Before answering you I looked at pp. 52–53, as you suggested. The list of eighteen accomplishments at age six months (5 June 1999) is astonishing. I have been a Chomskyan since I first met him forty years ago and listened to the evidence that he had compiled for infantile intelligence, but Emma Jane exhibits muscular and emotional intelligence which Chomsky hardly notices.

She is programmed to elicit the responses that you are programmed to exhibit. Isn't that a wonderful gift. And yes, the last accomplishment in the list is a philosophical lesson of the first order.

You and your wife are fortunate to have such a daughter, and she is fortunate to have parents who properly appreciate her.

03-07-03 *The Dangers of Analogy* (to R. Schack)

Schackcosm 70: *I just discovered that von Mises was right after all! Proof by analogy:*

Einstein: Gravitational mass and inertial mass do not just have the same numerical value—they are the same thing.

Von Mises: Probability and limiting frequency do not just have the same numerical value—they are the same thing.

True enough. But here's one I'm letting guide me ever more often:

$$\text{Hilbert space dimension} \quad \longleftrightarrow \quad \text{gravitational mass}$$

(If the Bekenstein bound is right ... or at least contains a grain of truth ... perhaps it should be mass × area.)

04-07-03 *Solid Ground, Maybe?* (to G. L. Comer)

Comerism 4: *P.S. When we're together, I want to press you somewhat on how spacetime concepts enter, appear, etc either implicitly or explicitly in your information theoretic program.*

Yep, this is what the note is about. Once upon a time I promised to write you something about the information theoretic roots or NONroots of the principle of equivalence if I ever had any thoughts on it. I think I had one thought. Let me try to get it onto paper.

I go up and I go down when it comes to speaking the words gravity and quantum in the same sentence. At times I find myself thinking that general relativity and quantum mechanics express two absolutely incompatible worldviews. The general relativistic universe is a "block universe" in William James's sense: It's just there. One can talk about foliations and dynamics, etc., WITHIN the 4-manifold, but in the largest view—the view from nowhere—the world and all its history is just there. It is a universe without life (in the creative sense). In contrast, the quantum world strikes me as a malleable world—one that is still in formation, and in particular, one for which it is impossible to get such a "view from nowhere" (as Nagel would call it).

At other times, I find myself feeling more lenient: Perhaps the two worldviews are incompatible, but that does not mean we cannot gain insight about one of the theories from the other. And when we find the analogy, maybe it is just at that place where we should start hammering away those inconsistencies.

Suppose you take any two pieces of the universe that your mind is willing to call 'matter.' What can *you* tell me with assurance, even if no further word is said about their constitutions? You would tell me that they attract each other, and the force of attraction (in the Newtonian view) is determined in part by two numbers, one intrinsic to each of the two pieces of matter—their masses m and M.

Suppose now that I take any piece of the universe that my mind is willing to label 'matter.' What can *I* tell you with assurance, even if no further word is said about its constitution? I can tell you that with my free will I can write some number of messages into it. Moreover, I can choose to write them in such a way that that piece of matter will reveal (with some probability) whether anyone else has had a look at my stored message. Both the number of messages I can write into the matter and my best probability of catching an eavesdropper is determined by a single number: The matter's Hilbert space dimension D.

In my paper `quant-ph/0205039` "Quantum Mechanics as Quantum Information (and only a little more)" and in my web samizdat *Quantum States: What the Hell Are They?* (on my homepage), I have argued strenuously that it is ONLY the Hilbert space dimension D that can be taken as a property intrinsic to a quantum system (a piece of matter). The quantum state, nothing to do with entanglement, or even anything to do with a Hamiltonian is intrinsic to it: Just the single, lonely number — the dimension.

It strikes me that we have here a phenomenon of the power and scope of universal gravitation, or maybe the principle of equivalence.

Why did I name this note 'solid ground'? It has to do with something I tried my best to express the last time I was at the Perimeter Institute, where it looks to me like there are so many people flailing about without a clue as to what they should be up to when they speak of combining general relativity with quantum mechanics. Lee Smolin asks me how I could possibly imagine that the linear structure of quantum mechanics will remain when one moves into such a nonlinear regime as that given by the laws of gravity? I say I'm not fazed at all: Most of what he means when he speaks of quantum mechanics as an expression of physics, is for me but a law of thought. A wave function and its evolution are not properties intrinsic to the system for which they are about. Rather, if they are properties of anything at all, they are properties of their user's head—for they capture all his judgments about what might occur if he were to interact with the system of interest.

The quantum foundational task as I see it is to baldly accept that A LARGE PART of the theory is simply not about a world without observers: It is only about our interface with the world. But there is a part that remains, and that part must be given a firm identification. For only once we know how to do that will we know how to move forward when it comes to gravity. Only then will we see that almost all of the ways that have hitherto been considered for combining quantum mechanics with general relativity were far too unconstrained: I am willing to bet that they all essentially boil down to sheer speculation.

So I write this note because I am starting to get a sense that there might be some solid ground in these considerations. Hilbert space dimension is the universal factor for quantum systems that mass is for gravitating systems . . . or something like that. Could they be the same thing? . . . Or something like that?

"What nonsense is this!??!? Any of the simplest 'real world' quantum systems—not these paltry, specialized things you study in quantum information theory—has an infinite dimensional Hilbert space. Just think of the hydrogen atom!" Maybe. But it's caused me to wonder if I should take the Bekenstein entropy bound more seriously than I have in the past. The trouble that I had had with it before—after making my transition to the subjective/Bayesian/Gibbsian school of entropy—was that a bound on the ignorance one can have just doesn't seem to make much sense: entropy is not an objective property. But we have to be careful in these things: there are levels of subjectivity.

What I mean by this is that, though, the cardinality N of a sample space may be subjective in the same sense that a probability assignment is, once one has set it, one is obliged to declare a maximum ignorance, $\log N$, with respect to that setting. And that may be what is really going on the Bekenstein bound.

In other words, maybe in my language, all and only the number ER/h signifies is a Hilbert space dimension. That is one thread of thought, wildly speculative and departing from solid ground though it may be.

But the other thread of thought is in the interpretation of this previous wild speculation. If it's even on the right track, where might it go? Let me give you an example of very bad language: "The Hilbert space dimension signifies the number of potential states a system can inhabit." The lesson of all my (and Bell's, and Mermin's, and many other guys) quantum foundational work is that that is nonsense. Hilbert space dimension signifies something else.

When I get poetic about it, I like to say it signifies something about a system's "sensitivity to the touch", and when I'm getting downright Paulian, I like to say it signifies something about its potential for taking part in creation. With my light touches, I can send it off in ways unknown (to me and to it) and, counter to intuition, the larger it is, the more I can do that. Wojciech Zurek has spent his life making up stories about why big things are "classical." I say he has it all wrong, the bigger the thing, the more Hilbert space it has, the more quantum it is! The more sensitive it is to the touch. And thus the more ignorance an outside observer generally has about it (except with respect to a very small number of features) — not for any particular reason to do with very particular properties of Hamiltonians, but simply because it is big. It is not the system that is classical, but the poor observer's description of it that is.

So, let me leave you with an image for your flight. It's about the fleshpots of creation. Take the Bekenstein bound with more than a grain of salt—I'm not sure that I do yet, but it is fun to play—and take a given region of space. Ask yourself what you should imagine to be there if you want the region to have the most potential for creation. And if you stumble across the answer I'm guessing you will, what on earth could it mean?

PS. Let me append another note I wrote a few months ago to David Mermin [6 January 2003]. Maybe there's a connection in there somewhere.

04-07-03 *Bekenstein Bound Status* (to W. G. Unruh)

Can you fill me in on the latest to do with Bekenstein's entropy bound? Is it still controversial? Have any loopholes been plugged? Is it dead in the water? Things like that. Or can you give me a pointer to something to read on the latest state in the debate?

The reason I ask has to do with a recent *analogy* I've been drawing between (finite) Hilbert space dimension and mass. Maybe it's taking me down heretical lines ...

Thanks!

07-07-03 *Your Letter* (to P. G. L. Mana)

Thanks for the very nice letter of 12 June; it all sounds very interesting. Have you made progress since then? Has Hardy replied with anything of interest?

I apologize for taking so long to reply myself, but many, many administerial distractions have come to me since our nice time in Sweden.

Concerning your first issue, let me ask a naive question. Does your discovery boil down to something other than saying, in the end, one can always embed quantum mechanics in a hidden variable model. (Bohmian mechanics is usually claimed to be proof by explicit example.) Of course, one has to give up some nice features of standard quantum mechanics—like locality—but nevertheless one can embed it into a hidden variable model. If that is what your result is, it may nevertheless be quite a new way of saying it which will lead us to a better understanding of what criteria of aesthetics we are using when we accept the standard quantum model.

Concerning your second issue of generalizing the quantum Bayes rule, I shouldn't think it too hard. Will it not just correspond to taking the matrices V_d in Eq. (95) of my paper to be (nonsquare) isometries rather than full unitaries?

Finally let me address one thing that would be useful for my efforts to raise funds for meetings, postdoctoral positions, and, in particular, sell this direction in quantum foundations that you, Hardy, I, etc., are exploring. In the first note you wrote me you said:

Manalogue 2: *Thank you so much for your letter, and for the words of appreciation for my paper. It is just a little more than a draft, and so its form is far from being nice, and many are the missing references. I already knew "Quantum Mechanics as Quantum Information (and only a little more)"; indeed, your idea, expressed there, that time evolution could be a density operator, stimulated (via Rodriguez' "Unreal probabilities",* `physics/9808010`*) some of the research that led to my paper.*

If that is true, would you mind re-posting a version of your paper that makes some citation to my own. The issue is, I have to make a case here and there that these ideas of mine have some influence, even if it is you young guys out there doing all the nontrivial work. Having proper documentation at those times would definitely help.

How far is Stockholm from Aarhus? If you have the time, you might consider coming to the following conference: `http://www.maphysto.dk/events2/QPFA2003/`.

It'd be great to talk to you again on the short timescale. On the longer timescale, we'll have to look into when you, Schack, and I can all get together in Dublin.

07-07-03 *Bekenstein Bound Status, 2* (to W. G. Unruh)

Unruhism 1: *My take has not changed. It is possible that some such entropy to energy bound exists in the real world. It is certainly not necessary and I can imagine theoretical worlds in which it is not true (the simplest is that the entropy goes up as the number of species of say massless particles goes up, so one can always violate any bound by assuming a large enough supply of species). But it is also not needed for saving black hole thermodynamics, which was what he invented it for.*

That is an almost trivial argument, and I was aware of it — heard it from you long ago. If, however, one could argue that (by fiat) in the GR setting, the assumption of a ER/h value is the *assumption* of a QM Hilbert space of the same dimension, then one would have it. Not a logical necessity, but in essence a new postulate. Still, it would have to be motivated from some considerations: So I guess I was asking about something along the lines of your last sentence above. What is the best thing to read in that regard?

08-07-03 *Slogans, Slogans* (to G. L. Comer)

Comerism 5: *Thinking a little about your idea of black holes and the dimensionality of the Hilbert space, how does the dimensionality of the spacetime enter? Thinking classically for the moment, the degrees of freedom of a Schwarzschild black hole can (at least qualitatively) be understood using the* *quasinormal modes. I imagine that one must sum over more and more l, m etc mode numbers the higher the spacetime dimension gets. If we could 'quantize' those modes, would not the dimension of the Hilbert space change as the spacetime dimension changes?*

Oh, I don't know about any of these things; I hadn't thought about spacetime dimensionality at all.

Mostly it's just my habit of driving research with slogans—you don't know where you're going (or even where you want to go) unless you can make a slogan of it. As I was walking in, I was thinking I could have just as well compacted my last long note into the following little play. Basically I was thinking, wouldn't it be so nice if . . .

> Greg: How much Hilbert space do you think this tin can has?
> Chris: I don't know; let's weigh it.

Don't tell me about its construction, its composition, its history; just weigh it.

It's because I've been having outlandish thoughts like this, that I started wondering about this Bekenstein bound again. Maybe it's all crap. (Overwhelmingly likely it's all crap!)

Does Mr. Bekenstein's bound depend upon spacetime dimension? (I'll dig up some papers when you get here.)

By the way, when do you get here?

08-07-03 *The Common Fear?* (to R. W. Spekkens & N. D. Mermin)

The last three days as I've been walking to work, I've been reading a little book on the thoughts of Jürgen Habermas. I thought of both of you (or, actually, my perceptions of both of you) when I read the following lines. Let me record them.

> Every undergaduate with a unit of behavioural psychology in his or her academic record will have had some experience of the most vulgar example of what Habermas means. In this, as in every other field of postivistic science, we are asked to approach the object world as a disaggregated jumble of discrete objects of perception, as a jumble of 'its'. We are set the task of uncovering the regularities in the behaviour of these atoms of substance by means of an experimental method. The criterion of success lies in the predictive power of the uncovered 'laws' that must produce replicable results. This means results that are *independent* of the author, the inventor, in short of the *thinking subject* who in the first place conceived the problem, the method and the experiment and who thereby created the knowledge. One half of the underlying assumption is that knowledge is always reducible to the totality of discovered properties of the object world. The other half is that the *subject*—the actor, the creator, the knower, the inventor, the scientist—is at worst a pollutant in his own purely objective world, or at best, a ghost in the machine of science and something that must be methodologically controlled and, so far as is possible, eliminated.

09-07-03 *You and PI* (to D. R. Terno)

Things are nifty here and my family—especially my four year old—are quite acclimated already.

It's good to hear that you're liking it at PI. What sorts of things are you working on now? I hope the unhealthy hidden-variablist ideas floating around there aren't infecting you . . .

10-07-03 *The Anointed Snark* (to N. D. Mermin)

Mermintion 115:

> [CAF wrote:] Importantly though—just trying to keep you on the cutting edge—have you read the de Finetti paper "Probabilismo" in your preparation?

Raced through it, probably too quickly, on a very hard bench in the library, after spending 30 minutes hunting it down. Non circulating journal. Too long to Xerox. Has it been reprinted at anybody's web site? It didn't help me much the first time through. The stuff on correlations without correlata seems to be just a footnote.

What has the four page limit of Physical Review Letters done to our brains? Raced through it?! I tell you that it's the best explication/defense of subjective Bayesianism I have ever seen, and you raced through it? I send you evidence that Rüdiger thinks the same, and you raced through it?!? Rüdiger and I both write detailed letters to show how embracing some of the ideas in it may be just the analgesic your 1985 paper needs, and you raced through it?!?!

Tomorrow when I go in to the office, I will Xerox my copy for you and send it across the ocean. Please don't race through it. (But feel free to give honest, open criticism of anything that doesn't make sense in it. With that, we'll all certainly learn something.)

One question in the meantime concerning this:

Mermintion 116: *Glad it's helped you. Hasn't helped me much yet, but I'm still interested in keeping it up.*

Fair enough. But can you tell me this: Did I, in my note "Utter Rubbish and Internal Consistency, Part I" capture what you think is the essential mystery of the subjective view of the quantum state? If so, then I've at least got the right starting point, and I can try to refine what needs to be said.

PS. Yes, the stuff about correlations without correlata was only a footnote with no further mention. I was just trying to use everything at my disposal to lure you into the paper. One thing really of significance though: All those philosophers he mentions near that footnote represent the Italian school of (Jamesian) pragmatism. My love affair with James only deepens and deepens. Some mixture of James, de Finetti, Pauli, and modern quantum information are gonna ultimately rule the day on these issues.

10-07-03 *Solipsism* (to N. D. Mermin)

Mermintion 117: *Thanks, I'd enjoy having a copy.*

I think my problem is not with the subjective view of probability. Between what I've learned from you and Rüdiger, reading around in Jaynes, Cox's famous paper [which I came upon ten years ago — did I ever tell you that I independently derived and solved precisely his functional equation in my "Relativity Without Light" paper (in boojums)], the stuff I read in the Business Library (!) after first meeting Rüdiger, etc., it all makes a lot of sense.

My problem is, and remains, how it ties in with Quantum Mechanics, which appears (among other things) to tell you how to derive precise probabilities under (apparently) precisely defined — if idealized — circumstances. "Quantum Mechanics Is a Law of Thought" is certainly a good slogan for getting started, and your poetry is very soothing, but I can't help feeling there is still an enormous gap, despite nice things like your quantum de Finetti theorem. Declaring the circumstances also *to be subjective judgments appears to be a good (perhaps even necessary) move, but I don't find it convincing and (at best) it seems to lead into some kind of infinite regress in which everything becomes subjective and we're back to solipsism (which is irrefutable and therefore trivial). I haven't been able to articulate what I feel is missing well enough to send it on to you even under the Littlewood-Hardy rules, but I'm still thinking about it.*

Rule 1 definitely applies to the above paragraph.

A) What do you mean by solipsism? And, B) how does the "Paulian idea" I sent you still strike you as falling into that category?

11-07-03 *Wow!* (to J. A. Smolin)

John Smolinism 4: *I am writing up a paper on the lockboxes, and I need to figure out where to send it. I'd prefer a real journal, but perhaps the conference proceedings of Sweden are the best place. In a couple of days I'll send you the paper if you're interested.*

Wow! Excellent. I never imagined that you'd actually write this stuff up. I'll have a look at the actual draft next week. I'll try to give you detailed comments.

The latter part of your note strikes me as really interesting:

John Smolinism 5: *My plan is to actually write two papers. I want to put a paper on the basic idea out there soon, then perhaps later a paper including a discussion of Rob's toy model and some foundational problems. I also have some things I want to work out about Rob's model if he hasn't done it already by the time he write it up. In particular, his love of the so-called underlying ontic states is, I believe, what leads to the disallowing of some mixed states–The rule is that a measurement on one system cannot change the ontic state of another, but the right way to do it is to say that what you can't change is the marginal measurement outcomes of the remote system. This is definitely different under his model and I think leads to a prettier result.*

You know I'm all for nonontonicity when it comes to the "stuff" that quantum states are about.

11-07-03 *THE Paulian Idea* (to N. D. Mermin)

Merminition 118: *Which "Paulian idea"?*

The one for which there are some notes on:

> In the new pattern of thought we do not assume any longer the detached observer, occurring in the idealizations of this classical type of theory, but an observer who by his indeterminable effects creates a new situation, theoretically described as a new state of the observed system. In this way every observation is a singling out of a particular factual result, here and now, from the theoretical possibilities, thereby making obvious the discontinuous aspect of the physical phenomena.
>
> Nevertheless, there remains still in the new kind of theory an objective reality, inasmuch as these theories deny any possibility for the observer to influence the results of a measurement, once the experimental arrangement is chosen.

> Like an ultimate fact without any cause, the individual outcome of a measurement is, however, in general not comprehended by laws. This must necessarily be the case …

Or in more modern language (from 11/4/02):

> 1) The POVM as a function from raw data to meaning.
>
> We generally write a POVM as an indexed set of operators, E_d. Here is how I would denote the referents of those symbols. The index d should be taken to stand for the raw data that can enter our attention when a quantum measurement is performed. The whole object E_d should be construed as the "meaning" we propose to ascribe to that piece of data when/if it comes to our attention. It is important here to recognize the logical distinction between these two roles. The symbol d stands for something beyond our control, something that enters into us from the world outside our head. The ascription of a particular value d is not up to us, by definition. The *function* E_d, however, is of a completely different flavor. It is set by our history, by our education, by whatever incidental factors that have led us to believe whatever it is that we believe when we walk into the laboratory to elicit some data. That is to say, E_d has much the character of a subjective probability assignment. It is a judgment.

11-07-03 *More Solipsism* (to N. D. Mermin)

Still trying to get your worry straight. By your definition, could a solipsist make changes? (The note below makes sense of this question.) [See 21 July 2001 note, "The Reality of Wives," to A. J. Landahl and J. Preskill.]

11-07-03 *One Final Thing in the Wee Hours* (to N. D. Mermin)

Merminition 119: *Solipsism because when I try to look at things your way I find that whatever I try to condition my subjective probabilities on turns out also to be subjective and conditional on further subjective judgments, ad infinitum.*

Then, for you, does Bayesianism in general equal solipsism (independently of quantum mechanical issues)? For every Bayesian has that infinite regress: They ball it all up into something called "the prior" and ask not where it comes from. (As Savage said it very nicely in the passage Rüdiger recommended you read, the prior might simply be a product of Darwinian evolution.)

Good night! (It's after 3:00 AM for me now.)

11-07-03 *Friendship* (to N. D. Mermin)

Your absorbing this de Finetti paper is important for our discussions. Consider it a present from the slush fund Kiki allows me to dip into once a year (for the really important things). It will arrive at your office in Clark Hall sometime Monday. (FedEx tracking number 8410-8544-4295)

Solipsism indeed!

11-07-03 *One Project Done* (to G. L. Comer)

Well I got one project done that I had promised myself to do before your coming to Dublin (even if I finished no others): I finished reading my copy of *Becoming William James*. I just couldn't bear the thought that you might know something about William James that I didn't know! But let me apologize to you: I found that I hated the book, and I'm sorry I burdened you with it. The only thing that comes across in it is that WJ and the whole James family is troubled. One gets no feel for the utter greatness that was developing all along at the same time as these (overemphasized) other bits. And the guy was just too full of it with of his own psychological theories, rather than giving us a rounded glimpse of the lives involved. Anyway, you can see it's on the bottom of my list of James biographies now. I wish I had dug you up a copy of Perry's *The Thought and Character of William James* instead. It carries the message I had wanted you to get, where this other book utterly fails.

See you tomorrow.

13-07-03 *Thanks Again* (to M. Pérez-Suárez)

Thanks for the latest notes. I'll forward them to Joe Renes, who's taking care of the final draft. (The paper will appear in *Foundations of Physics*.)

Concerning the Paulian-Wheelerish compendium, I have finally gotten my computer set up with a scanner and top of the line OCR package (optical character recognition). It works like a charm!! So the compendium will be greatly expanding very soon. I'm hoping to get the final product on the web by Christmastime.

14-07-03 *Unitary Equivalence* (to A. Peres)

Asherism 35: *During the Växjö conference (June 2001) someone (Ben Schumacher?) gave a talk explaining that any dynamical system could be canonically mapped onto a harmonic oscillator and discussed the corresponding quantum property. My comment was that unitary equivalence is not equivalence from the point of view of physics (and I gave a reference to Fong and Sucher). That talk does not appear in the conference proceedings. Do you remember that talk and who gave it?*

It was definitely Ben. He uses that as an example to argue for the inconsistency of the many-worlds interpretation. He's never published the talk as a paper, much to my dismay (I've tried to get him to on a couple of occasions).

What is the Fong and Sucher paper?

Asher's Reply

Fong and Sucher, J. Math. Phys. **5** (1964) 456 — see my book, penultimate paragraph of page 227.

17-07-03 *Utrecht November Conference* (to J. B. M. Uffink)

For your meeting in November, let's try this:

Title: Quantum Information Does Not Exist

Abstract: It is information *carriers* that exist—conceptually both classical and quantum. To confuse the epistemic category (the information) with the ontic (the carriers) is to cause any amount of trouble. Nonetheless, one thing is true when it comes to applications of information theory to classical and quantum phenomena: There is a difference. And, in that difference—this talk will argue—lies quantum theory's most direct statement about properties of the world by itself (i.e., the world without the information processing agent).

The title of the talk is actually a phrase popularized by Ari Duwell; in the talk I will give him proper credit.

17-07-03 *Merminism* (to R. Schack)

Just got the note below from David Mermin. Is this man being a smart ass or what? Or is he being serious?

Merminition 120: *Thanks for sending me Probabilism. It does indeed require careful perusal. I shall bring it along to the sea shore next week.*

Meanwhile I note that near the beginning it offers what I would call a dictionary definition of solipsism. I'm also inclined to recommend it to my constructivist sociologist friends who I suspect would find its point of view highly congenial.

17-07-03 *Seven Pines VIII* (to J. Preskill)

Preskillism 8: *Is this a good thing to do?*

I don't know. Probably. In my own case, I'd be interested in talking to Earman, Howard, Milburn, Unruh, and Wald. So it could be worthwhile.

In particular, I'd like to have the chance to field some questions to the GR people ... as the universal characteristics of Hilbert-space dimension have been on my mind, and I find myself wondering to what extent there might be a (conceptual) analogy to gravitational mass and universal gravitation here. Far-fetched in my usual way ... but maybe not completely stupid.

I think it'd be great if you'd be there.

17-07-03 *Big, Big Favor?* (to R. W. Spekkens)

I wonder if you'd mind doing me a big, big favor? I'd like to get my hands on some pretty wacky articles, and I'm a little embarrassed to use the interlibrary loan services of CNRI to help me in the quest.

All the articles appear in a journal called *Journal of Analytical Psychology* and it looks like the library at Laurier (apparently associated with Waterloo) has the right volumes. Could I ask you to bring copies of the articles with you when you come to the Aarhus meeting. (Did the organizers, by the way, give you a talk slot or a poster session slot?)

Let me know if you can, and I won't pursue any other options I might dream up. I'll put the references I need below.

- V. Mansfield, "The Opposites in Quantum Physics and Jungian Psychology, Part II: Applications," J. Analyt. Psych. **36**, 289–306 (1991).

18-07-03 *Solipsism Concerns* (to N. D. Mermin)

Referring to

Merminition 121: *I think my problem is not with the subjective view of probability. Between what I've learned from you and Rüdiger, reading around in Jaynes, Cox's famous paper [which I came upon ten years ago — did I ever tell you that I independently derived and solved precisely his functional equation in my "Relativity Without Light" paper (in boojums)], the stuff I read in the Business Library (!) after first meeting Rüdiger, etc., it all makes a lot of sense.*

My problem is, and remains, how it ties in with Quantum Mechanics, which appears (among other things) to tell you how to derive precise probabilities under (apparently) precisely defined — if idealized — circumstances. "Quantum Mechanics Is a Law of Thought" is certainly a good slogan for getting started, and your poetry is very soothing, but I can't help feeling there is still an enormous gap, despite nice things like your quantum de Finetti theorem. Declaring the circumstances also to be subjective judgments appears to be a good (perhaps even necessary) move, but I don't find it convincing and (at best) it seems to lead into some kind of infinite regress in which everything becomes subjective and we're back to solipsism (which is irrefutable and therefore trivial). I haven't been able to articulate what I feel is missing well enough to send it on to you even under the Littlewood-Hardy rules, but I'm still thinking about it.

and

Merminition 122: *Solipsism because when I try to look at things your way I find that whatever I try to condition my subjective probabilities on turns out also to be subjective and conditional on further subjective judgments, ad infinitum.*

and

Merminition 123: *Thanks for sending me Probabilism. It does indeed require careful perusal. I shall bring it along to the sea shore next week.*

Meanwhile I note that near the beginning it offers what I would call a dictionary definition of solipsism. I'm also inclined to recommend it to my constructivist sociologist friends who I suspect would find its point of view highly congenial.

I guess I am seriously concerned by the charge of solipsism you have made of our program. It is a serious charge. (All one has to do is look into the daily news to see the dangers of it. See the Salon article pasted below about G. W. Bush's shenanigans for a particularly moving example.) Why is it that we fail to communicate on this point?

The world is not what I will it to be. And there is nothing in this view of quantum mechanics that our group is trying to construct that hints of this.

Solipsism would come about if from the quantum formalism one could prove

1. that there are no "instruction sets," and
2. that the outcomes of all interventions (measurements) could actually be controlled by the agent instigating the intervention.

But that is not the case. I was thinking harder about this last night as I was doing a little editing on my CG Fire Series, Vol. II. The frontispiece contains a quote from John Wheeler that I'll paste below because it emphasizes precisely the right point. The radical constructivism or solipsism that you fear is blocked for each and every quantum agent by his own stark admission that the outcomes of his interventions are beyond his control. If they are beyond his control, then there is no need to suppose that they are products of his mind. What more needs to be said?

Let me leave it at that for this round. Rüdiger is hoping to construct a note for you within the next three hours or so—hopefully before you leave for the seashore—making explicit reference to some of the dangers we are starting to perceive in the opening sections of Probabilismo … probably precisely the ones that are worrying you. So, stay tuned to your email before leaving for vacation! (You're our most valued customer.)

First the Wheeler quote:

> The Universe can't be Laplacean. It may be higgledy-piggledy. But have hope. Surely someday we will see the necessity of the quantum in its construction. Would you like a little story along this line?
>
> Of course! About what?
>
> About the game of twenty questions. You recall how it goes—one of the after-dinner party sent out of the living room, the others agreeing on a word, the one fated to be a questioner returning and starting his questions. "Is it a living object?" "No." "Is it here on earth?" "Yes." So the questions go from respondent to respondent around the room until at length the word emerges: victory if in twenty tries or less; otherwise, defeat.
>
> Then comes the moment when we are fourth to be sent from the room. We are locked out unbelievably long. On finally being readmitted, we find a smile on everyone's face, sign of a joke or a plot. We innocently start our questions. At first the answers come quickly. Then each question begins to take longer in the answering—strange, when the answer itself is only a simple "yes" or "no." At length, feeling hot on the trail, we ask, "Is the word 'cloud'?" "Yes," comes the reply, and everyone bursts out laughing. When we were out of the room, they explain, they had agreed not to agree in advance on any word at all. Each one around the circle could respond "yes" or "no" as he pleased to whatever question we put to him. But however he replied he had to have a word in mind compatible with his own reply—and with all the replies that went before. No wonder some of those decisions between "yes" and "no" proved so hard!
>
> And the point of your story?
>
> Compare the game in its two versions with physics in its two formulations, classical and quantum. First, we thought the word already existed "out there" as physics once thought that the position and momentum of the electron existed "out there," independent of any act of observation. Second, in actuality the information about the word was brought into being step by step through the questions we raised, as the information

about the electron is brought into being, step by step, by the experiments that the observer chooses to make. Third, if we had chosen to ask different questions we would have ended up with a different word—as the experimenter would have ended up with a different story for the doings of the electron if he had measured different quantities or the same quantities in a different order. Fourth, whatever power we had in bringing the particular word "cloud" into being was partial only. A major part of the selection—unknowing selection—lay in the "yes" or "no" replies of the colleagues around the room. Similarly, the experimenter has some substantial influence on what will happen to the electron by the choice of experiments he will do on it; but he knows there is much impredictability about what any given one of his measurements will disclose. Fifth, there was a "rule of the game" that required of every participator that his choice of yes or no should be compatible with *some* word. Similarly, there is a consistency about the observations made in physics. One person must be able to tell another in plain language what he finds and the second person must be able to verify the observation.

— *John Archibald Wheeler*
Frontiers of Time, 1979

And, now from Joe Conason's Journal in *Salon*: "President Bush's Astonishing New Reason for the War with Iraq: Saddam Wouldn't Let Weapons Inspectors In."

> July 15, 2003 — A "darn good" quote that almost nobody quoted "We gave him a chance to allow the inspectors in, and he wouldn't let them in."
>
> George W. Bush uttered that amazing sentence yesterday to justify the war in Iraq, according to the Washington Post.
>
> What? Yes, I promise that's what the man said. (And by "him," the president clearly meant Saddam Hussein – not Kim Jong Il, who actually has refused to let international inspectors into North Korea.)
>
> Now a presidential statement so frontally at variance with the universally acknowledged facts obviously presents a problem for the White House press corps. He wasn't joking, and he didn't sound disoriented or unwell. Although Dana Priest and Dana Milbank wrote the story as delicately as they possibly could, they couldn't make it seem less weird:
>
> "The president's assertion that the war began because Iraq did not admit inspectors appeared to contradict the events leading up to war this spring: Hussein had, in fact, admitted the inspectors and Bush had opposed extending their work because he did not believe them effective."
>
> Appeared to contradict the events leading up to war? Indeed, that's an exceedingly mild description of what Bush said. There's no plausible explanation, unless the president suddenly flashed back to his Yale sophomore philosophy seminar, grappling with the argument that everything we perceive is mere illusion.
>
> For the moment, however, let's just assume reality does exist. What possessed the president to make an assertion that everyone on the planet knows to be untrue? . . .

18-07-03 *Most In One Place* (to N. D. Mermin & R. Schack)

As I've told both of you, I'm starting to put together another samizdat—this one to contain the last year's discussions. Let me drop it off with you as it stands at the moment. Even though it's not complete you might find it a little useful. I think it already contains all of the emails from my side in the latest round of discussions … if that's useful.

Parts of it are certainly diatribic … and needlessly so. But on the other hand, there are some notes—the note of 10 January 2003, "Filth Under the Rug," comes to mind—that I think express a truly heartfelt frustration.

David is right: "'Quantum Mechanics Is a Law of Thought' is certainly a good slogan for getting started, and your poetry is very soothing, but I can't help feeling there is still an enormous gap, despite nice things like your quantum de Finetti theorem." There is so very much that needs to be done by way of technical work. But that should not stop anyone from seeing that we are moving absolutely in the right direction. Just precisely what is it that is blocking the vision?

19-07-03 *Definitions from Britannica* (to N. D. Mermin)

Merminition 124: *As far as I know solipsism is the claim that there is nothing more than my own sense impressions. It does not imply that I can control what those sense impressions are. They could be like a film I am doomed to keep watching — or an uncontrollable dream.*

I believe that's the correct use of the term, but if I'm wrong, give my "serious charge" another name. Perhaps this clarification makes it less serious? Hope not.

I looked up several definitions for the heck of it. The first set below comes from the 2001 *Encyclopedia Britannica*. Following that, I place my search results from several dictionaries for the word solipsism in particular. I guess the definition from *Wikipedia* best captures what I thought the word meant.

In any case, regardless of the labels, David's biggest worry seems to be this:

Merminition 125: *A) Solipsism because when I try to look at things your way I find that whatever I try to condition my subjective probabilities on turns out also to be subjective and conditional on further subjective judgments, ad infinitum.*

Let me try to tackle this one directly, now that maybe I understand your worries better and after having talked to Rüdiger yesterday. Take a good solid physicist like Steven Weinberg who stakes his career on the search for a grand unified field theory. Suppose he finds it. To find it (I presume) is to declare: The world's Lagrangian is L. Now suppose I were to ask Mr. Weinberg, "Why L? Why not M?" I know for sure his answer will be of the form, "L just is. It is the starting point. It is an ultimate fact of nature; it calls for no explanation. In any case, if it calls for an explanation, its answer must come from outside the realm of science—religion? theology?—but I see no reason to go to such lengths."

Would that make Weinberg a solipsist? A sensationalist? A phenomenalist? The point is Weinberg's stance has nothing to do with any of these labels.

Similarly for the Bayesian (even of the de Finettian variety, despite the mumbo jumbo in the opening sections of Probabilismo). For him, "the prior" on any event space is treated as an ultimate fact—an ultimate fact about the agent. There is no infinite regress because, just as with Weinberg, ultimate facts call for no further explanation.

Bayesian practice—and Rüdiger and I would claim the formal structure of quantum mechanics too—is all about what to do once a prior is established. It is not about what to do before the prior is established. In the quantum mechanical case, establishing "a prior" is 1) to write down a quantum state for all systems considered, and 2) to write down a (conditional) quantum operation for all measuring devices considered.

If there are two agents, there may well be two priors in the sense above —i.e., two ultimate facts (with respect to this level of inquiry). In that sense, the priors are "subjective", but that does not take away their status as ultimate facts in this treatment. It only calls for a recognition that the facts are about the agents.

The role of the separate system and measuring device—now specializing on quantum mechanics—is that when the two are combined they give "birth" to a new ultimate fact: The "click." There is no sense, however, in which this new ultimate fact is *about* either of the agents: It has a life of its own. (In fact, it is because of these lines of thought that I sometimes call my view "the sexual interpretation of quantum mechanics.")

Does this clarify anything? Does this in any way address your fears of solipsism/sensationalism/phenomenalism?

Definitions below.

> **Solipsism:**
>
> in philosophy, formerly, moral egoism (as used in the writings of Immanuel Kant), but now, in an epistemological sense, the extreme form of subjective idealism that denies that the human mind has any valid ground for believing in the existence of anything but itself. The British idealist F. H. Bradley, in *Appearance and Reality* (1897), characterized the solipsistic view as follows:
>
> "I cannot transcend experience, and experience is my experience. From this it follows that nothing beyond myself exists; for what is experience is its (the self's) states."
>
> Presented as a solution of the problem of explaining human knowledge of the external world, it is generally regarded as a reductio ad absurdum. The only scholar who seems to have been a coherent radical solipsist is Claude Brunet, a 17th-century French physician.
>
> **Subjective Idealism:**
>
> a philosophy based on the premise that nothing exists except minds and spirits and their perceptions or ideas. A person experiences material things, but their existence is not independent of the perceiving mind; material things are thus mere perceptions. The reality of the outside world is contingent on a knower. The 18th-century Anglo-Irish philosopher George Berkeley succinctly formulated his fundamental proposition thus: Esse est percipi ("To be is to be perceived"). In its more extreme forms, subjective idealism tends toward solipsism, which holds that I alone exist.
>
> **Sensationalism:**
>
> in epistemology and psychology, a form of Empiricism that limits experience as a source of knowledge to sensation or sense perceptions. Sensationalism is a consequence of the notion of the mind as a tabula rasa, or "clean slate." In ancient Greek philosophy, the Cyrenaics, proponents of a pleasure ethic, subscribed unreservedly to a sensationalist doctrine. The medieval Scholastics' maxim that "there is nothing in the mind but what was previously in the senses" must be understood with Aristotelian reservations that sense data are converted into concepts. The Empiricism of the 17th century, however—exemplified by Pierre Gassendi, a French neo-Epicurean, and by the Englishmen Thomas Hobbes and John Locke—put a greater emphasis on the role of the senses, in reaction against the followers of René Descartes who stressed the mind's faculty of reasoning. Locke's influence on 18th-century French philosophy produced the extreme sensationnisme (or, less often, sensualisme) of Étienne Bonnot de Condillac, who contended that "all our faculties come from the senses or more precisely, from

sensations"; that "our sensations are not the very qualities of objects [but] only modifications of our soul"; and that attention is only the sensation's occupancy of the mind, memory the retention of sensation, and comparison a twofold attention.

Phenomenalism:

a philosophical theory of perception and the external world. Its essential tenet is that propositions about material objects are reducible to propositions about actual and possible sensations, or sense data, or appearances. According to the phenomenalists, a material object is not a mysterious something "behind" the appearances that people experience in sensation. If it were, the material world would be unknowable; indeed, the term matter itself would be unintelligible unless it somehow could be defined by reference to sense experiences. In speaking about a material object, then, reference must be made to a very large group or system of many different possibilities of sensation. Whether actualized or not, these possibilities continue during a certain period of time. When the object is observed, some of these possibilities are actualized, though not all of them. So long as the material object is unobserved, none of them is actualized. In this way, the phenomenalist claims, an "empirical cash value" can be given to the concept of matter by analyzing it in terms of sensations.

Positivism:

in philosophy, generally, any system that confines itself to the data of experience and excludes a priori or metaphysical speculations. More narrowly, the term designates the thought of the French philosopher Auguste Comte (1798–1857). The basic affirmations of Positivism are (1) that all knowledge regarding matters of fact is based on the "positive" data of experience, and (2) that beyond the realm of fact is that of pure logic and pure mathematics, which were already recognized by the Scottish Empiricist and Skeptic David Hume as concerned with the "relations of ideas" and, in a later phase of Positivism, were classified as purely formal sciences. On the negative and critical side, the Positivists became noted for their repudiation of metaphysics; i.e., of speculation regarding the nature of reality that radically goes beyond any possible evidence that could either support or refute such "transcendent" knowledge claims. In its basic ideological posture, Positivism is thus worldly, secular, antitheological, and antimetaphysical. Strict adherence to the testimony of observation and experience is the all-important imperative of the Positivists. This imperative is reflected also in their contributions to ethics and moral philosophy, and most Positivists have been Utilitarians to the extent that something like "the greatest happiness for the greatest number of people" was their ethical maxim. It is notable, in this connection, that Auguste Comte was the founder of a short-lived religion, in which the object of worship was not the deity of the monotheistic faiths but humanity.

Further definitions of Solipsism:

- **Merriam-Webster Online Dictionary:** a theory holding that the self can know nothing but its own modifications and that the self is the only existent thing.
- **Cambridge International Dictionary:** the belief that only one's own experiences and existence can be known with certainty.
- **American Heritage Dictionary:** 1. The theory that the self is the only thing that can be known and verified. 2. The theory or view that the self is the only reality.

- **Encyclopedia Britannica, 1911 edition:** a philosophical term, applied to an extreme form of subjective idealism which denies that the human mind has any valid ground for believing in the existence of anything but itself. It may best be defined, perhaps, as the doctrine that all "existence is experience, and that there is only one experient. The Solipsist thinks that he is the one!" (Schiller). It is presented as a solution of the problem of explaining the nature of our knowledge of the external world. We cannot know things-in-themselves: they exist for us only in our cognition of them, through the medium of sense-given data. In. F. H. Bradley's words (Appearance and Reality):

  "I cannot transcend experience, and experience is my experience. From this it follows that nothing beyond myself exists; for what is experience is its (the self's) states."

- **Wikipedia:** Solipsism is a metaphysical belief that one is like a God, creating the reality in which one exists. Solipsism is logically coherent, but not falsifiable, so it cannot be established by current modes of the scientific method.

  The classic objection to solipsism is that people die. However, you have not died, and therefore you have not disproved it.

  A further objection is that life causes pain. Why would we create pain for ourselves? There may be some reason which we have decided to forget, such as the law of Karma, or a desire not to be bored.

  Solipsism is a common theme in eastern philosophy. Various interpretations of Buddhism, especially Zen, teach that the entire universe exists only in one's mind.

24-07-03 *Subjective and Objective, Precursor* (to A. Sudbery)

I promised to say something a little more scientific this afternoon, rather than administrative. But time slipped away, and I ended up doing some mathematics with Chris King at the chalkboard. Consequently, I didn't get Nagel's article finished, which I started on the train yesterday.

But let me build up to a discussion on it (and then after it, on your paper 'Why Am I Me?' in the coming weeks). Mostly, I just want to say that, so far, it's not looking so good for Mr. Nagel in my eyes: I'm finding that I'm not liking the paper as much as I was hoping to. Of course, I could have guessed that I would get tangled in a sparring match with it . . . but I didn't think I would get tangled in disagreement even with the motivation it sets out in the first couple of pages.

