.*

Of course I embellished a little in our pub discussion, but I bet they are nevertheless an interesting 30 seconds.

Pérez-Suárezism 2: *I have downloaded Richard Jeffrey's book on probability. I have browsed through it and found it seems to be very readable (and quite funny, too). I also have the recently published CUP edition of Jaynes' book, and Rüdiger told me that Savage's book on probability was quite interesting, too, so I will be purchasing a copy. Could you give me some advice on what I should pay more attention to first?*

Savage and Jeffrey, I would say.

Pérez-Suárezism 3: *P. S.: I have found some typos (to be true, of no real significance) in your paper. If you want a list of them, just let me know.*

Absolutely! I'd greatly appreciate that.

20-06-03 *Very Late Reply* (to S. Weinstein)

I apologize for the very late reply: It was just that your email hit me at a very bad time when I was in a complete email-shutdown mode.

I think your first question may refer to a problem that still has not been resolved to complete satisfaction. Unfortunately I've never taken too much note of the issue, so I don't have a strong opinion myself. I do know of Ozawa's work [M. Ozawa, "Quantum Nondemolition Monitoring of Universal Quantum Computers," Phys. Rev. Lett. **80**, 631 (1998)], but I remember hearing from Richard Jozsa and ?? Fahmy last year, that Ozawa's paper had a flaw in it. Perhaps it would be best for you to write Richard yourself; maybe he'll explain what he was talking about and give some references. I wouldn't mind hearing the answer. Richard's e-address is `rjozsa@cs.bris.ac.uk`.

Concerning your second question:

Weinsteinism 1: *I think we talked briefly about the "little more" that must be added to information-theoretic postulates in order to get quantum mechanics. It strikes me that one of the key elements of quantum theory which is not captured (at least in any explicit way) by the information-theoretic approach is that Planck's constant, a new constant of nature which has the dimension of action, or angular momentum, plays a role. Why action? Why not some other physical quantity? Classically, action is associated with dynamics via the principle of extremal action. In quantum mechanics, however, action plays a kinematical role as well. What is that telling us?*

You're certainly right. Looking solely at the *structure* of finite dimensional quantum mechanics, one never sees Planck's constant at all. Where it comes from, I don't know. Nor do I know if information-theoretic considerations will ever tell us much about its origin. A dull answer, right? I wish I could tell you more.

Would you, by the way, like a copy of my samizdat *Notes on a Paulian Idea*; it's just published and I have a number of copies for giving away. Mostly, though, I'm trying to target people who might be interested (and won't throw it away immediately). If you'd like a copy send me your mailing address.

20-06-03 *Logical Probability and That* (to J. M. Renes)

I think I agreed with much of your note. That was the upshot of last week's (month's?) discussions. To answer your final question (about Cox), I guess I don't have a strong opinion ... at the moment anyway. Do any of the others in the discussion list have a strong opinion? Mainly I never found Cox nearly as compelling as Jaynes did. (Well, I did for a short while, but then I became less than enamored.) I think one could still accept Cox's derivation of the probability calculus—even though I'm not so inclined (already said that)—without accepting Jaynes' further dogma about some priors being compelled by "THE information". That's because Cox's derivation has nothing to do with priors.

Did you forget an "all" in the title?

Joe's Preply

> These arguments are already beginning to leak out of my mind, so I'd better commit them to paper or email to help reinforce them.
>
> Let me see if I have things straight. Let's call "Bayesians" those who don't believe in objective probability, logical Bayesians those who think from background information a unique prior logically follows, and subjective Bayesians those who think that background knowledge does not determine for each subject (person/observer), a prior probability. The two approaches do share the normative aspect that Bayes' rule is the correct way to update knowledge given data. Are these fair assessments? Of course, it's not fair that the subjectivists are somehow defined as illogical in opposition to the logical Bayesians, but you know what I mean.
>
> The argument against logical Bayesian probability I picked up at the conference I think goes like this. Let's specialize to the case of picking "ignorance priors" and recall how this is meant to work in the logical probability framework. The background knowledge B gives no information about one outcome over or under another. Thus we study the symmetry group of the outcomes a_j and our prior must be invariant under this group. Presto! the symmetry group of the outcomes determines the prior probability.

But this doesn't represent an implication from propositions B to probabilities $p(a_j|B)$ because to say that the outcomes have some kind of symmetry is to say that some function on them is invariant under the swaps of labels (surely the swaps are always permitted, even if the case of symmetry doesn't obtain) and this function is precisely the probability function. I said "is to say" which is quite different than "implies" the logical structure of B that was to imply the uniform prior turned out to be the uniform prior itself. Put differently: You can't say "B doesn't favor any outcome over another" without it being a statement of probability. So there's no real implication going on except to say that "when you believe in the symmetry, you believe in the symmetry".

On some re-readings of the above, I've thought that it says nothing and I haven't stated the problem properly. But consider the argument made by Jaynes in chapter 2 of probability as logic: "But now suppose that information B is indifferent between propositions a_1 and a_2; i.e. if it says something about one, it says the same things about the other, and so it contains nothing that would give the robot any reason to prefer either one over the other." Later, he says, "It shows — in one particular case which can be greatly generalized — how the information given the robot can lead to definite numerical values, so that a calculation can get started." But the point of the above argument is that the "information given the robot" must be the uniform prior: the statement of symmetry *is* the uniform prior. You can't say that "whatever B says about one it says about the other" in a non-probabilistic way, which means there's no logical implication to it. That last statement is the one I like best.

I think there's a couple of additional points to make. The background knowledge B doesn't pertain directly to the outcomes a_j themselves: if they do we're talking logical probability. B, in some sense, has nothing logically to do with a_j; the point is that the connection between the background knowledge B and the a_j *is* the probability distribution, which is subjective, as it's made by a person thinking about the relationship between the two. This is just a clarification in light of the above argument, about what the background knowledge is or what it means.

The second is that perhaps my understanding so far is only crudely scratching the surface of the real argument beneath. Perhaps it's this. One way to see that B doesn't pertain directly to a_j is that it doesn't tell you how to carve up the outcome space into the a_j and only then make a judgement of indifference. In fact, the judgement of indifference is precisely this "resolution" of the outcome space. This seems to be the point of Jeffrey's problems 2 and 3 (though curiously labeled 1 and 2 in the sequence 1,1,2,4) in chapter one of *Subjective Probability*. The carving up of the outcome space into equiprobable events is a probabilistic judgement: "these particular outcomes $a_1, a_2, a_3, \ldots$ are equiprobable".

Greater question: Just because one isn't a logical Bayesian doesn't mean that one doesn't subscribe to the Cox arguments about probability as generalized logic. Jaynes as a logical Bayesian stresses the Cox view of course, but when it gets down to the logical aspects, he wants probability to contain the syllogism: $(a \Rightarrow b \ \&\ a) \Rightarrow b$ and its inverse $(a \Rightarrow b \ \&\ \sim b) \Rightarrow \sim a$, which it does, using Bayes' rule. So are there some pitfalls to being a subjective (= illogical, remember!) Bayesian and thinking of probability as generalized logic rather than coherent/consistent betting preferences that I don't immediately see?

Joe's Reply

No I didn't really mean to put "all" in the title, but not for any particular reason. Carl and I hashed out a lot of that argument (the main problem was that I didn't state it very well). He had a good way of putting it: First we have to decide if the symmetry is a belief or a fact. The symmetry is a belief, of course, and this can be seen in the arguments given. There are a few. First, the symmetry is obviously not in the system, since there are distinct outcomes. They wouldn't be distinct if there were really a symmetry. Second, the argument I was making, the symmetry condition is only stated (and can only be stated) in terms of probability. Ergo, it's a belief. Third, and think what Jeffrey is getting at in his book, the facts of the matter don't actually bear directly on the outcome space, so there can be no logical probability. You must decide what the relation is, and of course this is the probability. He uses an example of two coins. What's the probability that there's 2 heads showing? Is it 1/4 because there's only one way in four for the coins to be arranged this way, or 1/3 because there's three possibilities? The background info simply doesn't tell you (or as he says, there's no way to answer this question without making a judgment as to what is important). This is similar to the first point in that the background info doesn't "carve up" the outcome space for you.

Anyway, just wanted to get that down for the record, as it were. I find these arguments completely devastating to logical probability, and I agree that one can still follow the Cox approach (I've not done a heap of thinking on this last point though).

23-06-03 *Bayesianism, Yes, but then Something More* (to N. D. Mermin)

Merminition 111: *Alice measures a Qbit, gets 0, and then sends it to Bob. When Bob measures it he always gets 0. How can this be if the instruction to give 0 is not carried by ("resides in") the Qbit Alice sent Bob?*

Schackcosm 68: *I believe that this formulation is part of the problem. "He always gets 0" is a loaded phrase. In my view, it can mean one of two things. It can mean (i) that Bob makes N measurements, and each time he happens to get 0. Or it can mean (ii) that for a single measurement, it is certain that he will get 0. The second meaning is what I try to deal with in my previous email, where I claim that certainty always refers to somebody's state of belief. "It is certain" is then always short for "it is my state of belief that it is certain".*

As for meaning (i), if Bob happens to get 0 every time in N measurements, he can use this result to update his belief about future measurements. Or he can update his beliefs about where the qubits came from. But I don't see why he would have to conclude that each qubit carried the instruction "0" before the measurement.

Merminition 112: *"Have to conclude" is too strong, but wouldn't it be natural for him then to wonder why these two 0 results were so nicely correlated and entertain as an explanation the notion that Alice's measuring 0 imposed the instruction "0" on the qubit? What is it in his Bayesian training that prevents this thought from entering his head? Why should he be content with correlations without correlata?*

There is nothing in his Bayesian training to prevent the thought from entering his head. Instead, it is his training in quantum mechanics that bears the burden: Bell inequality violations and Kochen-Specker. It is a question of looking at the whole package.

Quantum mechanics, as I see it (and maybe Rüdiger too), is a layer added to the top of pure Bayesian reasoning. Bayesianism by itself does not care about the precise character of the left-hand argument in a probability function $P(h|b)$. The h could be a pre-existent fact living in the cold, hard world, or it could be something yet to come— something in existential character completely dependent upon the catalyzing intervention of the agent himself.

All we ask of the community is that it recognize the category distinction between the function $P(h|b)$ and its argument h. That is the first step in clarification. Once one can accept that into one's heart, then—the hope is—great progress will follow.

In particular, I would say, look long and hard at Figures 1 and 2 in my paper `quant-ph/0205039`. That region and the extra "rotation" within it signifies, symbolically at least[44], the extra layer on top of Bayesianism that quantum mechanics is asking us to contemplate. Within the shape of that region (or how its volume scales with system size, or some other relevant feature of it) and the style of the "rotations" that we add after pure Bayesian conditionalization lays hidden that which we are all really seeking: A precise statement about the (existential) character of the h's.

I bank on the idea that we will find that they are not correlata or relata at all, but rather creatia. (Simply trying to ontologize or reify the correlations while giving up on the correlata, as you try with your slogan, won't do.) The world is in constant birth. And to the extent that we focus our actions on anything and ask ourselves, "What will come of them?"—i.e., make note of quantum phenomena—we too are involved in that birth.

But I draw the discussion outward, while you want to bring it inward. I'll trust that Rüdiger will do all the hard work of bringing it inward for the present. You should know, though, that you yourself have the whole answer already; you said it completely: "So of course there is no mystery if you don't feel the need for an explanation of the first feature." The best I can do (and the best I will do, when I follow through with my promise) is fluff that sentence into a whole paper. Why give up on quantum measurement outcomes as the revelations of pre-existent facts? It is all and only a case of once bitten twice shy: the other route has been tried and tried too many times.

But to spin the result this way,

Merminition 113 : *Why should he be content with correlations without correlata?*

is to make the project look so very negative. "Be content with"—I hate that. It seems to forget that there is a much better world in return for this piddling little loss. To give you more detail, I'll attach the best shot I've had so far to make that convincing. (I hear Rüdiger chuckling: "I've never said it better than in my note to . . . ".) The file is titled `ForSlusher.pdf`. If for some reason you can't open it—you often seem to have troubles—it comes from notes to Wiseman on pages 210 and 217 of my samizdat *Quantum States: What the Hell Are They?* on my webpage.

Still beaming from Rüdiger's notes.

[44]I said "symbolically at least" above because I don't want to commit myself to the particular representation of quantum mechanics discussed in `quant-ph/0205039` as in any sense the key to all mysteries. Instead I view it as a kind of scaffold for sharpening the issue—i.e. as a way of giving direct comparison between quantum mechanics and general Bayesianism. But like any scaffold it has to be taken away ultimately . . . and maybe there is a way to shortcut the process without ever introducing the scaffold in the first place.