Let me try to show you why. Attached is an excerpt, relevant to the present subject, from my smaller samizdat "Quantum States: What the Hell Are They?" posted on my webpage. [See notes to Wiseman starting on pages 210 and 217 respectively.] I hope it shows why I would be resistant to an 'external view' at the very outset. I will certainly read Nagel thoroughly before this is all over with, but already on the very first pages it looks that we come from very different worlds.

More eventually . . .

25-07-03 *Agendas and Rubrics* (to R. W. Spekkens)

Spekkensism 19: *These observations led me to wonder whether it might be impossible to achieve a HVT with non-contextuality for the preparations for any dimensionality of Hilbert space. I believe I have now proven such a no-go theorem using nine states from a 2d Hilbert space. I'll try to write up the proof tonight.*

If it stands, I hope that this result may serve as another clue in the mystery, another aid in determining the nature of the conceptual innovation that needs to occur before one can devise a proper realist interpretation of quantum theory, if such an interpretation can be had.

What a novel idea! I like the technical part.

Question: What does it take to be a proper realist interpretation of quantum theory?

I never did finish that note on black holes to you; I'll paste the point I got up to in it below. The only point I wanted to make (but I wanted to do it in style!) was that, in my thinking about quantum mechanics, Hilbert-space dimension plays a conceptual role that is a bit like black-hole mass. I.e., Hilbert-space dimension is the ontic state of a quantum system.

Now, why wouldn't that fall under the rubric of "proper realist interpretation" in your eyes? I'm guessing that it won't. In particular, I'm guessing that it has something to do with the "Common Fear?" I wrote you and Mermin about a couple of weeks ago. But, I don't know, you tell me.

— — — — — — — — — — —

From just before the IBM meeting:

I spent a little while digging around in my email archive this morning and was finally able to pull out this piece from June 7, 1991. It was in a letter to Greg Comer.

> The other night I had a dream in which I was trying to calculate how many black holes would fit in my ice chest. I could already see one in there and I was trying to figure out how many more would fit. They're really beautiful, you know—contrasting against the white of the ice chest and the glistening of the ice. So, I pulled out another beer and watched for a while.

Consider a Schwarzschild black hole, to the exclusion of all else in the universe. What is the black hole's ontic state?

There is only one thing to pin it on: It is the black hole's mass, M. Do you balk at that? Does the starkness of the black hole's characterization specify a dearth or emptiness of phenomena associated with this lovely physical object? Not at all, once the black hole is embedded within the wider context of general relativity, the orbits of various test bodies, and so forth.

Especially in light of the immense physics that comes from such a single, simple number M when ... [Never finished.]

25-07-03 *Short Replies* (to G. L. Comer)

Comerism 6: *I like that word "interlocutor."*

I'm not so taken with it. It's probably because I'm not so taken with the "asking questions of nature and getting answers back" imagery any more. I'm more taken with the imagery of "push on nature and see how it reacts." We never ask of nature, we only push on it—or at least that's my take at the moment. (It's the reason I'm calling my CG Fire Series, Vol. II, project "The Activating Observer".) But like my philosophy, I can be malleable.

25-07-03 *No, Thank You!* (to J. Honner)

Thanks for the nice compliments/complements. Why did you leave academia? Not only did I enjoy your Bohr/Derrida article, but many years before that, I enjoyed your book on Bohr—reading it was one of my formative experiences in the field. I'd love to get hold of it again, as now in working on my "The Activating Observer: Resource Material for a Paulian/Wheelerish Conception of Nature" project (partially posted at my webpage) I'm going through many old things once again, but with my own fine-toothed comb. (Though, I guess I have to admit, I did make a bit of fun of your book and its genre in my paper `quant-ph/0104088`. You can see what I mean in endnote 5 and the text leading to it.)

By the way, if you think you might get something out of `Notes on a Paulian Idea`, I'll have a copy sent your way. Växjö University Press published 100 copies (in proper book form) for my use, and I've still got about 30 copies to give away.

Anyway, it was really great hearing from you, and you can bet I'll probably consult with you again when I'm in the stages of tidying up "The Activating Observer" project.

25-07-03 *Question* (to V. Kargin)

Karginism 1: *I am trying to find out who said: "Probability theory is measure theory with a soul". It appears that some attribute this quote to Mark Kac and some to Kolmogoroff. I noticed that you used a couple of times this quotation in your papers. Can you help me in locating the source?*

Indeed it was Mark Kac; I'm sorry if I caused any confusion in my writings. In my review of Holevo's book, I wrote:

> It is a probabilistic model that differs radically in character from the classical model first laid down by A. N. Kolmogorov in 1933 as "measure theory with a soul."

but the way that sentence should be parsed is the following:

> It is a probabilistic model that differs radically in character from [the classical model first laid down by A. N. Kolmogorov in 1933] as ["measure theory with a soul."]

I didn't mean to imply that the phrase should be attributed to Kolmogorov. Basically I was leaving the attribution of the phrase blank so as not to complicate the sentence too much. Maybe that was a mistake.

Anyway, here is the exact quote attributed to Mark Kac that I found in Holevo's book:

> "Probability theory is a measure theory – with a soul."

I wish I knew the exact source. Perhaps Alexander Holevo would know.

Slava's Reply

> Thank you for your reply. I didn't mean to imply that the phrase in your review is misleading. I have seen the attribution to Kolmogoroff somewhere else.
>
> I actually located the source of this quote. It is from a preface by Mark Kac to a book by Luis Santalo *Integral Geometry and Geometric Probability*. Here is how it goes:
>
> > Above all the book should remind all of us that Probability Theory is measure theory with a "soul", which in this case is provided not by Physics, or by games of chance, or by Economics but by the most ancient and noble of all mathematical disciplines, namely Geometry.

25-07-03 *Relative Onticity* (to R. Schack)

There are two points I like in your last note:

Schackcosm 71 : *What makes all this exciting for me is the fact that there appears to be a straightforward logical argument from your "Is the Moon There?" article to de Finetti's position. Particles don't carry instruction sets. Hence $|x\rangle$ is subjective.*

and

Schackcosm 72 : *I believe that you get an infinite regress only if you try to find the objective ground behind your probability assignments. This is futile. Your infinite regress argument is an argument FOR the subjective viewpoint. The latter is not solipsism, but simply the realization that our description in terms of maths is not the same thing as the external reality.*

Let's see what kind of impact they'll have on Mr. Mermin now.

I thought a little more about our phone conversation on my walk to work this morning—in particular, your point about, "Why not let Mr. Caves (under the appropriate conditions) act AS IF his Hamiltonians are real? What's to be lost by it?" I think the thing to be lost is our hard won category distinction between A) the probability function $P(x)$ and B) the values x of its argument. I.e., the beliefs and the facts. Even when the Bayesian gives an "as if" theorem, like with the de Finetti theorem, he never drops this category distinction. I.e., he does not confuse the data he is gathering (which with the assumption of exchangeability will allow him to asymptotically settle on a product probability distribution) with the updated belief.

At best, the "as if" theorems can give us something like the new semi-ontic category that Shimony seeks: the potentia. That is to say, there are "actualities" represented by the CLICKS, but then there are the "potentia" represented by the probabilities of which we can act AS IF they are objective.

I continue to think that it is of ultimate importance for this program to not let Mr. Caves go only halfway. Where we are heading, I think, is toward a wholly new kind of ontology—despite what looks to me like your present attraction to sensationalism. For that task, we just shouldn't stop halfway. I see us discovering and finding convincing explanation for the idea that the world is truly on the make. To stop with the "as ifs" that we can all agree upon (presumably after inculcation by the right physics community)—let us say they really are Hamiltonians—strikes me overpoweringly as an effort to once again introduce an overriding stasis to the universe. The real, unchanging ground of the universe is *the* Hamiltonian, full stop. And what is a Hamiltonian? In effect, it is the potentia, or even a propensity. (I.e., it is the generator of a conditional probability which has been given an objective status by fiat.)

Here's maybe another way of putting what I fear. If we stop with identifying the conditions under which one can act AS IF, then at best we will draw a new picture of existing quantum mechanics. We will give new names to old prejudices. It is simply not radical enough for my tastes; when we solve the old problem of quantum interpretations, we must get something new. At the very least a new world view, but I suspect something much more substantial and technical than that.

But, anyway, why am I any better off with my Hilbert-space dimension? Surely there is a sense in which it too is a subjective judgment. True enough. But then, why do I not see myself as falling into the same trap as Mr. Caves? I want to claim that in opposition to the Hamiltonian which is on the A) side of the category distinction above, Hilbert-space dimension should be more rightly thought of as on the B) side. Hilbert-space dimension should be thought of as taking the role of cardinality of the sample space in classical probability theory. And as you and I have already discussed, the setting of a sample space (classically) is certainly a subjective judgment. But nevertheless the elements within the sample space play the role of (potential) FACTS, not BELIEFS, after the setting is made. So, it is a relative onticity of a sort, but that is all I have ever been trying to capture with my "objective with respect to the theory" (or whatever phrase I used to use).

Enough. I'll say more when I can say more. Whereof one cannot speak, thereof one must be silent ...

28-07-03 *Popescu-Rohrlich Correlations, Gleason, Our Stuff* (to H. Barnum)

Barnumism 5: *Actually, maybe Chris and/or Joe's work, if I recall correctly, has to do with perverted Gleason's theorems in which nonorthogonal sets of vectors (with specific angle-sets) are identified with measurements having mutually exclusive outcomes.*

You're right, but that was mostly work with Nurit Baytch. Sadly, I never got off my duff to publish it, and now it's not particularly timely (at least in my own head). Also the CG Fire put an end to the records of the calculation I had, which involved a lot of nasty stuff about spherical harmonics.

I think the result was the following. Consider qutrits. Suppose for whatever weird reason you wanted to consider three-outcomed "measurements" whose outcomes are associated with vectors that are angles α, β, and γ (all fixed) away from each other. In the usual notion of von Neumann measurement $\alpha = \beta = \gamma = 90°$. Now, try to build a concept of frame function for this kind of measurement and try to prove a Gleason theorem. The upshot was that the *only* frame function existing in such cases were the uniform ones (i.e., flat functions), except in the particular case that $\alpha = \beta = \gamma = 90°$ in which one recovers the usual Gleason theorem. [The style of problem is captured in my big samizdat, `quant-ph/0105039`, pages 86 through 88.]

I guess I'm not as interested in the result as before. It came from a time when POVMs looked like particularly arbitrary structures to me. Now though that I think I understand the deeper connection between the structure of measurements and Bayes' rule, I guess I wouldn't be going down such lines.

28-07-03 *Tickles and Wiggles* (to H. Barnum)

By the way, in the evenings before bed, I've been finally reading Thomas Nagel ... since both you and Tony Sudbery have pushed me toward it. I hope to give you a report of my thoughts on it in the decently near future.

28-07-03 *Understanding Buridan* (to R. Schack)

Schackcosm 73: *I think this is usually quoted in discussions about free will versus determinism. I like it because it illustrates the absurdity of indeterminism.*

Does this mean that deep underneath it all you're a determinist who believes in instruction sets? This worries me a bit.

28-07-03 *New Twenty Questions* (to R. Schack)

Schackcosm 74: *Presently I am very much under the antirealist spell of de Finetti. The way I understand de Finetti, indeterminism is just as meaningless as determinism. But maybe I am taking the first three paragraphs of Probabilismo too seriously…*

The lines below are from my paper `quant-ph/0204146`. Part of them, even I am in disagreement with now. But the part that gives a definition of indeterminism, I am still OK with. Are you OK with that, or do you still contend that it is meaningless?

> In choosing one experiment over another, I choose one context over another. The experiment elicits the world to do something. To say that the world is indeterministic means simply that I cannot predict with certainty what it will do in response to my action. Instead, I say what I can in the form of a probability assignment. My probability assignment comes about from the information available to me (how the system reacted in other contexts, etc., etc.). Similarly for you, even though your information may not be the same as mine. The OBJECTIVE content of the probability assignment comes from the fact that *no one* can make *tighter* predictions for the outcomes of experiments than specified by the quantum mechanical laws. Or to say it still another way, it is the very existence of transformation *rules* from one context to another that expresses an objective content for the theory. Those rules apply to me as well as to you, even though our probability assignments *within* each context may be completely different (because they are subjective). But, if one of us follows the proper transformation rules—the quantum rules—for going to one context from another, while the other of us does not, then one of us will be able to take advantage of the other in a gambling match. The one of us that ignores the structure of the world will be bitten by it!

28-07-03 *New Twenty Questions, 2* (to R. Schack)

Different question, but again referring to this:

Schackcosm 75: *Presently I am very much under the antirealist spell of de Finetti. The way I understand de Finetti, indeterminism is just as meaningless as determinism. But maybe I am taking the first three paragraphs of Probabilismo too seriously…*

What do you say about Mermin's anti-instruction-set derivation? Is that now contentless (at worst) or superfluous (at best) from this anti-realist view?

28-07-03 *Your Newest Turn* (to R. Schack)

I did truly get into quite a bit of trouble tonight, not getting home until 7:30. In general it's just been a very bad day for me.

Let me give you an example of something I don't think you can allow yourself to say in your newest turn.

When I wrote my ill-fated note "Got It!," I wrote in Section 4 of it:

> 4) POVMs and radical pluralism.
>
> Now let me go into a bit of the metaphysics of this. Here's a point of view that I'm finding myself more and more attracted to lately.

I think it is safe to say that the following idea is pretty commonplace in quantum mechanical practice. Suppose I measure a single POVM twice—maybe on the same system or two different systems, I don't care—and just happen to get the same outcome in both cases. Namely, a single operator E_d. The common idea, and one I've held onto for years, is that there is an objective sense in which those two events are identical copies of each other. They are like identical atoms ... or something like the spacetime equivalent of atoms. But now I think we have no warrant to think that. Rather, I would say the two outcomes are identical only because we have (subjectively) chosen to ignore almost all of their structure.

That is to say, I now count myself not so far from the opinion of Ulfbeck and Bohr, when they write:

> The click ... is seen to be an event entirely beyond law. ... [I]t is a unique event that never repeats ... The uniqueness of the click, as an integral part of genuine fortuitousness, refers to the click in its entirety .... [T]he very occurrence of laws governing the clicks is contingent on a lowered resolution.

For though I have made a logical distinction between the role of the d's and the E_d's above, one should not forget the very theory-ladenness of the set of possible d's. What I think is going on here is that it takes (a lot of) theory to get us to even recognize the raw data, much less ascribe it some meaning. In Marcus Appleby's terms, all that stuff resides in the "primitive theory" (or perhaps some extension of it), which is a level well below quantum mechanics. What quantum mechanics is about is a little froth on the top of a much deeper sea. Once that deeper sea is set, then it makes sense to make a distinction between the inside and the outside of the agent—i.e., the subjective and the objective—as we did above. For even in this froth on the top of a deeper sea, we still find things we cannot control once our basic beliefs—i.e., our theory—are set.

Without the potential d's we could not even speak of the possibility of experiment. Yet like the cardinality of the set of colors in the rainbow—Newton said seven, Aristotle said three or four—a subjective judgment had to be made (within the wide community) before we could get to that level. If this is so, then it should not strike us as so strange that the raw data d in our quantum mechanical experience will ultimately be ascribed with a meaning E_d that is subjectively given. (I expressed some of this a little better in a note I wrote to David last month; I'll place it below as a supplement.) More particularly, with respect to the EPR example above, it should not strike us as odd that the phenomenon comes about solely because of an interpretive convention we set: All quantum measurement outcomes are unique and incomparable at the ontic level. At least that's the idea I'm toying with.

to which you replied at the time:

Schackcosm 76 : *Section 4), I like. It highlights the chasm that exists between our approach and the many-worlders and decoherence people. We all agree that a click is not an elementary phenomenon. They want to reduce it to something more fundamental. We say it's irreducible (which does not mean that we cannot analyze a measurement apparatus or decoherence of a quantum register in as much depth and detail as anybody else). Your metaphysical bit is nice in that it makes clear that "irreducible" is not the same thing as "elementary". As you say it,*

> *All quantum measurement outcomes are unique and incomparable at the ontic level.*

In your newest turn, such discussion would be "meaningless"—correct? You would no longer allow yourself to contemplate what the CLICK d might be in its own essence. You would no longer say that "successive clicks with a single value d are truly the same," nor would you contemplate that "successive clicks with a single value d may actually be truly different."

That is to say, in this new philosophy you are toying with, if something (i.e., an event, a fact, etc.) is not a "hook" upon which a probability can be conditioned, you are not willing to speak of it. It is meaningless—I believe you say. You don't even let yourself conjecture about the stuff that is out there independently of us. (Or at least I don't see how you're going to be able to do this with such a strongly positivistic line.)

As I tried to express today, and as I'm trying harder to articulate now, I guess I don't like that.

Pragmatists are not positivists, but more opportunists. James allowed personal religions to be parts of reality, and I guess I'm inclined to that.

The part of de Finetti's introductory section that I do like is his organicist take on scientific theories. I'm inclined to view the PRESENT scientific theory of any type as part of the specification of our species. Such theories are part of the account of our being at the moment; they express our possibilities and our limitations. By this account, for instance, Hamilton and Lagrange belonged to ever slightly different species than you and me. Silly, huh? I don't think so: For what's important about this is that one sees by it that a theory (and the entities within it) are every bit as real or unreal as biological species. Whatever they are, they have a temporary hold on our description of things that cannot be denied. Are they all and only AS IF statements?

I guess I don't think so. In other words, I guess I'm saying that I think you're going too far with your ASIFism. As far as I can see, all a representation theorem (say of the de Finetti type) can give us is the conditions under which we can act AS IF our impredictability is coming from a true but unknown PROPENSITY. In particular, what the AS IF theorems do not give are the sample spaces. They are always set before these representation theorems can be posed at all. And, in that way, I say sample spaces obtain a status—though subjective in the character of how they are set—that is somehow different from what a representation theorem can give.

My goal continues to be ultimately realist in tone. All I have ever wanted to do in these last couple of years is strip away the objective character of all probability statements and any part of quantum mechanics that smells of being a probability statement in disguise. I have never imagined (nor do I think we have any warrant from anything technical within probability theory) that the whole structure of QM will go up in smoke in the process.

By the way—on a slightly different subject—let me readdress one of the points in your Buridan's Ass note again:

Schackcosm 77: *Well, Buridan's ass stands in front of two buckets of hay, neither of which looks to him any better than the other. Hence the poor ass remains standing there and eventually dies. I think this is usually quoted in discussions about free will versus determinism. I like it because it illustrates the absurdity of indeterminism. The state* $|R\rangle + |L\rangle$ *is symmetric with respect to left and right. If nature really IS in a symmetric state with respect to left and right, then what breaks the symmetry? If it is our state of belief, however, that is symmetric, there is no problem. The ass chooses one or the other, it's me who has no clue which one it will be. Either one or the other detector goes click, it's me who has no clue which one it will be.*

I would say the very lesson of Bell and Kochen-Specker is that we cannot (or rather should not) act AS IF nature is not at a juncture in the quantum measurement setting. "Unperformed Measurements Have No Outcomes."

29-07-03 *Wiggles and Bait* (to H. Barnum)

More about Nagel coming soon. Sudbery has prodded me further out of my slumber (yesterday) ... and I can feel those natural defense mechanisms kicking in! The email was starting to form in my head as I was walking in to the office today!

29-07-03 *Please Do* (to J. Honner)

Honnerific 1: *In 1995-7 I started writing what I thought was a half interesting book* [Bohr, Einstein, Bell, and the Feminist Critique of Physics] *... on physics and the unconscious basically ... but after three rejections of the core article I pulled my head in and changed my life. If you can bear reading the feminist critique of physics and a fairly devastating set of reflections on Einstein, I'd be happy to dig out a file and send it to you.*

Yes, please do send it! Chances are I won't read it immediately, but it'll be in the queue then (and it may get a citation in the "Activating Observer" compendium). When I do get to it, chances are I'll give you some feedback.

Also, by the way, if you could give me a complete list of all your quantum publications that would be most helpful.

30-07-03 *Title* (to C. King)

"Two Characterizations of Complete Positivity that Evoke No Imagery from the Everett Interpretation of Quantum Mechanics"

30-07-03 *Convictions, Courage, Clear Thinking* (to R. Schack)

Your note was so chock-full, I had quite a sleepless night. How I wish I had time to reply to you right now in great detail—it is something I need internally, there is no better therapy for me than composing a note—but it is going to have to wait most likely until I am in Germany.

I think you were right on most (or at least many) counts. In particular, I think this discussion represents a lack of courage on my part, along with a small lack of clear thinking: The former likely caused the latter. Funny how many times I have accused Carl (and sometimes you) for not having the courage of your convictions. Stones and glass houses.

Also there is a slight problem of emphasis and particular choices of words that might be getting in our way—i.e., that may be one of the things that helped shunt us from complete and immediate agreement. These things need fleshing out.

Mostly I want to say for the moment that your note inspired me, and I think (maybe unseen to you) it gives me a way to have my cake and eat it too.

I will be back with a vengeance in a few days (for hopefully an adequate mix of email and verbal communication) ...

In the meantime, though, would you think about the tension in these three statements of yours:

Schackcosm 78: *Well, Buridan's ass stands in front of two buckets of hay, neither of which looks to him any better than the other. Hence the poor ass remains standing there and eventually dies. I think this is usually quoted in discussions about free will versus determinism. I like it because it illustrates the absurdity of indeterminism. The state* $|R\rangle + |L\rangle$ *is symmetric with respect to left and* *right. If nature really IS in a symmetric state with respect to left and right, then what breaks the symmetry? If it is our state of belief, however, that is symmetric, there is no problem. The ass chooses one or the other, it's me who has no clue which one it will be. Either one or the other detector goes click, it's me who has no clue which one it will be.*

and

Schackcosm 79: *NOOOOOOO! You are joking, aren't you? The direct lesson of Bell and Kochen-Specker is indeed that we should not act AS IF unperformed measurement had outcomes. To conclude that nature is at a juncture is adding a lot of baggage, however. I am sure de Finetti would be rotating in his grave if he read this!*

and

Schackcosm 80: *What de Finetti's anti-realism attacks is the prejudice that to the terms of our description literally corresponds some real stuff out there in nature. Isn't it ridiculous, he asks, to conclude that nature is in the situation of Buridan's ass, only because we aren't certain about what will happen next? Does that mean de Finetti believes in instruction sets? I think this would do him injustice.*

I'm with you on the middle one at the moment. But the three together sure look like a tense mix to me. What actually would do de Finetti justice on this issue? It is not clear to me at all.

There's a lovely passage in an 1872 diary entry of William James: I wish I had it here to get the exact wording. It was something of the order, "my first act of free will shall be to believe in free will ... I will give it a shot for one year and see where that gets me."

01-08-03 *Mortified, Yes* (to N. D. Mermin)

Merminition 126: *SHPMP Sept 2003 just arrived.*

Well I knew you hated Copenhagen Computation*, but making it the one article in the collection that you don't say a word about in the Introduction seems a bit much, particularly since your theme is the vindication of Bohr over Einstein. Putting it last underlines the omission. It will be clear to readers that I foisted it on you. (As I remember I didn't want to send in anything, but you kept insisting...)*

I love you anyway. Actually I assume it was an accident — Freudian, of course — and trust that you are properly mortified.

I very, very, very much apologize. I feel like utter crap. How I could let that happen I do not know. Jeff wrote the first draft, and I jiggled some things in it, but that I did not notice the omission is inexcusable.

All I can say now is that I apologize, and I've got to find a way to make it up to you in some other aspect of life.

It is not true that I did not like your paper. I liked it a lot, and I especially liked your presentation at the Bennettfest. It seems to me that you get to the essential point when you point out the non-problematicity of the ultimate readoff: it is no more or less mysterious than reading off of a piece of information from a computer screen. Either they are both deep problems, or neither of them are. Showing that that is the best way to teach quantum computing to CS people makes a deep statement ... and you're in tune with it.

Please do forgive me. It wasn't intentional, and it wasn't even Freudian.

01-08-03 *Done* (to A. Peres)

Thanks! What will you speak on in Aarhus? Do you know if Petra has prepared a poster for the poster session? I would recommend to you, by the way, Rob Spekkens' talk. I think it is particularly deep, and the work has not been posted on `quant-ph` yet. Here is what I wrote to the organizers in my efforts to get him a speaking slot (at a late date): [See 01-07-03 note "Rob Spekkens" to R. D. Gill, K. Mølmer, and E. S. Polzik.]

01-08-03 *Spekkens and Letter* (to A. Peres)

Asherism 36 : *I believe I saw something like you told me about Spekkens in* `quant-ph`*, or in* Found. Phys. Lett.*, or elsewhere. I can't remember. I regret I have no patience for these games.*

But you should. The whole point of Spekkens' toy model is to bolster our point that a quantum state is a state of knowledge. The tactic is to show the extreme similarities between quantum mechanics and Liouvillian mechanics—a point I first learned from you. The thing that is new in Spekkens' game is that he not only uses Liouville mechanics, but he adds a further restriction that the distributions cannot be too peaked. With that he gets a theory that looks ever so much more (but not completely) like quantum mechanics.

The point to be made for people like Gisin and Jozsa who don't find quantum mechanics as palatable as they should: Quantum mechanics is not so very weird and different from plain old Liouville mechanics. That community should quit beating their heads trying to find nonlinear evolution equations and such.

I doubt you saw something like this (or at least of the prettiness of Spekkens' result) in *Found. Phys. Lett.*

Give it a chance. It is really very good and very creative work.

12-08-03 *Me, Me, Me* (to N. D. Mermin & R. Schack)

Me, me, me; it's always about me! —Yes. But nonetheless it is simply not solipsism. Let me explain.

I guess I was actually fortunate today: For the second time in a month, I was called a solipsist by one of my friends. (This time the accuser was Howard Wiseman.) On top of that, Asher Peres gave a talk this morning that made me cringe, saying things like, "When no one performs a measurement, nothing happens [in the world]." The combination of these two bad experiences caused me to wander the streets of Aarhus this afternoon in spite of the horrible heat. I suppose I needed to find a way to sweat the poisons from my body.

The fortune in this is that it caused me once again to strive for a clearer and more consistent form of expression. I want to try to capture some of that in this note. Mostly it is about not allowing oneself to get hung up in someone else's (inconsistent) expectations for what quantum theory ought to be.

In our 2000 opinion piece in Physics Today, Asher and I wrote:

> The thread common to all the nonstandard "interpretations" is the desire to create a new theory with features that correspond to some reality independent of our potential experiments. But, trying to fulfill a classical worldview by encumbering quantum mechanics with hidden variables, multiple worlds, consistency rules, or spontaneous collapse, without any improvement in its predictive power, only gives the illusion of

> a better understanding. Contrary to those desires, quantum theory does *not* describe physical reality. What it does is provide an algorithm for computing *probabilities* for the macroscopic events ("detector clicks") that are the consequences of our experimental interventions. This strict definition of the scope of quantum theory is the only interpretation ever needed, whether by experimenters or theorists.

But that is misleading and trouble-making. In the second to last sentence—with the experience of three more years of thinking on this subject—I so wish we had said something more to the tune:

> What quantum theory does is provide a framework for structuring MY expectations for the consequences of MY interventions upon the external world.

At least that is what the formal structure is about. There is no "we," there is no "our." At this level of consideration, quantum theory has nothing to do with intersubjective agreement. (By the way, I'm not fooling myself: Of course we could not have said what I said above without restructuring the whole article—it would have opened a can of worms! I just want to try to do the idea better justice right now.)

Here it is: Any single application of quantum THEORY is about ME, only me. It is about MY interventions, MY expectations for their consequences, and MY reevaluations of MY old expectations in the light of those consequences. It is noncommittal beyond that. This is not solipsism; it is simply a statement of the subject matter.

Is there any contradiction in this? I say no, but how do I get you into a mindset so that you might say the same? Maybe the best way to do this is to run through a glossary of quantum terms as I did once before ... but now with all the latest slant.

- SYSTEM: In talking about quantum measurement, I divide the world into two parts—the part that is subject to (or an extension of) my will, and the part that is beyond my control (at least in some aspects). The idea of a "system" pertains to a part beyond my control. It counts as the source of my surprises, and in that sense obtains an existence of its own external to me. (Point 1 against solipsism, but I will return for another.)

- POVM: In the theory, this counts as an extension of my will. It counts as a freely chosen action on my part. The whole concept of a "measuring device" as something distinct from me—I am now thinking—just gets in the way. It is a point that Pauli made, but I am coming ever more to appreciate it. A "measuring device" is like a prosthetic hand; its conceptual role is for the purpose of recovering from our natural incapacities and, thus, might as well be thought of as part of ourselves proper. I perform a POVM on a system—captured mathematically by a set—and one of its elements comes about as a consequence.

- QUANTUM STATE: As usual, the catalog of MY expectations for the consequences of MY actions (i.e., POVMs) ... but now with absolute, utter emphasis on the MY.

- UNITARY READJUSTMENT: I'm talking here about the readjustment appearing in Eq. (95) of my paper `quant-ph/0205039`. This, like a quantum state, also captures a belief or expectation. Its purpose is to quantify the extent to which I feel the need to deviate from Bayes' rule after learning the consequence of my action. This is what takes account of the nonpassive nature of MY interventions.

- QUANTUM DYNAMICS: This is the unitary readjustment (or mixture of decompositions and unitary readjustments) that I judge I ought to apply if my action on the system is passive, i.e., if my POVM is the singleton set. It is how I readjust my expectations when I am learning nothing.

Summing up the glossary, I would say quantum theory in its single user implementation is about ME. I act on the world and it reacts in a way unpredictable to me beyond the expectations I build from MY quantum state (about the system).

Why is this not solipsism? Because quantum theory is not a theory of everything. It is not a statement of all that is and all that happens; it is not a mirror image of nature. It is about me and the little part I play in the world, as gambled upon from my perspective. But just as I can use quantum theory for my purposes, you can use it for yours. Thus, if I had not been seeking dramatic effect above, I should have more properly said, "Any single application of quantum THEORY is about the ME who applies it." (Don't correct my English.) When David Mermin is a practitioner of quantum theory, what the theory does is provide a framework for structuring HIS expectations for the consequences of HIS interventions upon HIS external world. ... And that is Point 2 against solipsism.

Recall the definition of solipsism I dredged up from the Encyclopedia Britannica:

> in philosophy ... the extreme form of subjective idealism that denies that the human mind has any valid ground for believing in the existence of anything but itself.

It seems to me we have plenty of valid ground for believing in the existence of something besides ourselves: It comes from all the things we cannot control. Indeed, as already emphasized, for those things we can control, we might as well think of them as extensions of ourselves. Thus, to my mind, quantum theory already gives a karate chop to solipsism because of the indeterminism it entails: With each quantum measurement there is immediately something beyond my control.

Beyond Point 1, though, there is Point 2. It is a question of finally getting straight what should and should not be in the purview of the theory. In this account, quantum theory is a theory of personal action (and reaction). The law-of-thought aspect of it comes out with respect to each individual who uses it. The textbook poses an exercise that starts out, "Suppose a hydrogen atom is in its ground state. Calculate the expectation of ... blah, blah, blah." One might think it is asking us to calculate some objective feature of the world. It is not. It is only asking us to carry out the logical consequences of a supposed state of belief and a supposed action that one could take upon the system. And here's the clincher about Bayesianism. Just as no student in his right mind would find it worthy to ask why the textbook writer posed the problem with the ground state rather than the first excited state, no quantum theorist should make a big to-do about it either. It is simply an assumed starting point. An agent in the thick middle of a quantum application can no more ask where he got his initial beliefs from, than a pendulum can ask where it got its initial conditions from. The cause of bottom-level initial conditions is ALWAYS left unanalyzed. If such was not a sin in Newtonian mechanics, it should not be a sin in a Bayesian formulation of quantum mechanics.

So, it seems to me, if anything, the Bayesian account of quantum theory is essentially the opposite of solipsism. Rather than a unity to nature, it suggests a plurality. An image that might be useful (but certainly flawed) comes from Escher's various paintings of impossible objects. The viewer would initially like to think of them as two-D projections of a three dimensional object; but he cannot. Now imagine how much worse it would get if we were to have two viewers with two slightly different paintings, each purporting to be a different perspective on "the" impossible object. Since neither viewer can lift from his own two-D object to a three-D one, there is no way to unify the pictures into a single whole.

Yet we live in one world, you say. Maybe. But, you should remember that these quantum states we speak of are not perspectives. They are personal possessions. To paraphrase Tilgher's quote at the beginning of de Finetti's Probabilismo,

> A quantum state is not a mirror in which a reality external to us is faithfully reflected; it is simply a biological function, a means of orientation in life, of preserving and enriching it, of enabling and facilitating action, of taking account of reality and dominating it.

"Are there other minds beside your own?," Howard Wiseman asks. If a mind is what it takes to write down a quantum state, then why not? "If you leave the origin of the quantum state unanalyzed, why would two minds ever agree on anything?" That is the issue of intersubjective agreement—something thankfully we can study within the context of quantum theory. But the first thing to get straight is why the single user of quantum theory uses the very structure. What is it precisely that he is believing of the world and his place in it that leads him to the choice of quantum theory as his law of thought?

That is, it is about ME and what I believe. But what do I believe? That's the research program!

13-08-03 *The Tense Mix* (to R. Schack)

Now that I'm back in Munich, I've tried to become re-engaged with the conversation we left on, but I'm having difficulty. I've read your 30/7/03 note "levels" three times over since yesterday, and I'm not sure what I can add at the moment. Clearly I've absorbed some of it into my mentality. In particular, I like the scolding you gave me:

Schackcosm 81: *NOOOOOOO! You are joking, aren't you? The direct lesson of Bell and Kochen-Specker is indeed that we should not act AS IF unperformed measurement had outcomes. To conclude that nature is at a juncture is adding a lot of baggage, however. I am sure de Finetti would be rotating in his grave if he read this!*

You are right; the best I can say is that the lesson of quantum mechanics is that we should not act AS IF unperformed measurements had outcomes. And that is good enough for me. Like with William James, I will act as if nature is undetermined and see where that leads me. I can't do more than that. (In fact, I have said it many times that one may never be able to disprove either many-worlds or Bohmian mechanics. I only bank that those trains of thought will not lead in any productive directions. I suppose I suspended such carefulness as my passions started to flare in our discussion.)

But as you might guess from the paragraph I just wrote, I still see something of an uncomfortable tension in what you've written. For instance, I don't even understand your very next sentences:

Schackcosm 82: *I think de Finetti was both anti-realist and anti-indeterminist. The Buridan's ass passage illustrates this beautifully. Your position is clearly not anti-indeterminist. Be careful who you recommend Probabilismo to!*

Also I guess I don't like this emphasis of yours on the MEANINGLESSNESS of various statements. It doesn't ring true to me, especially with the determinist/indeterminist issue. It strikes me as perfectly useful to take a stance on the issue (of course in the AS IF sense that you have emphasized); and in that way it is not meaningless. That, I think, is why I brought up religions in an earlier note; religions are never verifiable or falsifiable, but faith in them is not meaningless.

It seems to me clear—and I don't think your note has changed this—that when we practice quantum mechanics, we are implicitly stating some beliefs about the world (as it is independently of the agent). You are right that we cannot move from that step to saying that that is actually the way the world is. Nonetheless we are expressing *beliefs* about the world without our presence. The issue is to make those beliefs explicit—and that is your program of AS IF. I am OK with that. To put so much emphasize on the meaningless of this or that, though, repels me slightly. That may be what caused me to swing the pendulum too far in the opposite direction.

I'm really looking forward to your visit to Munich. I hope we can find a way to get together. Aarhus was a useful meeting: Klaus Mølmer, Richard Gill, Ray Streater, Vladimir Bužek, Mauro D'Ariano, Hideo Mabuchi, and Howard Wiseman showed a some decent interest in the program. But I must say, the divergences between us and our desires and Rob Spekkens are becoming clearer . . . and more disappointing. I see him as having the potential to cause real damage. It really would be useful to have a more thoughtful critique of his "classical interpretation of probability over a fundamental event space" position. Bernardo and Smith's dismissal is simply too curt.

Somehow over the course of this meeting, I've decided the time is right to try to put together a paper explicitly and solely on the Penrose argument. The little title I've toyed with in my head has been "On Quantum Certainty." What would you think? Might we throw in on it together? (I guess I was partially induced to this by Spekkens' assertion that we still have no adequate reply to Penrose without the picture he is trying to construct . . . based on ignorance of an ontic state.) Anyway, I started thinking that that might be riper and more ready to go than a critique of the Horodeckis. Also it strikes me as paving the ground for all the other discussions, and worthy of its own thorough treatment.

This is the first of a couple of notes I'll be writing you today. Another one will be coming down the tubes in an hour or so.

13-08-03 *Renouvier* (to R. Schack)

I'm back a little faster than I thought I would be. In this note, I just want to send you a passage that I scanned into my computer from a book on Charles Renouvier—the philosopher who convinced William James to try out free will. There is something about the argument in the last two paragraphs of page 2 that takes me—but I want to see it made more rigorous, or stated better. Also I hope you are as impressed by Footnote 56 as I was. If those passages are not too far out of context, they may show that he is going down the same lines as de Finetti and us.

I'd love to get my hands on anything more technical to do with Renouvier, but apparently there is almost nothing written on him in the English language. The only article I have been able to unearth that might possibly be in some library in your university is: S. Hodgson, "M. Renouvier's Philosophy," Mind **6**, 31–61, 173–211 (1881). If you have time, could you check on that before Munich?

From: William Logue, *Charles Renouvier, Philosopher of Liberty*,
(Louisiana State University Press, Baton Rouge, 1993), pp. 86–92.

> Under the influences of discussions with his friend Jules Lequier, he [Renouvier] became convinced of the reality of human free will and its central importance for the understanding of everything else.[45] This conviction came to Renouvier while he was still deeply under the influence of his first contact with the Saint-Simonians. He experienced, not an overnight liberation from their deterministic viewpoint, but a more gradual readjustment of his views, which became a complete detachment from them only after 1851. Perhaps the failure of the socialist movements in 1848, rooted as they were in the

[45] Renouvier's account of his "conversion" to free will is in the last part of Vol. II of the *Esquisse*. Lionel Dauriac ("Les Moments de la philosophie de Charles Renouvier," *Bulletin de la société francaise de philosophie*, IV [1904], 23) defined the high point of Lequier's influence—the writing of the *Deuxième essai*—as one of four "moments" in Renouvier's philosophical development.

would-be scientific philosophies of the preceding three decades, finally persuaded him of the dangers of rejecting free will.[46] Alienated from political life during the Second Empire, he would spend nearly two decades in the construction and elaboration of his philosophy of liberty, establishing its foundations and exploring its consequences.

Renouvier was aware that for a long time the question had been of mainly religious significance: whether man's salvation depended on free will or on predestination.[47] This debate had reached its peak, in both vehemence and subtlety, in the famous exchange between Erasmus and Luther in the sixteenth century. The emergence of a secular debate over free will was a result of the rise of the scientific worldview in the seventeenth century. The ascendancy of the idea that the world was governed by invariable laws, taking the role previously occupied by an all-powerful, all-knowing God, seemed to leave less and less room for the view that man was somehow an exception to the general rule. The most heroic task for the modern philosopher was to find a means of validating science and free will simultaneously, and the most heroic effort of the eighteenth century was that of Immanuel Kant. But for many in the next century, it seemed that Kant had saved free will only at the cost of making it irrelevant.[48] Fichte tried to rescue Kantian philosophy from this unhappy outcome, but in the general opinion (only recently challenged by Alexis Philonenko, Luc Ferry, and Alain Renaut) his effort led to the fairyland of absolute idealism, denying reality to the material world.[49]

Against the rising tide of determinism, Renouvier would try to show that Kant could be the launching pad for a defense of free will that would maintain its practical relevance and demonstrate its compatibility with natural science, properly understood. He did not claim to be presenting any new arguments in favor of free will; he felt they were in any case unnecessary.[50] Renouvier's reasons for coming to the defense of free will were partly shared with Kant and partly his own. As we have seen in the previous chapter, the shared part was the most familiar: a concern for the connection between free will and moral behavior. Free will was for Kant the essential basis of *practical reason*; without it, the whole idea of moral obligation ceased to have meaning. For Renouvier, this consideration remained central. Without moral responsibility, man would not be distinct from the rest of the animal kingdom, and the whole of civilization would be meaningless. But this was not the sole basis for his concern with free will, and this additional concern moved Renouvier beyond Kant and Fichte, bringing him closer to our own time.[51]

[46]Mouy (*Idée de progrès*, 43) argues that the disappointments of 1848 played a key role in shaping Renouvier's idea of liberty. For Renouvier, free will came to be seen as the ultimate basis of political liberty (*Deuxième essai*, 551). See *Histoire*, IV, 431, and especially *Esquisse*, II, 382, and *Deuxième essai*, 371*n*1.

[47]Renouvier saw free will as one of the basic concepts of both philosophy and Christian doctrine (*Histoire*, IV, 277).

[48]What does it matter to man if he has freedom in the world of the noumena if his world of phenomena is entirely determined? Renouvier later felt that Kant held on to free will solely for the sake of morals while not really believing in it (*Quatrième essai*, 35–36).

[49]Renouvier praised Fichte as a defender of freedom and criticized him as a mystic (*Quatrième essai*, 46). See Alain Renaut, *Le Système de droit: philosophie et droit dans la pensée de Fichte* (Paris, 1986); Luc Ferry, *Le Système des philosophies de l'histoire* (Paris, 1984), Vol. II of Ferry and Renaut, *Philosophie politique*; Alexis Philonenko, *La Liberté humaine dans la philosophie de Fichte* (Paris, 1966).

[50]Renouvier was concerned to establish a rationalist and not an empiricist view of science. He saw free will as perhaps the main issue dividing the rationalists and empiricists (*Histoire*, IV, 262). He indicated that there had been no new arguments in favor of free will since Kant and Rousseau (*Esquisse*, I, 280).

[51]Renouvier saw Kant's German disciples as having abandoned liberty for determinism, optimism, and pantheism (*Histoire*, IV, 467).