27-06-03 *Utter Rubbish and Internal Consistency, Part I* **(to N. D. Mermin)**

> What's the good of Mercator's North Poles and Equators,
> Tropics, Zones, and Meridian Lines?"
> So the Bellman would cry: and the crew would reply
> "They are merely conventional signs!

It's time for me to pay the piper. On November 4 of last year, I had a mystical experience during my flight home from the Montréal meeting: I thought for the first time in my life I had seen with complete clarity why there was no mystery, either to EPR correlations or to the Penrose argument calling for the objectivity of the quantum state. The whole strange flight from Montréal to Chicago to Newark (i.e., American Airlines Advantage Platinum Number D7E5856) I typed away. To the result, David replied:

Merminition 114: *Thanks for cc'ing me the latest epiphany. I've only had a chance to glance at it and am still torn between whether my response is "that was how I understood your position to be all week" or "what utter rubbish" so I will take a little time before responding.*

David's second instinct was the best: IT WAS UTTER RUBBISH. The great discussions I had with Rüdiger the last two days a) brought me back to the subject, which I had shamelessly not thought about again since writing the original note (a sign that there must have been some inner skepticism or reluctance on my part, but I didn't have the intellectual integrity to confront it), and b) showed me the gross errors of my ways. This note represents both a heartfelt thanks to Rüdiger and an attempt to tell the Quantum Bayesian tale in a way that does it better justice.

Let me start out by describing what I was thinking previously, both to set the tone and because I think it adds a little clarity to the recent discussions Rüdiger and I have been having with David. What my own trouble boiled down to previously was a moment of weakness—a moment when even I lost faith in our Bayesian dream (and sadly did not realize it as such).

Bell inequalities and EPR correlations, what are they good for? I think one thing only: the conjunction of the two concepts provides us with the most dramatic evidence yet that quantum systems do not themselves carry "instruction sets" for specifying the outcomes of "measurements" we can make on them. As Rüdiger said it two days ago, never was there a better exposition of this point than in some of David's writings. Thus, it is a point David should appreciate and take to heart. I know that I did, and it is this that led me astray in other directions.

The question is, how to live with this result? It's one thing to say there is a formal demonstration that there can be no instruction sets inherent within a system. But it is another thing to feel good about it. In particular, why doesn't it get absolutely under our skins that there can be situations where quantum mechanics specifies that we have certainty about the outcome of a measurement? The million dollar question. You see, if there's no instruction set, where could the certainty possibly come from? Or again: If there are no instruction sets, measurement outcomes must come out of the thin air, determined by nothing else. However, if they do truly come out of thin air, how could we ever be certain which outcome WILL occur before it actually does?

The world does what it does, but yet I have certainty? Where did that come from?!? It couldn't come from the world (as demonstrated through the force of Mr. Mermin's writings); it must come from me. Or—to be absolutely clear—that was the path of thought I found myself traveling last November.

IF THE CERTAINTY CAN'T COME FROM THE WORLD, IT MUST COME FROM ME. The interpretation we ascribe our clicks must be a convention. (As Rüdiger pointed out, it all starts to sound too much like Umberto Eco, and I agree now, but I was blinded at the time.) How could that be?

The mystical insight—the false prophet!—was that the trail had just been blazed! It all had to do intimately with our newfound realization that at least some quantum operations must have the same subjective status as quantum states. (I put the "at least some" solely so that Carl will not stop reading at this point; if it were a letter to Rüdiger alone, I would leave out the qualification completely.) A quantum operation is a density operator in disguise. That was somehow to be the key.

In rough terms, I wanted to say that *ascribing* a pure state P to a system and *ascribing* a description $\{P, I-P\}$ to an associated measurement device was just the convention I needed: No matter what the outcome of the "true" physical intervention (measurement), the result would be interpreted as P. But what utter rubbish! And it's hard to see now what I could have been thinking, or even how I could have found it pleasing. It goes against everything I have ever viewed as the great insight of the Paulian idea:

> Like an ultimate fact without any cause, the individual outcome of a measurement is, however, in general not comprehended by laws. This must necessarily be the case . . .
>
> In the new pattern of thought we do not assume any longer the detached observer, occurring in the idealizations of this classical type of theory, but an observer who by his indeterminable effects creates a new situation, theoretically described as a new state of the observed system. In this way every observation is a singling out of a particular factual result, here and now, from the theoretical possibilities, thereby making obvious the discontinuous aspect of the physical phenomena.
>
> Nevertheless, there remains still in the new kind of theory an objective reality, inasmuch as these theories deny any possibility for the observer to influence the results of a measurement, once the experimental arrangement is chosen.

The last part of the idea is absolutely crucial. The observer must not be able to influence the results of a measurement, even by hiding it in a convention. I had lost my grip on reality during that flight, and something deep inside me must have sensed it.

Let me try to make this absolutely stark by running down the Rüdigerian path. Consider two agents, a quantum system, and a quantum measuring device. Suppose both agents agree that the relevant feature of the measuring device is that it has two possible clicks, and furthermore suppose they both agree that the clicks are to be interpreted as a measurement of the POVM $\{P, I-P\}$. In our language, these are both subjective ascriptions (more on the word subjective later), but they just so happen to agree. However suppose in contrast to this single belief about the measuring device, they are in wild disagreement about what they believe of the quantum system soon to be intruded upon: One says the quantum system's quantum state is P, the other says it is $I-P$. From our standpoint, there is in principle nothing wrong with this. A quantum state is a subjective ascription (more on the word subjective later), period. It is not determined by the world external to the agent; it is his personally. So what happens to the measurement device when the quantum system is dropped into it? There are two agents, two absolutely incompatible beliefs. Does the measurement device explode?

No. A click occurs, and one agent is *made* wrong. If that agent had bet his life on his utterly extreme belief, he will now be dead. Darwinian evolution will have stepped in to see that his extreme belief is not propagated. That is no convention. The world will smite one of the agents.

Now, let us join the Merminian discussion presently in progress. Let us conceptually erase one of the agents. What can possibly change for the other? Nothing. Once again a firm belief exists and once again there is nothing to keep the world from smiting the believer.

OK, take a restroom break, get some popcorn, and I'll be back with the second half of this note after lunch.

28-06-03 *Utter Rubbish and Internal Consistency, Part II* **(to N. D. Mermin)**

It was a long lunch. Let me pick up where I left off:

> A click occurs, and one agent is *made* wrong. If that agent had bet his life on his utterly extreme belief, he will now be dead. Darwinian evolution will have stepped in to see that his extreme belief is not propagated. That is no convention. The world will smite one of the agents.
>
> Now, let us join the Merminian discussion presently in progress. Let us conceptually erase one of the agents. What can possibly change for the other? Nothing. Once again a firm belief exists and once again there is nothing to keep the world from smiting the believer.

The ultimate issue is, is there really any difficulty with the idea of an utterly certain belief about an admittedly contingent fact? And, I'll add for later discussion, is that something uniquely quantum mechanical?

I'll tackle the first question by repeating something Rüdiger said yesterday, but in a windier way: I'll paste in two sections from de Finetti's article Probabilismo. (That, by the way, was the reason for my long lunch: I ended up reading Probabilismo from beginning to end again—I think my fourth time since 1996. If I would have only absorbed the darned thing the first time! Each time I read it, I am struck that it is the best thing on probability I have ever read. Yet each time, I miss something really important. In fact I end up feeling bad about myself, for it shows me just what an amateur I am. The article's *got* to be made standard reading!)

18.

> "A gambler wants to make a bet; he asks my advice. If I gave it to him I would rely on the probability calculus, but I could not guarantee success. That is what I would call *subjective probability*. But I suppose that an observer is there, who notes the outcomes over a long period; when he reviews the record he will see that the outcomes fall out in conformity with the probability calculus. That is what I would call objective probability, and it is this phenomenon that we must explicate." [A quote from Poincaré.]
>
> That is a difficulty that leads many into error: how can one not be persuaded—one would ask—that the value of probability is not simply subjective?
>
> In all these cases, in all similar arguments, what is impressive is only one fact: that a practically certain event actually comes about, or it is foreseeable that it will come about. But should we be impressed? When I say that an event is practically certain I mean that I should be amazed if it didn't occur: am I then entitled to be amazed at having guessed, to be amazed that an extraordinary fact whose occurrence would have amazed me did not in fact occur?
>
> Poincaré says that those who are present at the game "will see that the outcomes fall out in accordance with the probability calculus". First of all they would be able

to see that *some remarkable and practically certain circumstances* occurred, relative, e.g., to the frequencies, while it is impossible that *all* the practically certain facts have occurred. It suffices to think that it was practically impossible that the particular sequence of outcomes that has taken place would have taken place. Then we must limit attention to just one or a few remarkable and practically certain circumstances. Poincaré says that they will happen. But why does he say it? Because he is certain of it, not absolutely, but practically. And didn't we already have to assume that he was practically certain of it? When I evaluate a probability as very close to 1, I express this sensation: that, almost without doubt, the event will occur. Do I add anything more when I repeat that, almost without doubt, it will occur? Do I have the right to think: first I evaluate a probability, and then I ask myself if I can actually anticipate the event with the corresponding state of mind? This is what many do, and, when they can answer affirmatively, they say that probability has an objective value.

But, when I evaluate a probability, I only express my state of mind, and what does it mean to ask whether I can or cannot have a state of mind which corresponds with the state of mind which is actually mine? If such a doubt corresponds to something which is not meaningless and is actually mine, it was already a part of my state of mind, and I will already have used it in my evaluation of the probability. But once I have evaluated it (and as long as I suppose that my state of mind will not change: if it changes, then certainly I can modify my earlier evaluation!) it is meaningless to think that my evaluation is wrong, because it is meaningless apart from me, it has no other function than to express my state of mind.

Why, when an event appears to me as practically certain (i.e., when I evaluate its probability as close to 1) have I the right to be practically certain that it will occur? Because when I say that an event is practically certain (when I evaluate its probability as close to 1) I do not say nor can I want to say more or less than this: that I am practically certain it will occur.

If it is true that "*opium facit dormire*", can we think it true that "*opium habet virtutem dormitivam*"? This is no less difficult and no less deep a philosophical problem! I leave it to the reader's acumen to see whether the comparison is apt.

19.

It seems strange that from a subjective concept there follow rules of action that fit practice. And Poincaré keeps explaining why the subjective explanation seems insufficient to him, mentioning practical applications in the field of insurance. "There are many insurance companies that apply the rules of the probability calculus, and they distribute to their shareholders dividends whose objective reality is incontestable."

Basically, this is only the preceding case, simplified by the fact that here it is very clear what the "remarkable circumstance" is that one must consider, and it has a very concrete importance: the dividend. We make a budget in such a way that it is practically certain that the gains will be such-and-such. Naturally, it is meaningless to say "practically certain" if I don't say *for whom* they are so; in this case it will be the managers, the actuaries, the shareholders. When an enterprise is sound and has little risk, it is easy to reach a universal or almost universal consensus on this opinion, and there is nothing to be surprised about, since it is exactly because of this that the enterprise is said to he sound and have little risk.

> But this is not sufficient: it is not just a feeling of the managers, actuaries, and shareholders, someone will say. You will see that the dividend will prove them right. What does this mean? I mean that this someone shares the feeling, the persuasion, the faith, which the managers, the actuaries, and the shareholders already have. At the end of the year the dividend is regularly distributed. See that, one will say, that certainty was not just my feeling, it must have had an objective ground. But why? If he—even on the basis of a totally groundless conviction—thought it unlikely that there would be no dividend, he would have to find it very natural that there is the dividend, and it would be pointless, unnecessary, and useless to look for an explanation. Least of all for a purely verbal and abstract explanation, like the one that consists of inventing "chance" and "the laws of chance".
>
> But let us look into the function of the probability calculus in the field of insurance.
>
> Whatever enterprise one wants to undertake, whatever firm one wants to manage, one always proceeds by consciously or unconsciously making a budget, in which we equalize the hope of profits and the fear of losses, the hope and the fear that the profits and the losses will be more or less great. We can love risk more or less, we can be prudent or speculative, and our preferences will be different. We could be guided by the hope of a risky gain and risk everything, or we might prefer the modest tranquility of those who feel safe from the tricks of fortune. We are perfectly free with regard to this choice; everyone can do as he wishes. The probability calculus cannot say we are right or wrong: it is true, the concept of mathematical expectation is known, and it is very important, but its task is not (as some seem to think) that of constraining our freedom of choice in this case. The notion of moral expectation has also been introduced, which, besides not solving the problem, is also an artificial and unimportant notion. In any case, we must consider all the alternatives together with their probabilities and their consequences, and then act as we see fit.
>
> In the case of an enterprise that must be secure and have little risk we must act so that, as in the case of insurance, our profits may not be fantastic, but they should be sufficient and practically safe. That's all that non-speculative firms do, without using the probability calculus, and nevertheless this certainty is not too often belied by the facts. And there is nothing strange in this, for an obvious reason: if these forecasts were always belied, we would not make them, and we would act in some other way, and it would be this other way that would inspire us to have greater or less confidence in the various alternatives.
>
> That a fact *is* or *is not* practically certain is an *opinion*, not a *fact*; that *I judge it practically certain* is a *fact*, not an *opinion*. That I should act according to this opinion is only apparently a corollary, because this opinion only exists in that I think I must govern my action in accordance with it.