It is not just the moral aspect of civilization that hangs on the reality of free will, in Renouvier's opinion, but the whole of our intellectual life. Free will is also the foundation on which philosophy and the natural sciences rest.[52] Without free will, our ability to know anything, whether about man or about nature, is fatally undermined. Scientists do not need to believe in free will, and as he knew, they prefer to avoid this sort of question. In practice, they can legitimately do so because in their narrow spheres of inquiry they have developed techniques of investigation that work even when the scientist is unconscious of the fundamental assumptions on which his method rests. But without free will, the certainty of scientific truths becomes illusory; a consistent determinism must lead to a profound skepticism.[53] Renouvier would never despair of convincing the scientists that just as our concepts of right and wrong depend on free will, so do our concepts of true and false. Indeed, without free will, we could not even talk sensibly about things being true or false.

If, as he pointed out, I hold such and such a view to be true and I am determined by forces outside my control to hold this view, the person who disagrees with me is equally determined by outside forces in his position. If these mutually contradictory positions are equally necessary, what grounds can we have for the certainty that either view is the correct one?[54] If our belief that our ideas are determined is itself determined, so is the other person's belief in free will determined. Under these conditions how could it make any sense to speak of one view as "right" and the other as "wrong"? If, on the other hand, our choices are free, I may freely choose to believe in free will or in spite of the apparent contradiction, to believe in universal determinism. Of the four possible positions revealed by this analysis, the only one that can serve as a foundation for a rational certainty in the truth of our beliefs is to freely believe in freedom.[55] But as Renouvier insists, this means that we must give up any pretension to the absolute certainty of our beliefs.[56] The truth of free will cannot be proved so that no rational person can doubt it. It is a relative truth, like all our other truths, but more important because it plants a relativism at the very core of our thought.[57]

Scientists, Renouvier thought, should have no difficulty understanding and accepting this because science is built on an awareness of the conditional character of our knowl-

[52] See *Deuxième essai*, 227.

[53] *Histoire*, IV, 399; *Deuxième essai*, 327.

[54] *Histoire*, IV, 399; *Deuxième essai*, 306–307 (according to Hamelin, *Système de Renouvier*, 242). Necessity destroys truth: "If everything is necessary, error is necessary just as much as truth is, and their claims to validity are comparable" (*Deuxième essai*, 327). For a restatement of his argument that freedom is essential to the certainty of our knowledge, see *Esquisse*, II, 270–74; see also, *Science de la morale*, II, 377.

[55] The four are (1) we are determined to believe in freedom; (2) we are determined to believe in determinism; (3) we freely believe in determinism; (4) we freely believe in freedom. See *Deuxième essai*, 478; *Histoire*, IV, 399; Hamelin, *Système de Renouvier*, 273–74.

[56] "Certitude is not and cannot be an absolute. It is, as is too often forgotten, a condition and an action of man: not an action or a condition where he grasps directly that which cannot be directly grasped—that is to say, facts and laws which are outside or higher than present experience—but rather where he places his conscience such as it is and as he supports it. Properly speaking, there is no certitude; there are only men who are certain" (*Deuxième essai*, 390). For Renouvier's battle against the idea of evident truths, see *Histoire*, IV, 75, 261; certitude is a sort of "personal contract," "a real contract that a man makes with himself" (Lacroix, *Vocation personnelle*, 114).

[57] *Deuxième essai*, 309–10 (according to Hamelin, *Système de Renouvier*, 242). There were, however, "great probabilities in its [free will's] favor" (*Deuxième essai*, 475). "It ought to be a universally accepted maxim that *everything that is in the mind is relative to the mind*" (*Deuxième essai*, 390). Philosophy needs to take into account the existence of disagreement among philosophers (*ibid.*, 414). Renouvier's approach to the existence of these disagreements is one of the distinctive features of his philosophy.

edge, an openness to the discovery of new truths and the abandonment of old ones.[58] In fact, he had to admit, many scientists were still under the sway of older metaphysical conceptions of truth, except in the conduct of their personal research, and were unaware of any inconsistency in their position.[59] Some who were aware were evidently afraid that to admit that an act of belief was at the base of scientific knowledge would risk undermining the claim of science to objectivity and, even worse, open the way to the proliferation of pseudoscientific beliefs.[60] In reality, pseudoscientific beliefs were already proliferating under the aegis of the belief in determinism. Without a critical analysis of the nature and limits of scientific knowledge, however, our intellectual life is subject to a constant abuse of the name and prestige of science.

The abuse of science takes many forms: the application of research methods to fields where they do not apply, the application of particular concepts to areas other than those where they originated, the confusion of "Science" with the operations of particular sciences. One of the main intellectual trends of the nineteenth century, which Renouvier called *scientisme*, usually rendered as "scientism" in English, was the product of this abuse. Renouvier's relativism does not justify believing in whatever we want to believe.[61] It insists on submitting our opinions to every possible test of logic, experiment, and experience. But we have to admit that our logic, the hypotheses on which our experiments are based, the schemas of thought by which we interpret our experience, all rest ultimately on acts of belief and not on absolute certainties.[62]

If free will is thus essential to both morals and science, just what does he mean by it? Over the centuries, most of the debate over free will has failed to advance our understanding because of the lack of agreement about what is meant by the term.[63] I cannot solve that problem, but I think we will see that Renouvier's view makes the issue more comprehensible.

Free will, for Renouvier, is a capacity possessed by human beings, and only by human beings, that enables them to choose whether to accept one idea or another, whether to perform one act or a different one. It is thus a rejection of the doctrine that holds that all events, mental or physical, are absolutely determined and cannot be other than what they are.[64] Free will is also a rejection of the doctrine of chance, for it is an active power and not the "liberty of indifference" so belabored by determinists.[65] Chance is also hostile to liberty, since it denies man a real power of decision.

The existence of free will requires a measure of indetermination in the universe but

[58]On the use of hypotheses in science, see *Premier essai*, 200.

[59]Renouvier credited the English empiricists, following Hume, with freeing science from the metaphysical concept of cause (*Histoire*, IV, 273).

[60]This is the concern of Parodi (*Du positivisme à l'idéalisme*, 184–85), who finds in Renouvier a dangerous fideism. So does Brunschwicg (*Progrès de la conscience*, 625). For Renouvier's praise of Boutroux's argument that the contingency of the laws of nature is not a threat to science, see *Histoire*, IV, 673–74.

[61]Dauriac ("Moments de la philosophie," 30–32) strongly makes this point. It would be interesting to compare Renouvier's conclusion on this point with the similar view expressed by Richard Rorty, coming from a rather different direction.

[62]*Histoire*, IV, 692; on the need for faith in reason, even though such faith is in itself not a rational act, see Popper, *High Tide of Prophecy*, 218–19.

[63]Adler, *Idea of Freedom*.

[64]See definition of free will in *Histoire*, IV, 337; on liberty as choice, see *Deuxième essai*, 466; on real alternatives, see *ibid.*, 339. Renouvier is rejecting a causal necessity, not analytic necessity, as in the syllogisms of logical operations (*Premier essai*, 232–36).

[65]*Deuxième essai*, 330–34, 336, 337; Hamelin, *Système de Renouvier*, 242–43,249.

could not exist if nature were essentially indeterminate.[66] Our acts of free will are the beginnings of chains of consequences and would have no meaning if their consequences were not subject to cause and effect. "Free acts are not effects without causes; their cause is man, the ensemble and fullness of his functions. They are not isolated, but are always closely attached to the preceding condition of the passions and of knowledge. *A posteriori* they seem henceforth indissoluble parts of an order of facts, although a different order was possible *a priori*."[67] The laws that permit us to say this is followed by that do not admit of an infinite regression into the past, according to Renouvier. Therefore, every series of phenomena—and indeed the existence of any phenomena—must have a beginning that we cannot explain in terms of antecedents.[68]

The act of creation of the universe is thus replicated (in a much smaller way!) in every act of free will. Every act of free will is the creation of a new series of phenomena, a series that would not otherwise have existed.[69] These new chains of cause and effect are not simply the product of the intersection of existing but independent series, as A.-A. Cournot argued, for such intersections, though they appear random from the point of view of any one of the colliding series, would be necessary from a higher viewpoint.[70] They must be new beginnings, arising from a conjuncture in which, given the antecedents, more than one consequence was possible: "ambiguous futures," Renouvier called them.[71] Free will is the capacity to opt for one or another of those futures.

13-08-03 *Pragmatism and QM* (to G. Valente)

Valente-ism 1: *I hope [to be] finishing my dissertation in a couple of months and taking my degree in November. I think the title will read "Probability and quantum meaning: Chris Fuchs' pragmatism in quantum foundations". I've been trying to understand the development of your idea, especially in a philosophical light, but I'd also like to understand if I've been understanding . . .*

Very roughly, I recognized three instances (however connected) of pragmatism in your analysis:

- *one due to the mere acceptance of the theory; that implies, for example, the tensor product rule to represent a basic trail of the formalism and the quantum states to be pragmatic commitments (following a Bayesian approach to quantum probabilities and assuming Dutch-book as [the] criterion of consistency)*

- *one peculiar of the preceding itself in quantum foundations, which banishes any metaphysical interpretation and leads operatively to identify a core of "reality" as un-veiling ("reality is in the difference") and to drop important but not fundamental axioms of the theory (for example the time evolution)*

[66] "Liberty does not require the complete indetermination of particular future events, even of those that are directly connected to it" (*Deuxième essai*, 459); see also *ibid.*, 357; Hamelin, *Système de Renouvier*, 244.

[67] *Deuxième essai*, 359; see also *Science de la morale*, II, 361–62.

[68] *Premier essai*, 237; *Science de la morale*, II, 360–61. Most scientists today reject the idea that infinite regression is an absurdity; *Esquisse*, II, 378–79. We cannot explain beginnings because they are by definition at the limits of our possible knowledge.

[69] *Esquisse*, II, 196-97.

[70] A.-A. Cournot, *Considérations sur la marche des idées et des événements dans le temps modernes* (Paris, 1973), 9–10, Vol. IV of Cournot, *Oeuvres complètes*, ed. André Robinet.

[71] *Deuxième essai*, 210. "The real indetermination of various phenomena envisaged in the future" (*Premier essai*, 240). "[A determinist] would renounce everything called reflection and reason, for these functions do not work without the consciousness of a *representative self-motivation*, which is itself linked to an awareness of the *real ambiguity of future conditions* before it takes action" (*Histoire*, IV, 769). See also *Troisième essai*, xlvii; Hamelin, *Système de Renouvier*, 230.

- *one "deeper" inspired by William James, that suggests a notion of reality as construction.*

Thank you for your note, and I am flattered about your dissertation. I very much hope you will send me a copy when it is complete.

I think your three points are roughly on the mark, and I will enjoy seeing them developed. Concerning the last two points, I will add a little material for your thought. The first is an out-take from my samizdat *Quantum States: What the Hell Are They?* posted at my website. It delineates a little more directly than usual what I see as the great hope in melding quantum theory with Jamesian and Deweyan kinds of thoughts. (It is a file I put together for several other people, called `Construction.pdf`.) The other piece is pasted below. It is a letter written to David Mermin and Rüdiger Schack over the last three days (and sent off yesterday evening). I think it best captures my newest way of explaining things, and I hope it clarifies some points. You can feel free to use the thoughts in it in your development, even though it is not yet posted on my webpage.

In general, I would say the most encompassing source of the thoughts I've already gone public with is the document *Quantum States: What the Hell Are They?* (whose last entry is dated 29 June 2002). Since then, some ideas have changed but not too many; mostly I've spent my time developing the Darwinism issue . . . and that is somewhat uncoupled from the older material. Anyway, I am hoping to finally compress the whole *Quantum States: W.H.A.T.?* document into a proper paper before December, but we shall have to see. Unfortunately it will almost certainly not happen before you write your dissertation.

Concerning your very last question:

Valente-ism 2: *Please, can I ask you any bibliographical indication about this issue or something new about Bayesian probabilities?*

I would say the very best thing to read is Bruno de Finetti's paper, "Probabilismo." A month ago, I read it for my fourth time in six years, and this time I have to say it really, really sunk in . . . and I was ashamed that I had not so much absorbed it before. It is a masterpiece (except for the fascist statements at the very end) and has played a very deep role in my latest collaborations with Rüdiger Schack. Here is the English translation: Bruno de Finetti, "Probabilism," Erkenntnis **31**, 169–223 (1989). Immediately following that is an article by Richard Jeffrey titled "Reading Probabilismo" which it would also be good to have a look at, for it sets the context of the paper. In case it is more accessible to you, here is the original reference in Italian: Bruno de Finetti, "Probabilismo," Logos **14**, 163–219 (1931).

Good luck with everything!

14-08-03 *Uncertainty* (to W. E. Lawrence)

I'm glad you got my book. I hope you'll get some bits and pieces of insight from it. The development of the idea (the Paulian one) still goes on and seems to be gaining some momentum in the wider community. (I am a decently good salesman, even if not a decently good physicist.) Have you seen the September issue of *Studies in History and Philosophy of Modern Physics* devoted to quantum information? A lot of good articles there; Jeff Bub and I were editors. I'm excited that in some small number of years, we're really going to tie this up and move on to the next step of physics.

14-08-03 *Behind Again* (to P. G. L. Mana)

I'm in Munich at my in-laws' house, with some moments to finally catch up on old mails. Thanks for your insightful letter of 16 July.

I wish I had more to say at the moment; I just give a few nods of "yes" to you.

Manalogue 3: *With regard to my paper, I wonder if I can ask your advice on a point. I'd like to make there the bold statement that the concept of probability table and its decomposition offer a simple point of view to look at Gleason's theorem (and also at the one with general POVMs). The point of view is the following (sketched):*

1) The concept of preparations and effects can very intuitively (and precisely, I think) be expressed through the idea of a 'probability data table'.

2) The assumption that effects are to be represented by vectors implies that the only simple way to pass from a probability table to these vectors is through the table decomposition in the manner I do in the paper. Note that the 'effects = vectors' assumption is implicit in Gleason's premises, since the starting objects used as effects (projectors or POVMs) are additive. Note also that the table decomposition explains why the preparations are also to be vectors, and why linearity comes apparently for free in Gleason's theorem.

3) The decomposition and the fact that we are dealing with probabilities (bounded within $[0,1]$*) also leads easily to the fact that the 'shape' of the set of preparation-vectors determines the shape of the set of effect-vectors, and vice versa. Now, Gleason doesn't just make the assumption 'effects = vectors', but the stronger one 'effects = projectors' (or 'effects = POVMs'), which corresponds to assuming also a definite shape of the set of effects – thus it is also clear why the theorem gets almost for free the geometry of the set of quantum mechanical preparations.*

Do you think that these points make some sense?

Yes, I like this line of thought very much. Ever since first drawing the picture that became Fig. 2 in my `quant-ph/0205039`, I've been thinking that Gleason's theorem is almost superfluous. If you could dot the eyes and cross the tees in that in an even more general setting, that would be great!

Manalogue 4: *In connexion with point 3) above, there is a very interesting and non-trivial thing about the sets of effects and states in quantum mechanics: they are the same, modulo a renormalisation of effects. This, for a generic imaginary data table, doesn't happen; in fact, in general it is even meaningless to speak of a 'renormalisation'. For example, if the set of states is a simplex, the set of effects is a cube, which projects onto an hexagon; if the set of states is a semicircle, the set of effects is a bi-pyramid which projects onto a pointed ellipse ... Only in special cases does one have that symmetry (e.g., a circle, a sphere, etc.). This puzzles me, and I wonder if this symmetry has some physical meaning or if it just hides some assumption we make in our concepts of 'preparation' and 'outcome'. Because it amounts to saying, more or less, that there is a correspondence between a preparation and an outcome – which, in general, I cannot see.*

I think the deep reason there is precisely that quantum measurement corresponds to an application of Bayes' rule. In a measurement, one simply "refines" one's knowledge: i.e., one moves from the barycenter of a convex decomposition of a density operator to one of the outlying points in the decomposition.

Manalogue 5: *In Bayesian updating, I update the probability distribution that I assign to some (mutually exclusive and exhaustive) propositions – call them hypotheses – in view of new data. The point is that both my old and my new probability distributions refer to the same set of hypotheses.*

The quantum "updating", instead, can bring me from one kind of system to another kind of system, which can be completely different (in particular, of different dimensionality, eg, when the V_d are unitaries). From a Bayesian point of view, this looks more like going from a set of hypotheses to another set (which need not have something to do with the former) ie from a probability distribution $\{P(A_i|L)\}$ to another $\{P(B_j|DL)\}$.

Yes, you are right there, and I don't quite have my head around the point yet. But you might also note in the Fig. 2 that I mentioned above, one could interpret the extra unitary readjustment in exactly the same way: i.e., as readjusting the hypothesis set rather than the final state. The problem is in part that the hypothesis set (i.e., the standard quantum measurement device at the Bureau of Standards) is just a scaffold and not real. The main point of importance for me is the invariant piece: for *any* standard measurement chosen, quantum updating looks like an application of Bayes' rule + linear readjustment.

Manalogue 6: *Finally, I'd like to ask you something about hidden-variable theories and non-locality (I wanted to write and ask Mermin long ago, but doubted to receive a reply). From a Bayesian point of view, isn't the concept of "correlation" in the mind of the agent, and is it something non-physical, just like quantum states? In Bell's theorem, the assumption is made that the settings of the measuring devices are uncorrelated (between each other, and between different times for any one device). But can this assumption really be proven or disproven by experiment, for the Bayesian reason above? What happens if one drops it? Can one get a local deterministic hidden-variable theory that says that the devices' settings are pre-determined, together with the states of the two particles (of course, since the theory is deterministic), and that they are pre-determined in such a way to give the observed outcomes – whatever degree of "correlation" they have? In order to determine the behavior of all the pieces (particles, devices, experimenters, etc.) wouldn't one only need to set up appropriate initial conditions in a space-like slice of the past light-cone which contains all the pieces and all the events?*

Yes, and you are right: Several people have made that point. (Not the Bayesian point, but the latter point.) Unfortunately I can't think of any references—though, it may have been Bell himself first.

17-08-03 *Tearing Off the Duct Tape* (to N. D. Mermin)

Merminition 127: *Please take the damn tape off your mouth. If I'm going in the wrong direction I don't wish to waste anybody's time.*

I apologize for keeping you waiting for another two days. Once I signed off Friday at Beer:30, I wasn't able to get back to email until this morning. The whole family ended up in Munich proper yesterday (rather than a leisurely day here in Zorneding), and then by the evening I was exhausted.

So, let's get to it.

Merminition 128: *Quantum mechanics says (a) If two gates are measurement gates and (b) if no other unitary gates are in the circuit but those two then (c) if a qubit is sent through the circuit then with probability 1 both gates will give the same reading.*

This appears to be an assertion that under certain conditions any rational person will strongly believe that both gates will give the same reading. Furthermore, the conditions are not that in the past million runs only 00 and 11 have been registered and never 01 and 10 (as in the story you tell *me about how Bob comes to his strongly held belief). They are conditions about the structure of the circuit, through which no qubit may ever have been sent. If, under these conditions, all rational people must agree that the gates will give the same reading, some might worry that it was nitpicking (rather than deeply insightful) to nevertheless insist that this must be viewed as a subjective judgment rather than an objective property of the circuit.*

Yes, exactly; your last sentence would certainly be my own take if it were to stop at that. I doubt you remember this, but it was the BFM paper that started pushing me down the radical Bayesian path precisely because I perceived its message to be something like your point above. (Of course you didn't say "subjective judgment" but rather "knowledge," but for me it had the same effect.)

I just took a walk down memory lane rereading my correspondence to you, Brun, Finkelstein, Caves, and Schack between 7 August and 2 September 2001 to see if I could find any good quotes along those lines. Kind of depressing really: The sad thing was that I seemed to be far more lucid then than I was by the end of our Montréal meeting in November 2002 (capped off by my fatal mistake on 4 November). For instance, when I look back at my 22 August 2001 note to Caves and Schack "Identity Crisis," I see that it had a perfectly good discussion of CERTAINTY—the very starting point of this latest email conversation, as rekindled by Rüdiger's 18 June note this year. Traveling in circles and circles. Reread some of that stuff and tell me whether you don't think it is dead on the mark for today's very discussion. Let me give you an outtake, from a note to you 2 September 2001:

> The point of separating the categories "knowledge" and "reality" (or "subject" and "object" for that matter) is not to make knowledge an objective reality in its own right or, even worse, to make it the sole reality. Rather it is to say that there is a distinction and that that distinction should be recognized. ...
>
> What I have ultimately NOT been able to stomach about your wording of the whose-knowledge "answer", and Jerry's wording of the whose-knowledge "answer"—some of Todd's versions would actually survive—is that you say, under certain circumstances, two scientific agents (observers, or what have you) MUST assign "consistent" quantum states to a given system. In the case of pure states, the two agents MUST assign the *same* pure state to the system. ...
>
> What I object to is the word MUST. Todd once wrote it this way,
>
> **Brunism 9:** *We have been describing a consistency criterion.* If *one wishes to combine two state descriptions of a single system into a* single *state description, the criterion tells one* when *it is consistent to do so (i.e., when the two descriptions are not actually contradictory).*
>
> *I agree that nobody is holding a gun to Alice's head and forcing her to incorporate Bob's information.*
>
> and to this way of speaking I can agree. But if you take away Todd's "*If*", then everything collapses in my mind. Enforcing that two agents MUST make the same state assignment if they are going to be "right" at all reinstates the very objectivity, the very agent-independence of the quantum state that the Mechanica-Quantica-Lex-Cogitationis-Est program has been working so hard to exorcise. ...
>
> It is much like the old debate. Is materialism right? Or is it Berkeley's idealism that is right? Who cares, I say. Both philosophies are just simple samples of realism: They only disagree on the precise concept which ought to be taken as real, mundane matter

> or sublime consciousness. The way you characterize it above, one would think that the only fruit of the Mechanica Quantica program would be the RENAMING of a material reality into an ideal one—a shift more of emphasis, rather than anything of grit.

So, let me get to your better formulation straight away:

Merminition 129: *I believe your answer to such worriers would be something like this: that* (a) *and* (b) *imply* (c) *is not an objective fact about the world of circuits, but a law of thought (though it remains a part of the research program to show precisely how it emerges as a law of thought). In isolation it cannot affect anybody's degree of belief — for example it cannot guide betting behavior — unless* (a) *and* (b) *can be established. But* (a) *and* (b) *are subjective judgments. Bob requires a million runs not to establish the law of thought* $(a) + (b) \Rightarrow (c)$*, but to build up his strongly held belief in* $(a) + (b)$*.*

Yep, you're roughly on track here. The law-of-thought (or maybe better, law-of-ideal-thought) character in the implication $(a) + (b) \Rightarrow (c)$ is due to Gleason's theorem plus Dutch-book coherence. It's the kind of point we tried to make in `quant-ph/0106133`. The definition of your first measurement gate in (a) is that it gives "maximal information" about a reapplication of itself, i.e., it gives certainty for the click (as judged by any agent for which it is actually a measurement gate). DB coherence turns that certainty into a $p = 1$ assignment, and Gleason's theorem further turns that into a unique pure state. The judgment of (b) allows this pure state to be reconverted into a second $p = 1$ assignment for the outcome of the later measurement gate.

The goal of the research program is indeed to show that all of this together is a kind of Dutch-book coherence or, at least, Dutch-book coherence modulo some particular assumption about the properties of the (contingent, physical) world. (Rüdiger and I may still have slightly different goals here; it's hard to tell at this point.)

Merminition 130: *In isolation it cannot affect anybody's degree of belief — for example it cannot guide betting behavior — unless* (a) *and* (b) *can be established.*

Yes. In fact, it is just as normal Dutch-book coherence sets no probability assignments at all. (Emphasizing, of course, that even in the case of "certainty" we have had to recognize the subjectivity of the judgment.) If DB coherence is taken to be akin to a dynamical law in classical physics, (a) and (b) should be taken to be akin to the initial conditions. (I don't know if that analogy helps.)

Let me only take point with one issue:

Merminition 131: *But* (a) *and* (b) *are subjective judgments.*

You should stop your development right there. Conceptually, the origins of (a) and (b) should be left unanalyzed (just as with initial conditions in classical mechanics). You can of course do what you do in the next sentence (to somehow make it all more palatable),

Merminition 132: *Bob requires a million runs not to establish the law of thought* $(a)+(b) \Rightarrow (c)$*, but to build up his strongly held belief in* $(a) + (b)$*.*

but you should realize that in doing this you expand the context of the problem without adding anything of deeper significance to it. The data from those million runs are of no significance without still a further prior judgment. (Rüdiger introduced exchangeability to bring the language to the turf of your 1985 paper, but exchangeability is still nothing more than a judgment.) To know that a million runs (rather than a billion runs or a trillion runs) is of significance requires still more to be said: In particular one must choose a particular exchangeable assignment rather than another. So at some level, one is always stuck with making a quantum state (or quantum operation) assignment just to get the ball rolling. Thereafter, everything is empirical data plus law of thought applied to that initial judgment.

For (a) and (b) to be "subjective judgments" in our sense means (1) that their origins need not be analyzed, and (2) there is nothing in the world that *requires* two agents to have the same such judgments. The value of the game foundation-wise is that it tells you that if you are looking for the "objective" or "intersubjective" in quantum mechanics, you should look elsewhere.

I hope you'll send the second installment soon! Rüdiger and I are now set to meet late morning Tuesday, and it would be great to discuss your note face to face.

18-08-03 *The Big IF* (to A. Sudbery & H. Barnum)

I'm running far, far behind in all the things I've wanted to do this summer, but maybe there's a chance I'll catch up. In particular, I have been trying to give Mr. Nagel a concerted effort during my vacation here in Munich. I went out and bought *The View from Nowhere* and am a little ways into it. When I finish that, I'll re-approach your article "Why Am I Me?" and give you a detailed appraisal.

It's probably too early in my reading to tell, but my troubles with Nagel may all boil down to "The Big IF." That is, they may boil down to the religion that lies behind this passage plucked out of his article "Subjective and Objective." (I'll capitalize the big IF and a couple of other appropriate words so that you'll know what I'm talking about.) Here goes:

> Since a kind of intersubjective agreement characterizes even what is most subjective, the transition to a more objective viewpoint is not accomplished merely through intersubjective agreement. Nor does it proceed by an increase of imaginative scope that provides access to many subjective points of view other than one's own. Its essential character, in all the examples cited, is externality or DETACHMENT. The attempt is made to view the world not from a place within it, or from the vantage point of a special type of life and awareness, but from nowhere in particular and no form of life in particular at all. The object is to discount for the features of our pre-reflective outlook that make things appear to us as they do, and thereby to reach an understanding of things as they really are. We flee the subjective under the pressure of an assumption that everything must be something not to any point of view, but in itself. To grasp this by DETACHING more and more from our own point of view is the unreachable ideal at which the pursuit of objectivity aims.
>
> Some version of this polarity can be found in relation to most subject matter—ethical, epistemological, metaphysical. The relative subjectivity or objectivity of different appearances is a matter of degree, but the same pressures toward a more external viewpoint are to be found everywhere. It is recognized that one's own point of view can be distorted as a result of contingencies of one's makeup or situation. To compensate for these distortions it is necessary either to reduce dependence on those forms of perception or judgment in which they are most marked, or to analyze the mechanisms of distortion and discount for them explicitly. The subjective comes to be defined by contrast with this development of objectivity.
>
> Problems arise because the same individual is the occupant of both viewpoints. In trying to understand and discount for the distorting influences of his specific nature he must rely on certain aspects of his nature which he deems less prone to such influence.

> He examines himself and his interactions with the world, using a specially selected part of himself for the purpose. That part may subsequently be scrutinized in turn, and there may be no end to the process. But obviously the selection of trustworthy subparts presents a problem.
>
> The selection of what to rely on is based partly on the idea that the less an appearance depends on contingencies of this particular self, the more it is capable of being arrived at from a variety of points of view. IF THERE IS A WAY THINGS REALLY ARE, which explains their diverse appearances to differently constituted and situated observers, then it is most accurately apprehended by methods not specific to particular types of observers. That is why scientific measurement interposes between us and the world instruments whose interactions with the world are of a kind that could be detected by a creature not sharing the human senses. Objectivity requires not only a departure from one's individual viewpoint, but also, so far as possible, departure from a specifically human or even mammalian viewpoint. The idea is that if one can still maintain some view when one relies less and less on what is specific to one's position or form, it will be truer to reality. The respects in which the results of various viewpoints are incompatible with each other represent distortions of the way matters really are. And if there is such a thing as the correct view, it is certainly not going to be the unedited view from wherever one happens to be in the world. It must be a view that includes oneself, with all one's contingencies of constitution and circumstance, among the things viewed, without according it any special centrality. And it must accord the same DETACHED treatment to the type of which one is an instance. The true view of things can no more be the way they naturally appear to human beings than the way they look from here.
>
> The pursuit of objectivity therefore involves a transcendence of the self, in two ways: a transcendence of particularity and a transcendence of one's type. It must be distinguished from a different kind of transcendence by which one enters imaginatively into other subjective points of view, and tries to see how things appear from other specific standpoints. Objective transcendence aims at a representation of what is external to each specific point of view: what is there or what is of value in itself, rather than *for* anyone. Though it employs whatever point of view is available as the representational vehicle—humans typically use visual diagrams and notation in thinking about physics—the aim is to represent how things are, not *for* anyone or any type of being. And the enterprise assumes that what is represented is DETACHABLE from the mode of representation, so that the same laws of physics could be represented by creatures sharing none of our sensory modalities.

The two key ideas in this passage that I think quantum mechanics plays the most havoc with are:

1. the DETACHED agent (observer, scientist, etc.), and

2. IF there is a way things really are ...

I honestly believe one can take the Nagel worldview seriously—I suspect there is no logical flaw in it. One can legitimately try to make quantum mechanics fit that worldview with more or less success. My only point is the strong personal suspicion that with such a project one forces quantum mechanics into shoes it does not fit. And, as I see it, what bunions that will cause in the future!

The whole subject matter of my *Notes on a Paulian Idea* is in toying with the idea that the cleanest expression of quantum mechanics will come about once one realizes that its overwhelming message is that the observer cannot be detached from the phenomena he HELPS bring about. I capitalize the word HELPS because I want you to take it seriously; the world is not solely a social construction, or at least I cannot imagine it so. For my own part, I imagine the world as a seething orgy of creation. It was in that orgy before there were any agents to practice quantum mechanics and will be in the same orgy long after the Bush administration wipes the planet clean. Both of you have probably heard me joke of my view as the "sexual interpretation of quantum mechanics." There is no one way the world is because the world is still in creation, still being hammered out. It is still in birth and always will be—that's the idea. What quantum mechanics is about—I toy with—is each agent's little part in the creation (as gambled upon from his own perspective). It is a theory about a very small part of the world. In fact, I see it as a theory that is trying to tell us that there is much, much more to the world than it can say. I hear it pleading, "Please don't try to view me as a theory of everything; you take away my creative power, my very promise, when you do that! I am only a little theory of how to gamble in the light of a far more interesting world! Don't shut your eyes to it."

The question is, how to get one's head around this idea and make it precise? And then, once it is precise, what new, wonderful, wild conclusions can we draw from it? That is the research program I am trying to define.

Is it a SCIENTIFIC research program? I think so, and in the usual sense. There will be lemmas, theorems, and corollaries. (I would like to think that my work and the work of the fellows I've drawn down this path already evidences this.) Ultimately there will be calls for experiments. There will be technologies suggested and money to be made from the program's fruits. Failure of nerve? Anything but!:

Sudberyism 1: *Maybe you and [Rorty] can shift me from my instinctive reaction to pragmatism, which is that for a scientist it represents a failure of nerve, a failure of imagination, and most seriously a failure of curiosity. Being useful cannot, for a scientist, be the end of the story about a statement or a theory; we immediately want to know* why *one theory is more useful than another. That "why?" leads us to an external world of some kind, maybe very strange (the stranger the better, i.e. the more interesting, I would say) and to refuse to follow where it leads seems to me to be a scientific copout.*

I see it as anything but a failure of curiosity or a copout! What you wrote me above reminds me of a conversation I had with Chris Timpson in a pub one night. I made the mistake of mentioning William James, and Chris quickly intoned, "ALL James was about was the nonsense that truth resides in what is useful." The word ALL just boomed! A man's whole life was dismissed in a single sentence. I cut him short, "William James was about many things, ONE OF WHICH was that the correspondence theory of truth holds no water." Similarly I will say to you, there is far more explored by the pragmatist thinkers than that which is delimited by their ideas on truth and warranted belief. Pragmatism is not positivism; it is not that there is nothing to be sought in science beyond the connections between sense perceptions. I see the classical pragmatists (and myself) as ultimately realists, but honest realists—ones who have realized that our theories are not mirror images of the underlying reality, but rather extensions of our biological brains.

But that is going in a direction I don't want to go down at the moment. In any case, don't read Rorty first! Read James' little book Pragmatism to start off with. More immediately, with respect to the present Nagelian discussion, read "Genesis and the Quantum" on pages 122–123, the dialogue between Adam and God on pages 118–120, "Evolution and Physics" and "Precision" on pages 267–270, and some of Jeff Bub's expressions on the idea in Chapter 9, most notably pages 139–140 and 141–142—all these things in the samizdat I sent you. The game of ASSUMING the possibility of a detached observer, as Nagel does, is just that: a game of assuming. Thereafter, Nagel tries to make sense of our more personal worlds in spite of this. The pages I've just referred to in my samizdat try to sketch what quantum mechanics might be talking about if one does not make such an assumption. In fact, they try to justify NOT making the assumption at all. I hope from these readings you will get the impression that though there may be a fundamental disagreement between Nagel and me at the outset, such a disagreement does not necessarily amount to a copout on my part.

Finally, let me paste in a note below that I sent to David Mermin and Rüdiger Schack the other day. It's titled "Me, Me, Me!" and gives my very latest attempt to express the content of quantum mechanics in these lights. I think it does an adequate job ... but experience tells me I am always over-optimistic. In any case, it is directly related to all that was said above.

I'll be back again after completing Nagel and your paper.

PS. I'll also attach the note on Rorty-ish stuff that I sent you previously. That way Howard will have a better handle on why I find excitement in dismissing the starting point "IF there is a way things really are ..."

21-08-03 *Everywhere and Nowhere* (to H. Barnum)

Thanks for the note in reply to my pre-Nagel thoughts. You've given me courage in a way: I feel more strongly than before that reading Nagel is worth my time. I will follow it through to completion.

A couple of very little points.

Barnumism 6: *I'm not sure if "religion" is supposed to be a bad thing in this instance, but couldn't we just as easily call it a "research program"? Even a SCIENTIFIC one? I guess my point here is that I don't think quantum mechanics can yet be considered decisive against such a program... and the theorems, lemmas, technologies you mention (below) are coming from quantum mechanics taking a wide variety of interpretational positions (or none at all)... sometimes very similar theorems from people having (I think) different points of view.*

Fair enough. I suppose my choice of the word was conditioned on the number of times I've had my own research program depicted as "ignoring the results of science" or as "antithetical to the very idea of science" (D. Deutsch and D. Albert, two examples). The point I wanted to get at with the term "religion" was only that the possibility of satisfying "The Big IF" is a *faith*, not a self-evident truth.

(By the way, while I'm thinking of Deutsch and Albert and pointing out the depths of their religiosity, let me go the rest of the way and tell you the remainder of the thought. These are religions, yes, but worse than that, they are *easy* religions. Evidence: Deutsch and Albert both have already found *the* answers, whereas I still strive away.)

Barnumism 7: *Again, I tend to think this "assuming the possibility" may just amount to "attempting to coordinate the various perspectives into a coherent whole". Quantum mechanics suggests difficulties with this, enough to make it worthwhile to pursue your vision of "assuming the impossibility of a detached observer" ... but to me, it would be a failure of scientific nerve/imagination to think quantum mechanics justifies abandoning the attempt to coordinate. Let both approaches bloom ...*

Life is short!

22-08-03 *Chance and Paper Letters* (to W. C. Myrvold)

Funny you mentioned getting a paper letter from Abner. Just yesterday when I returned from Munich I found a letter from Abner that had been forwarded to me from Bell Labs: It was dated June 3!! I was so delighted with it I scanned it into my computer this morning for my permanent records. If Abner had only emailed it, it would have been in my computer three and a half months ago!

Concerning a conversation I'd ultimately like to start up with you, though—namely, subjectivist or personalist probability in quantum mechanics—a better source is my samizdat *Quantum States: What the Hell Are They?* posted at my webpage. In particular, you might enjoy skimming though it in connection with your project with Bill Harper. Most of the fun in the document starts up on pages 19 and 35 (and thereafter). That's where I take the turn of giving up on "objective certainty," having realized that through quantum mechanics its logical derivative is ineluctably "objective chance."

Rüdiger Schack and I will be condensing much of that subject matter into a proper paper starting in the middle part of this month.

I'm actually surprised to hear what you say in this:

Myrvoldism 2: *I don't know of a good source on why Bayesians should believe in objective chance (or, better: at least regard the notion as intelligible), and neither does Bill Harper.*

I recall the words in David Lewis's paper, 'A Subjectivist's Guide to Objective Chance': "As philosophers we may well find the concept of objective chance troublesome, but that is no excuse to deny its existence, its legitimacy, or its indispensability. If we can't understand it, so much the worse for us." I would have thought a lively discussion would ensue in the subjectivists' camps thereafter.

Anyway, I'm very much looking forward to this paper of yours.

25-08-03 *Coordinate Systems* (to G. L. Comer)

I read two things this morning that put me in the mood of coordinate systems. The first was a remarkable letter from Pauli to Bohr, dated 11 March 1955. [See 29-03-01 note "There's At Least One More" to H. J. Folse.] The second was your latest draft of "linear structures." I'm just trying to get these things clear in my head and put them into a common language. (By the way, I'm sorry I've been so absent lately. Unfortunately, after this brief return I'll probably be absent again for a while; I've got to get a book review to *Physics World* by September 4, and I am far, far behind on my ARDA roadmap duties. Also I've got to finally get my application off to the Bohr Institute this week—a much more difficult process than you might imagine. In total I'm going to be inundated through mid-September.)

Anyway, I want to attach a PDF file containing two letters on quantum mechanics that I've written recently (one to Mermin and Schack, and one to Sudbery and Barnum), along with the Pauli letter mentioned above. Strangely enough—you must get tired of my saying this!—I feel like I've had another epiphany in expression. My two letters try to capture that.

Now for the common language business. What I found remarkable upon rereading the Pauli letter—I last read it maybe a year ago—was his discussion of coordinate systems and the way he alludes to calling them "actions on the part of the observer." Or, at least in my cherry-picking mood, that's what I would like to glean from the letter (ignoring that he did also use the word "knowledge"). You'll see why that takes me when you read the letter I wrote to Mermin and

Schack. There I explicitly identify the set of POVMs (i.e., the full set of quantum measurements upon a system) as the set of ACTIONS one's *will* can take upon the system.

Clearly, Pauli sees the coordinate system as the classical analog of the POVM (and vice versa, the POVM as the quantum analog of the coordinate system). They are both mathematizations of "the observer," or better "the agent," in the respective theories. But there are differences. For one, classical coordinate systems are completely passive—this Pauli recognizes. Equipping a manifold with a coordinate system does not change the manifold or any of its contingent properties (i.e., any of the fields living on it). On the other hand, POVMs are anything but passive. This was a major point for Pauli. A POVM elicits the world to do something it would not have otherwise done. The combination of the action of one's will (the POVM) with a system external to it gives rise to a birth of sorts—the flash, the event which we usually call (in older language) the measurement outcome.

What is funny, however, is Pauli's discussion of Einstein. As far as I can tell, what he intends by the word "consequent" would better be expressed by "consistent." (Actually, upon looking up the word in my dictionary, I find that this is its very meaning!) Consequently I find Pauli's contention that Einstein was being inconsistent puzzling. The very reason Einstein felt no qualms about introducing coordinate systems when necessary was because in relativity theory the underlying observer-free description—i.e., the manifold equipped with its fields—had been achieved. In contradistinction, this is something quantum theory has yet to achieve (and may never be able to). In fact, it was this that troubled Einstein ... saving him from inconsistency.

Let me belabor the similarity and distinction. I think you are certainly right to point out one of the similarities via the mutual use of projections in the two theories. In the case of relativity theory, a projection is used to tell what one WILL "see" from one's perspective—you gave energy as an example. The projection is an operation used for expressing an aspect of a preexisting reality, e.g., a tensor field. In the case of quantum mechanics, one projects one's state of knowledge (i.e., one's density operator for a system) onto the potential consequences of one's action (i.e., onto the POVM elements) to obtain a probability distribution. This is just the Born rule in a generalized setting. The probability distribution so obtained expresses one's expectations for the consequences of one's action, not one's expectations for a preexisting reality.

So, projections both, but they encode very different things.

Let me close with another distinction that I'm wondering what to make of. It's connected to a point in the Anti-Växjö paper I sent you and a point in your latest draft. As far as I can tell, I believe both:

> **Me:** The OBJECTIVE content of the probability assignment comes from the fact that *no one* can make *tighter* predictions for the outcomes of experiments than specified by the quantum mechanical laws. Or to say it still another way, it is the very existence of transformation *rules* from one context to another that expresses an objective content for the theory. Those rules apply to me as well as to you, even though our probability assignments *within* each context may be completely different (because they are subjective). But, if one of us follows the proper transformation rules—the quantum rules—for going to one context from another, while the other of us does not, then one of us will be able to take advantage of the other in a gambling match. The one of us that ignores the structure of the world will be bitten by it!
>
> **You:** Even if the observers are at the same place, at the same time, when they make their measurement, they will in general not record the same energy because their motions will in general be different. So how can they ever agree on anything? Relativity tells them how to "translate" one measurement into the other so that a consistent description

> results. What is objective about the energy? Nothing. Its value depends on the motion of the observer. Where is the objectivity? Only in the rules of translation. The only objective thing to me seems to be how one object is to be compared with another.

I.e., both theories make use of transformation groups in a crucial way. But what different ways! In the case of relativity, I guess I would have said that the translations are for external purposes. They tell me how to connect one observer's potential observations to another's. Or another way to say it, they tell me how to translate from one aspect of the preexisting reality to another. In the case of quantum theory, however, the translation is all internal: What should I believe of this, given that I believe such-and-such of that? The quantum transformation rules I am thinking of here say nothing of how to translate one person's beliefs into another person's. In fact, the whole point of personalistic probability is that there is IN PRINCIPLE no way to connect someone's beliefs to anyone else's: Probabilistic statements are personal betting strategies.

Thus I guess I find no warrant in what Pauli says when he tries to make the point: "That the situation in quantum mechanics has a deep similarity with the situation in relativity is already shown by the application of mathematical groups of transformation in the physical laws in both cases."

But then again, I start to wonder that if I took Pauli's starting point completely seriously—i.e., if I were to start to think of coordinate systems as ACTIONS of an individual observer—all my troubles would melt away and maybe I'd start to see a deeper analogy as he saw it. I guess I'm still very much in the process of thinking.

Enough for now. (Don't forget the attached files—the one already mentioned plus one further one relevant to the Sudbery discussion.)

31-08-03 *Acceleration is Intervention!* (to G. L. Comer)

What is it about Sundays that sets off the thought muscles? Anyway, I hope my title says it all. That was the thought that hit me as I was washing the dishes this morning. Maybe coordinate systems are interventions after all, when considered in the quantum context. [Cf. last Sunday's discussion.] What happens when a "particle detector" is accelerated? You've told me before that it goes click. The usual explanation goes that it has something to do with the perceived quantum state of the field – namely it becomes something like a thermal density operator. But maybe instead, we should think of the process as a change in the character of the measurement device. That is, maybe an accelerated particle detector is a distinct POVM from its inertial cousin. I.e., it intervenes on the field in way different than the inertial detector. (In older language, that is to say, it "measures" a different observable.)

At least that's the thought that hit me.

Look at me getting pulled down the path of GR: Analogies between Hilbert-space dimension and gravitational mass, analogies between coordinate systems and measurement devices. What's happening to me?!?!

28-08-03 *Update* (to C. King)

Kingism 2: *What are you working on now? Any more neat additivity conjectures to throw my way?? You had mentioned the possibility of coming to Boston some time – now that Peter Shor is here, perhaps you have even more reason to pop over?*

Mostly I'm trying get my part of the ARDA roadmap finished. It's a big annoying project. And I may have to go to DC Sept 14-16 for it.

Mathematically, mostly I'd like to see whether or not there is a set of quantum states with $d^2 - 1$ elements which achieves the quantumness of the Hilbert space (i.e., $2/(d+1)$).

Coming to Boston definitely sounds nice! By the way, would you have any to get (or get me) into the Harvard library? There's an old PhD thesis that I'd like to get a copy of:

- W. H. Long, *The Philosophy of Charles Renouvier and Its Influence on William James*, Ph. D. thesis, Harvard University, 1927.

and it is not available through University Microfilms, etc.

01-09-03 *Answering Correspondence with Correspondence* (to S. Savitt)

Savittism 1: *I've always (though perhaps incorrectly) thought of solipsism as the view that my mind was the only mind that exists (or that I knew exists, or that I could know exists). This way of looking at it is, of course, compatible with materialism.*

The predominant view seems to be that it connotes an extreme form of idealism in which (one) self is the only reality, or at the very least, the ground of reality. I have a correspondence with Mermin in which I compile several definitions for the word pulled from various sources; I'll attach that rather than pull it out of context.

Savittism 2: *I didn't get your remarks about Unitary Readjustment. Is the kind of updating of your beliefs that you do as the result of a measurement in QM supposed to be incompatible with standard Bayesian updating. (I thought one theme of your "Quantum Information" paper is to show that these processes were at root the same.) Alas, the details of your massive paper have begin to blur in my mind.*

Yes it is generally incompatible; the deviation represents part of the "only a little more" in the paper's title. In Sections 6 and 6.1 of my paper I deemphasized the incompatibility (or rather, "deviation from Bayes") because I wanted to first clinch it in the minds of the readers that quantum collapse has a large component that is simply Bayesian conditionalization. The unitary readjustment quantifies the "deviation from."

There is an interesting case where quantum collapse is nothing at all more than Bayesian updating: That is, when there is no physical interaction with the system being considered—for instance in the standard EPR scenario. By making a measurement on one of an entangled pair of particles, one updates one's description for the other particle. The interesting thing one sees by writing collapse in the way I endorse is that, in this case, the unitary readjustment is just the identity operation . . . which makes collapse precisely Bayesian conditionalization.

The idea is that, when there is a deviation from Bayes, what one is seeing is a mild trace of the much deeper statement: The observer cannot be detached from the phenomena he helps bring about.

Savittism 3: *Finally, despite your protest and because many will read your writing, I will make the odd remark about grammar. It's not the one you forestalled, though. It's that 'like' is a preposition, introducing a clause. So on page one of the 12 August note, I think you really should say "Maybe* *the best way to do this is to run through a glossary of quantum terms as I did once before. . . " And there's a similar mis-use on p. 2. Obviously, I don't think that Winstons carried the day on this one.*

Much appreciated. I only started learning grammar about ten years ago, and it shows. I will readjust the sentences as soon as I send off this email. Please explain the Winstons remark though. What does it refer to?

Savittism 4: *Well, maybe I have another thing to add. I have read only little of Shimony's technical work in QM, but here's someone who worked on personal or subjective Bayesianism and doubtless had some ideas as to how it applied to QM. Looking at your brief email correspondence with him in the samizdat, it occurs to me that* perhaps *your difference (if there really is a difference) as to whether an interpretation of QM must be "ontological" or not obscures the fact that his Bayesianism is like yours.*

Oh, there's quite a difference between Shimony and me on this score. But there is enough mutual understanding that progress may be had in the future. In the attachment, I'll also include some correspondence to and from Shimony. The way I would characterize Abner is that he is Bayesian (of a flavor) *about* theories, but, within a theory, he is objectivist about its uses of probability (or at least this is so for him with respect to quantum theory).

To me, making that move—i.e. giving up on the Bayesian account *within* quantum theory—is the greatest impediment to understanding. The empirical evidence I would give for this is simply the number of years Abner spent taking as serious and reasonable a search for collapse theories (say of the GRW variety). Also the lengthy discussions he's had about the "surprising" consistency between special relativity and wave-function collapse—an effect he dubbed "passion at a distance" to contrast it with "action at a distance" (i.e., trying to make it clear that one could not use wave-function collapse for signaling superluminally).

The thing Abner does not yet appreciate is the immense leading power of taking Bayesianism seriously *within* quantum theory. The way I would characterize the present stage of my research program is, "Seek and ye shall find." An awfully good example comes from the thing I pointed out above: The EPR scenario actually represents pure Bayesian conditionalization if written in the right way. Far from being anything mysterious—like passion at a distance—it simply represents the usual conception of conditionalization. In fact, it is only the method of updating one's probabilities for systems with which one makes physical contact that has any mystery or calls for an explanation. (I.e., the situations where one must insert an extra unitary update.)

So, seek and ye shall find: Look for a Bayesian reason for this or that within quantum mechanics, and one finds—my experience tells—that the theory is a much tighter package than maybe first imagined. It's only in the slight deviation from Bayesianism that things really get interesting.

01-09-03 *One Further Thought* (to S. Savitt)

One further thought. I retumbled the note I wrote you earlier this morning in my head as I was walking to work, and it dawned on me that maybe I went too far in the other direction in trying to clarify things for you. I wrote:

> Yes it is generally incompatible; the deviation represents part of the "only a little more" in the paper's title. In Sections 6 and 6.1 of my paper I deemphasized the incompatibility (or rather, "deviation from Bayes") because I wanted to first clinch it

in the minds of the readers that quantum collapse has a large component that is simply Bayesian conditionalization. The unitary readjustment quantifies the "deviation from."

I want to emphasize that this deviation only concerns *updating*. However, I show in the fat paper that there is another role Bayes' rule plays in quantum measurement (just prior to the update), and in that role it is indeed "Bayes' rule full stop" that is the crucial idea. Namely, I show that there is a one-to-one correspondence between the full set of quantum measurements (i.e., the POVMs) and applications of Bayes' rule.

So, when you wrote

Savittism 5: *Is the kind of updating of your beliefs that you do as the result of a measurement in QM supposed to be incompatible with standard Bayesian updating. (I thought one theme of your "Quantum Information" paper is to show that these processes were at root the same.)*

you were more right than I was giving you credit for. There is a one-to-one correspondence between possible applications of Bayes' rule and measurement devices (or, as I expressed it in "Me, Me, Me," actions that my will can take). But, whereas in classical measurement the updating stops there, in the quantum case there is a little more.

01-09-03 *Fragmentation and Wholeness* (to N. D. Mermin)

I hope you are enjoying all the wholeness in well-being Japan and the bodhisattva can afford.

As for your fragment, I am having quite some difficulty understanding it: There was only one thing I could latch onto enough to dislike. Namely, I object to this phraseology:

Merminition 133: *It's terrible for teaching computer scientists quantum mechanics. The subject can't get off the ground with warnings that you can't be sure a measurement gate is a measurement gate, a cNOT is a cNOT, that no gates act except the ones you set up, etc.*

You still slip into a mode of language that acts as if there is some magical fact out there that is going to confirm that a cNOT is really a cNOT or not. The point is, I would just never talk this way. Let me give an example. Suppose I am talking about a single toss of a coin, and I say, "For me, personally, the probability that it will land heads is 50/50." In making such a statement, should I worry myself that maybe my personal probability is not really 50/50 after all? Or to put it another way, and borrow your sentence structure, would one ever say of classical probability theory:

> Things I don't like.
> 1. It's terrible for teaching gamblers how to gamble. The subject can't get off the ground with warnings that you can't be sure a 50/50 probability assignment is a 50/50 probability assignment, ...

In our language, a measurement gate is a prior. A cNOT is a prior. Neither are open to empirical verification beyond soul-searching. The only thing that ever needs be said to the student is, "IF your judgment of this is 'measurement gate', and your judgment of that is 'cNOT', and that is 'phase gate', etc., etc., then for coherence you must judge the outcomes of the computation with such-and-such a kind of probability." Notice the single quotes; they are important. I did not say "If your judgment of this is that IT is a measurement gate, and your judgment of that is that IT is a cNOT, ..." The latter kind of phraseology would lead one to think that the words 'measurement gate' correspond to a FACT of which one's judgment can either be correct or incorrect.

I'll leave it at that for now. Honestly, I got quite confused on everything else you said. Perhaps Rüdiger will fair better than I did.

As you once told me, don't eat the fugu! (At least until after you clean up your fragment a bit.)

02-09-03 *Peres Festschrift* (to 48 colleagues)

Dear Colleague,

Asher Peres is turning 70 years old next year! On this important occasion we would like to honor him with a festschrift for his seminal contributions to quantum theory, quantum foundations, quantum information, and relativity theory. The festschrift will be published as a number of reserved issues in the journal *Foundations of Physics*.

It is our pleasure to invite you to submit a research paper of about 20 to 30 pages, or even longer if the subject matter requires. The manuscript would be due at the end of February 2004, leaving a reasonable time for reviewing and revision purposes if necessary.

Please let us know at your earliest convenience whether you will be able to contribute. Your contribution would certainly be valued, and we hope for a positive reply!

With best regards,

Chris Fuchs and Alwyn van der Merwe

02-09-03 *'Gleason' Paper* (to P. Busch)

Buschism 1: *Unfortunately I haven't made any progress on the problem you proposed. Have you got anywhere with it in the meantime?*

We've made progress in better understanding the quantumness function—that's recorded in `quant-ph/0308120`—but I've made essentially no progress in the question I asked you ... if I recall correctly the question I asked you. I think I do. Namely, to prove (or find a counterexample) that if the cardinality of a set of states is $d^2 - 1$ or less, then the quantumness of the set is bounded away from the minimum value $2/(d+1)$.

For Holevo's festchrift, I'm going to write a little paper proving the minimum value just mentioned and make a few statements about sets of states that achieve it. Unfortunately, I'm just going to have to conjecture the converse theorem above.

02-09-03 *The Archivist* (to I. Pitowsky)

Thanks for sending those pieces. The Maxwell one was especially nice in that Rüdiger and I are presently working up a paper on "On Quantum Certainty." Some of the phrases used in the letter fit it well! Anyway, it's kind of nice being the historian of the field.

Itamar's Preply

> From: *The Life of J. C. Maxwell* – L. Campbell and W. Garnett, London: Macmilian and Co., 1882.
>
> A letter from Maxwell to Campbell probably from June 1850:

"...I was thinking to-day of the duties of (the) cognitive faculty. It is universally admitted that duties are voluntary, and that the will governs understanding by giving or withholding Attention. They say that Understanding ought to work by the rules of right reason. These rules are, or ought to be contained in Logic; but the actual science of Logic is conversant at present only with thing either certain, impossible of *entirely* doubted, none of which (fortunately) we have to reason on. Therefore the true Logic for this world is the Calculus of Probabilities, which takes account of the magnitude of the probability (which is, or which ought to be in a reasonable man's mind). This branch of Math., which is generally thought to favour gambling, dicing, and wagering, and therefore highly immoral, is the only "Mathematics for Practical Men," as we ought to be. Now, as human knowledge comes by the senses in such a way that the existence of things external is only inferred from the harmonious (not similar) testimony of the different senses, Understanding, acting by the laws of the right reason, will assign to different truth (or facts, or testimonies, or what shall I call them) different degrees of probability. Now, as the sense give new testimonies continually, and as no man ever detected in them any real inconsistency, it follows that the probability and *credibility* of their testimony is increasing day by day, and the more a man uses them the more he believes them. He believes them. What is believing? When the probability (there is no better word found) in a man's mind of a certain proposition being true is greater than that of its being false, he believes it with a proportion of faith corresponding to the probability, and this probability may be increased or diminished by new facts. This is faith in general. When a man thinks he has enough of evidence for some notion of his he sometimes refuses to listen to any additional evidence *pro* or *con*, saying, "It is settled question, *probatis probata*; it needs no evidence; it is certain." This is knowledge as distinguished from faith. He says, "I do not believe; I know". "If any man thinketh that he knoweth, he knoweth yet nothing as he ought to know". This knowledge is a shutting of one's ears to all arguments, and is the same as "Implicit faith" in one of its meanings. "Childlike faith", confounded with it, is not credulity, for children are not credulous, but find out sooner than some think that many men are liars."

03-09-03 *Stuff* (to A. Plotnitsky)

Plotnitskyism 10: *It's good to hear from you–and not without some synchronicity, as I was in fact reading your "correspondences," now in print, of course. [...] Although I have of course read most of it earlier, there are parts of it, to which I continue to return, since they deal with truly essential and as yet (for me at least) not quite resolved points, plus it's a real pleasure to read. So I keep a copy handy.*

Thanks for all the flattery. Actually, you know something that would be really useful to me, and maybe more entertaining for you, would be if you'd have a look at my newer samizdat *Quantum States: What the Hell Are They?* posted at my webpage. It's probably much harder reading than the older one, but also—by my own reckoning—it's much deeper: It can't quite be nibbled on in the same way. Anyway, Rüdiger and I are going to try to condense a good piece of that document into a single paper this fall. The working title is "On Quantum Certainty." After we post our paper on `quant-ph`, I plan to post the said samizdat too. So it'd be useful to get any feedback I can on it. For instance, if you notice any missing cross-connects that make it difficult to read, etc., it be great to know about that!

By now that's old stuff for me, but it might be new stuff for you. Rüdiger counts it as where we make our most decisive break with Bohr. Here's the way he once put it to me. He said, "Bohr would always draw measuring devices as these heavy pieces of equipment, firmly bolted to table tops to emphasize that they are classical matters of fact. But you don't that. You bolt your measurement devices to the tops of turtles! And then it's turtles all the way down."

The next stage of my development is captured in still another samizdat, titled "Darwinism All the Way Down (and probabilism all the way back up)"—about 100 pages—but unfortunately Mermin hasn't given me permission to share that with anyone yet. I guess I need to edit him out a bit more first.

Plotnitskyism 11: *I feel, though, a bit intimidated by the list of potential contributors and I am worried that whatever I'd write may not be technical enough.*

You shouldn't be intimidated at all. I know that Asher respects you; that's why I put you in the list. Also you met Asher's approval: Believe me, not everyone in my initial list survived! So, just write us an interesting paper, and everything will be OK.

Plotnitskyism 12: *P.S. I was thinking of you in yet another context the other day. Are you aware that both formulas $E = mc^2$ (no surprise here of course) and $E = h\nu$ apparently occur for the first time in Einstein's articles, on special relativity and on photoeffects, both in 1905? Planck, it appears, did not write $E = h\nu$, although it is of course implicit in his articles on the black body radiation. He must have pondered their connections, especially given Lorentz's work, although photons are of course not electrons in terms of their (quantum) mechanics or electrodynamics.*

I thought $E = mc^2$ first come up in a 1907 paper. You might check into that. As far as $E = hv$, I guess I wasn't aware of that. However, I do seem to recall that in Planck's original paper he had an incorrect *derivation* of the (correct) black-body radiation formula. And I believe it was Einstein who fixed that up in his PhD thesis (in 1903 or 1904). This is not a fact emphasized in the physics textbooks. But it must have put Einstein on the map with respect to Planck's attention. I think a good source of these stories might be Kuhn's book on black-body radiation, but I've never read it.

By the way, I finally met Paula's friend Jane Nordholt at a quantum cryptography meeting in Virginia in June. She said that she hadn't heard from Paula in quite a while (and I think maybe didn't know how to get in touch with her since her move to NY). I said I'd write you about this—but then promptly forgot to! Tell Paula I apologize. Is everything going well with her? Has she settled into NY fine?

03-09-03 *Pronouncing Fuchs* (to R. Schack)

If you are around, could you send me a pronunciation guide (perhaps using LaTeX) symbols for how to pronounce the German words for "book" and "fox." I might want to capture how Gell-Mann mispronounced my name in this *Physics World* book review I'm writing (when describing the author's own discussion on the subject). If it do it, I'm going to have to do it with tact. But still, I would like to know how to write these things anyway.

Rüdiger's Reply

> Here is your pronunciation guide, with explanations of the symbols. The phonetic alphabet used is that of the International Phonetic Association (IPA), the explanations come from the Langenscheid Großwörterbuch Deutsch-Englisch.

[**u:**] Buch [bu:x] long, resembles English oo in boot, but closer and more retracted than this

[**x**] Buch [bu:x] similar to Scottish ch in loch

[ʊ] Fuchs [fʊks] short, resembles English u in bull, but closer and more retracted than this

Good luck!

04-09-03 *Letting You Down, but Bringing You With* (to G. Brassard)

I had to make a tough decision yesterday: I decided not to come to the Wye River Meeting. My travel schedule just got too hectic again, and Richard Hughes had written me, "if you would be coming from Ireland especially for this I would recommend saving the wear and tear unless you have other business in the US." So, I took him up on it: I didn't really have any other business in the US. But you probably don't need me anyway; you'll have plenty of fun with Charlie if you go.

Anyway, that's the bad news. But let me follow through with a proposal that we've discussed before—you might find some good news in it. Let us DO write a paper together for Asher's festschrift. "Brassard and Fuchs, together for the first time," the show bill could say. I'd like to call the paper "Quantum Foundations in the Light of Quantum Cryptography" (or some variation thereof) and I'll do almost all the work for it. The only thing you'd have to do is decide whether you can agree with most of the outlandish statements I'll be making. I'll have plenty of equations, though, so that it'll look respectable. In this paper, I want to emphasize an information-disturbance principle (akin to the mechanism behind secure QKD ... thus the title and your involvement) more than I have in the past with my "Quantum Foundations in the Light of Quantum Information" papers. It'll be a good quality paper. Will you join me?

More immediately, after I finish the book review I'm writing for *Physics World* today, I plan to immerse myself in the ARDA roadmap business starting tomorrow or Monday latest. I sure hope we'll be able to put our heads together for this. I'm gonna need a lot of guidance!!

04-09-03 *Nietsnie dna Rhob* (to R. Schack)

Schackcosm 83: *In Munich, I visited a small Einstein exhibition in the Deutsches Museum, where the appended small letter* [[from Bohr to Einstein]] *(my translation) was displayed. Isn't that exactly the Buridan's ass point?*

> *Dear Einstein,*
>
> *Many thanks for your kind lines. It gave us all great joy to express our feelings on the occasion of your birthday. To continue in the same playful tone, I can't help saying about the unsettling questions that, in my opinion, the issue is not whether or not we should stick to a reality amenable to physical description, but to follow the path shown by you and to identify the logical conditions for the description of the realities. In my bold way I would even like to say that nobody—not even the good Lord—can know the meaning of an expression such as "playing dice" in this context.*
>
> *With best wishes Niels Bohr*

You and your ass! As always, I have trouble deciphering Bohr. There is something about the language pattern that never sinks in to me. I know you want to say that he is saying that it is *meaningless* to discuss whether the world itself is either determined or undetermined. But why? I don't see why it is meaningless. It may not be fruitful to ask. It may not be answerable from within our inside or finite perspectives. Both of those things I would be willing to grant you, and I regimen my life appropriately taking them into account. But why is it meaningless? I don't think Bohr ever gave an answer, and that is why it is pretty hard to find him convincing.

And don't forget to tell me how to pronounce Fuchs.

07-09-03 *correspondentx.com* (to Correspondent X)

I have gone to your website and looked at your open letter. You seem like a sincere person—one who practices a healthy amount of self-criticism, which is one of the most important assets of a scientist.

Concerning the content of your letter however, I am not the best person to write. Unfortunately I have gathered the reputation of an enthusiastic correspondent: No doubt it comes about predominantly from my having published reams of my own correspondence. In the last year alone, I count 14 unsolicited letters from people unknown to me offering either a) to derive quantum mechanics on the cheap, or b) to demonstrate that quantum mechanics is completely wrong. This is not an exaggerated number; I keep all these letters in a single folder within my email program.

What I mean by "deriving quantum mechanics on the cheap" is a magical combination of English words—very rarely an equation—that makes the whole edifice (i.e., all those equations, relations, and mathematical structures) of quantum mechanics make sense or even, all of a sudden, become obvious.

You've got to realize it is a difficult call for me. On the one hand, you might be the one who really has hit that magical combination—one that conveys an idea that has never before been conveyed, or at least, of an old idea, says it in a way that finally makes it become crystal clear and undeniable. Who am I to stifle that? On the other hand, of your letter, I can say it didn't "feel right" to me.

Now, I could give you reasons for that, but if I were to do so I would have another correspondent on my list. And that would mean more Saturdays and Sundays away from my family as I plug away on letters to another complete stranger who hasn't yet entertained me. It's harsh, but I have to make a judgment call or I would be inundated—I already am inundated! You ask is there a difference between POVMs and q-numbers somewhere in the middle of your letter, and I think, "If he couldn't get this straight from my paper, what good is more correspondence going to do?"

All I can say is, if you are confident of your work, publish it or post it on `quant-ph`. Someone will eventually take the bait and give you feedback, and if no one does, that is feedback in itself.

As I say, and I am serious about this, you strike me as a sincere person. I apologize if I have hurt your feelings, but I really can't take on another correspondent right now.

09-09-03 *The Missing Word* (to A. Plotnitsky)

The missing word was "leads."

> It is surely a significant feature of the theory that consideration of impossible outcomes and very little else leads, without any invocation of "the uncertainty principle" or "maximal information", to the fact that pure state assignments must be unique, as well as the more general constraint on mixed-state assignments.

Thanks for catching that!

09-09-03 *Nonperiodic Penrose Tiles* (to R. Schack)

Below is the transcription of the notes from our conversation. They're pretty holey—the e is pretty important at this stage, even if it might not appear in the end product.

- "On Quantum Certainty"
- Brief mention of Bayesian program.
- Penrose seems to rely on correspondence theory of certainty. (unwarranted assumption)
- If we could act "as if"—Martin Gardner—then why not the above?
- But why we can't act is because of Bell.
- Must reassess certainty.
- Draw attention to our own bad ways? A footnote. Simply say we were less noncommittal in our meaning of certainty previously.
- (emails) Objective Certainty + QM $\Longrightarrow$ Objective Probability
- (Montréal) Objective Operations $\Longrightarrow$ Objective Quantum States
- Repeat key arguments for subjectivity of states.
- Argument for subjectivity of POVM and preparation operation.
- Very careful to state(ment) what we mean by subjective judgments. It does not mean one can believe anything one wants to believe. One issue is to decide when intersubjective agreement can be had.
- Spekkens!
- What means quantum randomness? It means that if I make a pure state assignment, I am also certain that no one else has more privileged information than me. (Rüdiger's point against Gisin crew + anti-Växjö paper)
- Once one has got the concept of certainty straight, what would having an underlying instruction set add? (Rüdiger's point.)

Unfortunately, that's all I have written down. It seems like we said so much more. Also, I'm not even sure what some of the notations above mean.

09-09-03 *Warm Hearts* (to H. J. Kimble)

Thanks! I think there'll only be one more application going off soon: [. . .]
But now this

Kimble-ism 1 : *I remain a big fan of your work, including your recent manuscript that explored the question of the "quantumness" of states (even if you should be burned at the Quantum Optics stake!).*

really warmed my heart! Thanks. I'll post another paper soon on the quantumness of a Hilbert space, which I can now prove is $2/(d+1)$ for dimension d. In it I want to say some fantastical things about the Eötvös experiment ... how quantumness plays the role of mass in these new considerations. And I'll say some things along these lines in my talk at Preskill's group meeting Oct. 16. Hope you can come. (And don't miss Rob Spekkens' talk Oct. 14; it's really really really good work.)

09-09-03 *The Big Man Speaks* (to M. Sasaki)

We just got a little more positive feedback on our paper. This sentence just came from Jeff Kimble:

> I remain a big fan of your work, including your recent manuscript that explored the question of the "quantumness" of states (even if you should be burned at the Quantum Optics stake!).

Do you understand the joke? In any case, it is a compliment to us. He is saying that we should be set to fire and burned alive as religious heretics have been in the past. A stake is what people are tied to when they are burned this way. The reason he is saying this is because we said in our paper (essentially): "[Coherent states] cannot be cloned, and this holds whether the quantum optics community calls such states 'classical' or not." In other words, Fuchs and Sasaki are heretics!

09-09-03 *Feynman's Rainbow* (to M. Durrani)

Durrani-ism 1: *In the final paragraph you say: "I know that Hilbert space makes my heart flutter, but does an atom?" Do you mean that your current work (on atoms?) doesn't really interest you and that you would rather be working on Hilbert space? Or that you are glad of the field you're working in.*

Does an atom make my heart flutter? Not really. But the Hilbert spaces of quantum mechanics do. The implication is the question: Would Feynman think of me as a physicist or not? Should I think of myself as a physicist or not? In other words, this is just like the self-examination Feynman gave Mlodinow. Also, the word "self-examination" refers back to the third paragraph in the review, which is the running theme of the essay.

I read the paragraph to three guys down the hall, and they all got it. I say, let's leave it as written. Or how about this: Just to make it absolutely clear, let me change "Hilbert space" to "quantum-mechanical Hilbert space":

> Still, the book contains a nub of wisdom here and there. Near the end of it, Mlodinow tells how Feynman challenged him to think hard about the emotions he finds upon viewing an electron-microscope image of an atom. "Does it make your heart flutter?" I have found myself thinking about this all week. I know that quantum-mechanical Hilbert space makes my heart flutter, but does an atom? Sometimes the self-examinations of Caltech life are hard to leave behind.

10-09-03 *cond-mat/0309188* (to S. H. Simon)

Simonism 1: *I've heard some buzz about the quantum measurement paper* `cond-mat/0309188`*. Have you guys looked at it? Any comments?*

Well, I see I'm depicted as one of the good guys in their reference 8. Still I doubt they've absorbed what Caves, Schack and I have been writing about.

The way I approach the issue of quantum measurement is to first forget about quantum mechanics and talk about undergraduate probability theory. The textbook gives you a probability distribution $P(h,d)$ over two variables h and d. From it you can derive a marginal distribution over h alone; namely $P(h)$. Now suppose you gather an explicit piece of data d. That may be some information you can use for updating your expectations about h. The mechanism is simply to use Bayes' rule: You update from $P(h)$ to $P(h|d)$.

No big deal, right? So, let me ask you this: Might I have pulled the wool over your eyes any? In particular, shouldn't I tell you about the precise mechanism the brain uses for updating from $P(h)$ to $P(h|d)$? Shouldn't I give a physical explanation for the process? Isn't the undergraduate textbook treating the problem incompletely by not requiring that I fill in those missing steps?

I think you'd be crazy if you said "yes" to any of those things. The axiom of updating is primitive within probability theory. It calls for no physical mechanism behind it, and none should be sought.

With that out of the way, let us go back to quantum mechanics and quantum measurement. One can show formally that quantum measurement is precisely the process above—i.e., Bayes' rule in action—modulo an extra readjustment that takes into account the idea that in quantum measurements one might actually have to touch the system one is interested in (and hence cause some kind of disturbance). This is worked out in Sections 4.2, 6 and 6.1 of my paper `quant-ph/0205039`. (Have a look at it: I'll bet money—real money—that my paper is clearer than theirs.)

Anyway, from this point of view, collapse calls for no explanation in the same way that the process of updating from $P(h)$ to $P(h|d)$ calls for no explanation. In fact, you would have to give a physical explanation for latter in order to give a physical explanation for the former—i.e., you would have to give a physical mechanism for Bayes' rule itself. And we've already agreed (or at least we should have) that that would be silly.

Now concerning the paper you've asked about: They clearly think they've done something. But I'll bet, in the last analysis, they've done essentially nothing ... except lead the reader down an infinite regress that they haven't had the guts to analyze.

Anyway, that's my take after giving the paper not more than a three-minute skim. After thinking about these issues for years, one realizes that papers like this aren't so different than the latest proposal for a perpetuum mobile. It's a question of finding the flaw, and then—and this is always the hard part—convincing the authors that it is a flaw. It's almost never worth the time.

Now, my sarcasm aside: Why has there been some buzz about this paper in the community? What's been found exciting in it?

10-09-03 *Careful Reading Sir* (to D. M. Appleby)

... will be rewarded.

Thanks for the long note and the self-esteem course. I needed the latter!

And I was happy for the former too. However, I think most of the fight you fight in those pages has to do with a Chris that was too sloppy with his words in his youth.

A better Chris to fight with is the one represented in the "Me, Me, Me" note. You might think you read it carefully, but all the evidence shows that you didn't.

In particular, I would localize a good bit of your troubles in your paragraph:

Applebyism 3 : *You say somewhere that Alice has the right to assign any state she wants, just as Bob has the right to assign any state he wants. So what is to stop Bush saying he has the right* *to assign any probability he wants to the proposition "every person held at Guantanamo Bay is a terrorist murderer"?*

But how does that mesh with the following lines from "Me, Me, Me":

> The textbook poses an exercise that starts out, "Suppose a hydrogen atom is in its ground state. Calculate the expectation of . . . blah, blah, blah." One might think it is asking us to calculate some objective feature of the world. It is not. It is only asking us to carry out the logical consequences of a supposed state of belief and a supposed action that one could take upon the system. And here's the clincher about Bayesianism. Just as no student in his right mind would find it worthy to ask why the textbook writer posed the problem with the ground state rather than the first excited state, no quantum theorist should make a big to-do about it either. It is simply an assumed starting point. An agent in the thick middle of a quantum application can no more ask where he got his initial beliefs from, than a pendulum can ask where it got its initial conditions from. The cause of bottom-level initial conditions is ALWAYS left unanalyzed. If such was not a sin in Newtonian mechanics, it should not be a sin in a Bayesian formulation of quantum mechanics.

In the words of the great Marcus Appleby, "It's really hard to believe something you don't actually believe." When—long ago!—I said that Alice had the "right" to assign, I meant that there is nothing about the system itself that determines her state for it. I did not mean that she had the right to believe something she does not actually believe.

Here's another way that I've put it more recently, in a different excerpt from the same samizdat:

> Take a good solid physicist like Steven Weinberg who stakes his career on the search for a grand unified field theory. Suppose he finds it. To find it (I presume) is to declare: The world's Lagrangian is L. Now suppose I were to ask Mr. Weinberg, "Why L? Why not M?" I know for sure his answer will be of the form, "L just is. It is the starting point. It is an ultimate fact of nature; it calls for no explanation. In any case, if it calls for an explanation, its answer must come from outside the realm of science—religion? theology?—but I see no reason to go to such lengths."
>
> Would that make Weinberg a solipsist? A sensationalist? A phenomenalist? The point is Weinberg's stance has nothing to do with any of these labels.
>
> Similarly for the Bayesian (even of the de Finettian variety, despite the mumbo jumbo in the opening sections of Probabilismo). For him, "the prior" on any event space is treated as an ultimate fact—an ultimate fact about the agent. There is no infinite regress because, just as with Weinberg, ultimate facts call for no further explanation.
>
> Bayesian practice—and Rüdiger and I would claim the formal structure of quantum mechanics too—is all about what to do once a prior is established. It is not about what to do before the prior is established. In the quantum mechanical case, establishing "a prior" is 1) to write down a quantum state for all systems considered, and 2) to write down a (conditional) quantum operation for all measuring devices considered.
>
> If there are two agents, there may well be two priors in the sense above—i.e., two ultimate facts (with respect to this level of inquiry). In that sense, the priors are "subjective", but that does not take away their status as ultimate facts in this treatment. It only calls for a recognition that the facts are about the agents.
>
> The role of the separate system and measuring device—now specializing on quantum mechanics—is that when the two are combined they give "birth" to a new ultimate fact:

> The "click." There is no sense, however, in which this new ultimate fact is *about* either of the agents: It has a life of its own. (In fact, it is because of these lines of thought that I sometimes call my view "the sexual interpretation of quantum mechanics.")

Now, I will make the bold claim (because I don't have three days to spend on writing a new note), that if you look carefully at the words above and carefully back at "Me, Me, Me," you will see a lot of your other troubles melt too. For instance, look harder at the glossary. Is there not something in there that corresponds to your "a way things really are"? (Though I would prefer, "a way things really come out.") And further, notice the explicit dualism in the system/POVM definitions. I'm going to claim that that dualism saves me from being *either* an idealist or a materialist.

I believe in FACTS just as much as the next guy: Quit accusing me of not. I only stress that facts are made, they do not preexist. And it is because of this that there is no one way the world is. (The capitalization in Nagel, by the way, was all my addition.)

Finally, here are two excerpts from your note that I really, really liked. I tend to agree with the first (whether you agree with it or not) and I tend to like the sound of the second.

Applebyism 4: *One final point. You say that probability assignments float above the world (or words to that effect). This is true (on your principles) however much they are updated. Rationality resides purely in the updating procedure. The assignments themselves are never rational. Not only are they not rational at the outset, before any updating has been performed. They are no more rational at the finish, after all the evidence has come in. In short, they float. They tell us nothing at all about "the way things really are".*

and

Applebyism 5: *I am tempted to say that the ordinary human world essentially CONSISTS of probability assignments. That probability, so far from floating, is actually constitutive of the world (what we normally and humanly take to be the world).*

10-09-03 *Facts* (to D. M. Appleby)

One final thought, to complete my last note. Looking back at this passage:

Applebyism 6: *One final point. You say that probability assignments float above the world (or words to that effect). This is true (on your principles) however much they are updated. Rationality resides purely in the updating procedure. The assignments themselves are never rational. Not only are they not rational at the outset, before any updating has been performed. They are no more rational at the finish, after all the evidence has come in. In short, they float. They tell us nothing at all about "the way things really are".*

though I generally liked it, I would not use the word "evidence." Facts and data are just facts and data. To say that they are "evidence" already presupposes a (subjective) probability assignment.

11-09-03 *Peres Festschrift* (to R. Omnès)

That is too bad. If you decide to reconsider at any time, please just let me know. I think philosophy of science would be just fine. And certainly you would not have to commit to 20 pages; that was listed only so that contributors would realize that they could use this as an opportunity for a long paper if they wished. But it is not necessary.

Speaking of your philosophy of science, I was so impressed with some of the lines in one of your papers that I copied them into my computer. They are beautiful. (I'll paste them below so that you can see the ones I am speaking about.)

Things go well for me, though I could use some mathematical help!

> R. Omnès, "Consistent Interpretations of Quantum Mechanics," Rev. Mod. Phys. **64**, 339–382 (1992).
>
> Perhaps the best way to see what it is all about is to consider what would happen if a theory were able to offer a detailed mechanism for actualization. This is, after all, what the advocates of hidden variables are asking for. It would mean that everything is deeply determined. The evolution of the universe would be nothing but a long reading of its initial state. Moreover, nothing would distinguish reality from theory, the latter being an exact copy of the former. More properly, nothing would distinguish reality from logos, the time-changing from the timeless. Time itself would be an illusion, just a convenient ordering index in the theory. ... Physics is not a complete explanation of reality, which would be its insane reduction to pure unchanging mathematics. It is a *representation* of reality that does not cross the threshold of actuality. ... It is wonderful how quantum mechanics succeeds in giving such a precise and, as of now, such an encompassing description of reality, while avoiding the risk of an overdeterministic insanity. It does it because it is probabilistic in an essential way. This is not an accident, nor a blemish to be cured, since probability was found to be an intrinsic building block of logic long before reappearing as an expression of ignorance, as empirical probabilities. Moreover, and this is peculiar to quantum mechanics, theory ceases to be identical with reality at their ultimate encounter, precisely when potentiality becomes actuality. This is why one may legitimately consider that the inability of quantum mechanics to account for actuality is not a problem nor a flaw, but the best mark of its unprecedented success.

11-09-03 *Bayesian Beginnings* (to G. M. D'Ariano)

D'Ariano-ism 1 : *I really enjoyed our discussions in Aahrus on Quantum Mechanics, and when I got back to US, I careful read your long paper "Quantum Mechanics as Quantum Information (and only a little more)" published on the Proceedings of the Växjö Conference, keeping also notes for myself (something that I do with quite few papers). I should say that I completely agree with your point of view, and I was happy to see that in many considerations that I made recently, I'm not alone. You know, my school was Masanao Ozawa, and in the last years I taught quantum mechanics of measurements using the Bayes principle. However, after reading your paper I really became a strenuous Bayesian (including tomography).*

Thank you so much for your heartwarming letter. I'm really glad you got something out of my paper. I've been really enjoying your new ones on the structures of POVMs too: But I already told you that.

Yes, it would be great to visit Pavia. Maybe we could work out a good time in the Spring.

D'Ariano-ism 2 : *Sorry if I bothered you. My problem is that now I became too much involved in such re-considerations, that I can hardly think to anything different.*

You didn't bother me at all. This is what I live for! They say every parent wants a better world for their children—a better world than they themselves grew up in. This is true: I want to see a complete understanding of the structure of quantum mechanics developed before my daughters go to college.

We're going to do it!

16-09-03 *Two Typos, One Disagreement* (to A. Peres)

Two typos:

1) One day, I came into Rosen's office, and I found sorting out his papers.

2) The EPR article was not wrong, but it had be written too early.

One disagreement:

Asherism 37 : *Information is not an abstract notion. It is a physical object which requires a physical carrier, and in particular is localized.*

Let me lodge my disagreement with this language, by pasting in two old notes. [See 25-04-02 note "Short Thoughtful Reply" to C. H. Bennett and 02-02-02 note "Colleague" to C. G. Timpson.] The first explains my disagreement I think fairly well. The second is there mostly for the purpose of relating an anecdote about Landauer.

Where your language above and [Charles Bennett's] language below come closest to each other is when he talks about the "information you just ate."

17-09-03 *More Than Semantics, I Think* (to A. Peres)

Asherism 38 : *Information is not an abstract notion. It is a physical object which requires a physical carrier, and in particular is* localized.

Our disagreement is localized in your phrase (effectively) "information is a physical object." I would say the thing that we have learned from quantum information is that we cannot, even in abstracto, ignore the physical properties of information CARRIERS. That was something ignored in the original Shannon information theory. But recognizing that is a far cry from saying "information is a physical object" . . . which, to me at least, conveys the idea that information is something that can exist independently of the agent possessing it.

At the end of your article, you write: "Quantum states are not physical objects: they exist only in our imagination." True enough. But, by the view we expressed in our *Physics Today* Opinion, a quantum state is nothing beyond one's information about a system. Here's one of the ways we said it then:

> From this example, it is clear that a wavefunction is only a mathematical expression for evaluating probabilities and depends on the knowledge of whoever is doing the computing.

It seems to me that if you are going to claim that information is a physical object you will be stuck in an inherent contradiction (at least in phraseology).

17-09-03 *Went on to Organize* (to W. M. Fuchs)

Dear Mike,

I've been thinking about what I'd like to write you for your birthday. 50 is quite an important one. On the one hand, I wanted to say, "Well, you're half way there." But that would have been a lie. Life is much, much bigger than that: Even a hundred years isn't the half of it.

There's a song that's been tumbling in my head the last few days that Joan Baez sings. It's called *Joe Hill*, and it's about a labor organizer who was active in the 1910s. It's an important song. It conveys the idea that an honest and true life never dies. With every smile you give your nieces, your brothers, your sisters, your mom, your friends, your coworkers, you'll never die. With every piece of wisdom you pass on, you'll never die. Every bit of science I do stems from the starlit conversations we had in the 70s. Life propagates in a lot more ways than the material.

Keep up the good work!

Happy birthday brother,

Chris

Joe Hill

I dreamed I saw Joe Hill last night,
alive as you or me.
Says I "But Joe, you're ten years dead"
"I never died" said he,
"I never died" said he.

"The Copper Bosses killed you Joe,
they shot you Joe" says I.
"Takes more than guns to kill a man"
Says Joe "I didn't die"
Says Joe "I didn't die"

And standing there as big as life
and smiling with his eyes.
Says Joe "What they can never kill
went on to organize,
went on to organize"

From San Diego up to Maine,
in every mine and mill,
where working-men defend their rights,
it's there you'll find Joe Hill,
it's there you'll find Joe Hill!

I dreamed I saw Joe Hill last night,
alive as you or me.
Says I "But Joe, you're ten years dead"
"I never died" said he,
"I never died" said he.

18-09-03 *Instrumentalism* (to A. Peres)

After reading your new article, I looked up the word "instrumentalism" in my *Encyclopedia Britannica*. Here is what I found.

> **Instrumentalism:** also called Experimentalism, a philosophy advanced by the American philosopher John Dewey holding that what is most important in a thing or idea is its value as an instrument of action and that the truth of an idea lies in its usefulness. Dewey favoured these terms over the term pragmatism to label the philosophy on which his views of education rested. His school claimed that cognition has evolved not for speculative or metaphysical purposes but for the practical purpose of successful adjustment. Ideas are conceived as instruments for transforming the uneasiness arising from facing a problem into the satisfaction of solving it.