What of any of this loses force when we come to quantum mechanics, or when we come to Mermin's 1985 *Physics Today* article? I think almost nothing, except possibly de Finetti's rhetorical question:

> If it is true that "*opium facit dormire*", can we think it true that "*opium habet virtutem dormitivam*"? This is no less difficult and no less deep a philosophical problem! I leave it to the reader's acumen to see whether the comparison is apt.

But even that's up to debate, depending upon which part of the quantum confusion one wants to place alongside the analogy. Thus, if you will allow me to drop those three sentences from the passage, I will boldly declare that nothing whatsoever of de Finetti's point changes when we come to quantum mechanics. In particular nothing changes even when we come to EPR/Bell phenomena.

The issue is just one of mindset. I think Rüdiger said it very nicely yesterday:

Schackcosm 69 : *David approaches him and asks "But aren't you dying to find out how the whole thing can possibly work?" Bob is puzzled. He doesn't understand the question. When he finally thinks he understands, he is even more puzzled. "Why would I be more confident about my predictions if the photons carried instruction sets?", he asks. Clearly, Bob and David speak at cross-purposes.*

Apparently, for David the only acceptable way to understand "how it can possibly work" would be a mechanistic, clock-work type model for it. Bob, Bayesian to the bone, thinks that David meant to ask: "How can you possibly be (almost) certain that tomorrow's outcome will be 0?" And Bob's answer is "What difference would the existence of an instruction set make to my beliefs about tomorrow's outcome?"

So, it is not certainty that is a mystery ever. Certainty is just the expression of someone's state of mind, whether the world will bear it out or not. Certainty is, at best, about internal consistency. But, we would have no right to draw from this that there is no deep lesson to be learned from EPR/Bell phenomena. On the contrary, EPR/Bell is just as important as it ever was—it's only been the conclusion that has been misplaced. David drew from it a mystery that has nagged him (and us) for at least 20 years. Instead, its lesson should be accepted at face value, regardless of the feelings of mystery that motivated Bell's initial analysis: There are no instruction sets. That's the lesson. It is telling us something about (what we believe of) the world.

Wow! What more could one ask for than a precise, well-formulated statement of what one actually believes. Sometimes I have a precise statement of the implicit beliefs that motivate my actions, but not very often. Here's a case where I can actually nail one down.

So, the whole business of understanding quantum mechanics starts to feel even better. It is about understanding one's priors! (I wish I could boom that out in a Ben Schumacheresque fashion! I hope you can hear it.) In accepting quantum mechanics, one is making an implicit statement about one's priors. It is the structure of those priors and not their precise values that is telling us something about what we believe of the world independent of our particular experiences.

In summary, let me just say this. Letting go of the mystery in EPR/Bell is not defeatism. Instead, through it we accumulate a fact for our Bayesian understanding of quantum mechanics, i.e., as a statement about the structure of our priors. There's far more work to be done in that regard. And if one wants metaphysics (or at least a post-positivism, i.e., something more than raw experience), that's where it is to be found.

Thus, let me end Part II. There'll still be a Part III, but now I've got to go to dinner.

30-06-03 *Probabilistic Dialogue* (to R. W. Spekkens)

Spekkensism 17 : *I found myself thinking about probability theory last night. I realized I need to really go deeply into these issues. If radical Bayesianism is the answer, then presumably the only thing preventing me from adopting this view is my ignorance of the problems with the alternative.*

So, what should I read to learn about the arguments for and against both the logical and subjective interpretations of probability? If you could tell me the classic texts for both camps, as well as any good articles providing a modern perspective on the debate, that would be ideal. (I'm not interested in the propensity interpretation.)

I'm glad you're taking a deeper interest in the foundational issues of probability now. I think, as your own toy model shows to some extent, getting the idea of probability straight is a large part of the task of getting quantum mechanics straight. In any case, it is a part of the problem that cannot be ignored.

I think the most devastating critique of the classical and/or logical interpretations is the problem of defining the reference class for any given event. What is the set of possibilities that an event *must* be considered an element of? In the real world of statistical practice and decision, there is never a unique answer. Of course, in fundamental physics, one might think that one is in a holier position: One can always declare a reference class by fiat. But then the onus is on the declarer to show why that reference class and a uniform (or even any nonuniform but otherwise fixed) probability measure over it is actually relevant to statistical practice.

I was hoping to pin down some really good quotes over the weekend to accompany this note. You see, for instance, Richard Jeffrey, the inventor of the idea of "radical probabilism" and a wholehearted supporter of de Finettian ideas, started off in the school of Carnap, where the hope was that logical probability would someday be the new messiah. As I understand it, it was years of watching the project fail that ultimately led Jeffrey in the other direction. But I couldn't find anything quite forceful enough for my tastes.

In any case, here are the things I think you ought to read (in the following order):

1. Leonard J. Savage, *The Foundations of Statistics*. Read all of Chapters 1 and 4, especially Section 4.5.

2. Richard Jeffrey, *Subjective Probability (The Real Thing)*. Read pages 8 to 11. The book can be found at: `www.princeton.edu/∼bayesway/`

3. José M. Bernardo and Adrian F. M. Smith, *Bayesian Theory*. Read all of Chapter 1 and pages 99 to 102. And finally, the very best thing that anyone can read is

4. Bruno de Finetti, "Probabilism," Erkenntnis **31**, 169–223 (1989). (I have never gotten so much out of any of my reading on probability as I have from this article. But I should warn you that I can already guess you will find Sections 1, 2, and 3 of it unpalatable, at least on first reading. Therefore I hope you will be a little lenient on the man until you get past them. After that (and excepting the very last section on fascism) I think there is so much that is absolutely firm in the article, I don't see how anyone could disagree with it.)