19-09-03 *de Finetti vs. Jaynes* (to D. Poulin)

Poulinism 11: *In thermodynamics, the hypothesis of exchangeability seems well motivated, for noninteracting systems at least. Therefore, if one was to measure a complete set of observables, one would be left with a product state of the form $(\rho \otimes \rho \otimes \rho \otimes \cdots)$, i.e. the "probability distribution over states" appearing in the de Finetti representation would have converged to a delta. But if one measures less observables, e.g. a single one, his state assignment should not be a product space unless his "prior distribution over state" has a very special form, which I wouldn't know how to justify. On the other hand, Jaynes tells us that after having measured say the average energy, our state assignment should be a product state as above with $\rho = \exp(-\beta H)$. As you know very well, this is done by maximizing the entropy given the constraint observed: the product emerges as a consequence that the systems are not interacting.*

I understand your problem, and it's a mistake a lot of people make. The main point to keep in mind is that a max-ent assignment is a SINGLE system assignment. One cannot extend it to a multi-system assignment unless one is confident that further measurements will reveal no further information useful for updating.

There is a fairly thorough discussion of this issue in `quant-ph/0010038` by Brun, Caves, and Schack, though in a different context than the one you bring up above. The substance of the issue is the same, however. The Horodecki's had made the assumption that max-ent gives a multi-system assignment and it caused them to get a nonsense result. But rather than thinking hard about where they might have gone wrong, they just plowed ahead and declared the max-ent program to be "wrong" in quantum mechanics.

A more important thing to read is Jaynes' own discussion of the issue. You can find that in reference 13 of the paper above.

Poulinism 12: *How are you? Here, things are going very well, many interesting research projects on the way. As always, I am preaching for the epistemic interpretation of quantum mechanics. Believe it or not, I have almost convinced Valentini that this is the right way to think about states.*

Now this is very interesting!! The last I remembered, you were still fairly agnostic on the issue. I'm really glad to hear of this.

I've been doing some fairly technical things lately. In particular, I've been trying to shore up my old idea that quantum mechanics looks the way it does because it is predominantly about how we should manipulate and update our information in light of the fact that quantum systems have a kind of "sensitivity to the touch." Thus I've been playing with this measure of quantumness that Sasaki and I posted on `quant-ph` a while ago. In the coming month I'll put another paper on `quant-ph` showing how the quantumness of a Hilbert space (by this measure) connects up to doing quantum mechanics on a simplex (remember the pictures I incessantly drew in Montréal?).

The deeper thing on my mind, though, has been how this "sensitivity to the touch" is universal ... in a weird analogy with gravitation. An 18 dimensional Hilbert space, for instance, does not care whether it is embedded in copper or gold. Just like a given amount of gravitational mass does not care if it is embedded in copper or gold. (I use copper and gold because I think those were the metals used in the Eötvös experiment; I should look it up.) This intrigues me to no end. I'm going to give a talk at Caltech on it in October; I wish you could be there to keep me on my toes.

Also Schack and I are finally distilling my big thing "Quantum States: What the Hell Are They?" into a single paper. The tentative title is "On Quantum Certainty." In it we'll tackle the Penrose argument head on and also how quantum operations are epistemic in exactly the same way as quantum states. Your revelation of non-agnosticism, by the way, was the second piece of good news I read today. Concerning this new paper of Schack and mine, David Mermin wrote me this:

Merminition 134: *I think we're closer than it might appear (but I doubt that it's close enough to write a joint paper about it with you and Rüdiger, much as I would enjoy doing it (and I really would, in spite of my fulminations against collaborating in "writing physics".)*

I was absolutely floored! Now that signaled progress! That he would even contemplate joining in on the project signaled that something is really going right here.

Workers of the world unite!, I say. Good hearing from you, and I hope the max-ent references given above will make the answer to your question clear—I think they will.

22-09-03 *Cosmology* (to C. H. Bennett)

Here's something I've been wanting to tell you about for a while, but I kept forgetting. Do you recall the conversation we had after our dog Wizzy died? You thought briefly that I had beat around the bush with Emma, not quite telling her the truth about the event. (I'll place the old note below in case you don't remember.)

Anyway, about six months to a year after that—I wish I could remember precisely when—Emma was hanging out in my office one day, kind of swinging back and forth with the door, and out of the blue asked, "Dad, will you die one day?" That one was a tough question: I knew I had to say yes, but I didn't want to say yes. In the end, I told her, "Yes, but you shouldn't worry about it so much; it won't happen until you're grown and have children of your own." Now, that WAS beating around the bush—of course I couldn't know when I'm going to die. Funny though how I thought the promise of having one's own children at the time would soften the blow.

The reason I'm telling you this story after all this time is because Saturday seemed to mark another, perhaps not unconnected, event in Emma's development. For the first time she asked me a cosmological question. She's about 4 and 2/3 years old now. She asked, "What was here before the dinosaurs?" I explained a little about the earth before life, and about how the earth was formed in the formation of the sun. Then she asked, "What was here before the sun?" I said, "Ah, you see the pattern: You can always ask a 'before' question, can't you?" She said, "Wow!" (Not a lie.) Then I said, "Well I don't really know to any extent what was here before the sun," deciding to skip a discussion about the big bang and all that. I guess she decided to have some fun with me because then she came back with, "You don't know what happened before the sun??!" I said, "Nope, no one does really," deciding to be metaphorical for the moment—i.e., switching the sun and the big bang in my mind. She questioned in surprise, "Not even William James?" I said, "Not even William James."

22-09-03 *More General Relativity* (to C. H. Bennett)

Bennettism 20: *Reading your paper on quantumness of a set of states, I see that you define quantumness of a set of states by pessimizing the QCQ channel's I/O fidelity over all choices of probabilities of states in the ensemble, while optimizing it over measurements and preparations of the states resp. before and after they are forced through the C part of the channel. In this sense you view a set of states as more fundamental than an ensemble. But isn't a mixed state ρ even more fundamental than either a set of states or an ensemble? What would be wrong with defining the quantumness a density operator ρ as the least expected I/O fidelity for any ensemble realizing ρ; or if that diverged, for any ensemble consisting of r linearly independent pure states, where r is the rank of ρ?*

I don't think it would diverge because the maximum eigenvalue function (which appears in a higher order expression for accessible fidelity) is a convex function. So, the definition is mathematically sensible. I just hadn't seen a motivation for a quantity like that. It kind of reminds me of a quantity that Oliver Cohen once wrote about ... just digging it up, `quant-ph/9907110`.

Actually if you want to go down a route like that, I think it is better to think of accessible fidelity as a function of an entanglement-breaking channel—it is the channel that is the fundamental thing. As Audenaert, King, Winter and I show in the other paper on quantumness, for each ensemble, one can make a channel of particular interest. However then, for any ensemble that gives rise to the same channel, one gets the same accessible fidelity.

In any case, what I'm most interested in at the moment is the quantity I called "quantumness of a Hilbert space." I can now prove that it is numerically equal to $2/(d+1)$, and that to achieve that value on a tensor-product Hilbert space one must use an ensemble of entangled states. I'm writing that paper right now.

What intrigues me most is the universality of some of these concepts like quantumness (as a potential characterization of Hilbert space itself). I guess you've been saying something similar for a lot of years, talking about the fungibility of quantum information, but it had never really taken me until I started thinking about analogies with general relativity. Here's the way I put it to David Poulin the other day:

> The deeper thing on my mind, though, has been how this "sensitivity to the touch" is universal ... in a weird analogy with gravitation. An 18 dimensional Hilbert space, for instance, does not care whether it is embedded in copper or gold. Just like a given amount of gravitational mass does not care if it is embedded in copper or gold. (I use copper and gold because I think those were the metals used in the Eötvös experiment; I should look it up.) This intrigues me to no end. I'm going to give a talk at Caltech on it in October; I wish you could be there to keep me on my toes.

If you were there, maybe I'd be dancing a ballet!

22-09-03 *Lockbox Louder* (to J. A. Smolin)

Attached are my remarks. They're almost all trivial and about presentation.

I enjoyed the paper a lot. In fact, once you touch the paper up, I wouldn't mind reading it again. I was particularly taken with your real toy model: Mainly by just how much it resembles an EPR pair ... or correlation without correlata as David Mermin would say. (Well, the correlata are there but completely hidden—they almost might as well not be there.) That is intriguing.

I'm sure I did a lot of things to the draft that will annoy you. Certainly feel free to ignore any and everything you wish.

John Smolinism 6: *A* lockbox*, the basic unit of matter in this theory, is an object akin to a physical box locked with a combination lock, which can contain a bit value b. The value cannot be read out of the lockbox except if a particular string of bits C—the combination—is presented to it. The bit b and combination C are chosen by the lockbox's creator at the time of its creation. If the lockbox is presented with an incorrect combination, the bit value is destroyed. This box need not be allowed by physics, it is instead the building block of the toy theory.*

Such a box cannot exist in classical mechanics. It is often said that one way in which quantum mechanics differs from classical mechanics is that it cannot be represented by a local hidden variable theory. This statement hides a common oversight about classical mechanics. Classical mechanics also is not correctly represented by a local hidden variable theory, but by a local unhidden *variable theory—in principle every possible property of a classical system can be measured perfectly.*

You might cite the "nonlocality without entanglement" paper here. Apparently also, Bell himself somewhere along the way made this distinction. There's a nice discussion of it in Marcus Appleby's paper `quant-ph/0308114`, pages 14–16. Why don't you cite him too? He, or Bell, called them "exposed variables" interpretations.

John Smolinism 7: *Thus a lockbox explicitly mimics the quantum property that unknown non-orthogonal states cannot be cloned (copied) or even measured without disturbance.*

Have I ever told you how much I hate it that physicists have taken it upon themselves to start a new rule in English: Thou shalt hyphenate all words beginning with the prefix non. And they do this in spite the fact that almost every dictionary writes nonabsorbent, nonabsorptive, nonadaptive, nonaddictive, nonadhesive, nonadjacent, nonadsorbent, nonadsorptive, nonaged, nonagenarian, nonaggressive, nonalcoholic, nonaligned, nonappointive, nonarbitrable, nonarbitrary, nonarboreal, nonassertive, nonassociative, nonastringent, nonautonomous, noncitizen, noncombatant, noncommissioned, noncompliance, nonconductor, nonconformance, nonconformist, nonconformity, nondepository, nondescript, nondevelopment, nondirectional, nondiscretionary, nondisjunction, nondrinker, nondriver, nonentity, nonequivalence, nonessential, nonevent, nonexistence, nonfat, nonfeasance, nonfiction, nonfictional, nonflowering, nonfluent, nongonococcal, nonindulgence, noninterference, nonintervention, nonlinear, nonmalignant, nonmember, nonmetal, nonobservance, nonoccurrence, nonparametric, nonparticipant, nonparticipation, nonparticulate, nonpartisanship, nonpayment, nonperformance, nonrapid, nonreader, nonreligious, nonremittal, nonresistance, ... This is a habit that has got to be squashed.

John Smolinism 8: *It is straightforward to implement secure key distribution using lockboxes. As in quantum key distribution, Alice and Bob are assumed to share an ordinary classical channel, which is unjammable and authenticated, and to have the ability to create and send states, in this case lockboxes, to each other.*

We've had this discussion before: One sends systems not states. There is a difference in my eyes and an important difference. One never speaks of sending the color red. One never speaks of sending happy down the channel. Lockboxes are not states, but systems.

22-09-03 *A Thought of You* (to A. Shimony)

I thought of you when I wrote a little story about my daughter Emma and cosmology to Charlie Bennett earlier this morning. In particular, I was thinking about how you wrote me this:

Shimonyism 3: *Another bridge is our common admiration of the pragmatic tradition in American philosophy. You love William James, and I have respect for James but reverence for Charles S. Peirce.*

Clearly, you and Emma have attuned to the same vibe!

I'll attach the story (for your enjoyment) and the previous obituary of our dog Wizzy (so you'll understand the complete context). Everything below is copied in reverse chronological order. [See 22-09-03 note titled "Cosmology" to C. H. Bennett, 17-02-02 note titled "The Process" to C. H. Bennett, and 16-02-02 announcement titled "Some Things Should Not Pass".]

No need to reply. I was just thinking of you.

Abner's Reply

> Thank you for the beautiful letter concerning Wizzy and Emma. I was very moved by your conversation with her, both with her questions and remarks and with your psychological difficulties in telling her some painful truths. You were certainly right to meet her fear of your death by the supposition that she would have children of her own. Why not share with your child the thoughts that give you the most consolation – namely, that something you care infinitely for will live after you? Most of all you care for your daughter living after you, but why not generalize somewhat and tell her that you care very much that there will be a better world following you. Even a small child can understand the idea of a surrogate for immortality in the continuation of things one is devoted to. I feel that my sons have internalized this idea, and I hope that it helped them when they lost their mother eight years ago.
>
> Her elevation of William James to the status of prophet is both amusing and inspiring.

23-09-03 *The Trivial Nontrivial* (to S. Savitt)

Savittism 6: *Secondly, I realized (as I had not before) that a good way to think about the issue I'm currently struggling with (in philosophy of time, of course) would be to see it as trying to reconcile subjective (or, at least, perspectival) and objective views of time. So, I am using that slender excuse to send you a copy of my paper-in-progress. If you do look at it, you won't see the connection till you get to the second half, the constructive argument.*

Well, I tried to give your paper a shot over the weekend, but it was pretty tough going for me. At times like this, I really feel the lack of a philosophical training! It can be a real impediment. Probably the best critique I could muster for you would be to point out two typos ("Temporal Ontolgy" and "simpliciter, on might say") and tell you to take away the hyphens behind your nons. (Except for possibly "non-usual," which is a non-usual word anyway.)

More seriously, I wonder if you could help me classify the view of George Herbert Mead presented in his little book *The Philosophy of the Present*? For the moment it strikes me as neither a species of presentism nor a species of eternalism (to the extent that either of those terms are coherent, or more to the point, to the extent that Mead is coherent!). I'll attach a copy of a passage I scanned out of Arthur Murphy's introduction to the book; I just happen to have it in my computer (for my "Resource Material for a Paulian-Wheelerish Conception of Nature" project)—you've probably long since forgotten about Mead.

Weirdly I'm starting to take this view more seriously than I had before—even though I have previously used a version of it via John Wheeler's slogan "the past exists only insofar as it is recorded in the present" for dramatic purposes. (See the "Postpartum" chapter, pp. 680–681, at the end of my samizdat.)

Of course, the reason I'm taking it weirdly seriously has to do with quantum measurement theory. It has to do with the Bayesian updating I wrote you about previously. One of the things I emphasized there is that quantum updating (upon the recognition of a measurement result) can be viewed as Bayes' rule simpliciter—thanks for teaching me that word—as long as the quantum system whose quantum state is being updated is causally disconnected from the measurement action. That is true. One thing I did not emphasize, however, is the nature of the argument, x, for such a probability function, $P(x)$—i.e., the one we are talking about using Bayesian conditionalization upon.

The value of the random variable x cannot be viewed as a pre-existent fact of which we are ignorant. Rather it must be viewed as a potential consequence of our actions (i.e., measurements, in older language). Our ignorance is about what will be the actual consequence of our actions, not about what is pre-existent. Well, the same holds true when we are using the outcomes of our quantum measurements here and now for updating our quantum states for something there and then. The updating does not update our ignorance of what was existent there and then, but rather updates our predictability of what would come about *were* we to interact with that system there and then. Unfortunately, the latter we cannot do. The best we can do is to wait for the system to move into our present and interact with it then.

I think this is an important point. Let me try to put it another way: Our quantum measurements in the present never tell us about the past. They only tell us about the consequences of the past for any of our other measurements in the present.

I wish I could put it more clearly than that, but that's the best I can do for now. Despite first appearances, I don't think this is a species of presentism: It does not say "only things in the present exist" (unless it is going to be in your non-usual way). It just says, the quantum states I write down are always ultimately about the present: They gauge my expectations for what *would* happen as a consequence of my reaching out and touching my systems *now*.

Maybe I'll let it go at that for the moment.

From: "Introduction" to George Herbert Mead's *The Philosophy of the Present*,
by Arthur E. Murphy

> The present is to be taken as the locus of reality. This means, I take it, that to consider anything as real is to consider it as existing in, or in relation to, a present. Now what, in relation to any present, is the status of its past? This is not to ask what it was when it was present, for then it was not past and did not stand in that relation by virtue of which it acquires the status of pastness. The past of an event is not just an antecedent present. This is Mr. Mead's main thesis throughout, but it does not often get as clearly expressed as in the following statement. "When one recalls his boyhood days he cannot get into them as he then was, without their relationship to what he has become; and if he could, that is, if he could reproduce the experience as it then took place, he could not use it, for this would involve his not being in the present within which that use must take place. A string of presents conceivably existing as presents would not constitute a past."

The distinctive character of the past in its relation to the present is manifestly that of irrevocability. As conditioning the present, as making its occurrence possible, the past must have been of a determinate character. It expresses the settled condition to which the present must conform and without which it could not have been what it is. And this means not merely antecedent occurrence, it means causal determination or, as Mr. Mead tends to put it, the "carrying on of relations." The past is that out of which the present has arisen and irreversibility—the appeal might here have been made to Kant—has its critical value in terms of such conditioning.

Yet this carrying on of identical relations is never the whole story. The doctrine of emergence asks us to believe that the present is always in some sense novel, abrupt, something which is not completely determined by the past out of which it arose. A present, if it is really new at all, will have in it an element of temporal and causal discontinuity. Recent quantum physics has taught us to believe that such indetermination is quite consistent with rigorous physical analysis. But how is it possible to reconcile this novelty with scientific determinism?

The answer to this question supplies the basic principles of the theory. Before the emergent has occurred, and at the moment of its occurrence, it does not follow from the past. That past relative to which it was novel cannot be made to contain it. But after it has occurred we endeavor to reconstruct experience in terms of it, we alter our interpretation and try to conceive a past from which the recalcitrant element does follow and thus to eliminate the discontinuous aspect of its present status. Its abruptness is then removed by a new standpoint, a new set of laws, from which the conditions of our new present can be understood. These laws could not have been a part of any previous past, for in the presents with relation to which those pasts existed there was no such emergent element. To assume a single determinate past to which every present must wholly conform is to deny emergence altogether. But at the same time, to treat the emergent as a permanently alien and irrational element is to leave it a sheer mystery. It can be rationalized after the fact, in a new present, and in the past of that present it follows from antecedent conditions, where previously it did not follow at all. As the condition of the present, the past, then, will vary as the present varies, and new pasts will "arise behind us" in the course of evolution as each present "marks out and in a sense selects what has made its own peculiarity possible."

Is there any contradiction between this novelty of the past and its essential irrevocability? None at all, for the two apply in different senses. The irrevocable past is the past of any given present, that which accounts for its occurrence. Its determining conditions will be ideally if not actually fully determinable in the present to which it is relative. But when a new present has arisen, with emergent facts which were really not contained in the former present, its determining conditions, hence its past, will of necessity be different. The determinism then holds of the past implied in any present, the emergence in the relation of one such present, with its past, to another.

This hypothesis, in Mr. Mead's opinion, has two main advantages. In the first place it accounts for the attitude of the research scientist toward the data he is describing, an attitude otherwise highly paradoxical. The laws of any science do in a sense reconstruct the past out of which its given elements have arisen. So much is assumed in the establishment of determinate laws, and for the scientist to suppose that the present did not follow from the past in terms of the laws he had established would be to deny their adequacy to the data they interpret. So far as it goes in any field science tends to be deterministic. Yet this "following" of present from past is wholly relative to the data on which the interpretation is based, and the scientist looks forward with equanimity to a new interpretation, and hence a new past, relative to the emergent data which the future will supply. And this combination of relative determinism and future reconstruction which holds for the research scientist, holds also, on this theory, for the nature he is describing.

Secondly, this view is in harmony with the emergence of novelty in experience, and the reorganization of experience in terms of it. This is the theme of the first Supplementary Essay. Even those who "bifurcate" nature most relentlessly must admit that in experience data may appear as intrusive elements in a world which has, in its present constitution, no place for them. They stand in contradiction to that world as currently interpreted and set a problem for reconstruction. To interpret the world exclusively in terms of the conditioning objects which a given period has isolated as the permanent background of becoming is to relegate novelty to a merely subjective experience. But in the case of data relevant to his own problems a scientist makes no such bifurcation. Rather does he treat the data as provisionally isolated in a world that does not now account for them, but as candidates for admission to a reconstituted world which may make the facts previously rejected the very center of its interpretation. So it was, for example, in the status of the Michelson-Morley experiment, first in its relation to classical mechanics, then in the theory of relativity. Within experience new objects are continually arising and a new present reorients the settled conditions of an older era in the light of its discoveries. And if the past is this orientation of settled conditions with respect to present data, the past does empirically change as evolution proceeds. This empirical description has been a part of Mr. Mead's philosophy for many years. The novelty of the present account arises from its correlation with the structure of temporal reality as such, in the relation of a determining past to an emergent present.

At this point the reader will be all too likely to object that it is clearly only our viewpoint or interpretation of the past that has altered here. The past in itself has surely not been changed by the new way in which we have come to look at it. This however is just the distinction that Mr. Mead's whole analysis attempts to supersede. For a temporalist philosophy the past "in itself" is not a past at all—its relation to the present is the ground of its pastness. And this relation is empirically a causal one. If becoming is real that causal relation is never such as to exclude emergence. When emergence occurs a new perspective of the past, a new relatedness, will ensue—a relatedness which is a natural fact about the new situation, though it could never have occurred in the old. And what is here new is precisely the way in which what, in the older present, was merely novel and abrupt has become a part of the world of causal objects, hence a part of the past through which they are supposed to operate. The relatedness is real, and the perspective past it generates, the past of the new present, is the real past of that present, and only for a present can the past be real at all.

Mr. Mead's most objective version of his thesis occurs in Chapter Two, in the contrast between the past as relative to a present and the past as absolute. He holds, especially in criticizing Alexander, that the past which physics requires is simply the expression of identical relations in nature, not an antecedent environment, existing in itself and giving rise, in its isolated being, to all subsequent reality. Space-Time in Alexander's metaphysic, seems to be a mathematical structure taken out of relation to the physical data it interprets and transformed, in all its abstract independence, into a metaphysical matrix from which all the complexities of nature are somehow to be derived. This, on Mead's view, is just what the past "in itself" would be, a conditioning phase of natural process turned into a metaphysical substance. The search for such a substance is not ruled out for those whom it may concern. But the research scientist cares for none of these things.

We seem, then, to have discovered in temporal transition itself a unique sort of relativity, and a set of what we are now to describe as "temporal perspectives" or "systems." Each such system is distinguished by the temporal center from which its relation to past events is organized, and they differ primarily in this, that what is external, contingent, hence "emergent" for one such standpoint will "follow from" and hence be reflected in the past of another. How are such perspectives related, and how does the transition from one to another take place? The answer can be given only when we have inquired into the nature of relativity, and into its social implications.

and

The argument returns at the end, as it should, to its point of departure. It is in a present that emergent sociality occurs. And we can now see that such a present is no mere moment of time, arbitrarily cut out from an otherwise uniform "passage of nature." A present is a unit of natural becoming; it is the period within which something temporally real can happen. What has been and what may be have their focus and actualization in a present standpoint and it is from such a standpoint that creative intelligence, transforming the novelty of emergence and the fatality of mere repetition into a measure at least of meaningful development, brings to articulate and self-conscious expression the pervasive form of natural process. It is as the scene of such process that the present is the locus of reality.

So original a hypothesis will naturally raise doubts and generate formidable problems.

24-09-03 *The Helping Hand* (to R. W. Spekkens)

Spekkensism 20: *This allegory is especially apt for the situation in a toy theory universe, but it misses part of what is going on in quantum theory, specifically, the contextuality of quantum theory: the involvement of the observer in what is observed. My sense is that contextuality is telling us that we need to abandon part of the traditional conceptual framework of the realist, specifically, the notion of a primary quality. This notion dates back at least to Galileo and was refined after the advent of Newtonian mechanics by John Locke. It is meant to be a quality that is inherent to a system and independent of its relation to an observer. I think that many of Berkeley's criticisms of this notion are valid, but whereas his idealism seems to me to have little content or guidance for a theoretical physicist, the relationalism espoused by Leibniz may be a useful conceptual alternative. My hope is that if one takes seriously the idea that the paradigm of systems and properties should be replaced by some sort of paradigm of relations and relations among relations, then the quantum state will be found to have a natural interpretation as a state of knowledge about these relations.*

Quantum theory is whispering something important to us, and these vague ideas are the best I have come up with so far in trying to make out the subject of the conversation.

I was reading a book as I was walking home the other day, as is my habit here in Dublin, trying to avoid running into street lamps, etc., when I came across a passage that seemed perfect for this desire of yours. It was actually something I had read before but never thought to bring up to you.

Anyway, I scanned the passage in this morning and will attach it as a PDF file to this note. Let me know if it helps you articulate what you're trying to get at.

For myself, it still doesn't feel sexual enough, but I have to admit it feels like a move in the right direction. It'll be interesting to hear your reaction.

> **NOTE**: The following passage was taken from Richard Rorty's article "A World without Substances or Essences"—pp. 47–71 in R. Rorty, *Philosophy and Social Hope* (Penguin, London, 1999)—but it is *not* copied verbatim. In particular, I have removed all instances of the words "Dewey," "James," "Peirce," "pragmatism," "human purpose," and a few other words of the same ilk. Also I deleted some whole sentences and paragraphs and, at least once, substituted the word "antiessentialist" for "pragmatist." The goal was to see how the passage would be received with such an ever so slightly different slant. Of course, I didn't reveal this to Spekkens at the time; I revealed it only after the experiment was complete.

We need to break down the distinction between intrinsic and extrinsic—between the inner core of X and a peripheral area of X which is constituted by the fact that X stands in certain relations to the other items which make up the universe. The attempt to break down this distinction is what I call antiessentialism. For antiessentialists, there is no such thing as a nonrelational feature of X, any more than there is such a thing as the intrinsic nature, the essence, of X.

In the rest of this essay I shall be trying to sketch how things look when described in antiessentialist terms. I hope to show that such terms are more useful than terminologies which presuppose 'the whole brood and nest of dualisms' which we inherit from the Greeks. The panrelationalism I advocate is summed up in the suggestion that we think of everything as if it were a *number*.

The nice thing about numbers, from my point of view, is simply that it is very hard to think of them as having intrinsic natures, as having an essential core surrounded by a penumbra of accidental relationships. Numbers are an admirable example of something which it is difficult to describe in essentialist language.

To see my point, ask what the essence of the number 17 is—what it is *in itself*, apart from its relationships to other numbers. What is wanted is a description of 17 which is different in kind from the following descriptions: less than 22, more than 8, the sum of 6 and 11, the square root of 289, the square of 4.123105, the difference between 1,678,922 and 1,678,905. The tiresome thing about all *these* descriptions is that none of them seems to get closer to the number 17 than do any of the others. Equally tiresomely, there are obviously an infinite number of other descriptions which you could offer of 17, all of which would be equally 'accidental' and 'extrinsic'. None of these descriptions seems to give you a clue to the intrinsic seventeenness of 17—the unique feature which makes it the very number that it is. For your choice among these descriptions is obviously a matter of what purpose you have in mind—the particular situation which caused you to think of the number 17 in the first place.

If we want to be essentialist about the number 17, we have to say, in philosophical jargon, that *all* its infinitely many different relations to infinitely many other numbers are *internal* relations—that is, that none of these relations could be different without the number 17 being different. So there seems to be no way to define the essence of seventeenhood short of finding some mechanism for generating *all* the true descriptions of 17, specifying all its relations to *all* the other numbers. Mathematicians can in fact produce such a mechanism by axiomatizing arithmetic, or by reducing numbers to sets and axiomatizing set theory. But if the mathematician then points to his neat little batch of axioms and says, 'Behold the essence of 17!' we feel gypped. There is nothing very seventeenish about those axioms, for they are equally the essence of 1, or 2, of 289, and of 1,678,922.

I conclude that, whatever sorts of things may have intrinsic natures, numbers do not—that it simply does not pay to be an essentialist about numbers. We antiessentialists would like to convince you that it also does not pay to be essentialist about tables, stars, electrons, human beings, or anything else. We suggest that you think of all such objects as resembling numbers in the following respect: there is nothing to be known about them except an initially large, and forever expandable, web of relations to other objects. Everything that can serve as the term of a relation can be dissolved into another set of relations, and so on forever. There are, so to speak, relations all the way down, all the way up, and all the way out in every direction: you never reach something which is not just one more nexus of relations. The system of natural numbers is a good model of the universe because in that system it is obvious, and obviously harmless, that there are no terms of relations which are not simply clusters of further relations.

To say that relations go all the way down is a corollary of psychological nominalism: of the doctrine that there is nothing to be known about anything save what is stated in sentences describing it. For every sentence about an object is an explicit or implicit description of its relation to one or more other objects. So if there is no knowledge by acquaintance, no knowledge which does not take the form of a sentential attitude, then there is nothing to be known about anything save its relations to other things. To insist that there is a difference between a nonrelational *ordo essendi* and a relational *ordo cognoscendi* is, inevitably, to recreate the Kantian Thing-in-Itself.

For psychological nominalists, no description of an object is more a description of the 'real', as opposed to the 'apparent', object than any other, nor are any of them descriptions of, so to speak, the object's relation to itself—of its identity with its own essence. Some of them are, to be sure, better descriptions than others. But this betterness is a matter of being more useful tools—tools which accomplish some purpose better than do competing descriptions. All these purposes are, from a philosophical as opposed to a practical point of view, on a par. There is no over-riding purpose which takes precedence.

Common sense—or at least Western common sense—has trouble with the claim that numbers are good models for objects in general because it seems counterintuitive to say that physical, spatiotemporal objects dissolve into webs of relations in the way that numbers do. When numbers are analyzed away into relations to other numbers, nobody mourns the loss of their substantial, independent, autonomous reality. But things are different with tables and stars and electrons. Here common sense is inclined to stick in its toes and say that you cannot have relations without things to be related. If there were not a hard, substantial autonomous table to stand in relation to, e.g., you and me and the chair, or to be constituted, out of hard, substantial, elementary particles, there would be nothing to get related and so no relations. There is, common sense insists, a difference between relations and the things that get related, and philosophy cannot break that distinction down.

The antiessentialist reply to this bit of common sense is pretty much the one Berkeley made to Locke's attempt to distinguish primary from secondary qualities. The contemporary, linguistified form of Berkeley's reply is: All that we know about this hard, substantial table—about the thing that gets related as opposed to its relations—is that certain sentences are true of it. It is that of which the following statements are true: It is rectangular, it is brown, it is ugly, made out of a tree, smaller than a house, larger than a mouse, less luminous than a star, and so on and on. There is nothing to be known about an object except what sentences are true of it. The antiessentialist's argument thus comes down to saying that since all sentences can do is relate objects to one another, every sentence which describes an object will, implicitly or explicitly, attribute a relational property to it.[72] We antiessentialists try to substitute the picture of language as a way of hooking objects up to one another for the picture of language as a veil interposed between us and objects.

Essentialists typically rejoin, at this point, that psychological nominalism is a mistake, that we should retrieve what was true in empiricism, and not admit that language provides our only cognitive access to objects. They suggest that we must have some prelinguistic knowledge of objects, knowledge that cannot be caught in language. This knowledge, they say, is what prevents the table or the number or the human being from being what they call a 'mere linguistic construct'. To illustrate what he means by non-linguistic knowledge, the essentialist, at this point in the argument, usually bangs his hand on the table and flinches. He thereby hopes to demonstrate that he has acquired a bit of knowledge, and a kind of intimacy with the table, which escapes the reach of language. He claims that that knowledge of the table's *intrinsic causal powers*, its sheer brute *thereness*, keeps him in touch with reality in a way in which the antiessentialist is not.

Unfazed by this suggestion that he is out of touch, the antiessentialist reiterates that if you want to know what the table really, intrinsically, is, the best answer you are going to get is 'that of which the following statements are true: it is brown, ugly, painful to banging heads, capable of being stumbled over, made of atoms, and so on and on'. The painfulness, the solidity, and the causal powers of the table are on all fours with its brownness and its ugliness. Just as you do not get on more intimate terms with the number 17 by discovering its square root, you do not get on more intimate terms with the table, closer to its intrinsic nature, by hitting it than by looking at it or talking about it. All that hitting it, or decomposing it into atoms, does is to enable you to relate it to a few more things. It does not take you out of language into fact, or out of appearance into reality, or out of a remote and disinterested relationship into more immediate and intense relationship.

The point of this little exchange is, once again, that the antiessentialist denies that there is a way to pick out an object from the rest of the universe *except* as the object of which a certain set of sentences are true. With Wittgenstein, he says that ostension only works against the backdrop of a linguistic practice, and that the self-identity of the thing picked out is itself description-relative.[73] Antiessentialists think that the

[72]The properties usually called 'nonrelational' (e.g., 'red', as opposed to 'on the left-hand side') are treated by psychological nominalists as properties signified by predicates which are, for some purpose or another, being treated as primitive. But the primitiveness of a predicate is not intrinsic to the predicate; it is relative to a way of teaching, or otherwise exhibiting, a use of the predicate. The putative nonrelationality of a property signified by a predicate is relative to a certain way of describing a certain range of objects having the predicate. One way of putting the lessons taught by both Saussure and Wittgenstein is to say that no predicate is intrinsically primitive.

For a firm statement, of the contrasting view, see John Searle, *The Rediscovery of the Mind* (Cambridge, Mass.: MIT Press, 1992), p. 211.

[73]On the fundamental importance of this latter Wittgensteinian point, see Barry Allen, *Truth in Philosophy*

distinction between things related and relations is just an alternative way of making the distinction between what we are talking about and what we say about it. The latter distinction is, as Whitehead said, just a hypostatization of the relation between linguistic subject and linguistic predicate.[74]

Just as the utterance of a noun conveys no information to people who are unfamiliar with adjectives and verbs, so there is no way to convey information except by relating something to something else. Only in the context of a sentence, as Frege told us, does a word have meaning. But that means that there is no way of getting behind language to some more immediate nonlinguistic form of acquaintance with what we are talking about. Only when linked up with some other parts of speech does a noun have a use, and only as the term of a relation is an object an object of knowledge. There is no knowledge of the subject without knowledge of what sentences referring to it are true, just as there is no knowledge of a number without knowledge of its relations to other numbers.

Our sense that we can know a thing without knowing its relations to other things is explained away by antiessentialist philosophers as a reflection of the difference between being certain about some familiar, taken-for-granted, obvious relations in which the thing stands and being uncertain about its other relations. Seventeen, for example, starts out by being the sum of 17 ones, the number between 16 and 18, and so on. Enough such familiar statements, and we begin to think of 17 as a thing waiting to get related to other things. When we are told that 17 is also the difference between 1,678,922 and 1,678,905 we feel that we have learned about a rather remote, inessential, connection between it and something else, rather than more about 17 *itself*. But when pressed we have to admit that the relation between 17 and 1,678,922 is no more or less intrinsic than that between 16 and 17. For, in the case of numbers, there is no clear sense to be given to term 'intrinsic'. We do not really want to say that 17, in the secret depths of its heart, *feels* closer to 16 than to numbers further down the line.

Antiessentialists suggest that we also brush aside the question of whether the hardness of the table is more intrinsic to the table than its color, or whether the atomic constitution of the star Polaris is more intrinsic to it than its location in a constellation. The question of whether there really are such things as constellations, or whether they are merely illusions produced by the fact that we cannot visually distinguish the distance of stars, strikes antiessentialists as being as bad as the question of whether there really are such things as moral values, or whether they are merely projections of human wishes. They suggest we brush aside all questions about where the thing stops and its relations begin, all questions about where its intrinsic nature starts and its external relations begin, all questions about where its essential core ends and its accidental periphery begins. Antiessentialists like to ask, with Wittgenstein, whether a chessboard is *really* one thing or 64 things. To ask that question, they think, is to expose its foolishness—its lack of any interesting point. Questions which have a point

(Cambridge, Mass.: Harvard University Press, 1993).

[74]It is useful to think of this Whiteheadian criticism of Aristotle (a criticism found in other early twentieth-century philosophers—e.g., Russell—who tried to formulate a non subject-predicate logic) as paralleling Derrida's criticism of logocentrism. Derrida's picture of a word as a node in an infinitely flexible web of relationships with other words is obviously reminiscent of Whitehead's account, in *Process and Reality*, of every actual occasion as constituted by relations to all other actual occasions. My hunch is that the twentieth century will be seen by historians of philosophy as the period in which a kind of neo-Leibnizian panrelationalism was developed in various different idioms—a panrelationism which restates Leibniz's point that each monad is nothing but all the other monads seen from a certain perspective, each substance nothing but its relations to all the other substances.

are those which meet the requirement that any difference must make a difference.

The residual essentialism of common sense may rejoin to all this that antiessentialism is a sort of linguistic idealism: a way of suggesting that there was really nothing there to be talked about before people began talking—that objects are artifacts of language. But this rejoinder is a confusion between the question, 'How do we pick out objects?' and, 'Do objects antedate being picked out by us?' The antiessentialist has no doubt that there were trees and stars long before there were statements about trees and stars. But the fact of antecedent existence is of no use in giving sense to the question, 'What are trees and stars apart from their relations to other things—apart from our statements about them?' Nor is it of any help in giving sense to the sceptic's claim that trees and stars have non-relational, intrinsic, essences which may, alas, be beyond our ken. If that claim is to have a clear meaning, we have to be able to say something more about *what* is beyond our ken, what we are deprived of. Otherwise, we are stuck with Kant's unknowable Thing-in-Itself. From the antiessentialist's point of view, the Kantian lament that we are for ever trapped behind the veil of subjectivity is merely the pointless, because tautologous, claim that something we define as being beyond our knowledge is, alas, beyond our knowledge.

The essentialist's picture of the relation between language and world drives him back on the claim that the world is identifiable independently of language. This is why he has to insist that the world is initially known to us through a kind of nonlinguistic encounter—through banging into it, or letting it bounce some photons off our retinas. This initial encounter is an encounter with the very world itself—the world as it intrinsically is. When we try to recapture what we learned in this encounter in language, however, we are frustrated by the fact that the sentences of our language merely relate things to other things. The sentences, 'This is brown', or 'This is square', or 'This is hard', tell us something about how our nervous system deals with stimuli emanating from the neighborhood of the object. Sentences like, 'It is located at the following space-time coordinates' are, even more obviously, sentences which tell us about what the essentialist mournfully calls 'merely relational, merely accidental, properties'.

Rob's Reply

Sorry I didn't respond to your last email sooner. I really enjoyed the excerpt on relationalism. This is definitely along the lines I've been thinking. We will have to discuss this at Caltech.

For now, I have a more mundane question. [...]

25-09-03 *The Immediate* (to M. Pérez-Suárez)

I am intrigued by your proposal, but I am also a little frightened by your proposal. A student—especially one in a foreign land far away from his home for any length of time—can be an immense responsibility. I'll try to indicate the sorts of thoughts on my mind, by attaching a letter I wrote to (an undergraduate) Gabe Plunk when he inquired about working with me one summer. [See 26-02-02 note "A Tired Old Man" to G. Plunk.]

Do you feel of yourself that you can fulfill the criteria I laid out for him? Also, do you think of yourself that you can skirt the worries I expressed to David Mermin? Beyond that, what I think *the* program (i.e., the Bayesian quantum information program) *needs* is tireless criticism from withinside—that is the only way it will ever achieve consistency. Do you think you could fulfill that role? The last thing the program needs is a "yes man" who will take much of it on faith.

Think a little bit about it and write me back.

26-09-03 *The Austin Interpretation of Quantum Mechanics* (to A. Fine)

Chris Timpson (a grad student in the philosophy of science at Oxford) brought up the idea of suggesting a 'Quantum Information and Foundations' symposium at the Philosophy of Science Association meeting in Austin, Texas in November 2004. I think that's an absolutely great idea. Would you be interested in throwing in with us on this? (Or maybe just him, if I myself don't have the time.) In any case, do you have any advice on the matter?

I'm picking on you because I read somewhere that you had been a president of the PSA, and also I noticed you seemed to have a developing interest in quantum information.

Here's a link Timpson gave me to look at:

`http://web.archive.org/web/20040511031253/http://`
`www.temple.edu/psa2004/Call_for_Symposia_and_Workshops.htm`

There's evidence that someone on the program committee might already find this an interesting idea.

28-09-03 *PI Workshop on QC-QI-QG* (to F. Girelli & E. R. Livine)

The idea of the meeting sounds great. You can count on my being there; just give me the exact dates as soon as you can. In the meantime, I've marked my calendar tentatively for February 25 through March 3. Strangely enough, lately my work in quantum cryptography has been showing a significant analogy between (finite) Hilbert-space dimension and gravitational mass; I'll be posting a paper on the subject on the LANL archive in the coming month. I have this little desire that it's more than just an analogy, though that's probably just a wild thought. Anyway, the meeting will be a good opportunity for me to get some feedback on this stuff (outside my usual circles).

28-09-03 *Rainy Dublin* (to A. Fine)

Thanks for the reply; I've forwarded it on to Chris Timpson. It'll be nice if something gets organized: I think the time is definitely ripe.

Fine-ism 1: *I see you are in Dublin. Never been there. Is it nice?*

I like Dublin a lot. The people are about the friendliest in the world, and the population in general is quite educated (in comparison with America's). For instance, it's quite easy to strike up an *interesting* conversation with a taxi driver. Not a lie: Three times now, I've met taxi drivers who knew something about quantum cryptography or quantum computing (at the level of *Scientific American* sort of stuff).

But boy does it rain here: Seattle ain't got nothin' on us!

29-09-03 *Equiangular Lines* (to H. König)

I am a physicist at Bell Labs, and I have been working on a problem in quantum measurement theory that requires me to construct d^2 equiangular lines in a complex vector space of dimension d. By this I mean, can one find d^2 unit vectors x_k such that $|(x_k, x_l)|^2 = 1/d$ whenever $k \neq l$? It seems to be a much more difficult problem than I had initially suspected.

Anyway, in searching on the subject, I came across your paper "Aspects of the Isometric Theory of Banach Spaces" with Alexander Koldobsky. Just preceding your Proposition 18—if I understand you correctly—you seem to say that such sets have only been found in dimensions 2, 3, and 8.

Does that remain the state of the art? Also, can you give me a reference for where to find that result? (I could not find a direct reference to it in your paper.) I have been able to work out the $d = 2$ and 3 cases myself, but I would be interested to see the $d = 8$ case. Finally, do you know if this is a problem with a long history? Is it a well-known difficult problem and maybe I shouldn't spend too much time on it? (I.e., I am not a mathematician, and don't want fool myself if the problem will not be reasonably within my reach.)

Thank you for any help you can give.

H. König's Reply

> It is only known for $n = 2, 3, 8$ that there are n^2 equiangular complex lines, probably there are no more cases of existence. In the real case the situation is explained very much in Lemmens-Seidel's paper which is referred to in my paper which I attach. Actually, in the real case, only $O(n^{3/2})$ equiangular lines are known to exist. For $n = 8$, I believe the construction is mentioned in Hoggar's or Delsarte-Goethals-Seidel's paper. It uses quaternions for simpler representation, as far as I remember. In the paper I attach ["Cubature Formulas on Spheres"] I constructed for $n =$ prime power $+ 1$, N equiangular vectors, where $N = n^2 - n + 1$, so it is almost the maximal number n^2 but not quite (see page 6). I attach the TEX as well as the dvi-file of the paper.

29-09-03 *Quotes That Bugged Me* (to A. Sudbery)

I give up: My backlog of email that needs replying to has grown too enormous, and I'm going to have to make some cuts.

Let me just lodge a complaint about two of your quotes that bugged me. These are:

Sudberyism 2: *So I should keep to myself my enthusiasm for ambitious all-embracing theories of reality and not go around insulting people who don't need them, accusing them of copping out and God knows what. But I'm afraid it's still true for me that not to be curious about what makes QM work would be to stop doing science, to switch off what made me want to learn about QM in the first place.*

and

Sudberyism 3: *I have to say that I don't find the existence of objective reality so easy to dismiss as just a faith, which one could simply choose to abandon. The reason that the tension between subjective and objective is a real philosophical* problem *is that there seem to be good reasons for holding the objective view.*

Curt Replies:

1)

Let me try to reiterate the goal of the program Caves, Schack and I are developing. It is not to say that there is no world external to us; it is only to say that there are no quantum states external to us, and then to see where that leads us in understanding quantum mechanics. There is a difference; why can't you see it?

I think it would be hard to call my 59 page paper, `quant-ph/0205039`, a "lack of curiosity about what makes QM work." The whole point of the paper was that we don't have a decent handle on what makes quantum mechanics work. It then tries to systematically explore a particular line of thought—that the quantum state represents information, rather than material property. It does not eschew the very existence of material properties. It simply says that among them, the quantum state is a very bad candidate.

Here is the way I would caricature where you seem to stand in relation to me. Imagine a young student who first learned classical electrodynamics solely in terms of the vector potential. Then one day someone pointed out to him that all the physical phenomena he could see actually depended only upon the fields, not the complete vector potential after all—there is a gauge freedom. Well, flabbergasted, it felt to this student that he was stripped of something he ought to have. So he spent the rest of his life doggedly trying to find a justification for the TRUE gauge. Of course he had to give umpteen ad hoc reasons for why the true gauge could not be measured, but that was the price to pay to do science. (For if you're not trying to see the vector potential as a real property of the world, you're not doing science.) What a pity.

Likewise I would characterize where you want to go and where I want to go with quantum mechanics. You want to see the quantum state simpliciter as a representation of reality. Whereas I think we are more likely to find reality in the "differential." I.e., in the support structure in which quantum states live and in the rules for changing those states in light of how we are stimulated (by the world external to us). The structure of those rules represent something we are assuming of the world as it is independently of us.

And wouldn't we like to know what we are assuming of the world as it is independently of us?

2)

Why do I go to pains to say things like this:

> SYSTEM: In talking about quantum measurement, I divide the world into two parts—the part that is subject to (or an extension of) my will, and the part that is beyond my control (at least in some aspects). The idea of a "system" pertains to a part beyond my control. It counts as the source of my surprises, and in that sense obtains an existence of its own external to me.

as I did in my "Me, Me, Me" note, when you nevertheless respond with things like this:

> I have to say that I don't find the existence of objective reality so easy to dismiss as just a faith, which one could simply choose to abandon.

In any case, my issue with Nagel—the big IF—is not about whether there is a world external to or beyond all agents—objective reality if you will. But whether it is sensible to assume that there can be a REPRESENTATION of it. Like the boy fixated on his vector potentials, one can always act as if there is such a REPRESENTATION from the outside—the view from nowhere—but also like the boy, one might be wasting one's time in doing so. It is my sense that quantum mechanics hints at the latter.

03-10-03 *IC POVMs* (to G. M. D'Ariano)

I just finished reading your new paper on informationally complete measurements. It is fascinating and very nicely done; I learned a lot.

I wonder however if I could ask to cite my paper `quant-ph/0205039` (the one you referred to above) in a reposting of yours—only the `quant-ph` number please, not the Växjö version. I ask this, not because anything in your paper depends in a technical way on my paper, but because I want to spread the word as far as possible. As I see it, it is an issue of getting a large enough workforce to move in these directions if we're going to make long-lasting progress. The picture of doing quantum mechanics on a simplex and the "standard quantum measurement device" that I try to make attractive in that paper depends crucially on the existence of minimal informationally complete POVMs, which I emphasize. For our colleagues to see the deeper connection between your work and mine, I think, can only be healthy.

Also, by the way, the existence of minimal informationally complete POVMs was crucial for our proof of the quantum de Finetti theorem (nonminimal IC POVMs could not be amended to that proof technique): C. M. Caves, C. A. Fuchs and R. Schack, "Unknown Quantum States: The Quantum de Finetti Representation," *Journal of Mathematical Physics* **43**(9), 4537–4559 (2002). [Reprinted in *Virtual Journal of Quantum Information* **2**(9).] `quant-ph/0104088`.

It is interesting that your paper can be used to connect the de Finetti theorem to group theory.

Anyway, if you could make a citation or two, I'd much appreciate it.

03-10-03 *A Plea* (to R. Blume-Kohout, J. M. Renes, & C. M. Caves)

I want to make a plea to you guys to write up what you and your collaborators have on SIC-POVMs and get it out on the web in a hurry. What I would suggest is that you write it up in a style appropriate for the journal *Linear Algebra and Its Applications* and then ultimately submit it there. For that journal, all you need to do is state the raw mathematical problem—that is enough motivation—and then state what you've got (including numerics). I estimate that it would not take more than a week to write such a paper, at least to the quality of posting it on `quant-ph`.

The reason I am writing this plea now are fourfold.

1. I have only recently come to appreciate how old and well respected this problem is, and it appears to me you guys actually know more than anyone else. I'll put a list of references with annotations below. The upshot is that the problem is about 30 years old and has been hit by some *real* mathematicians. The most telling tale comes from Hermann König (a mathematics professor in Kiel) who wrote me: "It is only known for $n = 2, 3, 8$ that there are n^2 equiangular complex lines, probably there are no more cases of existence."

2. Have a look at `quant-ph/0310013` posted this morning by D'Ariano and collaborators. You'll see that they're already working with your beloved group $\mathbb{Z}_d \times \mathbb{Z}_d$ for generating IC-POVMs. I deem that it can't be long before they realize the interest in adding an S to that. And, look, if they write a paper posing this problem you guys will lose a lot of credit for a lot of work: It is not worth it to hold on to it privately anymore.

3. I myself would like to talk more openly about the sensitivity of SIC ensembles with respect to eavesdropping, and I don't feel completely comfortable doing this while you guys continue to sit on your paper. In particular I am writing something for the Holevo festschrift that I'll

call “On the Quantumness of a Hilbert Space” showing that these ensembles (if they exist) are maximally quantum and some related facts. It would be nice to have something solid of yours to cite.

4. The most important reason: You’re holding up science! What I suspect is, if you put your paper in the right audience, someone will be able to run with your $\mathbb{Z}_d \times \mathbb{Z}_d$ conjecture and prove it to completion. Simply be happy that you’ve contributed this much, and give someone else a turn.

I hope I’ve made my case strongly enough.

1. P. W. H. Lemmens and J. J. Seidel, “Equiangular Lines,” Journal of Algebra **24**, 494–512 (1973). This seems to be the father paper of the field, even though they do give some references to earlier work studying equiangular lines in the terminology of “elliptic geometry” (whatever that means). This paper, however, is devoted solely to real vector spaces.

2. P. Delsarte, J. M. Goethels, and J. J. Seidel, “Bounds for Systems of Lines and Jacobi Polynomials,” Philips Research Reports **30**, 91–105 (1975). This paper studies both real and complex spaces. They make it clear that they know of the existence of maximal equiangular sets (i.e., the ones that achieve the “Gerzon bound,” namely n^2 in the complex case) in dimensions 2 and 3. Looking at their references, these cases might have been known as early as 1914 but I have not confirmed that.

3. H. König and N. Tomczak-Jaegermann, “Norms of Minimal Projections,” `arXiv:math.FA/9211211`. I don’t think this paper proves anything of use to the SIC-POVM problem—though I don’t know—but it does show that these questions are intimately related to other issues in mathematics that people take seriously. I.e., this is another reason your paper should be out there.

4. S. G. Hoggar, “64 Lines from a Quaternionic Polytope,” Geometriae Dedicata **69**, 287–289. Apparently the problem considered in this paper proves the existence of a SIC-POVM in $d = 8$.

5. A. Koldobsky and H. König, “Aspects of the Isometric Theory of Banach Spaces,” in *Handbook of the Geometry of Banach Spaces*, Vol. 1, edited by W. B. Johnson and J. Lindenstrauss, (North Holland, Dordrecht, 2001), pp. 899–939. Available online at: `http://www.math.missouri.edu/~koldobsk/`. I’ll repeat what I said above: I don’t think this paper proves anything of use to the SIC-POVM problem, but it does show that these questions are intimately related to other issues in mathematics that people take seriously. You can find an indication of the SIC-POVM problem on page 19 of the web-based manuscript.

6. T. Strohmer and R. Heath, “Grassmanian Frames with Applications to Coding and Communication,” `arXiv:math.FA/0301135`. Not much of interest here, except a rederivation of the Gerzon bound.

7. H. König, “Cubature Formulas on Spheres.” Available online at: `http://analysis.math.uni-kiel.de/koenig/pub.shtml`. This paper is interesting and getting close to the real thing. He derives the existence of $d^2 - d + 1$ equiangular lines when $d = p^m + 1$, p a prime number and m a natural number.

8. B. Et-Taoui, “Equiangular Lines in C^r,” Indagationes Mathematicae **11**, 201–207 (2000). Despite the title, this paper is not particularly interesting (I think): The problem he addresses is much more particular than the title lets on. But, again, it does show that people are thinking about these things.

9. B. Et-Taoui, “Equiangular Lines in C^r (Part II),” Indagationes Mathematicae **13**, 483–486 (2002). Ditto.

10. G. M. D’Ariano, P. Perinotti, and M. F. Sacchi, “Informationally Complete Measurements and Groups Representation,” `arXiv:quant-ph/0310013`.

06-10-03 *Keep It Up!* (to J. M. Renes and C. M. Caves)

I skimmed over your draft this morning [of what eventually became J. M. Renes, R. Blume-Kohout, A. J. Scott and C. M. Caves, “Symmetric Informationally Complete Quantum Measurements,” J. Math. Phys. **45**, 2171 (2004)]. I think it is starting to look good. (However, when I suggested *Linear Algebra and Its Applications* as a target, I was imagining something even more skeletal than that. The whole point of that journal is to leave the words behind.)

Unfortunately I’m starting to think there is even more need for speed than I had thought before. For instance, Koenraad Audenaert wrote me the following last night (I opened up the note this morning):

Audenaertism 1: *I may have something interesting here! (and then again, maybe not ☺) In Dublin you told me about the problem of constructing a SIC-POVM in any dimension. Now I have been thinking about this now and again, but without further results. Last Friday, however, there was this preprint by Mauro d’Ariano et al about the construction of IC-POVMs (not necessarily symmetrical ones). Upon reading it I was struck by their first example (in section 4), where they constructed an IC-POVM starting from an initial pure state and applying what seems to be all possible displacement operators in the associated phase space of the Hilbert space. Well, my left toe immediately started to itch. Can one come up with SIC-POVMs in this way, starting from an appropriately chosen pure state? I wrote a MatLab program that did a brute force numerical search (simplex search) and, believe it or not, for all dimensions I tried (2, 3, 4, 5 and 6) it did come up with a SIC-POVM (the inner products being correct up to 12 decimals!).*

But maybe this is precisely the “numerical evidence” you mentioned.

I asked Koenraad to make sure if he finds something, he would not post before you, but I am not going to be able to ask everyone that.

Now, a couple of notes on your draft.

1. I’m not an author. I wish I had contributed enough to the project to be in the list, but unfortunately I haven’t. (I would be very happy, however, if you would find a way to cite my papers 0205039 and *0302092*.) In general for this paper, you should be careful not to let the author list get out of hand. I would say that hours spent working privately on the project should not be a criterion of authorship.

2. I didn’t understand your argument for linear independence on page 1. The Gram matrix for an SIC ensemble (i.e., the matrix of inner products), will not be a real matrix; there will be phases everywhere. I don’t see why you don’t use Carl’s simple straightforward argument from his web notes to establish linear independence.

3. "However, it is known that for $t = 2$, the minimum number is $n = d^2$, so the SICPOVM is the smallest spherical 2-design." Where is this established?

4. For Section III, I think you should exhibit the form of the expansion of a fiducial projector in terms of the displacement operators D_{jk}. Then comment that the problem of existence boils down to any satisfying assignment for all the phases, and exhibit how nonlinear of a problem that looks to be.

I'll send any further comments as they come to me, but this will probably be my last note for today: I've got to give a talk at Trinity College this afternoon.

06-10-03 *Agreement/Disagreement* (to J. M. Renes and C. M. Caves)

Renesism 10: *OK, I'll try to tighten it up. But Carl also suggested Journal of Mathematical Physics, which in the end is probably what I was going for. (Actually, I don't know so much about that journal either, so what I was going for was the archive. I treat POVM as if the reader already knows what it is, for instance.)*

I agree that `arXiv.org` is the very most top priority. However, I disagree with J Math Phys. It's a pure maths problem, and I deem it will have a much better chance of being solved if the paper ends up in Lin Alg App. In the end it is a problem about equiangular lines, full stop; and the LAA audience is an audience hungry for those kinds of problems. The mathematical-physics community, I suspect, will quickly forget about it if it's not easily tractable ... whereas the LAA audience will plug away at it year after year. They won't denigrate it just because it is a finite-dimensional vector-space problem, where the JMP crowd might—at least that's the sort of reaction I personally have had from them before. Finally, especially if it does turn out not to be so easily tractable, I think you'll ultimately generate more citations (outside of the `quant-ph` crowd) with LAA.

07-10-03 *Congratulations!* (to A. J. Leggett)

Congratulations on the Nobel prize!! Now, almost for sure, I'm not going to get you to write something for the Peres festschrift—who would have the time?!

Anyway congratulations; from what David Mermin tells me about your work, I know it is well-deserved.

07-10-03 *More Covariance* (to G. M. D'Ariano)

Thanks for your long letter, and certainly thanks for the citations in your "informationally complete" paper. I printed out your "Extremal Covariant Quantum Operations" paper today, but now that one I cannot finish off in a lunchtime reading (as I did the last)! It will take me sometime to digest it all.

In fact it will take me some time to digest your long note. Unfortunately, I don't have any answers to your questions.

I think a visit to Pavia would be great as I said before. Two weeks, in fact, would probably be optimal. Unfortunately though, I really can't make any new plans until after the new year. (I will be in Dublin until April 15.)

Finally, let me ask you: Would you like a copy of my book *Notes on a Paulian Idea* (quant-ph/0105039)? It is a samizdat, as David Mermin calls it, more for perusing than systematic reading, but I think it does capture some of the philosophical flair of what we are mutually shooting for in quantum foundations. I have some copies of the Växjö University Press edition for giving away, if you think you or your students might get something out of it. (Kluwer will be reprinting it in a more proper edition, in their *Fundamental Theories of Physics* series, but that will probably be a year away; and I won't have many copies to give away then.) Anyway, if you want a copy, just tell me which mailing address to send it to.

08-10-03 *Heart of the Matter* (to M. Pérez-Suárez)

Pérez-Suárezism 4: *And, finally, on your note about "You, you, you ...". I usually enjoy your papers and notes, and this is no exception. I have never thought of your approach as implying solipsism. I don't even understand how someone might have thought it did. The only point I haven't been able to come to terms with yet is that sort of "unitary readjustment". I do still think that it would have been "nice" being able to get Bayes' rule without any further modifications. Is this thought an indication that I am missing or misunderstanding something which is fundamental?*

No, I don't think it would have been nice at all. I think the modification to Bayesian conditionalization that we see here is one of our clearest (and most quantitative) indications yet that quantum measurement should not be viewed as a passive process by which the agent's mind comes to mirror a pre-existent reality. If the agent were not changing his external reality in the process of having a look, his update rule would have been the regular Bayesian one. The mantra is: The quantum rule only reduces completely to the Bayesian rule when the agent believes he has no causal influence upon the system he is updating his beliefs about. A good case in point for this is to consider making a measurement on one half of an entangled pair. The update rule that one uses on the other half (subsequent to the data gathered on the first half) is precisely the Bayesian rule.

Open question: Why is the readjustment unitary, rather than some more general linear or nonlinear transformation?

08-10-03 *EnNobelization* (to N. D. Mermin)

That was great news hearing about Tony Leggett winning the Nobel prize yesterday. Strangely though, it made me feel very nervous. I guess I had always seen Tony as "wasting a perfectly good mind" (I dug almost exactly that phrase in a note I had written to Asher Peres in July 2000). As I wrote to my friend Greg Comer in reply to one of his points:

> Yep, he's definitely a bread and butter physicist. And clearly very smart and rigorous and—if you could see the equations in his talks—you'd understand that he must be absolutely single-minded when it comes to calculating. It is only that all his later work is predicated on the obstinate belief that the quantum state *must* correspond to an objective property. The Nobel prize was for the sort of work you are talking about. I've only seen him in his later incarnation, i.e., worrying about (and proposing experiments for) quantum foundations. He always expresses surprise and confusion that quantum mechanics has not been seen to break down yet.
>
> Anyway, I just sent him a note of congratulations. It is a very impressive feat to so change the world as he (and the other two) have done.

Well, I guess his Nobel prize taught me! A man shouldn't be judged by his interpretation of quantum mechanics alone!

08-10-03 *Can't Resist* (to H. Barnum & A. Sudbery)

I know that I said I would not write again until I had finished reading Nagel's book, but I came across a passage yesterday in an essay of Richard Rorty's that I could not resist scanning into my computer. It deals somewhat with something Howard wrote us:

Barnumism 8: *During the "Bohmian dialogue" years ago at Hampshire (organized by Herb Bernstein), I came to a couple of important realizations mostly in the process of defining my views against "what we've all learned over the last twenty years" (which included things like "you can choose your own myth," as I recall).*

One of them was that, though I am not explicitly religious, I value "transcendence" (the term was being used as a putdown, I think). That is perhaps a nicer word for what Nagel is calling "detachment"... getting beyond your own limited point of view to an expanded point of view.... even though of course that expanded point of view is still gotten to by you, interacting with others, using more of the different modalities and apparatuses available to you. It is <u>part of</u> *"variety and freedom," (the truth will set you free, dontcha know) and "growth," for me.*

What I dislike most in some strains of "antirealist" modern thought, is their disdain for the value of transcendence, their desire to make everything a useful, folksy, comforting tool for humans.... not that useful, folksy, comforting are not good, but so is getting outside oneself and recognizing the vast unbelievableness of what becomes apparent as one does so....

I don't necessarily think your approach will end up negating that value, in end..... our views may be closer than it seems. I'll read on....

In the present passage, Rorty is talking about culture and politics, but he might as well have been talking about views of physical theory. In fact, in much of the rest of the book *Philosophy and Social Hope* he was.

I will return on Nagel (sooner rather than later).

Here's the passage:

> Insofar as 'postmodern' philosophical thinking is identified with a mindless and stupid cultural relativism—with the idea that any fool thing that calls itself culture is worthy of respect—then I have no use for such thinking. But I do not see that what I have called 'philosophical pluralism' entails any such stupidity. The reason to try persuasion rather than force, to do our best to come to terms with people whose convictions are archaic and ingenerate, is simply that using force, or mockery, or insult, is likely to decrease human happiness.
>
> We do not need to supplement this wise utilitarian counsel with the idea that every culture has some sort of intrinsic worth. We have learned the futility of trying to assign all cultures and persons places on a hierarchical scale, but this realization does not impugn the obvious fact that there are lots of cultures we would be better off without, just as there are lots of people we would be better off without. To say that there is no such scale, and that we are simply clever animals trying to increase our happiness by continually reinventing ourselves, has no relativistic consequences. The difference between pluralism and cultural relativism is the difference between pragmatically justified tolerance and mindless irresponsibility.

So much for my suggestion that the popularity of the meaningless term 'postmodernism' is the result of an inability to resist the claims of philosophical pluralism combined with a quite reasonable fear that history is about to turn against us. But I want to toss in a concluding word about the *un*popularity of the term—about the rhetoric of those who use this word as a term of abuse.

Many of my fellow philosophers use the term 'postmodernist relativism' as if it were a pleonasm, and as if utilitarians, pragmatists and philosophical pluralists generally had committed a sort of 'treason of the clerks', as Julien Benda puts it. They often suggest that if philosophers had united behind the good old theologicometaphysical verities—or if James and Nietzsche had been strangled in their cradles—the fate of mankind might have been different. Just as Christian fundamentalists tell us that tolerance of homosexuality leads to the collapse of civilization, so those who would have us return to Plato and Kant believe that utilitarianism and pragmatism may weaken our intellectual and moral fibre. The triumph of European democratic ideals, they suggest, would have been much more likely had we philosophical pluralists kept our mouths shut.

08-10-03 *Can't Resist, 2* (to A. Sudbery)

Sudberyism 4: *Curiously enough, I am toying with the idea of writing in defence of quantum-mechanical pluralism for my contribution to Asher's festschrift. Where does the Rorty quote come from?*

It comes from the last essay in the book, *Philosophy and Social Hope*. Unfortunately I don't have the book with me at the moment to see what the title of the essay is. I suggest you run to the bookstore and get a copy just as fast as you can. The best things to read are the introductory essay (spurning Platonism), along with the three essays:

- "Thomas Kuhn, Rocks and the Laws of Physics"
- "A World without Substances or Essences"
- "Truth without Correspondence to Reality"

08-10-03 *Jaynes Stuff* (to D. Poulin)

Thanks for the long letter, and thanks for the invitation to work on a project with you and Raymond. I've printed out your draft, and I'll see what I can understand from it. But I fear you might have to give me a lecture in person before much will sink in! (At the moment I am preoccupied with trying to get off to Caltech this weekend and making a talk that won't make me a laughingstock.)

I liked your way of putting things in the Jaynes' principle debate: "One can use Jaynes' principle to assign probabilities at the price of treating it like it wasn't a probability distribution." It seems to be of the right flavor ... though I can't say for sure that I have completely made up my mind on the value of the principle. Since I am now drawn more to de Finetti's personalistic Bayesianism than Jaynes's version of it all, I suspect I would not put nearly as much stock in the "principle" as I used to.

Poulinism 13: *I have also had a look at Jaynes' 1986 paper. I don't see what Brun et al. refer to when they say that "Jaynes [13] has given a thorough discussion of this problem." Maybe he did, but not in this reference.*

Yeah, 1986 would be much too late. Unfortunately, I don't have Jaynes' book to figure out which is the right reference. It had to do with an issue brought up by Friedman and Shimony in the 1970s. I did do a little web search and found this nice paper by Jos Uffink:

`http://www.phys.uu.nl/~wwwgrnsl/jos/mep2def/mep2def.html`.

I think it is dead on the mark with respect to the issue you're interested in. Also, Jos is a very thoughtful person, so I think it is probably a very important one to read.

I'll try to write you again during my California stay.

08-10-03 *Renormalization* (to F. Girelli)

I apologize for the delay in responding to your note. I didn't realize until this morning that it had been eight days since I received it.

Girelli-ism 1: *My question is about renormalization. It is well known that there is an interpretation of renormalization in terms of information: eg when renormalizing we coarse grain so we loose some local information. The ideas of renormalization started with some spin systems, so it seems that the de Finetti representation is a right tool to use.*

Are you aware if the interpretation in terms of information has been pushed forward? And is it possible?

When you do the successive measurements in the context of the de Finetti representation you refine your knowledge, which can be seen as the opposite operation of the coarse graining. It would make sense as well to see how the Bayesian approach is implemented in the renormalization scheme. For example if you deal with only the bare coupling constants (I am taking the Polchinski point of view, or Wilson's), it is not working, you have to measure some of them (the relevant ones) and then update your measurement and everything gets fine.

Do you have any references, ideas, intuitions about those things? I would be very glad to hear about it.

I wish I could say something intelligent on the subject, but I don't think I can at the moment. I had never thought about renormalization in information theoretic terms before reading your note. I did a google search on the words "renormalization group information theory" and the only thing that caught my eye was Robert Tucci's paper "An Application of Renormalization Group Techniques to Classical Information Theory" posted on `quant-ph` ... but I doubt it can be relevant.

Maybe when I come visit Perimeter during your meeting, you can fill me in in more detail what sort of thing you have in mind. I have a hard time formulating a precise question at this stage. It's probably the sort of thing we need a chalk board for. You'd probably have to give me a few lessons before I'd have any good input.

Maybe for this problem—seeing that you are talking about throwing away information or disregarding information—it is best to scrap considerations to do with the de Finetti theorem. Keep in mind that in quantum mechanics, the general expression (or mechanism) for information loss is the trace preserving completely positive map. Which brings me to this point of yours:

Girelli-ism 2: *I am working with David Poulin on the notion of time that we can extract from information theory, in order to understand the notion of time in quantum gravity.*

On this track, I have had some thoughts on recovering the general expression for quantum time evolution (i.e., CP maps) from a Gleason type theorem for the probabilities of outcomes of sequential measurements upon single systems. In a way, that would be an information theoretic accounting of it. What I had hoped to do was something along the lines of what I did in Section 5 of my paper `quant-ph/0205039`, the difference being that the two "systems" should be separated in time rather than in space. The hope was, enforcing causality on the joint probabilities of outcomes (referring to measurements at two different times) would be enough to recover the general form of a completely positive map. I made some progress, but I could never quite get it to work out. Maybe this is another thing we could talk about when I visit.

08-10-03 *The Push* (to J. M. Renes and C. M. Caves)

I'll try to have a look at the new draft tonight. One thing I'm just noticing is that you should put the $d = 2$ case in there. It's the only damned case anyone can visualize; put it in Bloch sphere language. You can crib it directly out of Carl's notes.

Another thing: I think it would be slightly cleaner to write the unitary operators in your Conjecture 1 as D'Ariano does in Eq. (21) of `quant-ph/0310013`. Finally (for the moment): I did not understand your equation 18 nor the discussion right around it.

Why am I giving you more push? Because Koenraad just wrote me that he has now numerically confirmed the conjecture out to $d = 24$ (and counting). He really has come up with all this independently, but I don't think you deserve to add another author and water down the list that much more.

What is a Gabor frame? What is a Weyl-Heisenberg frame?

I've got to run home now. I'll probably be online later.

09-10-03 *Pauli Back* (to K. Gottfried)

Thank you for warm letter; it was quite nice of you.

Gottfriedism 1: *First, from where are those great quotes from Pauli on p. v1? The two words in italics – are they yours – are so central to the enigmas posed by quantum mechanics.*

The italics are Pauli's. The two passages on that page come from his article "Matter", which is included in *Writings on Physics and Philosophy*. There are more Pauli quotes that intrigued me recorded on pages 192 through 195 of the samizdat, in the "Greg Comer" chapter. It was in February and March 1995 that the Paulian Idea really took hold of me, while reading the collection you mention.

Gottfriedism 2: *I am a life-long Pauli devotee, and as a student in the early 1950s, taking advantage of my childish knowledge of German, devoted a large effort to studying his superb Handbuch article, which except for Dirac, was the only serious text then available. Last year David M steered me to "Writings on Physics and Philosophy" but I have not been able to find the quotes there in an admittedly cursory search.*

I understand that Charles Enz has just published a biography of Pauli, but I haven't read it yet. I have a much more extensive compilation of Paulian quotes in a document I'm putting together—including some amazing letters between Pauli and Bohr—called "Resource Material for a Paulian-Wheelerish Conception of Nature." It's sitting at 112 pages (and 452 references), but it needs to be twice that size before I'll call it complete and post it. (I.e., a lot of the references don't have quotes inserted into them yet.) I will let you know when it's ready for perusal if you wish. (Or if you'd like to see a sneak preview, I'm always looking for people who might catch a typo.)

Gottfriedism 3: *This summer the completely new second edition of my text finally appeared and I'd like to send you a copy if you'll tell me your mailing address.*

I'd love to have it! Thank you. One of these days I'd even love to teach a quantum mechanics course. As long as the post will arrive before April 15, 2004, the mailing address to use is the one below.

09-10-03 *Mocking Bird* (to N. D. Mermin)

Merminition 135: *So don't underestimate him* [Tony Leggett]*. He's one of the most impressive and thoughtful theoretical physicists I've ever met. Have you ever looked at his little book "The Problems of Physics"?*

I hope you understand that the note I wrote to you yesterday was written self-mockingly. That was its whole purpose.

I hadn't seen or heard of the book before. I'll try to have a look at it while I'm at Caltech next week.

09-10-03 *Parsing for the Uninitiated* (to J. M. Renes and C. M. Caves)

Now I've skimmed the latest version of your paper. At first I thought I'd read it very, very carefully this time around and give you detailed comments. But then I found myself pulling my hair out with you first paragraph and ultimately gave up: It's your paper not mine.

Take your first two sentences for instance: "A quantum measurement is termed informationally-complete if its statistics completely determine the input quantum state. An aesthetically appealing and potentially useful measurement is one which also possesses the symmetry that all pairwise inner product magnitudes are equal."

What are these inner products taken between? States? Positive operators? Complex vectors? If that's not bad enough already, in the next sentence one starts to feel schizophrenic: "In the full regalia of quantum information jargon, such a set of states is a 'symmetric informationally-complete positive operator-valued measure' ... " In one half of the sentence you talk about states, in the other half you talk about positive operators. Clearly you're thinking of a POVM as a set of state vectors (rather than positive operators adding up to unity), as you make more explicit in the next paragraph, but that is quite a nonstandard definition. Finally, you talk about "the existence of it" as if there is only one.

Contrast this with your use of language in Section IV: There you tell the reader that are only 2 SIC-POVMs when there are clearly a continuous infinity. Presumably what you mean is that there are only two possible fiducial vectors (for this particular method of generating SIC-POVMs). But what can it hurt to be precise?

I could keep going on. For instance, just after Theorem 1, you invoke a nonstandard Gram matrix—I say it is nonstandard because previously you had only talked about sets of state vectors, but now you are considering sets of operators (in their own linear space), and you haven't even told us about the inner product you're using. (You don't introduce that inner product until Section III.)

The point is, you should be have mercy on your reader, who, by definition, will not be sitting in your head. Try to anticipate his questions and potential frustrations. It's a worthy exercise and will help keep people reading your papers.

Enough. I guess I'm just voicing frustration because I had wanted to give you detailed comments and you thwarted me—it became clear that it wasn't worth my while.

Here is one thing, however, that is worth my while. Would you change your sentence, "In quantum information theory such measurements are relevant to foundational issues

`\cite{fuchssasaki03a,fuchssasaki03b}`,

and useful for creating classical representations of quantum states, doing quantum state tomography, and quantum cryptography," to something more along the lines of the following:

> In quantum information theory such measurements are relevant to quantum state tomography `\cite{A}`, quantum cryptography `\cite{B}` and to foundational studies `\cite{C}` where they would make for a particularly interesting "standard quantum measurement".

A) C. M. Caves, C. A. Fuchs and R. Schack, "Unknown Quantum States: The Quantum de Finetti Representation," J. Math. Phys. **43**, 4537–4559 (2002).

B) C. A. Fuchs and M. Sasaki, "Squeezing Quantum Information through a Classical Channel: Measuring the 'Quantumness' of a Set of Quantum States," Quant. Info. Comp. **3**, 377–404 (2003).

C) C. A. Fuchs, "Quantum Mechanics as Quantum Information (and only a little more)," `quant-ph/0205039`, and private communication.

You can throw out the reference to the other paper by Sasaki and me.

While I'm here I might as well make a couple of other trivial points.

1. Your title: No journal is going to accept POVM in it. You might just make it "Symmetric Informationally-Complete Measurements".

2. I think it is worthwhile to mention in the introduction that one of the results of Lemmens/Seidel is that symmetric informationally-complete measurements do not generally exist for real Hilbert spaces. Therefore it is somewhat surprising (and very intriguing) that they seem to for the complex case.

3. I noticed that Theorem 1 has changed. The upper bound is gone (maybe it shouldn't have been there in the first place?); and a state vector is not a subset. Also you haven't given a proper citation to Benedetto et al.

4. Definition of f_t. Missing a subscript t on $\mathcal{H}$. Also f_t is NOT equivalent to a choice of F_t, only on the symmetric subspace. Also equations 6 and 7 are bad notations, if you're going to first write equation 5.

5. Why introduce terms like Gabor frame if you don't use them?

6. I still didn't get equation 18 and its surroundings.

I'll desist at that.

10-10-03 *Letters and Quantum Canaries* (to P. Hayden)

Of course I'll send off a letter for you. I'll even spruce up the old one a bit before doing so. I seem to recall you've published some decent papers since the last time I wrote for you. ☺

And I'll take you up on a dinner at your house—it won't count as a bribe. But here's what I'd really like in return for my efforts: Solve this problem. You're probably just the man to do it anyway.

Fix a given set of pure states Π_i on a Hilbert space of dimension d with some associated probabilities π_i. Imagine drawing from that ensemble just once and handing off a state to a very reserved eavesdropper. She's very reserved in that she's not interested in gathering all the (expected) information she can; rather she settles for $I = \epsilon$. Finally she gives back the system you originally gave her, and you check the yes-no question associated with the original state you had prepared. Tabulate the disturbance in terms of fidelity F, just as Sasaki and I did in `quant-ph/0302092`.

The preliminary question is what is the functional dependence between I and F in that limit? The answer should depend upon the ensemble—for instance one might get $F = 1 - I^\alpha$, where α depends upon the details of the ensemble. Thus, more to the point, I would like to know what is the most sensitive ensemble in this sense, and how does the ultimate sensitivity depend upon d? I.e., what are the best canaries for sniffing out the fumes in these mines?

In the case of the earlier stuff considered by Sasaki and me, I can now show that (along with the uniform ensemble) a symmetric informationally complete ensemble consisting of d^2 elements is a maximally sensitive ensemble. I.e., in the terminology there, it achieves the "quantumness of the Hilbert space." (I only kind of semi-conjectured it in the earlier paper.) [[BTW, we must have talked about SIC-POVMs at some point? It's a set of d^2 rank-one positive operators for which all pairwise Hilbert-Schmidt inner products are identical. We still don't know for sure whether they exist, but that shouldn't stop one from using their formal properties. In any case, Renes and company will post a paper next week showing numerical evidence that they exist at least up to $d = 39$. So I think it's darned likely they really do exist for all d. And they even have a very nice symmetry that's been uncovered (again numerically)—namely, $\mathbb{Z}_d \times \mathbb{Z}_d$.]] So a natural guess is that the SIC ensembles will also be good canaries in this sense, but I wouldn't have a clue about whether it's really true or how to solve it.

You solve that or give me some good ideas about how to do it, and you can bribe me for a lot of things.

12-10-03 *Torture and Sleepless Nights* (to C. King)

Well, after a lot of self-torture and sleepless nights since I last wrote you, I decided to give up on the SIC-POVM problem (for the time being). It had become an obsession. Then I turned my attention to prodding Renes and company to quickly get their conjecture out on the web before someone else did. (A paper by the D'Ariano group a couple of weeks ago made it clear that he might be only one step away from the conjecture himself. So promptness seemed called for!)

The upshot is, their paper will appear on `quant-ph` Tuesday. Have a look at it if you get a chance.

12-10-03 *Moving On* (to C. M. Caves)

If I can muster the strength, I'm going to plunge ahead on my Holevo festschrift "On the Quantumness of a Hilbert Space." Hopefully I'll have it finished by the end of the week. There isn't much that it doesn't mimic from your paper, but at least I found some of it on my own (though maybe through a subliminal suggestion from you guys).

If I can figure out the words to say it with, I'd like to make a metaphysical point in its introduction. It is that Hilbert-space dimension plays a role in our Bayesian considerations that has an eerie conceptual similarity to rest mass in relativity theory. When an agent hypothesizes a Hilbert-space dimension for an object, he is hypothesizing something *it* possesses. (In contrast, when he hypothesizes a quantum state for the object, he is hypothesizing something *he* possesses.) Also I want to make the point that the fungibility—a word I really dislike—of quantum information should maybe more properly conjure up images of the Eötvös experiment and the equivalence principle than monetary considerations. I hope that if I can say it in the right way in the end you'll approve (at least that this is a worthy direction to explore), but I have a long history of such hopes.

14-10-03 *quant-ph/0310075* (to J. M. Renes, R. Blume-Kohout, A. J. Scott, and C. M. Caves)

Good to see its appearance. I think this is going to be a very important paper.

19-10-03 *Fidelity* (to A. Peres)

Good to hear from you. I am visiting Caltech at the moment. Rob Spekkens is also visiting. Through our combined forces, we are trying to make a full frontal assault on John Preskill's quantum foundations sensibilities: The goal is to make him see that the best way to think of the quantum state is as a state of knowledge.

Concerning fidelity, the first time I ever heard the term was in Ben Schumacher's talk in PhysComp '92 in Dallas, TX. The term subsequently appeared in

- Benjamin Schumacher, "Quantum Coding," *Physical Review A* **51**(4), 2738–2747 (1995)

(which was based on the PhysComp talk) but the article had actually been submitted about two years previous to that—you can check the submission date. By the way, this is also the article where the word "qubit" made its first appearance.

Finally, let mention this article:

- Richard Jozsa and Benjamin Schumacher, "A New Proof of the Quantum Noiseless Coding Theorem," Journal of Modern Optics **41**(12), 2343–2349 (1994).

It rederives the result in Schumacher's original (and also used the terms fidelity and qubit), but it actually appeared in print earlier!

19-10-03 *SIC POVMs* (to A. Sudbery)

Sudberyism 5: *We had our first weekly QIT meeting on Thursday. I talked about mutually unbiased bases, which Sam picked up and is running with. And my new student is full of ideas (but too shy to talk to anyone but me so far). It's looking good!*

Good. If you're interested in that, you might also be interested in `quant-ph/0310075` by Renes and company on "symmetric informationally complete POVMs". I think it's a very important problem, and as opposed to the MUBs, it looks like a solution exists in all dimensions.

19-10-03 *Question* (to A. W. Harrow)

Which postmodern writer was it that made some sense to you? And what was the book? I was telling what I could remember of the story to some people here at Caltech tonight, but I want to make sure I get my facts right in the future.

Aram's Reply

> Believe it or not, there have been a few postmodernists who have made some sense to me at some point or other. In particular, I liked Foucault and Zizek.
>
> However, the story I told you was about Jacques Derrida's "Of Grammatology," specifically part II, chapter 1. He was writing about "On the Origin of Language" by Rousseau and "Tristes Tropiques" by Levi-Strauss, I think.
>
> Glad this is still making the rounds.

22-10-03 *Upside-Down Quantumness* (to S. J. van Enk)

van Enkism 4: *He thought your measure of quantumness had the wrong "sign", with which I agreed. Namely, your measure of quantumness is smaller when the set is more quantum ... You agree?*

Yes, I agree. But here's the justification I used in the paper, for whatever it's worth:

> Finally the *quantumness* of the set $\mathcal{S}$ is defined by
>
> $$Q(\mathcal{S}) = \inf_{\{\pi_i\}} F_{\mathcal{P}} \ . \tag{42}$$
>
> This definition has the slightly awkward property that the *smaller* $Q(\mathcal{S})$ is, the more quantum the set $\mathcal{S}$ is. This, of course, could be remedied easily by subtracting the present quantity from any constant. However, if we wanted to further normalize the quantumness so that, say, its value achieves a maximum when no set of states has a higher quantumness, we would have to make use of a (presently) unknown constant in our definition. Thus, it seems easiest for the moment to simply remain with Eq. (42). This does, however, raise an important point—indeed one of paramount concern for the ultimate use of quantumness. Just how quantum can a set of states be in the most extreme case?

30-10-03 *Minor Correction* (to C. G. Timpson)

I quickly skimmed your proposal. It looks pretty good.

One minor point about my biography: [...]

Now, no need for a change on this one—it's not so important at this stage—but I'm not very comfortable with the language that "measurement induces an uncontrollable disturbance in the object system." The reason for this is that I would not characterize the process of giving birth as an "uncontrollable disturbance" to one's wife. I'll attach two excerpts from the latest samizdat that I think best characterize my present broader thoughts on quantum mechanics—the more key issue is the nondetachableness of the observer. BTW, you actually played a bit part in one of the notes. (Looking back at it, I realize I probably characterized you too harshly, but I hope you'll forgive me.)

04-11-03 *Slow Draw McGraw* (to R. W. Spekkens)

Spekkensism 21: *I forgot to ask you while you were here: where did you quote van Enk as saying that there is nothing inherently nonclassical about a 2d Hilbert space? I'd like to throw that reference into the contextuality paper.*

The discussion you're thinking of about van Enk is in my paper `quant-ph/0205039`. It went like this:

> There are two things that are significant about this much of the proof. First, in contrast to Gleason's original theorem, there is nothing to bar the same logic from working when $D = 2$. This is quite nice because much of the community has gotten into the habit of thinking that there is nothing particularly "quantum mechanical" about a single qubit. Indeed, because orthogonal projectors on $\mathcal{H}_2$ can be mapped onto antipodes of the Bloch sphere, it is known that the measurement-outcome statistics for any standard measurement can be mocked-up through a noncontextual hidden-variable theory. What this result shows is that that simply is not the case when one considers the full set of POVMs as one's potential measurements.