Let me also add three attachments to the present note that I think are directly relevant to you. One is a little thing Joe Renes wrote recently. Despite the free-formness of the note, I think it hits the points related to your present query quite well. The other two are notes that I wrote recently: They have to do with the "mystery" (or lack thereof) of EPR from the Bayesian standpoint, and lean heavily on the concept of "certainty" in the Bayesian sense. I do hope that they'll somehow make something click in you. The best answers are going to be the most trivial, not the most contrived.

I hope you'll let me know what you think of all these things. In particular, it'd be nice if we could start up a dialogue. Can you articulate what troubles you most about the de Finettian version of probability? What looks less than scientific about it to you?

I suspect it all boils down to the fact that you feel that Bayesianism is somehow too arbitrary: "For God's sake, they won't declare *any* probability assignments right or wrong! Science is not just 'anything goes."' … but I don't want to put words into your mouth. If however that is roughly the case, I hope you'll think hard about a point Marcus Appleby likes to make: "It's really hard to believe something you don't actually believe." I.e., Bayesians, from my point of view, think anything but ‘anything goes.’ A probability assignment, when it is made, is one’s best shot at articulating what one believes; and what one believes is not up to one’s whim.

I would have thought that the de Finetti version of Bayesianism should have been quite attractive from the point of view of the cut you want to introduce into physics: the ontic and the epistemic. Try your best to say what the world does or is; that’s what the ontic is about. Fine. I’m OK with that. But then why try to make our fallible beliefs rigidly connected to the ontic world? If you’re going to try to make probability assignments adhere to the concepts of right and wrong (just like those ontic states of yours), why not make them part of the ontic world too? Another way to put it: What’s so blasted wrong about allowing a perfectly rational agent to be ‘wrong’ about the actual state of the world? You want a) that there is a world (with its one true state), and b) that any agent worthy of being called rational or ideal, must by right about it to within some tolerance. But why?

Or maybe it is just the fear of having an agent in the background as the anchor for a probability assignment that bothers you. Didn’t Copernicus teach us that our place in the universe is not the center of the universe? Aha! Maybe that’s it. So, if we could just find a sound notion of objective probability, we could imagine the calculus of quantum mechanics hanging around even when there’s no one about in the quad to make use of it. Is that the deeper of the issues for you?

OK, enough blabbering. I’ll shut up for a little while until you give me some guidance. In the meantime I’ll leave you with some of my favorite Bernardo and Smith quotes. They’re pasted below. [See *Quantum States: W.H.A.T.?*, pp. 19–20.]

30-06-03 *Fear of the Anchorman* (to N. D. Mermin & R. Schack)

Did you notice the ending lines I put in the note to Spekkens?

> I suspect it all boils down to the fact that you feel that Bayesianism is somehow too arbitrary: “For God’s sake, they won’t declare *any* probability assignments right or wrong! Science is not just ‘anything goes.’ ” . . . but I don’t want to put words into your mouth. If however that is roughly the case, I hope you’ll think hard about a point Marcus Appleby likes to make: “It’s really hard to believe something you don’t actually believe.” I.e., Bayesians, from my point of view, think anything but ‘anything goes.’ A probability assignment, when it is made, is one’s best shot at articulating what one believes; and what one believes is not up to one’s whim.
>
> I would have thought that the de Finetti version of Bayesianism should have been quite attractive from the point of view of the cut you want to introduce into physics: the ontic and the epistemic. Try your best to say what the world does or is; that’s what the ontic is about. Fine. I’m OK with that. But then why try to make our fallible beliefs rigidly connected to the ontic world? If you’re going to try to make probability assignments adhere to the concepts of right and wrong (just like those ontic states of yours), why not make them part of the ontic world too? Another way to put it: What’s so blasted wrong about allowing a perfectly rational agent to be ‘wrong’ about the actual state of the world? You want a) that there is a world (with its one true state), and b) that any agent worthy of being called rational or ideal, must by right about it to within some tolerance. But why?
>
> Or maybe it is just the fear of having an agent in the background as the anchor for a probability assignment that bothers you. Didn’t Copernicus teach us that our place in the universe is not the center of the universe? Aha! Maybe that’s it. So, if we could just find a sound notion of objective probability, we could imagine the calculus of quantum

mechanics hanging around even when there's no one about in the quad to make use of it. Is that the deeper of the issues for you?

Now that I've written that, I wonder how much of a problem exactly the latter might be for the larger community. Take, for instance, David Mermin's Desideratum 1 in his original Ithaca interpretation paper: "The theory should describe an objective reality independent of observers and their knowledge." How would he ever fulfill Desideratum 1 if probability must be interpreted in the Bayesian way? Maybe it's that that worries people so much about the Bayesian creed when it comes to quantum mechanics ... even (and particularly) Bayesians!

01-07-03 *Your Papers* (to N. Hadjisavvas)

I have been meaning to write you for some time to thank you for sending me the collection of papers that you did:

- N. Hadjisavvas, "Étude de Certaines Consequences d'une Interprétation Subjective de la Notion d'Etat," Ann. Fond. Louis de Broglie **3**(3), 155–175 (1978).
- N. Hadjisavvas, "Distance between States and Statistical Inference in Quantum Theory," Ann. Inst. Henri Poincaré **35**(4), 287–309 (1981).
- N. Hadjisavvas, "The Maximum Entropy Principle as a Consequence of the Principle of Laplace," J. Stat. Phys. **26**(4), 807–815 (1981).
- N. Hadjisavvas, "Properties of Mixtures of Non-Orthogonal States," Lett. Math. Phys. **5**, 327–332 (1981).

Particularly, I was very pleased to learn that you had toyed with Bayesian ideas within quantum mechanics already in your Master's thesis, so many years ago. I will study all of your papers in detail and cite them duly in my upcoming work.

I wish I knew of which of my papers you found some interest in. In case you haven't found it previously, you can find a body of my writings on quantum foundational things on my personal website (link below). Also, Caves, Schack, and I have an accumulating list of Bayesian-type quantum results posted on the quant-ph archive at `www.arXive.org`.

Nicolas's Preply

> I recently saw (by chance, given that my research interests changed completely since almost 20 years) a couple of your papers on quantum information. Please find enclosed some very old papers of mine on related subjects. Actually, the paper in French was my Master's (DEA) thesis. In it, the idea of a state describing the knowledge of the observer, rather than the system itself, is exploited for (still another) derivation of the projection postulate.