But actually that was a dirty trick on Steven. (I thought I was being cute, but he probably hates me for it!) The reason is because I was partly responsible for Steven's having put a statement like that at the end of his anti-Meyer paper—I remember advising him on it, it was definitely the sort of thing I was thinking at the time. Anyway, I looked for my email to him on the subject but couldn't find it; maybe it was something that came out of our discussions. I'll cc this note to Steven to see what he says.

04-11-03 *Belle and Beau* (to S. L. Braunstein)

Braunsteinism 2: *Do you have explicit forms of Wootters' "belle" and "beau" mutually unbiased bases? I am trying to pin down an error in something I am doing and I suspect it occurs here.*

Actually I don't even know what the belle and beau bases are. They do sound interesting though. Can I infer from your question that complete sets of mutually unbiased bases come in at least two flavors? What is the criterion?

This intrigues me mostly, because it dawned on me the other day that symmetric informationally complete POVMs may come in many different flavors. For instance, the character of the "triple products"

$$\mathrm{tr}(\Pi_i \Pi_j \Pi_k)$$

can make all the difference in the world for certain questions.

07-11-03 *Airline Tickets* (to J. B. M. Uffink)

Since I see Jean Bricmont is among the speakers, I will have to do my homework: I.e., I'll read his book with Sokal, *Intellectual Impostures*, before coming. I have a sinking feeling that he'd label any attempt to Bayesianize quantum probability—and thus me—in the same way.

By the way, a couple of weeks ago when I had a little leisure time at Caltech I discovered your paper "The Constraint Rule of the Maximum Entropy Principle." It's great!

07-11-03 *Quantum Pragmatology* (to G. Valente)

Thank you for sending me your thesis "Probability and Quantum Meaning: Chris Fuchs' Pragmatism in Quantum Foundations". Unfortunately it came through my emailer as a "corrupted file," so I had to do a good bit of reconstruction on it before I could get the LaTeX to compile properly. But when I did finally get it to print this morning, what a nice thing to behold! I am very flattered by it all. I never imagined that you were embarking on a work of such scope (140 pages!). Is this a kind of "senior honors thesis" or rather is it a "master's thesis"? Somehow I had gotten the impression before that you were an undergraduate, but maybe I was wrong?

Anyway, at this point, I've read the first 21 pages and also Chapter 5, and it seems to flow very nicely. I especially enjoyed your discussion in Section 2.1.2. I think you're the first person to ever show any appreciation of that idea. Also your analysis on pages 124 and 125 were quite enjoyable. I have had some connected thoughts myself recently (i.e., that dimensionality would be a pretty worthless 'property' unless all Hilbert spaces are, in fact, finite) . . . which leads me to some rather fantastic thoughts about the various entropy bounds cropping up in black hole theory and quantum gravity. I'll report some of this in my upcoming paper "On the Quantumness of a Hilbert Space" (which I'm working on at the moment). If you would like, I'll send you a copy when the crucial pieces are in place.

Already seeing this much of your thesis—I hope the rest of it won't make me reassess!—I hope you will consider posting the final version of it on the `quant-ph` archive. At the very least it may stir up some discussion and get more people involved.

By the way, I've caught a few typos. Maybe the most important is in your Musil quote: You write, "It is reality that awakens possibilities, and nothing would more perverse than deny it." Is it missing a "be" and a "to"? Maybe you should check the whole passage very carefully:

> To pass freely through open doors, it is necessary to respect the fact that they have solid frames. This principle, by which the old professor had lived, is simply a requisite of the sense of reality. But if there is a sense of reality, and no one will doubt that it has its justifications for existing, then there must also be something we can call a sense of possibility. Whoever has it doesn't say, for instance: Here this or that has happened, will happen, must happen; but he invents: Here this or that might, could, or ought to happen. If he is told that something is the way it is, he will think: Well, it could probably just as well be otherwise. . . A possible experience or truth is not the same as an actual experience or truth minus its "reality value" but has—according to its partisans, at least—something quite divine about it, a fire, a soaring, a readiness to build and a conscious utopianism that does not shrink from reality but sees it as a project, something yet to be invented. After all, the earth is not that old, and was apparently never so ready as now to give birth to its full potential. . . It is reality that awakens possibilities, and nothing would be more perverse than to deny it. Even so, it will always be the same possibilities, in sum or on the average, that go on repeating themselves until a man comes along who does not value the actuality above idea. It is he who first gives the new possibilities their meaning, their direction, and he awakens them. . . And since the possession of qualities assumes a certain pleasure in their reality, we can see how a man who cannot summon up a sense of reality even in relation to himself may suddenly, one day, come to see himself as a man without qualities.
>
> — Robert Musil, *The Man without Qualities*

(I've never actually read Musil myself. In fact, I had never heard of him until last year when Frank Verstraete told me that his book seems to express my views on quantum mechanics! The quote you used has convinced me that I should buy the book and try to read it!) Another important mistake: Look closely at Eq. (2.8). Also the explanation "moreover, the passage in the fifth line ..." following the equation array on page 20 is incorrect. G will not necessarily commute with the Π_d. Rather it is the general property that for any two operators A and B, the products AB and BA have the same eigenvalues.

I am glad to hear that you will take a PhD in the philosophy of physics, and I hope you will continue to pursue this pragmatic line of thought. Where to go? Most of all, I'd recommend to stay away from the UK! Pragmatism is certainly not viewed particularly positively there! A few places to consider in the US might be: 1) the University of Maryland, Jeff Bub is there and he is really getting taken with this stuff, 2) University of Washington, Arthur Fine is there and seems to have quite an interest in it too, and finally 3) Princeton University, Bas van Fraassen is there and he seems to have some affinity (or at least understanding) of Bayesian ideas. Unfortunately Richard Jeffrey died a few months ago, he would have probably been an excellent advisor at Princeton. Those three choices definitely follow my personal preferences, so you should compensate for that in your calculation. The are plenty of very strong Philosophy of Science programs in the US—like the University of Pittsburgh—but I doubt those places are as prepared for your line of thought as the three places I listed above.

I'll leave you with that. As I wind my way through your thesis, I may write you more. Oh, you asked about a visit to Dublin. Sounds great; but my calendar won't be free until at least mid-January.

10-11-03 *Ever Vigilant* (to S. Aaronson)

Where are you sending that lovely paper `quant-ph/0311039`??

10-11-03 *Peres Theme* (to V. Buzek)

Buzekism 1: *I am honoured to write a paper to the Festshcrift for Asher Peres. Do you have any specific underlying theme in mind?*

That's great! The underlying theme is Asher ... and all that entails. There will be some submissions on relativity theory, but most will be on quantum information and quantum foundations. Take your pick.

10-11-03 *Who Knows What I Am?!* (to G. Valente)

Valente-ism 3: *Finally, let me know something I have been wondering since I started reading your ideas. Isn't what I called "un-veiling the reality" with respect to your program a suggestion you interiorized from your interest for Schopenhauer (dropping Maya's veil)?*

About Schopenhauer, I really haven't read much of him ... only a little (actually very little) about him from secondary sources. Effectively the only thing I really know about him is the quote below that I had put into my computer. [See 08-08-01 note titled "The First Eye" to C. M. Caves.] So, your "un-veiling"—I think—is new to me.

11-11-03 *Working Title* (to G. Brassard)

We can't have a paper without a prospective title. We've got to settle first things first. How about, "Prospects for Quantum Cryptographic Interpretation of Quantum Mechanics"?

Flying to Canada on a 747 tomorrow. I hate those things.

11-11-03 *Budget Butter* (to R. E. Slusher)

I wish I could say I had some exciting news, but mostly I'm just plugging away. These symmetric POVMs have turned into an interesting and long-lasting problem. Have you looked at Caves and Co's paper `quant-ph/0310075`? They had originally had me on the author list of that, but in the end I withdrew thinking I hadn't done enough to merit it. I'll probably kick myself in the butt for years to come: I'm starting to feel that the conjecture there may remain open for quite some time. I discussed it a lot when I was visiting Caltech and even the great Kitaev thought it nontrivial.

Anyway, Patrick Hayden and I do have some results on the accessible information of such an ensemble (i.e., no longer thinking of the states as elements of a POVM, but instead a signaling ensemble). I'm in the process of writing that part of the work up. I hope I'll put it on `quant-ph` soon.

How is Bernie's patent coming along? And how about your experiment of the same?

13-11-03 *Pearle, Hampton, Hampshire* (to R. W. Spekkens)

While it's on my mind, I've confirmed that Phil Pearle was at Hamilton College in New York State. He retired in 2000. Last night I said it was Herb Bernstein who was at Hampton College, but that was a glitch: Herb is at Hampshire College in Massachusetts (with a name like that, you might have thought it'd be in New Hampshire). And finally, on further reflection I don't know that I know of a Hampton College. The only thing I can think of is Hampton Inn, but that's a hotel chain.

13-11-03 *Variety and Freedom* (to L. Hardy)

Attached is the Rorty passages I sent to Howard Wiseman. [See note titled, "The World is Under Construction."] The phrase was actually "variety and freedom"—that's the only goal. Reading the passages again I still like them. I think they nicely capture what would make a lawless world a better world than a law-fixed one.

13-11-03 *Elephants* (to L. Hardy & F. Girelli)

Below I place some excerpts I dug out of my paper `quant-ph/0204146`, "The Anti-Växjö Interpretation of Quantum Mechanics." They certainly do a better job of what I was on about last night than I did ... though in my sober reading this morning they only seem slightly less drunk!

To Lucien's remark that scientific theories are cumulative—which he wanted to use as an indication that succeeding theories are better and better representations of reality—my reply might be that, from this point of view which I'm trying to develop, the more relevant concept is that succeeding theories have better "feedback mechanisms." That is, one might say that the human species is more developed than the elephant species—even though neither species was foreordained by nature—simply because humans can better adapt to the changing conditions around them. The human species has more feedback mechanisms for adjusting to the environment around it. Similarly, let us say for general relativity and Newtonian gravity. The former can survive more experimental onslaughts than the latter because its structure is more malleable and less rigid than the latter's. But I'm just shooting from the hip at the moment.

15-11-03 *TOE Jam* (to C. Snyder)

I very much enjoyed listening to your excitement last night about a TOE-less world. I think we're kindred spirits in this project. Let me give you a pointer to two of my writings that you might enjoy in this regard.

1) Look at Sections 4 and 5 of my paper "The Anti-Växjö Interpretation of Quantum Mechanics"

and

2) the little essay "The World is Under Construction" on pages 210–215 in my samizdat "Quantum States: What the Hell Are They?".

Both documents can be found on my webpage in PDF format. If you have trouble viewing the files, let me know and I'll send you excerpts in plain text.

By the way, the samizdat that Kluwer Academic will be publishing for me is *Notes on a Paulian Idea*. It's posted on the same webpage.

Hope to see you again later this week.

15-11-03 *The Artist* (to C. Snyder)

I was just flipping through "Quantum States: WHAT?" after telling you about it, and came across the birth announcement I wrote for my second daughter. It's on page 121. [See 19-12-01 note "Katie Viola Fuchs" to the world.] Maybe it captures a little bit (in a single sentence) of what moves you as an artist—that your painting will change the world.

15-11-03 *Conjugalation* (to G. L. Comer)

I bet you've never used the words "lascivious" and "conjugal" in a talk abstract before. Call me crazy, but I did. (See below.) Somehow it seemed like crazy words were called for at a crazy place. I'm visiting the Perimeter Institute for a week and a half [. . .]

Maybe one fortunate thing has come from this visit to Perimeter: I've been reading loads of review material on quantum gravity. I have particularly liked the stuff I have read by Jacob Bekenstein and Raphael Bousso. I'm definitely tipping toward the entropy-bound side now, which I am convinced can only mean "assign a finite dimensional Hilbert space to what was once thought to be a continuous system." I think this stuff is very likely revolutionary, and I am so sorry it took me 15 years to appreciate it.

Another thing that has hit me is that with this Bayesian view of quantum operations developed in *Quantum States: What the Hell Are They?* is that there is simply no information-loss "paradox" associated with black holes. From my point of view, as long as a time-evolution map is linear, completely-positive there is nothing to keep one from assigning it as long as it is actually one's firm belief for a system. In particular there is no requirement that the map be derivable from a unitary evolution on some composite physical system. Thus the paradox, like the black hole itself, evaporates. I'm going to try to write this up a little more clearly and pass it by John Preskill soon. I know, of course, that he won't buy it—he could only do that if he had bought the starting point, i.e., that quantum states and quantum operations are not ontic, but subjective—but it'll still be a good exercise, and I know I'll learn from his reaction (as long as it is not silence).

> Title:
>
> What is the Difference between a Quantum Observer and a Weatherman?
>
> Abstract:
>
> Not much. But where there is a difference, there lies quantum theory's most direct statement about properties of the world by itself (i.e., the world without observers or weathermen). In this talk, I will try to shore up this idea by writing quantum mechanics in a way that references probability simplexes rather than Hilbert spaces. By doing so, the connection between quantum collapse and Bayes' rule in classical probability theory becomes evident: They are actually the same thing up to a linear transformation depending upon the details of the measurement method. Looking at quantum collapse this way turns the usual debate in quantum foundations on its head: only local state changes look to be a mystery. State changes at a distance (as after a measurement on one half of an EPR pair) are completely innocent—they simply correspond to applications of Bayes' rule itself, without the extra transformation; that is, collapse-at-a-distance is nothing more than the usual method of updating one's information after gathering data. Thus the idea develops that if a quantum reality is to be found in the quantum formalism, it will be found only in the formalism's *deviations* from classical probability theory: Reality is in the difference. Time permitting at the end of the talk, I will try to sketch, without getting too lascivious, how such a reality may be best thought of in conjugal terms.

John's Reply — Yes, Really, John's Reply

> I was disappointed to hear that you won't learn from my silence. I may need to rethink my method of communicating ...

15-11-03 *Elementary Quantum Phenomena* (to R. Laflamme)

I looked in my email for that dinner or beer you said I promised you, but I couldn't find it. You know, with my weird beliefs about quantum mechanics, a quantum phenomenon may not be an actual phenomenon until it is written in an email somewhere! (Or was it John Wheeler who said that?)

17-11-03 *Tossing and Turning* (to L. Smolin)

Well you caused me quite a sleepless night of tossing and turning with your "needling" question yesterday. When I snapped that your question is like my asking you why you haven't quantized gravity yet, maybe I should have bitten all the way through the flesh: Maybe our two projects are the same damned thing! And if you can't do it by yourself, why should I be expected to? More seriously, I wonder whether identifying the ontic piece of quantum theory—i.e., the research program I am trying to build—might not just amount to (a large part of) getting at a quantum theory of gravity.

You said, "Come back to me when you've got the ontic piece." (Well, you didn't quite say ontic but something of the same flavor.) The part I see most clearly at the moment is Hilbert space *dimension* … and maybe that's all there is. At present, I am toying with the idea that D quantifies a kind of "nervous creative energy" on the part of a quantum system. More speculatively, I find myself wondering if it is too far-fetched to think that that creative energy gravitates much like its less metaphorical cousin.

So I was really quite excited last night on the bus ride home when I came across your appendix on Relational Quantum Cosmology in the review article you gave me! I had never heard of Crane before, and I didn't know about your work with Fotini on what you call the weak holographic principle. I almost melted when I read the sentence, "The only property a screen has beyond its place in the causal network is the dimension of its Hilbert space."

Anyway, in good faith to this excitement, let me place below some excerpts from my newest email samizdat, *Darwinism All the Way Down (and Probabilism All the Back Up)*. The connections to your sentence above should be evident, and I hope the passages convey a little of why I am thinking in these directions. Of course the mumblings are not science yet (or they would be appearing in papers, not samizdats), but rather dreams of a solid direction to follow. The real science strikes me as just around the corner.

18-11-03 *Don't Forget Rorty* (to R. W. Spekkens)

Don't forget to bring my Rorty back before I fly out.

Oh bring back, oh bring back, oh bring back my Rorty to me, to me …

25-11-03 *Philosophy Sauce* (to A. Valentini)

Valentini-ism 1: *Sorry about the testosterone-fueled rant last night. It did come out with an aggressive edge. Hope you have a good return trip.*

No bothers; it just made for a saucier night.

For the record though:

The anti-Växjö paper was passed by (at least): Jeff Bub, Henry Folse, Bas van Fraassen, Wayne Myrvold, and Chris Timpson.

The "World is Under Construction" note was passed by (at least): Richard Healey, Wayne Myrvold, Chris Timpson, and Steven Savitt.

To my knowledge `quant-ph/0205039` "Quantum Mechanics as Quantum Information (and only a little more)" has been read at some level by: Guido Bacciagaluppi, Jeff Bub, Bill Demopoulos, Armond Duwell, Arthur Fine, Bas van Fraassen, Stephan Hartmann, Richard Healey, Wayne Myrvold, Itamar Pitowsky, Steven Savitt, Abner Shimony, Chris Timpson, and Giovanni Valente.

The large samizdat *Notes on a Paulian Idea* has been distributed to: Guido Bacciagaluppi, Jeffrey Bub, Jeremy Butterfield, Arthur Fine, Henry Folse, Bas van Fraassen, Alexei Grinbaum, Hans Halvorson, Stephan Hartmann, Richard Healey, David Malament, Wayne Myrvold, Itamar Pitowsky, Steven Savitt, Abner Shimony, Chris Timpson, Giovanni Valenti, and Steve Weinstein.

Of the people above: Amit Hagar has written a critique of my stuff in the journal *Philosophy of Science*, Giovanni Valente has just submitted a Master's thesis in philosophy at the University of Padua on it, and Stephan Hartmann is including it as a component in his course at the London School of Economics.

The point: I don't know whether you would be willing to call these guys philosophers, but it can be verified that they are all employed by philosophy departments. The last thing I see myself doing is hiding from critique—a better word would be "test."

The only real goal is in understanding quantum mechanics. And on this, we are in it together.

25-11-03 *The Unfortunate Phrase* (to A. Valentini)

Let me follow up on your question about my view of the phrase appearing in one of my papers with Caves and Schack: "Gleason's theorem can be regarded as the greatest triumph of Bayesian reasoning."

The place to look is my web samizdat *Quantum States: What the Hell Are They?*. See:

- page 75, "The Stopgap"
- page 84, Cavesism 27 and below
- page 118, "Trumps and Triumphs".

My own view of what the paper accomplishes can be found in the letters

- "Identity Crisis" on pages 35 to 38,
- "Unique Assignment" on pages 53 to 54.

I thought I had said it somewhere more clearly in there, but I don't have the time at the moment to keep digging for it.

25-11-03 *Worthwhility* (to J. E. Sipe)

I just wanted to say I'm sorry I didn't get a chance to talk to you longer at PI. Your reaction after my talk made my day; in fact, it alone was enough to make my giving the talk worthwhile. You wouldn't believe how much strength and stamina to go on I derive from reactions like yours.

Anyway, there's so much to do in this program and so many subtleties that still need hammering out, I welcome your interest.

25-11-03 *I Dream of Everything* (to C. Snyder)

I just reread the note you sent me and enjoyed it again indeed. Thanks for the great conversations last week.

Snyderism 1: *As artists we are subjective in the extreme ... (there are no wrong descriptions (or models), only personal ones.*

This you might say is the program of "Quantum States: What the Hell Are They?": It is to make the physicist realize that he has more in common with the artist than he might have thought. The quantum state, in particular, I say, represents a subjective ascription. Mimicking your words, there are no wrong quantum states, only personal ones. I did a quick search and found some discussions of this on pages 39 (right after Merminition 9), 49–50, 54–56 (the underappreciated point), and 159–166 (parts of the letter to Hardy) of the document you printed for me. You might enjoy reading about this overlap of our concerns—it is quite real.

I hope we'll have an infinite time in the future to build on this.

Christian's Preply

> Thanks for directing me to the various articles ... it will take some time to digest (I'm afraid I did a little more reading then perhaps I should have.)
>
> I slept last night (got to bed late, as per always) and was pushed into a rather awkward dream (or state that resembled a dream). In this dream I was able to observe many things: myself, the universe, the lines of the forever.
>
> Now I must apologize because I just spent 30 minutes trying to explain what it was that I saw in this dream, and realized I couldn't do it without some sort of pen and paper ... so I've erased it. Let's just say there was an x, y and z axis, a reflected sine wave and a bad morning hangover where everything I observed on the inside of my eyelid kept changing from a particle to a wave. It is a bad way to wake up when you have a soccer game an hour later.
>
> Anyway, I was thinking, artists and you physics guys aren't really so dissimilar you know. We are both observers of the world, we both try to describe the world, but our models of the world are so fundamentally different it makes me wonder about you guys sometimes. As artists we are subjective in the extreme ... (there are no wrong descriptions (or models), only personal ones). As physics guys (and gals of course) you always want to be objective and your models (or descriptions) are always wrong. You know this going in ... you might get closer to the truth (assuming of course there is an objective overriding truth, which you don't believe in) but you guys do it with *your* data, with *your* machines.
>
> Why is it that we expect objective data from machines we build?
>
> *LONG BREAK*
>
> Sorry, the clock on the wall says 3 AM, I'm going to bed. I'll write more later.
>
> *LONGER BREAK*
>
> Ahem, looks like I forgot to send this last night. Well here's to the early morning forgetfulness. Now I must promise not to re-read this thing before I send it 'cause otherwise I'll never send it.

26-11-03 *Bartleby and What I Really Mean* (to C. H. Bennett)

I'm off to the Utrecht meeting tomorrow morning to declare "Quantum Information Does Not Exist."

Title: Quantum Information Does Not Exist

Abstract: It is information *carriers* that exist—conceptually both classical and quantum. To confuse the epistemic category (the information) with the ontic (the carriers) is to cause any amount of trouble. Nonetheless, one thing is true when it comes to applications of information theory to classical and quantum phenomena: There is a difference. And, in that difference—this talk will argue—lies quantum theory's most direct statement about properties of the world by itself (i.e., the world without the information processing agent).

02-12-03 *Alive and Well, but back in Dublin* (to A. Peres)

I am just back in Dublin from a few days of email blackout in Utrecht. Kiki accompanied me to this conference, and we left the kids in the care of their grandmother (who flew to Dublin from Munich just for the purpose).

I gave a talk with the belligerent title "Quantum Information Does Not Exist", but it was a variant of the one you saw me give in Aarhus. I chose the title that I did to give Ari Duwell's nice paper of the same title some advertisement, but also because I wanted to emphasize de Finetti's version of Bayesian probability more this time. For most of the audience though, I think the talk was a disaster. The main thing was that I did not enter the arena with enough forethought of the "crowd control" I would need. Roger Balian and Theo Nieuwenhuizen, in particular, heckled me quite a bit. They would not accept that a POVM could actually be measured (since it contains noncommuting operators). It was silly and only demonstrated that they just were not listening. In the tradeoff at least, I could see the lights flashing in the eyes of Jos Uffink and Michał Horodecki. Michał, for one, seemed to finally understand how you and I view the wavefunction ("Quantum Theory Needs No Interpretation"), and how we are not "inconsistent"—something that he apparently thought of us all these years. So, that was very nice to see such a change in him.

02-12-03 *You Really Must Hurry* (to R. W. Spekkens)

I'm just back from the Utrecht meeting and pretty exhausted, but I've got to tell you about a conversation I had with Michał Horodecki. He was telling me about how Robert Alicki has been pushing them to think of quantum mechanics as just a restriction on knowledge. And thus they had developed some "toy model" that, for instance, exhibits a kind of no-broadcasting theorem on top of a no-cloning theorem. Prompted by that, I figured I had better tell him (a very little) about your toy model. You could actually see the panic in his face. He said something like, "We must post our paper soon." I told him that priority shouldn't be an issue because your work has already been cited three times on `quant-ph` and gazillions of people have heard your talk on the subject. But I doubt I fazed him much with that: These Horodeckis are wham-bam-thank-you-ma'am kind of guys when it comes to getting their ideas out there.

I know that you understand the point: You are walking on thin ice with this result. It's a beautiful piece of work, however the time is starting to become ripe for its re-appearance out of sheer Darwinism. The pressures are mounting for the quantum state to be viewed epistemically and science is responding.

02-12-03 *Now, For the Important Stuff* (to L. Henderson)

Here's the PhD thesis I was talking about:

- W. H. Long, *The Philosophy of Charles Renouvier and Its Influence on William James*, Ph. D. thesis, Harvard University, 1927.

There's another one along the same lines that I also want to get my hands on:

- H. C. Sprinkle, *Concerning the Philosophical Defensibility of a Limited Indeterminism: An Enquiry based on a Critical Study of the Indeterministic Theories of James, Renouvier, Boutroux, Eddington, Bergson and Whitehead*, Ph. D. thesis, Yale University, 1929.

but that's beside the point. (I just wanted to have a record of both in the same email; I store most of my information in emails.)

Anyway, it would be lovely if you could check out the Long thesis before coming to Maryland conference next April 30. Or maybe I could figure out a way to get to Cambridge before then.

Thanks so much for this help!

02-12-03 *Paper and Visit* (to R. Schack)

I'm just back from Jos Uffink's meeting in Holland. Among other things, I got to meet Stephan Hartmann there; he's quite a Bayesian. Also I had a fruitful time talking to Jos himself. I asked him his views on the interpretation of probability and got quite a surprising answer: He has not made up his mind, but he leans 1) mostly toward radical von Mises type frequentism (with kollectivs, randomness and place selections and all that), but 2) to a smaller extent toward radical subjectivism. He sees those as the only two consistent alternatives. In particular, he rejects propensitism, logical interpretations, objective Bayesianism, etc. Strangely he also knows (and admits) that frequentism has no empirical content, but that doesn't seem to sway him.

Have you ever read his paper on the MaxEnt principle and thought about whether it is valid? It's actually quite nice, and I think an indication that he is a thorough thinker. You can find it here: `http://www.phys.uu.nl/~wwwgrnsl/jos/mep2def/mep2def.html`.

02-12-03 *Scrap Paper* (to L. Hardy)

I just sent the attached picture to my brother so that he could print it out for my mom. It's a drawing of Emma's from last week. Upon reviewing it before sending it, its relevance to Perimeter dawned on me: You'll see what I mean. Whenever I come home from a trip, Emma asks me if I have any scrap paper for her. I usually give her whatever was in the conference packet, etc. This time it was a Perimeter Institute pad. Her drawing skills are getting better and better; I'm pretty proud of her.

03-12-03 *Holism, Nonholism, or Nihilism?* (to M. P. Seevinck)

I had a chance to look at your paper as I walked in to work today. So, I absorbed about 45 minutes worth of it. I don't think I have anything substantial to say at the moment, other than I think I like your approach based on LOCC and operationalism. It seems to be moving in the right direction.

I am a little curious to know how this train of thought I've been trying to hammer out in quantum foundations fits into one or another holism/nonholism distinction. Tentatively I call my (forming) view "The Sexual Interpretation of Quantum Mechanics". Its beginnings are in `quant-ph/0205039` "Quantum Mechanics as Quantum Information (and only a little more)" and `quant-ph/0204146` "The Anti-Växjö Interpretation of QM" (Sections 4 and 5), but it only really takes on a kind of force in my document "Quantum States: What the Hell Are They?" posted on my webpage. For only there do I come to realize that I fairly explicitly drop what you call the eigenvalue-eigenstate link in these newest trains of thought.

Is it holism? Or, is it not holism? On the one hand I wouldn't think my view a kind of holism, as the only *property* I find myself willing to suppose of a quantum system is its Hilbert-space dimension. But then on the other hand, I find myself wondering how to interpret the following statements that I find myself saying:

page 48 of "QS: W.H.A.T.?":

> Excellent! This is only a joke partially, but lately I've been so taken with the idea that unions can give rise to things greater than those contained in the parts—thinking of quantum measurement, in particular, from this angle—I've thought about calling my view on QM "the sexual interpretation of quantum mechanics."

page 49 of "QS: W.H.A.T.?":

> Lately, I've been jokingly calling my view (as it stands) the "sexual interpretation of quantum mechanics." (Most people turn red and become uncomfortable when I do that and explain why. I suspect the same will be true even in your reading of this note. So, brace yourselves.) The essential idea is that something new really does come into the world when two of its pieces are united. We capture the idea that something new really arises by saying that physical law cannot go there—that the individual outcome of a quantum measurement is random and lawless. The very fact that the consequence of the union is random signifies that there is more to the sum than is contained in the parts. But I promise you I won't reflect the licentious details of this view in the glossary below. I'll leave the missing terms to your imagination.

page 190 of "QS: W.H.A.T.?":

> I suppose if I were to start to label things, then this thing I was telling you about the other day—"the sexual interpretation of quantum mechanics (SIQM)"—would be a kind of dualistic theory. I said it metaphorically this way: When things bang together, something is created that is greater than the sum of the parts. Or again: When things—that's the materialistic aspect—bang together, something is created—that's the mentalistic aspect, for it is like an act of the will or a decision. But that's just a thought that's hitting me at 4:00 in the morning. (So trust it less than even the usual things that come out of my mouth.) I hadn't thought about it in this way before, and I'm not sure I want to continue to thinking about it this way. In general, I don't like dualisms. (Though even saying that is paradoxical; for I think I like "pluralisms" in the sense of James.)

If you need more of the surrounding conversation to make sense of these statements, please go to my webpage and look at "QS: W.H.A.T.?" directly.

Also here are some pieces from my more recent correspondences: [See 19-07-03 note "Definitions from Britannica," to N. D. Mermin and 18-08-03 note "The Big IF" to A. Sudbery & H. Barnum.] (In fact, I'll just attach a pre-packaged thing related to the Sudbery/Barnum correspondence. Maybe you'll find it of interest in its own right.)

Anyway, all these statements certainly feel like a kind of holism as you define it early in your paper, except for possibly the "creative" aspect of a quantum measurement and "subjective" aspect of the quantum state that I keep emphasizing.

Is it holism, nonholism, or nihilism? The last part of that is a joke, but you have piqued my interest in the question.

So, this note was hardly a comment on your paper, but I hope you see that you've gotten me thinking.

03-12-03 *Recovery* (to M. Pérez-Suárez)

Pérez-Suárezism 5: *Well, the point is that I thought there was a one-to-one correspondence between quantum tests (by which I mean, basically, a certain number of possible outcomes, with a probability assignment for each one, as well as an updating for any quantum state assignment after having gathered the actual data) and POVMs (by which I mean a set of nonnegative operators comprising a resolution of the identity). But there is not. Due to the dependence of the quantum state updating on the particular Kraus representation for the effects (up to a unitary relation) in the POVM, it turns out that one and the same POVM corresponds to different tests, all of which, nonetheless, share the number of outcomes (of course) and the probability distribution for them. Thus, the different tests corresponding to the same POVM differ only in the updated quantum state assignment. The reasoning behind this is so simple that I don't think I have made any mistake, but I felt surprised at this, though I guess it is a well-known result I had simply not read about. I'd like to know what you think this is telling us (if anything) about the relation between those tests and, maybe, by the way, about the nature of a quantum state assignment.*

I've already tried to tell you what I think about it. It is in my explanation of the extra "mental readjustment" in Section 6 of `quant-ph/0205039`. Namely, one's (subjective) estimate of one's influence on a system in the process of measurement is something over and above simple Bayesian updating. I think there is still a whole lot more that needs to be said to flesh this out properly, but maybe that should wait until you arrive.

03-12-03 *Växjö Contributions* (to H. Barnum)

By the way, here are the titles that have been promised on the Växjö proceedings. Also I'm going to try to write something small. I don't recall ever seeing a wink from you on whether you'll submit your big paper. Are you gonna do it?

Scott Aaronson:: short, recreational paper about what goes wrong if you replace $|\psi|^2$ by $|\psi|^3$ or change QM in various other ways.

Guido Bacciagaluppi:: "Classical extensions, classical representations and Bayesian updating in quantum mechanics"

Paul Busch:: "Less (Precision) is More (Information): Quantum Information in Classical Embeddings"

Bob Coecke and Keye Martin:: "Partiality in Physics"

Piero Mana:: "Why can states and measurement outcomes be represented as vectors?"

Rüdiger Schack:: Titleless at the moment.

Alexander Wilce:: "Probability: classical, quantum, and otherwise", or "Symmetry and compactness in quantum logic"

03-12-03 *A Question of Condensation and Time, 2* (to J. I. Rosado)

Because of the new paper that Rüdiger Schack and I are constructing, tentatively titled "On Quantum Certainty", I was thinking of you the other day. At first it was quite hard to find our correspondence in my files because I could not remember your name, but after some work I found it. [See 21-04-03 note "A Question of Condensation and Time" to J. I. Rosado.]

I don't think you made a further reply on the note below, but I just wanted to make sure. In any case, if you have ever written anything on the subject of your note, Schack and I should cite you. Please let me know.

Where are you located? Are you a student, postdoc, professor, etc.? Tell me a little about yourself, so that I can better remember your name in the future.

04-12-03 *Incompleteness* (to R. Plaga)

Plaga-rism 1: *I read with great interest you paper "Quantum Mechanics as Quantum Information" (*`quant-ph/0205039`*). I really like your idea that QM is in a similar state as special relativity before 1905.*

One question about your discussion of Einstein's criticism on p. 11. You write "the world has seen much in the mean time" and quote the theorems Bell and Gleason. Why do these theorems refute Einstein's unwillingness to accept incompleteness?

Thanks for your interest in my paper! I do not think that Bell and Kochen-Specker *refute* Einstein's goal of finding a more complete theory. In fact, I do not think it can be refuted. Rather, I would say that the theorems I refer to better delimit the costs of such a venture. And by my own scale, the costs are now high enough that I find it worthwhile pursuing the opposite extreme: I.e., to search for a sound, palatable, and instructive reason for why such an Einsteinian-type completion need not be sought. Can we imagine a model of the world in which such a completion is blocked by the world's very properties? That's the sort of thing I am after.

04-12-03 *Degrees of Belief* (to C. Snyder)

Wow, you lot from the Jane Bond (this is my new name for the residents of Waterloo that I did not meet explicitly at the Perimeter Institute) are some pretty serious scholars.

Snyderism 2: *So ... Why this word BELIEF? (Please don't ask me to read de Finetti, Bernardo or Smith ... I'm more interested in your own words.)*

I don't think any of the Webster's definitions capture the particular meaning I had in mind. What I meant was something particularly abstruse. Let me give you an example, that'll maybe clarify my usage a little.

Will it rain here in Dublin tomorrow? I don't know. At best I might have some kind of internal degree of belief p (p is a number between 0 and 1) for whether it will rain. What does that mean? Its operational meaning is this: If anyone were to offer me a wager of S dollars, then I should have no qualms about laying down (p times S) dollars on the condition that IF it rains, he will return S dollars to me. Otherwise, he will keep my (p times S) dollars for his own profit.

In this sense my degree of belief p is experimentally testable: It is manifested in how many dollars I would put down on some uncertain event. But there is no sense in which my degree of belief can be right or wrong. It will either rain or not in Dublin tomorrow, and it will do that independently of my beliefs (i.e., which bets I will accept). To mimic you words a last time: there are no wrong degrees of belief, only personal ones.

When I say that a quantum state for a physical system is a belief, what I really mean is that it is a SET of degrees of belief for the outcomes of all the different kinds of experiments I might imagine performing on that system.

Hope that helps.

Snyderism 3: *I would expect most quantum guys (this is my new name for your lot) to not be terribly keen on the word BELIEF (even if you do define it in the context of quantum discussion.)*

Yep, but my gut and my logic both tell me that I'm pushing the community in the right direction. Some of them are only coming kicking and screaming at the moment, and some of them are fighting with all their lives, but that's slowly changing.

Christian's Preply, "To BELIEVE or to KNOW"

> Sorry about the delay in responding … it has been quite a busy spell here for me. Listen … I was reading your last email, and reading the things you asked me to read in your last email about subjectivity, but I had trouble getting beyond your "Note on Terminology." I found your term BELIEF a very interesting one. You, of course, define it in the context of quantum discussions. And in that context define BELIEF as a quantum state. Good enough … however Mermin would rather talk about knowledge, not belief.
>
> Granted the game being played is one of definition, not entirely unlike the the white on black illusion you refer to on the previous page (you're both talking about the same thing, just defining/seeing it differently.) So to my question …
>
> I would expect most quantum guys (this is my new name for your lot) to not be terribly keen on the word BELIEF (even if you do define it in the context of quantum discussion).
>
> The original form (definition) of the word (outside of your context) is an assent to a proposition or affirmation, or the acceptance of a fact, opinion, or assertion as real or true, without immediate personal knowledge; reliance upon word or testimony; partial or full assurance without positive knowledge or absolute certainty; persuasion; conviction; confidence; as, belief of a witness; the belief of our senses. (That would be Webster's not Oxford … but whatever.)
>
> So is it the last line you like? (The belief of our senses and therein the subjective.) But there is almost a contradiction in the word isn't there … the assertion as real or true, without immediate personal knowledge, and yet can also be the belief of our senses. It is interesting that Webster's also lists opinion as a synonym.
>
> It is also interesting that there is also a definition for ultimate belief (last in a train of progression or consequences; tended toward by all that precedes; arrived at, as the last result; final.) I wonder if there is a definition for ultimate knowledge … if there is, it would no doubt be identical.
>
> So … Why this word BELIEF? (Please don't ask me to read de Finetti, Bernardo or Smith … I'm more interested in your own words.)

10-12-03 *Girelli's Workshop* (to W. G. Unruh)

I've been meaning to write you for some time, but I kept forgetting to. Seeing the line-up at the Seven Pines thing in my email today finally reminded me. Anyway, in particular, I had said to

Florian Girelli that I would write you to encourage your participation in his workshop Feb 23–29 on quantum information and gravity at the Perimeter Institute. I hope you will come. The time does seem ripe to put these two things together (and knowing that you'll be there will help me justify in my mind my own participation!). I'm hoping he'll also be able to get Raphael Bousso to come; it'd be interesting what comes out of the mix of you two. In any case, the bigger, the better the crowd, the more interesting it'll be all around.

10-12-03 *Thanks* (to J. B. M. Uffink)

By the way, I've been wanting to thank you for inviting me to your meeting. I learned some things, and it certainly helped me discover that the Netherlands is every bit as nice as my wife had been telling me!

I conveyed a report of your unique view on interpretations of probability to Rüdiger Schack. (Unique, because you could see the merit in *both* strict-von-Mises frequentism and radical subjectivism.) I hope I got the details right! Anyway, I think it would be good for us to talk this through at length one of these days. If Rüdiger and I can just pull off our "Being Bayesian in a Quantum World" conference (to which you would be invited), that'd be the perfect place.

10-12-03 *Slogans* (to A. Duwell)

I've been meaning to write you for a couple of weeks to tell you a little story. Sorry I didn't get a chance before now. Anyway, it is about Jos Uffink's and Dennis Dieks' conference in Utrecht a couple of weeks ago. Since they wanted me to talk about the meaning of quantum information, rather than quantum states per se, I knew that there was nothing more accurate I could title my talk than with your slogan, "Quantum Information Does Not Exist." I hope you don't mind! In particular, I opened my talk with some lines that went something like this:

> Unfortunately, I have to start my talk with a horrible admission: You have a thief among you! For I have stolen the title for my talk from a nice paper of Ari Duwell that I would encourage all of you to read. [Then I put up a slide with the title, your name, and the paper's publication details.] At the end of my talk, I hope you will see a connection between what I am about to say and this slogan. However, for most of my time I will be talking about a formalism that might help you see the interpretational problems of quantum mechanics in a new light. Though I stole the title, I hope you won't think I stole the contents of my talk!

It got a good laugh all around, and I hope it did encourage some in the audience to pay attention to your paper.

Which reminds me of something else I've been wanting to say to you for some time: You really ought to post your paper on the `quant-ph` archive. A lot of people in the quantum information community are going astray. If you don't post your paper there, a lot of people in that community are never going to see it . . . and never get a chance to get their thoughts straightened out from it.

10-12-03 *Sneaky Ways to See You* (to C. H. Bennett)

I'm writing you to encourage you to go to Jeff Bub's meeting April 30 through May 2 in Maryland. See this link for details: `http://carnap.umd.edu/philphysics/newdirections04.html`. If you're going to go, could you drop him a line to let him know that you'll be there? (And if you're not going to go, could you let him know that too?)

But I do hope you'll go. The argument that you didn't actually settle the Maxwell demon problem seems to be gaining some momentum in that crowd, and I think if you'd just face them one-on-one for once, it would do a world of good. In particular at the Utrecht meeting last week, a fellow named Owen Maroney—who will most surely be at the upcoming meeting too—gave what appeared to be a decently reasonable talk trying to pinpoint where you had gone wrong. (I'll put his abstract below.) If you had just been in the audience to ask the right question at the right time—I hate to say it again—it would have made a world of difference.

Given that you never wrote your planned review article for RMP, this is probably the best thing you could do as a substitute for the time being. And besides, you and David Mermin and I could all have some fun. Certainly David and I will have a lot more fun if you're around than not.

Please write me to let know if you'll be coming. But more importantly, do please write Jeff with your decision.

> **Owen Maroney: "The (absence of a) relationship between logical and thermodynamic reversibility"**
>
> Landauer erasure seems to provide a powerful link between thermodynamics and information processing (logical computation). The only logical operations which require a dissipation of energy are logically irreversible ones, with the minimum dissipation being $kT \ln 2$ per bit of information lost. Nevertheless, it can be shown that logical reversibility neither implies nor is implied by thermodynamic reversibility. By examining thermodynamically reversible operations which are logically irreversible, it is argued that information and entropy, while having the same mathematical form, have significant conceptual differences.

10-12-03 *City of Light* (to D. B. L. Baker)

Do you know it's been over a year since I've written you a proper letter? (You ought to know by now that a letter from me is not proper unless it contains at least 5K of raw text.)

I'm sure you've guessed from the title of this note that I'm in Paris. What a charming city ... even if it is full of surly waiters! I haven't been here since 1994, and then only for one day in a not-particularly-interesting part of the city. So really my memory has to reach back to 1991 for anything that remotely compares to this weekend. However even then, I would say I've grown so much and learned to appreciate Europe that it is altogether quite something new. Frankly I'm carried away in a romantic/bohemian mood. It probably also helps that I earn a lot more money now, and so don't really mind dropping 70 euro on a meal, as I did last night. It opens up exponentially more of the city, and even takes some of the edge off the waiters. Last night, a colleague and I dined next to a Picasso. It didn't make the food or the ambiance any better, but maybe *they* gave Picasso the extra something he needed to finally (after all these years) draw my attention more than fleetingly.