01-07-03 *Rob Spekkens* (to R. D. Gill, K. Mølmer, and E. S. Polzik)

I just wanted to alert you guys to Rob Spekkens, who has just applied to give a talk at the MaPhySto/QUANTOP meeting in August. I hope his talk will be accepted. I think he has truly one of the most interesting quantum foundational / quantum informational results I've seen in quite a while. What he does is explore a toy model that is admittedly not quantum mechanics, but is a certain local hidden-variable theory. What's interesting about the model in spite of this nonsense is that it incorporates a principle that Carl Caves and I were once hoping to found quantum mechanics itself upon: Namely, that in quantum mechanics maximal information is not complete information. The truly surprising result about Spekkens' toy model is just how much of standard quantum-information looking stuff his model contains:

a) a no cloning theorem

b) superdense coding (without entanglement)

c) a no broadcasting theorem

d) a no-go theorem for bit commitment

e) an information-disturbance principle that can be used for secure key distribution

f) something that looks like entanglement monogamy (without entanglement)

and the list goes far beyond this. The point is, one does not (and cannot) recover all of quantum mechanics from his toy model, but one can get a hell of a lot of it even in a hidden variable model (with the principle that maximal information cannot be made complete).

I think we stand to learn a whole lot about real quantum mechanics from this exercise. And it is just a marvelous construction. I hope there is still room in the schedule for young Spekkens.

01-07-03 *Gasp or Shudder?* (to J. W. Nicholson)

Actually was it gasp or shudder? My memory is getting fuzzy on the whole affair. I know that I need to write this story down before it is completely gone. Could I interest you in sending me some notes on what you remember? Of course, when I write it up, I'll probably embellish things a little to try build atmosphere, but I would like to be decently accurate to what actually took place (and how things were said).

01-07-03 *Samizdat* (to A. Fine)

It was good meeting you at the Clifton memorial meeting a few weeks ago; I've long been a fan of your writings. I'm writing to tell you, though, that my quantum samizdat *Notes on a Paulian Idea* has just been published by Växjö University Press, and I have a number of copies to give away. (If you don't know what I'm talking about, you can peruse the file on my webpage (link below).) If you think you might get something out of it, I'll have the publisher send you a copy. All I need is your mailing address.

01-07-03 *My Samizdat* (to W. E. Lawrence)

I've been meaning to write you for a while. Would you be interested in a copy of my quantum samizdat *Notes on a Paulian Idea*? The book has just been published by Växjö University Press, and I have a number of copies to give away. If you don't know what I'm talking about, you can peruse the file in PDF format on my webpage, link below. (Mermin wrote a foreword to the book.)

If you think you might get something out of it, please let me know and I'll have the publisher send you a copy. All I need is your mailing address.

01-07-03 *Objective Chance* (to W. C. Myrvold)

Myrvoldism 1: *It's several projects down the queue, and we may not get to it this summer, but Bill Harper and I plan to write an article on why Bayesians should believe in objective chance. I'll send you a draft when one exists.*

I look forward to it. It's about the biggest thing on my mind at the moment. Particularly, I'm fairly of the opinion that trying to force objective chance (rather than objective indeterminism) onto the world is going to be counterproductive for a good understanding of quantum mechanics. But I'll give you a chance to convince me! (I made the distinction above, by the way, because I rather like indeterminism of a sort, but I would be reluctant to try to ascribe a numerical measure to it.)

In the mean time, anyway, can you give me some pointers to any literature that tries to argue the same point as you'd like. I'll bank on your paper with Harper being a better version of it all, but still I'd like to see some its predecessors.

01-07-03 *Gasp or Shudder?* (to Friend X)

Actually was it gasp or shudder? My memory is getting fuzzy on the whole affair. I know that I need to write this story down before it is completely gone. Could I interest you in sending me some notes on what you remember?

01-07-03 *Making the World Gasp Your Name* (to R. W. Spekkens)

Spekkensism 18: *I had not heard of the Aarhus workshop until now. I am thinking about asking the organizers whether it is too late to attend and whether there are any free slots left. Do you think it will be a good workshop for someone, like myself, who finds himself currently absorbed with foundational rather than practical issues? [...]*

I had a feeling it was something like that. Have a look at this article before it disappears from the NY Times:

`http://nytimes.com/2003/07/01/international/europe/01DENM.html`

"Free Spirits in Their Fortress, the Law at the Gate."

01-07-03 *Samizdat and Potentia* (to A. Shimony)

Shimonyism 1: *About two weeks ago I sent you a note thanking you for your book, but I fear that the address was wrong. If you have already received my note of thanks, no harm is done. I certainly appreciated receiving your remarkable book. You gave good excerpts from emails sent to you, and these together with your replies constituted interesting dialogues. As you know, there are serious differences of opinion between us on the ontology of the wave function, but your arguments always seem to me thoughtful. I shall consult your book often and find stimulation in it.*

Thank you for the kind words.

I also reread the lovely letter you sent me on May 27 of last year. I know that there are differences of opinion between us, but I hope that in the end they will not be so serious. In particular it would be nice if physical theory itself would lead the way to minimizing those differences: I think there is a chance, with a suitable rewriting of quantum mechanics into more Bayesian-like terms. At the very least it'll be a new way to see things, and that may sharpen our real (rather than apparent) points of contention.

You write, "[I]n my opinion the greatest philosophical innovation of QM is the discovery and exploration of a new modality of reality – something in between actuality and logical possibility – which Heisenberg named 'potentiality' in his book *Physics and Philosophy*." But I would like to think that I am quite attracted to the same idea. Throughout *Notes on a Paulian Idea* you'll find image after image of the quantum measurement process as a creative process, something that brings about a transition from the possible to the actual. Indeed it is captured by the Paulian idea itself (the conjunction of the two quotes at the beginning). Here's a slightly longer version of the same:

> In the new pattern of thought we do not assume any longer the detached observer, occurring in the idealizations of this classical type of theory, but an observer who by his indeterminable effects creates a new situation, theoretically described as a new state of the observed system. In this way every observation is a singling out of a particular factual result, here and now, from the theoretical possibilities, thereby making obvious the discontinuous aspect of the physical phenomena.
>
> Nevertheless, there remains still in the new kind of theory an objective reality, inasmuch as these theories deny any possibility for the observer to influence the results of a measurement, once the experimental arrangement is chosen.
>
> Like an ultimate fact without any cause, the individual outcome of a measurement is, however, in general not comprehended by laws. This must necessarily be the case . . .

Where we part company, I think, is only in a) my resistance to summing up this new category with a numerical measure (i.e., objective probability or objective chance), and b) my desire to make it clear that the quantum formalism is a calculus for manipulating agent-centered probabilities. Sometimes I put the latter point this way: Can a dog collapse a wave function? Dogs don't use wave functions. I myself didn't collapse a wave function until I was 23. But that doesn't mean that the quantum world will disappear without the agent! It only means that (judgmental, personalistic, subjective) quantum probabilities disappear without the agent.

Here's the way I put it (again) to David Mermin the other day:

> I bank on the idea that we will find that they are not correlata or relata at all, but rather creatia. (Simply trying to ontologize or reify the correlations while giving up on the correlata, as you try with your slogan, won't do.) The world is in constant birth. And to the extent that we focus our actions on anything and ask ourselves, "What will come of them?"—i.e., make note of quantum phenomena—we too are involved in that birth.

Thus, the transition from possible to actual I am toying with is of a sort of William Jamesian flavor (now that I know a little bit about James's philosophy).

Does that leave us with an even more gaping trench between us? Or is there some room for finding a common ground?

Abner's Reply

There are some bridges between your Weltanschauung and mine, and there are also some chasms. Among the first are these:

(1) I too am a Bayesian, but in my view of scientific methodology. There are, however, many different versions of Bayesianism – logical probability theory, subjective probability theory, personalist probability theory (similar to subjectivism except for the constraint of consistency), and communalist probability theory. Mine is none of these. The probability theorist whom I most admire is Harold Jeffrey[s], who announces himself as a logical probabilist but modifies that position with what he calls "the simplicity postulate", which is really a strategy. Maybe I should call my rewriting of Jeffreys "strategic Bayesianism." The position is presented at excessive length in "Scientific inference", reprinted in vol. 1 of my *Search for a Naturalistic World View*. An improved and shorter version is in the paper that follows it, called "Reconsiderations on Inductive inference."

(2) I maintain that Bayesian inductive methodology can be employed at the level of generality of metaphysics. It seems to me that Pauli thinks the same, but the metaphysical principles which he derives don't convince me, because of his emphasis on the subject – a residue of Kant. My best expositions of my theses are in the same volume, one called "Search for a world view that can accommodate our knowledge of microphysics," and the other "Reality, causality, and closing the circle."

Another bridge is our common admiration of the pragmatic tradition in American philosophy. You love William James, and I have respect for James but reverence for Charles S. Peirce. If you look at their names in the indices of both volumes of "Search…" you will see my reasons for these attitudes. Something that gave me great satisfaction when I was Wigner's student was pointing out to him an affinity between some of his philosophical papers and those of Peirce, whose name he had never heard of. He then read some Peirce and was excited: "this man has brains and imagination!". And later he cited Peirce several times. It could happen to you, too. I am not a missionary, but I like to share my enthusiasms with my friends [Maybe that's another way of describing a missionary!].

(3) Although Bayesian probability theory does not, in my opinion, suffice to characterize the probabilities implicit in quantum states, it can be a valuable adjunct. I am now in the middle of writing a Bayesian treatment of the problem of probability in ensembles that are both pre- and post- selected – a problem opened in a famous paper by Aharonov, Bergmann, and Lebowitz, Phys. Rev. **134B**, 1410 (1964), anthologized by Wheeler and Zurek, and treated in many papers by Aharonov and his school. There are, in my opinion, systematic errors in their work, easily resolved by carefully using Bayes's theorem. I'd like to present this work if we have the conference on Bayes and QM that we talked about, but in any case I shall send you the paper when it is done. I've written on the topic before, but am dissatisfied with earlier expositions.

This is a beginning. I hope there will be sequels.

Did I tell you how impressed I was by the beautiful photo of you with your daughter? No philosophy can pretend to depth without the message of that picture!

01-07-03 *Endorsing Probabilismo* (to N. D. Mermin)

I do hope by the way, when you come up for air from the wedding (is it one of your children's?) you'll take a shot at reading de Finetti's article "Probabilism." Here are the coordinates:

Bruno de Finetti, "Probabilism," Erkenntnis **31**, 169–223 (1989).

The article is immediately followed by one titled "Reading Probabilismo" by Richard Jeffrey. It'd be a good idea to take a look at that one too.

I thought I would send you two things to help prod you into taking this homework assignment seriously. One is an endorsement of the paper by Rüdiger that I noticed he hadn't cc'd to you. The other is a quote from within the paper that sounds ever so much like 'correlation without correlata'. (I know that nothing else so whets your appetite.)

First the quote:

> Concerning Aliotta, I think it necessary to report the following passage, to avoid what might be an easy misunderstanding.
>
> "It is necessary to distinguish relativism from relativism. There is one of its forms (the one commonly pointed to when relativism is accused [of skepticism]) that relegates our knowledge to the realm of relativity, opposing to it an absolute reality that will always elude knowledge. In this form relativism has a skeptical and agnostic flavor and often goes together with mysticism. In the blinding light of the absolute our relative world devaluates, degenerating into a vain apparent shadow. We are the dream, the absolute is reality. And life becomes the painful chase of those shadows, vainly trying to become light.
>
> "But there is another form of relativism (and this is mine), in which what is relative is itself the reality and leaves nothing outside itself. What we know is not the shadow, but the light, not a copy, but the true and concrete original" (*Relativismo e Idealismo*, Naples, 1922, p. 92).
>
> This is exactly my opinion, and I wish to note, for more complete rigor, that the sentence "what is relative *leaves nothing outside itself*" must not be understood as saying that the sentence "there exists something outside what is relative" is FALSE, but that it is meaningless, so that it is impossible even to pose the question as to its truth and falsity. This is, after all, the interpretation that conforms to Aliotta's thought, as appears clearly further along in the text, where "*the being in itself and outside any relation of things*" is seen as "one of the many verbal statements to which there correspond no ideas, and which have become true and proper puzzles of philosophy" (ibid.).

02-07-03 *Photographs and Memories* (to A. Shimony)

Thank you again. I will read your note many times over (as is my habit), and I do hope this is only the beginning.

Shimonyism 2: *Did I tell you how impressed I was by the beautiful photo of you with your daughter? No philosophy can pretend to depth without the message of that picture!*

You flatter me … but you might also enjoy two letters in the Charlie Bennett chapter, titled "Emma Jane." They start on pages 52 and 53. The second of the two—[ending with the line "giving her dad more reason to suspect that the world is so much more than a mechanical contraption clinking along"]—was certainly meant to be a philosophical statement.