The brick streets, the cheese shops, the wine shops, the cafés, the life of the bohemian. I am having a great time. And I'm reawakening slightly.

... The long weekend has come and gone, and I'm now at the airport, waiting on a delayed flight. I thought I'd have a chance to write you much more from the Parisian cafés, but a proper flux of writing juices never materialized. Looking back, what can I tell you? What do I feel like telling you? Maybe the thing that will interest you most had to do with an Italian student, Giovanni Valente, who just finished his master's degree in philosophy in Padua, writing a thesis titled, "Probability and quantum meaning: Chris Fuchs' pragmatism in quantum foundations." He'd been wanting to meet me for a while, so a month ago I sent him my travel schedule, saying that he could drop by Dublin one of the times in between. Out of the blue, I got this from him Friday:

Valente-ism 4: *What about meeting in Paris? You wrote me that you have planned to go there (6-9 December) and I could be there. I've been taking a little rest after my viva and the GRE and my parents own a little flat in front of the Moulin Rouge, so it may be a good occasion to meet. Since I haven't been there for a while, I feel I could spend a few days in my favorite place. Anyway, if you think we may meet and drink something, let me know quite soon: I need to book a flight very quickly.*

Well, he wasn't lying! He showed up in Paris the next day, and he actually did have a flat just across the street from the Moulin Rouge! He made me a nice spaghetti dinner and we had a couple of bottles of wine there one evening. The flat was in an old bordello. I certainly never imagined on that infamous New Year's Eve at your house so many years ago that I'd one day get an opportunity like that. Apparently the boy's father was a socialist politician in Italy for some years. Who said socialism was the equalizer of mankind?[75]

Monday I lectured at École Polytechnique. It went well. But, the really nice thing was that they put me up in a hotel nearby. So I was in the middle of the Latin Quarter for the stay. That put a few thousand restaurants within my reach, even if only to walk by and look at (quite an experience in its own right). And I was just a mild walk away from the Pantheon, Notre Dame, the Louvre, Musée d'Orsay, Luxembourg Gardens, the Sorbonne, etc. I walked into the courtyard of the Louvre today around 4:00 PM, just after all the bustle had died down and just as the sun was moving into twilight. (The sun sets early this far north.) One could hear just a tinge of traffic noise coming over the top of the building. What a profound aloneness: I savored every second of it. I just kept saying over and over to myself "Le Grand Palais du Louvre." It is quite a monument to the power and creative force of mankind! Big buildings always do me in.

10-12-03 *First Meeting* (to M. Bitbol)

It was great meeting you the other day. As I told you then, I have greatly enjoyed finally reading some of your papers.

Let me paste below the passage from my samizdat *Quantum States: W.H.A.T.?* that refers to you. The text between the `bjb` and `ejb` symbols are quotes of Jeff Bub. Now that I understand that Jeff's "neo-Kantian" might just mean "somewhat pragmatic," I am much more intrigued than I was before. Have you written anything in English on the "blinding closeness" that Jeff mentions?

If you get a chance to have a look at it, I would greatly appreciate hearing your thoughts on sections 5 and 6 of my paper "The Anti-Växjö Interpretation of Quantum Mechanics". The paper can be found at my web page; there is a link to it below.

Michel's Reply

> Better late than never (I hope this faithfully translates the French "Mieux vaut tard que jamais").

[75] In the editorial stage of this samizdat, Giovanni pointed out that I "still don't fully get the difference between socialism and communism."

I thought I had to answer your mail one day, but many other tasks piled up. However, I finally found a free sunday morning and I read some of your stuff with pleasure. The "Anti-Växjö interpretation" sounded very relevant since Andrei Khrennikov is coming to visit us in CREA tomorrow!

I must say I was delighted to discover that, in this paper written by a physicist (you!), there is more excellent philosophy of quantum mechanics than I had ever seen before. As you already know, I am disposed to agree on most of what you say. I was drawn independently to very similar conclusions by combining a radical version of Copenhagen interpretation (plus some insights from Schrödinger) and a network of philosophical readings ranging from neo-kantianism to pragmatism. Here is, to begin with, a short list of points of agreement (with some nuances):

1) Quantum mechanics is a theory of contextual probabilities: Kolmogorovian probabilities in each context, several such probability spaces being "glued" in a unified Hilbert space structure. To summarize this idea, I called QM a "Meta-contextual theory of probabilities".

2) The main terms of the theory refer to certain gambling attitudes. With some stringent constraints however: coherence and intersubjectivity (or rather inter-situationality, invariance of the formal tools with respect to changes in situations/contexts), etc. When this constraint of inter-situationality or intersubjectivity is emphasized, one lands into a central concept of Kant's transcendental philosophy: constitution of objectivity.

3) I also agree that physical theories express the conditions for our successful life within the world rather than a faithful picture of the world. Your insistence on Darwinian evolution, on viability rather than mirroring, is very close to the ideas I developed after a long contact with Varela's autopoietic theory of cognition. Here is a short statement of this theory I recently wrote:

> In the autopoietic theory of cognition, the relevant concept is not inputs provided by the external world, but only local environmental conditions for maintaining an operationally closed unit. The invariants of this type of unit do not represent any feature of the world, but rather identify with steady aspects of its own internal dynamical organisation. As for the appropriate changes of an operationally closed unit, it does not prove that the unit possesses a faithful picture of the world, but only that its internal working is viable in relation to environmental disturbances. One must redefine the "cognitive domain" of the operationally closed unit accordingly. This domain is no longer some fraction of a pre-existing world liable to representation, but a region of the environment which has co-evolved with the closed unit and in which the latter's organization may persist, develop, and reproduce despite the disturbances.

As you rightly pointed out, the structure of an elephant (a special case of autopoietic unit) does not represent its environment, but is the end product of a long history of environmental alterations and adaptative changes: it is a summary of the adaptative moves the species had to do. One interesting (and very relevant) features of this example is that the adaptation to the environment is not purely passive. The behavior of elephants, their search for better-suited environments (by migration) or even their own transforming activity, is also part of the adaptative process. The adaptation then becomes somehow mutual. The organism and its environment can be said to "co-emerge". In the same way, our theories are likely to be an elaborated and stabilized byproduct of a cognitive history (made of "conjectures and refutations", gambling rules and failures) which massively involves our experimental activity (our "interventions" by means of apparatuses).

The latter general overview was partly expressed in my "blinding closeness of reality", which unfortunately exists only as a book in French. But the basic idea is easy to summarize: Bernard d'Espagnat (my master in this field) told that reality is quite difficult to picture (actually, in the micro-domain, even impossible to describe) because it is somehow remotely distant from us, because it is separated by a "veil" from us. This was only a metaphor as I soon understood by discussing with B. d'Espagnat, but the happy effect of this was to trigger a diametrically opposite metaphor. My idea was that the reason why reality is impossible to describe as such is that we are so deeply and intricately immersed in it, that we do not have the opportunity of creating the objectifying distance. My motto, inspired from Wittgenstein, can be translated thus: "The subject is not facing the world; it is so much committed in it that this does not allow description." But this does allow orientation in it, or anticipation of part of what may happen for us in it.

I thus warmly approve your "oceanic" picture!

4) Reality manifests itself by its "unpredictable kicks". This is perfectly true. But, as you know, there exists another, very popular, conception of how reality occurs to us. According to many people, we reach some real structure when we have extracted an invariant from phenomena. Since it is invariant, they say, it does not depend on particular points of view, or on particular subjects, and "therefore" (I am very reluctant when I read this "therefore"), it faithfully describes some independent feature of the world "in itself".

Scientists usually combine (in various proportions) these two conceptions of reality in the very dialectic of elaboration of their theories. But they are basically wrong. And, I believe, you are completely right: the only manifestations of something like reality beyond the narrow boundaries of our little persons are unpredictable kicks. Why is it so? Because there is a logical fallacy in the usual inference from invariance to "independent" reality. Any feature of a pre-structured "independent" reality would take for us the form of an invariant; but invariants are not bound to express features of some "independent" reality. We are not even sure that "independent" reality, if this sequence of words is meaningful at all, has already a structure in store, ready to be disclosed (Rom Harre calls the micro-world "the glub" to express the idea that it is likely to be a plastic and dispositional stuff rather than a pre-structured network of actual properties). So, if the cognitive invariants do not disclose the structure of "independent" reality, what do they do? They disclose stable, viable, and intersubjective forms of our anticipations (our gamblings).

Instead of opposing two conceptions of the manifestation of reality (as unpredictable variations and as structural invariants), we should only keep one of them: yours, namely unpredictable variations. The other conception only deals with what Kant calls "objectivity" in his consistently anti-metaphysical acceptation. Reaching objectivity in Kant's sense is by no means identical to mirroring reality. This is what Kant meant when he carefully distinguished objectivity from faithfulness to the "thing in itself".

I applied this remark to the status of QM in several papers (including "Some steps towards a transcendental QM", published by Philosophia Naturalis in 1998 and available on my website). In a paper in French about "Laws of Nature", I concluded thus:

> The boundary between what is transcendentally necessary and what is irreducibly contingent has moved beyond recognition. All the structural features of QM, including its law of evolution, are transcendentally necessary in so far as they express the conditions of possibility of any coherent (probabilistic) anticipation of the contextual phenomena obtained by means of a systematic experimental investigation. And the only element which remains definitely non-contingent is non-structural; it is the very occurrence of isolated experimental outcomes. Hence the aphorism: in QM, nothing structural is contingent, and nothing contingent is structural.

5) I also agree with you that the many-worlds picture of reality is amazingly daring and much more anthropomorphic than its supporters think. However, there are other possible meta-interpretations of Everett's interpretation than the many-worlds, and some of them proved very close to your (to our!) view. An example of them is the indexical view supported by Simon Saunders (and by me in "L'aveuglante proximité du réel"). Here, the universal state vector is not bound to describe the world as a whole, but rather to display the set of possible particular situations we may occupy within it, obtaining this or that unpredictable isolated outcome as a result of an experiment.

6) At this stage, I have to state my major point of disagreement with you: I suspect the remark you made about the "many-worlds interpretation" applies quite well to some of what you say. Let me explain this.

You write: "What I find egocentric about the Everett point of view is the way it purports to be a means for us little finite beings to get outside the universe and imagine what it is doing as a whole." I deeply agree with you.

But, then, you begin to do essentially the same as the naive Everettian. You try to describe our situation in the world from a sort of vantage point. Here is the sentence in your paper that made me suspicious: "I think the solution is in nothing other than holding firmly—absolutely firmly—to the belief that we, the scientific agents, are physical systems in essence and composition no different than much of the rest of the world. But if we do hold firmly to that—in a way that I do not see the Everettist as holding to it—we have to recognize that what we're doing in the game of science is swimming in the thick middle of things."

Of course, once again, I am delighted by the Pascalian metaphor of "swimming in the thick middle of things". But you seem to take it as more than a metaphor: a definite belief about (not to say a faithful description of) the world and our position in it. You write seriously that "we, the scientific agents, are physical systems in essence and composition no different than much of the rest of the world". Isn't this a way of extrapolating one of our pragmatic - adaptative concepts, one of the concepts we need to swim with some success in the midst of the "glub" (here, the concept of a "physical system"), in order to describe everything including us as if it were seen from outside? I hear you saying something like "the world as I see it from my cosmic exile is made of physical systems and each one of us is one of these physical systems". But if we are "swimming" in the deep ocean of whatever we call "reality", we have absolutely no context-independent concept at our disposal, not even the very general meta-concept of "physical system". We must say that we ignore everything of the "thing in itself", including whether it is organized or not in a plurality of "physical systems". And we must therefore content ourselves with stating the formal conditions of our cognitive aptitudes (within it). This latter attitude is typical of the Kantian and neo-Kantian

> lineage of philosophy (when one gets rid of the foundational aspect of Kant himself and hold a pragmatic variety of Kantianism, as I do). I hope you'll recognize it as a radical variety of your view… I wonder whether you'll become a member of our radical club or rather decide to stick to your position as it stands.

10-12-03 *Thoughts in France* (to J. Bub)

I'm just back from a few days in Paris. I had a great thoughtful time reading your paper "Why the Quantum?" during a long lunch and during my morning and afternoon coffees in the Latin Quarter yesterday. I read it as I threaded in and out of the Louvre and Notre Dame. There is much I like about the paper, but there is also much I disagree with (especially in the last third). I owe it to you to get those thoughts down solidly. At the moment, I'm shooting to get them to you before the end of the weekend. Just a heads-up so you'll have a chance to stock up the liniment oil!

10-12-03 *Down with Frequentism* (to K. R. Duffy)

Sorry I forgot to contact Schack for a title to his talk Monday. (Are you out there Rüdiger?) Let's title it this tentatively:

> Defining (Carefully) a Quantum-Mechanical Relative Frequency Operator.

Schack's affiliation is below.

11-12-03 *My Communication Skills* (to R. Balian)

It was very good meeting you in Utrecht two weeks ago. I was dismayed a little bit by your reaction to my talk, however. Without a doubt, I must have presented something in a confusing manner—for in the end all the things I said were rather trivial and elementary. I.e., they were not the sorts of things that could even be controversial, much less between two Bayesians.

In any case, I hope that the paper associated with my talk "Quantum Mechanics as Quantum Information (and only a little more)" will do a better job than I did in person. For your reference, you can find it here: `http://www.arxiv.org/abs/quant-ph/0205039`. If you find anything in it that is still unclear after your reading, I would much appreciate your feedback.

11-12-03 *Thomas, Pauli, Lubańaski, and Enz* (to A. Peres)

Asherism 39: *You are an inexhaustible source for references: where is the Pauli-Lubańaski vector? I asked Charles Enz who wrote a scientific biography of Pauli, but got no answer (Enz, who is not young, was a student of Pauli). Thanks.*

- L. H. Thomas, "The Kinematics of an Electron with an Axis," Phil. Mag. **3**, 1–22 (1927).
- J. K. Lubańaski, "Sur la théorie des particules élémentaires de spin quelconque. I.," Physica **9**, 310 (1942).

I'm not sure how Pauli came into the game though. If you find out, please let me know.

About Enz, I had some contact with him soon after the fires in Los Alamos: He replenished my supply of historical papers on Pauli that he had written. His last note came to me 6/20/2000.

Since then I have written him on two occasions, the last being 6/10/2003, and have not gotten a reply. This year or so, his book *No Time to be Brief: A Scientific Biography of Wolfgang Pauli* appeared, but I found no reference to Lubańaski in it. I understand the book to be good, but I have not read it myself.

15-12-03 *Alchemy* (to G. Valente)

I have been meaning to write you since my departure from Paris. I hope you will accept my apologies for taking so long. Mostly, I just want to say that I had a fabulous time discussing philosophy/politics with you. Thanks also for the nice pasta meal.

Let me share one of my more secret projects with you as a little recompense. I'll attach a document I'm compiling called "The Activating Observer: Resource Material for a Paulian/Wheelerish Conception of Nature". It's still very far from complete, but I think you'll enjoy it even at this stage.

At times, I have dreamt fleetingly that the ancient alchemists may not have been so very far off course. You have rekindled that dream in me again.

16-12-03 *BIPM* (to R. Balian)

Thanks so much for your notes. I am pleased and excited to hear that you have printed out some of our papers. For myself, I think quantum mechanics is at a crucial time. The issue as I see it is that if we all can just muster the stamina and courage to be absolutely consistent in following through with a Bayesian interpretation of quantum probabilities some of the greatest physics may be just around the corner.

Roger's Preply

> When printing your paper on qm and information, I noticed that you locate the "Bureau International des Poids et Mesures" in Paris. It is actually in a suburb, close to the one where I live, in a nice park on a hill just above the famous china manufacture of Svres. Its address, that is mythical since we learn it at school when we are taught the metric system, is: "Pavillon de Breteuil, Sèvres".
>
> The kilogram of the SI system of units is indeed in deep caves below this small end of XVIIIth century castle, but the meter, which is also there, has lost its official status . . .

16-12-03 *Reading Assignment* (to M. Pérez-Suárez)

I've been thinking a little bit on what we might work on. There's a cluster of problems I've been thinking about to do with symmetric informationally-complete sets of states. We'll probably pick up there after you get settled in here.

But let me give you a reading assignment as you suggested.

Take a look at:

- Symmetric Informationally Complete Quantum Measurements
  `http://www.arxiv.org/abs/quant-ph/0310075`

- Quantum Key Distribution Using the Trine Ensemble
  `http://www.arxiv.org/abs/quant-ph/0311106`

And the draft of a paper I am writing, that I will attach. I won't have any time to correspond about the ideas in these, but that's the sort of thing you can familiarize yourself with.

17-12-03 *Pragmatism for the Holidays* (to L. Henderson)

Hendersonism 1: *And by the way, have you sent me a copy of your book yet? I would like one.*

Yes ma'am. ... Well, actually I've sent your address to VUP. But I don't know if the Swedish holidays will get in the way of a prompt delivery.

Hendersonism 2: *I have also been eyeing my roommate's books on pragmatism with a certain curiosity since our train conversation—it's not something I know much about. Maybe in the holidays I will get a chance to have a look. What do you suggest of William James? We have* Pragmatism *and* The Meaning of Truth *on the shelf.*

Definitely *Pragmatism*. It's the book that first hooked me. I think *The Meaning of Truth* causes more trouble than it mends. When or if you're ready for that stage, I'll try to dig up some selections of Putnam, Dewey, or Rorty for you. I might also suggest some very pleasant leisure reading in Louis Menand's book *The Metaphysical Club: A Story of Ideas in America*. Here's the Amazon.com link in case you want to read about it.

17-12-03 *State of the Union* (to R. E. Slusher)

The world of quantum information remains firm. I'm trying to get three papers out before February. One on my quantumness measure for the Holevo festschrift, one with Schack on quantum-state tomography from a Bayesian view, and one with Brassard on the fundamental nature (for specifying quantum mechanics itself) of quantum cryptographic tasks. Also, Bennett, Brassard, Preskill, and I just turned in our section for the ARDA quantum crypto roadmap. So that's finished for a while!

Was there any progress putting Bernie's tetrahedral measurement box together? I've got a PhD student joining me in January from Spain, and my plan is to get him working on some theory to do with these measurements. Also I've started up a collaboration with a statistician, Richard Gill from Utrecht, to continue the search for things such a measurement would be optimal for. One of these days we're bound to find something it's good for!

18-12-03 *Finally Some Answers* (to A. Sudbery)

Sudberyism 6: *I wanted to make some general points about the nature of our disagreement and also some particular (to the point of being finicky) points about* 0205039*. I'll probably have to stop before I've finished, so I'll take the general points first.*

Sudberyism 7: *I want to write a piece called "Quantum interpretation needs no mechanics", but perhaps "polemics" would be a better last word.*

I try to use every trick in the bag to motivate the community to think about the connections and contrast between quantum mechanics and general probabilistic reasoning. Sometimes some of the tricks work—and when they do they sometimes work spectacularly—and sometimes they just grate on the reader's nerves. If you wait long enough before giving up hope on me, I might just find a trick that'll work on you. The reason I believe this is I see *truth* here, and the truth will ultimately prevail (no matter how bad a prior one's earlier education may have drilled into them).

Sudberyism 8: *I'm sure I'm not alone in seeing your dissolving of the "violent" state change (on p. 34) as a cheat. Calling it a "mental readjustment" doesn't make it any less violent. Incidentally, there's something wrong with eq. (97); these U_i are not unitary.*

Fair enough. It is violent—every bit as violent, discontinuous, and irreversible as a usual application of Bayes' rule. But the point is that it is on the inside of the agent's head, and no one cares what is going on in the agent's head. What physicists should be worried about is the physics of the external world (and not the agent's head). And who knows what really happens there ... especially if physics itself is only really about the interface.

About the U_i's you are correct. I'm sorry, I've prepared an updated version with a lot of the typos, etc., fixed, but I haven't reposted it yet. Here's what the new edition says:

> That is to say, there is a sense in which the measurement is solely disturbance. In particular, when the POVM is an orthogonal set of projectors $\{\Pi_i = |i\rangle\langle i|\}$ and the state-change mechanism is the von Neumann collapse postulate, this simply corresponds to a readjustment according to unitary operators U_i whose action in the subspace spanned by $|\psi\rangle$ is $|i\rangle\langle\psi|$.

Sudberyism 9: *There's something I'm failing to understand on p. 20. You seem to be arguing that equiprobable events must be identical. Is that what you mean, or am I being obtuse? (Also, in para 3, why do you think the word "measurement" belongs only to quantum mechanics?)*

Looking back, I don't know how to say it any more clearly than I said it there:

> The consequences (m_i and n_j) of our disparate actions (M and N) should be labeled the same when we would bet the same on them in all possible circumstances (i.e., regardless of our initial knowledge of S). To put this maybe a bit more baldly, the label by which we identify a measurement outcome is a subjective judgment just like a probability, and just like a quantum state.

You might contemplate that God can see the difference between m_i and n_j, but we can't. And to that extent, we should call them the same thing.

Sudberyism 10: *I also, last weekend, enjoyed some more skimming through your* Paulian Idea*, particularly the glimpse of the smithy where you and Asher forged your* Physics Today *article, but I haven't got my notes with me. I remember only your impatience with your commentators. I repeat, we all have to learn tolerance. But not of interfering APS editors; fight with David Mermin under the boojum banner!*

The worst example I have ever seen of this came from the *Physics World* editor I had to deal with for the thing I wrote for the November issue. Here is a sample of my exchange with him. (Note what an annoying character I appear to be in the first part of this, but then read my second exchange to see why I was furious.)

ME: Thank you; that was a good and well-reasoned change, and I appreciate it. However for most of the rest I am annoyed. Could your copy-editor not see that I was in complete control of my writing? All my words were chosen for reasons, and it would have paid him to spend a little time trying think of what those reasons might be. There is a difference between "mustered" and "muttered", for God's sake. In any case, the article will be written in my style (as long as it is grammatically sound), or it won't be written at all. Luckily I have not yet released the copyright to *Physics World*. I will spend much of my morning reinstating a lot of my old word choices—ones that reflect my writing style and personality, not his—and send you a revised draft before the day is out.

HIM: I am sorry you did not like the subediting, which was done entirely by me. Please rest assured that it was not done to annoy you, but — I hope — to make sure your article is as readable as possible. I'm sorry also for the mustered/muttered confusion, which we can of course change.

ME: Changing almost every sentence in the text—19 out of 23 in the first column alone—is not acceptable.

In the end, that fraction had carried through to the whole article: He had literally changed 83% of the sentences! I spent almost a whole day at Caltech changing almost all of his changes back, and writing an explanation for why I preferred my wording over his. The final product is almost exactly as I had originally written it. Tell me, does it look so bad to you? Did it look worth an 83% change?

Sudberyism 11 : *However, all the modern dictionaries I have give an overwhelming majority of hyphens with "non" – it must be a transatlantic thing.*

I had a similar encounter with John Smolin on this issue. Here is what he wrote me:

John Smolinism 9 : *Regarding the "non" prefix. I agree with you for the most part. At first I didn't. I considered your extensive list of non words as evidence that you DO need the hyphen, since if the dictionary lists so many words, it must consider all the ones it doesn't list as nonwords. And far be it from me to make up a new word, so I preferred the hyphen. But after looking around the net I found basically one style guide that agreed with me and many that more or less tell you to never use the hyphen. So I'm changing sides. I still find it hard to write "nonsecret" as I'd never accept that as a scrabble word. Of course, the solution there is to use "public" instead of making up the word "nonsecret" anyway. Oh, and "nonagenerian" should not have been in your list. Cut-and-pasting from the dictionary is a nongood idea.*

18-12-03 *Finding Gleason* (to R. Schack & C. M. Caves)

Just wanted to say how much I'm starting to like your work on the frequency operator stuff. At first—though I never said so aloud—I thought, why beat a dead horse? Eventually the ugliness and mystery of the construction would make it disappear on its own right, ably assisted by the simplicity of the POVM-Gleason construction. But after Rüdiger's talk here, I started to reassess. What I was particularly impressed with is how you were able to uncover a hidden application of Gleason's very starting point. And that's nice.

This leads me to pose a challenge, whose solution I would relish that much more. Find a hidden use of Gleason's assumptions or theorem in Wojciech's "envariance" argument for the quantum probability rule.

You see, what more could there be to the quantum probability rule than Gleason? Anyone who finds it by some other supposed means has to be faking something.

18-12-03 *General Summary* (to R. W. Spekkens)

Spekkensism 22: *Howard mentioned that you got the news today about your candidacy at PI. A disappointing outcome. How are you feeling about the whole affair? What are your plans?*

Spekkensism 23: *I am still quite bummed out about the outcome of the discussions on your candidacy. You should know that there were many strong advocates for you here.*

Thanks. I feel quite dicked over by this, you know. One night at the Jane Bond, Valentini said jokingly (not so jokingly), "We need to bump you off before you influence any others." That must have been the consensus in the mind(s) of whoever it was that actually quashed me.

Well, I haven't been bumped off. And this is too powerful of a turn in quantum foundations that it won't live by itself. But my life has been made immensely inconvenient by this decision. And I am so pissed off that I won't now be able to be fully engaged in the birth of this baby. It does quite sicken me.

It's just not a good thing to be up at 4:00 AM ...

18-12-03 *Invitation* (to H. J. Briegel)

Congratulations again on the big move. I suspect you are quite enjoying your new life. Or, in any case, the promise of directing great progress must be very satisfying.

I would love to visit Innsbruck and am flattered by your invitation. However, at the moment, my travel schedule is so full, I dare not make any more commitments for the foreseeable months. Perhaps I will take you up on your offer of a visiting position at the new institute in (late) Autumn 2004 or Spring 2005. However, even then, I hesitate to make a firm commitment at this point. The truth is, I am quietly seeking an academic position outside of Bell Labs. And if that materializes somewhere, I know that I will have to learn new responsibilities with respect to my travels.

But oh, how I would enjoy a discussion with you on some deep quantum thoughts. I saw a very good talk by Andrew Childs recently in which he showed a couple of distinct ways to systematically generate states of the cluster-state type or variety (though they appeared to be inequivalent to your own cluster states). It was quite fascinating, and I was once again struck by the depth of the approach. I really want all of the most fascinating stuff in quantum mechanics to reduce to the structure of measurement, and your computational model seems to be a move in that direction (modulo the initial state)—I've told you that before. But the opportunities look great with just the right thinking.

19-12-03 *Time to Think about Time* (to G. L. Comer)

Comerism 7: *What's that line of Wheeler's about the past? Is it something like "... the past exists insomuch as at is consistent with the present"? I've had this crazy idea about closed timelike curves, information theory, no-cloning theorems, and time travel. The craziness is this, can I perform a whole suite of information-gathering exercises today, that would in effect change the past so that it looks like I actually travelled back in time and effected the changes directly? Can nature be so cockeyed as to allow something like that? I mean, can I squeeze and prod nature in such a way that I can extract a present that is consistent with some other past? In effect, could I then "travel" back to the "past", and "kill" my grandparents? Surely nature is not this screwy.*

It was never quite clear what Wheeler was saying on this subject, i.e., whether we can change the past with our quantum measurements, or rather just change what we can say about the past. I think he flip-flopped from time to time. My own present take is that it is neither. A quantum measurement here and now cannot actually change the past there and then (whatever that might mean). That is just as a quantum measurement here cannot actually change anything physical there (i.e., a spacelike separation away). Rather with regard to time, it is all and only about the present. I would say this is inspired by Wheeler's take on the subject, but not quite the same. (Though who can say, maybe it is). The closer alliance is to the thought of the pragmatist philosopher George Mead. I'll attach a note that hopefully makes some sense of this. [See note to Savitt, dated 23 September 2003.] Reading back over it, I still like my quantum discussion, but there's no doubt it needs fleshing out. Tell me if my discussion or the Mead passage provokes any thoughts.

19-12-03 *Prizes, Hippies, and Vectors* (to A. Peres)

Congratulations on the Rothschild prize. What was the particular citation for? Years of theoretical service? Or was it for a particular paper or series of papers that you wrote? Did you get any money with the prize?

Thanks for the cheer-up note. It certainly helped! I just couldn't stop laughing about the commune-of-hippies remark:

> I must confess that I am not well impressed by the research being done at PI. It looks more like a commune of hippies, very pleasant to be there, but not fruitful for physics.

(I read the whole thing to Kiki, who had just woken up.)

Asherism 40: *You gave me a reference to a paper by Thomas, about the Pauli-Lubańaski vector (the paper is in Phil. Mag. 1927). There is in it no mention of anything like the P-L vector. What I am looking for is a statement that it actually is a classical vector, indep of quantum mechanics. The reason is that Czachor has sent to PRL a Comment on a paper by Danny, Petra and me, and I have now to prepare a rebuttal.*

All I did was a google search on Pauli-Lubańaski vector, and those were the references I found. They appeared in a few papers, so I felt confident that they must be right. But maybe one cited the incorrect reference, and the effect just snowballed as one author simply went to another's paper rather than the original reference.

Anyway here is the passage I find in Enz's biography of Pauli that refers to Thomas:

> Frenkel did the only sensible thing: that is, use the analogy with the electromagnetic field to enlarge the magnetic moment vector $\vec{\mu}$ into a covariant antisymmetric tensor by combining it with an electric dipole moment and to develop the associated equation of motion [24d]. This work, which confirmed a Thomas factor of 2, was submitted for publication on 2 May 1926. In January of the following year a second paper by Thomas appeared in which essentially the same formalism was developed [24b]. But Pauli had been convinced of the correctness of Thomas's result already before.

Reference [24b] is the one I've already given you. Reference [24d] is:

- J. Frenkel, "Die Electrodynamik des rotierenden Elektrons," Zeit. fur Phys. **37**, 243 (1926).

Maybe I am not quite understanding the vector you speak of. I found this essay on "Relativistic Angular Momentum" on the web http://panda.unm.edu/Courses/finley/P495/TermPapers/relangmom.pdf

that makes a distinction between the "spin vector" and the Pauli-Lubańaski vector. It is written by an undergraduate, Nick Menicucci, who was Carl Caves' student for a while. I know that Carl has much respect for him, calling him the best undergrad physics student he had ever had. (They have one or two papers together.) Maybe he's the right person to contact with your question. He is now a graduate student at Princeton. In any case, there is no quantum mechanics in Menicucci's essay, and it certainly defines something called the Pauli-Lubańaski vector (in section 5).

22-12-03 *Tail Tuckers* (to D. B. L. Baker)

Sorry to hear about the decline of your pool skills. But, to mimic Einstein, "Whatever your troubles with pool, I assure you that mine are worse."

Bakerism 1 : *I'm glad to hear about your latest book. Do you get any money out of the deal?*

With the VUP edition, I didn't make anything monetarily. The gain was purely the satisfaction that comes with spreading the word. (They printed 200 copies and financed it with a Swedish science grant.) For the Kluwer edition (initial printing 450 copies), I'll get 6% of the net receipts and 20 free copies. That's effectively making nothing again, except the satisfaction of spreading the word even further.

Bakerism 2 : *I suppose your title refers to Linus Pauling? Can't see how any of my thoughts could have been any help. Maybe my comment about wearing a beret? I thing the coolest pictures of any "respectable" person wearing a beret would be him and Leonard Bernstein.*

The title refers to Wolfgang Pauli. The "Paulian Idea" is something I made up: It's effectively the conjunction of these three quotes, which I took out of one of his papers.

> Like an ultimate fact without any cause, the individual outcome of a measurement is, however, in general not comprehended by laws. This must necessarily be the case.
>
> In the new pattern of thought we do not assume any longer the detached observer, occurring in the idealizations of this classical type of theory, but an observer who by his indeterminable effects creates a new situation, theoretically described as a new state of the observed system. In this way every observation is a singling out of a particular factual result, here and now, from the theoretical possibilities, thereby making obvious the discontinuous aspect of the physical phenomena.
>
> Nevertheless, there remains still in the new kind of theory an objective reality, inasmuch as these theories deny any possibility for the observer to influence the results of a measurement, once the experimental arrangement is chosen.

The book as a whole is mostly a study in the sociology of science—it is quite literally only a collection of my emails—but strangely they have been emails with quite an effect on quantum foundations. For instance, they've been responsible for at least two Bohmians leaving the fold! (That alone probably made the writing worth it, I would say.)

What was your role? Lending me an ear, pure and simple. In particular, the first letter in the collection "Noodles of Nothing"—wherein I tell you how much I love the writing style of William James and how I love to read letter collections—sets the tone for the whole book.

Bakerism 3: *Any thought to text books?*

That's a much more serious project, and yes I have thought of it and even started it. The title will be *Quantum Foundations in the Light of Quantum Information*. I've been courted by three publishers so far (Kluwer, Springer-Verlag, and World Scientific), and I've told them all "yes". But I haven't signed any papers. For this one, I'm going to work much harder to get the best deal I can. Don't hold your breath: It'll be two or three years in the making.

Thinking of William James, let me attach a little story I wrote up about Emma a couple months ago. [See 22-09-03 note "Cosmology" to C. H. Bennett.] Actually maybe I'll put the whole context, since we've never had too much parenting talk between ourselves. I bet you've had to go through similar things yourself. (Put yourself in the place of Abner and read from bottom to top.) [See 22-09-03 note "A Thought of You" to A. Shimony.]

23-12-03 *Back in the Fight* (to H. J. Kimble)

You may have heard that the Perimeter Institute—or should I say a faction within the PI—finally gave me the axe (and showed me just what a dangerous thing it is to act like one cares about quantum foundations). So I'm out there acting like an unemployed physicist again for all intents and purposes (working under the assumption that Bell Labs will eventually tank).

23-12-03 *Great Americans* (to C. M. Caves)

I was thinking of the above title, and I was thinking of you. And I decided to send you a small gift for the holidays. Amazon.com says the package will arrive in about a week. It contains two books that I have enjoyed very much: *Philosophy and Social Hope*, by Richard Rorty, and *The Metaphysical Club: A Story of Ideas in America*, by Louis Menand. The writers were my two favorites of this year's reading. You might know Menand from his writing in the New Yorker; the book is a Pulitzer prizewinner in history.

Anyway, I learned a lot about quantum mechanics from these books. And I learned a lot about true Americanism (i.e., the kind of Americanism we need to strive to get back to ... and actually mould into a more stable, long-lasting form). Done right, I think the two subjects are probably the same thing.

I hope you get as much out of the books as I did. When I read a book, I keep an index card in it for recording small notes and page numbers on the things that really interested me (usually things I deemed somehow connected to quantum mechanics). Below is the tabulation for these books.

Louis Menand, *The Metaphysical Club: A Story of Ideas in America*

Holmes on immortality – 60
Holmes's pragmatism – 62, 63
Darwinism discussion – 122, 123
Darwinism as nonscience – 127
James's speech on Shaw – 147, 148
Quetelet's view on crime – 188
Schweber reference – 473 #31, 474 #44
nature and open markets – 195
Bayesian probability – 197
higgledy-piggledy – 199

Richard Rorty, *Philosophy and Social Hope*

Zen and the Art of Motorcycle Maintenance – 8
anything goes (not!) – 18
Appleby's point – 37
some things beyond our control – 51
truth as a nonepistemic notion (Davidson) – 164 #5
What is evidence? – 149-151

23-12-03 *Little Comments* (to R. Schack)

I've read your paper now. I like it; it's fine. [. . .]

By the way, I'd definitely like to swipe some material from this for the Matteo Paris thing. Your discussion on subjectivity has me thinking about the proper definition again. I wonder if I would now go so far as your first sentence in your section 2? Mind you, I just don't know. An alternative I'm playing with at least might go something like this: "To say that a quantum state for a system is subjective means that the state is not determined by any objective facts about the system. The quantum state, instead, takes its ground in the agent, whose beliefs the state is a compact summary of." Or something like that. It is a little more careful in that it does not say that the state is determined by no facts, but rather if it is, those facts are not determined by the actual system itself.

Here is a lovely passage drawn from near the conclusion of *The Metaphysical Club*:

> Academic freedom and the freedom of speech are quintessentially modern principles. Since the defining characteristic of modern life is social change—not onward and upward, but forward, and toward a future always in the making—the problem of legitimacy continually arises. In a premodern society, legitimacy rests with hereditary authority and tradition; in a modernizing society . . . legitimacy tends to be transferred from leaders and customs to nature. Agassiz and the senior Holmes and Benjamin Peirce all assumed that social arrangements are justified if they correspond with the design of the natural world . . . But in societies bent on transforming the past, and on treating nature itself as a process of ceaseless transformation, how do we trust the claim that a particular state of affairs is legitimate?
>
> The solution has been to shift the totem of legitimacy from premises to procedures. We know an outcome is right not because it was derived from immutable principles, but because it was reached by following the correct procedures.

And our own point is that Dutch-book coherence—and more generally, though yet to be worked out fully, quantum 'coherence'—is the correct procedure.

07-01-04 *Probability Tables* (to P. G. L. Mana)

Sorry for the long absence. I think your paper is great; it'll make a good contribution. I also encourage you to post it on `quant-ph` once you have finalized it.

A couple of comments on the parts of your text related to me.

1) "It is unknown to me how the photons produced in this process tend to respond to various interventions." You call this sentence "unquestionably meaningful" even for the (de Finettian) Bayesian. I don't think it is nearly as meaningful as you think. For instance, how would you precisely define "tend" without a notion of ignorance or probability? On the other hand, if you try

to define it through a notion of objective chance or propensity, then you'll give the de Finettian heartburn again.

I think what you're driving at is that you really want to think of your "preparations" as "objective facts". So, if they're objective facts, why don't you just drop the fancy language of preparations and be done with it? But then, show me an independent definition or meaning or description of these objective facts outside of their use in your probability tables. For me, your s_1 ... s_M are just prior states of belief, and I think that is the only consistent account a Bayesian can have. The conceptual role of the $r_1 \ldots r_L$, however, are different. They represent data upon which we update; they represent sense impressions. (Better yet: They represent the feedback the world gives to our prior beliefs, consequent to our stimulations to or interventions upon it.)

Concerning the preparation-vectors s_j themselves it is just as bad. For you yourself say, "Note, in particular, that the numerical values of the vectors s_j and r_i ... depend upon the *whole* collection of probabilities p_{ij}: if one of these is changed, then ... all the vectors will change." For the de Finettian, all probabilities—no matter where and for what phenomenon they are used—are of the same subjective flavor. Thus, just as there can be no such thing as an unknown probability, there can be no such thing as an unknown preparation-vector.

2) "[I]n fact, the quantum state rather appears to be *part* of a state of knowledge (or belief) ... Perhaps the point is that CFS's notion of a 'quantum' state of belief implicitly assumes the *existence* and the *particular structure* of the whole set of quantum POVMs (i.e., the interventions)."

Agreed. The upshot of Gleason's theorem (and Gleason-like theorems with POVMs) is that GIVEN the structure of measurements, a quantum state is nothing more and nothing less than a compendium of probability distributions (and thus a state of belief for the de Finettian). However, the upshot of my analysis in Section 7 in `quant-ph/0205039` and much of my web book *Quantum States: What the Hell Are They?* (posted at my webpage) is that the assignment of a given POVM to an intervention is every bit as subjective as the quantum state itself. I.e., a POVM is a kind of belief itself. So, the GIVEN in Gleason's theorem is not to be taken lightly or ignored. And you, with your probability tables, have identified this issue from another track. That's excellent.

Anyway, as I say, I enjoyed your paper. I think you're doing excellent work. Send us the reformatted version as soon as you can. We can argue about the business above at our leisure.

07-01-04 *Deep Breath* (to G. Brassard)

Brassardisme 7: *My talk at QIP is next week and I still have not a clue how I could possibly fill 50 minutes with musings on*

> **Title:** Quantum Foundations in the Light of Quantum Information
>
> **Abstract:** The late Rolf Landauer has once claimed that "information is physical". The main point of this talk is to argue that "physics is informational"! At the moment, quantum information theory is replete with beautiful theorems on what is and is not possible according to quantum mechanics. For example, quantum key distribution is possible but quantum bit commitment is not. But the axioms of quantum mechanics are strange and ad hoc, reflecting at best the history that led to discovering this new world order. It's time to pause and reflect on what is really fundamental and what are merely consequences. Could information be the answer?

Panic is high and steadily rising.

Take a deep breath. There's a lot of good stuff on the theme out on the web now. You could take the opportunity to give a summary of the various issues out there and how they all converge in the same direction: Namely—as I see it—quantum states and operations are expressions of information, rather than expressions of a reality independent of information-using agents. If we can just swallow that idea whole and learn to savor it, rather than fight it—your conclusion could be—may be the best thing we can do to prepare ourselves for the best, most outlandish physics yet to come.

Here's some papers to look at that come to mind:

1. `quant-ph/0205039`, "Quantum Mechanics as Quantum Information (and only a little more)," Christopher A. Fuchs.
2. `quant-ph/0310017`, "Classical Teleportation of Classical States," Oliver Cohen.
3. `quant-ph/0203070`, "The Nature of Information in Quantum Mechanics," Rocco Duvenhage.
4. `quant-ph/0101012`, "Quantum Theory From Five Reasonable Axioms," Lucien Hardy.
5. `quant-ph/0211089`, "Characterizing quantum theory in terms of information-theoretic constraints," Rob Clifton, Jeffrey Bub, Hans Halvorson.
6. `quant-ph/0310101`, "A note on information theoretic characterizations of physical theories," Hans Halvorson.
7. `quant-ph/0310067`, "Can Quantum Cryptography Imply Quantum Mechanics?," John A. Smolin.
8. `quant-ph/0311065`, "Can quantum cryptography imply quantum mechanics? Reply to Smolin," Hans Halvorson, Jeffrey Bub.
9. `quant-ph/0306179`, "Gleason-Type Derivations of the Quantum Probability Rule for Generalized Measurements," Carlton M. Caves, Christopher A. Fuchs, Kiran Manne, Joseph M. Renes.
10. `quant-ph/0304159`, "Quantum information processing, operational quantum logic, convexity, and the foundations of physics," Howard Barnum.
11. `quant-ph/0208121`, "Betting on the Outcomes of Measurements: A Bayesian Theory of Quantum Probability," I. Pitowsky.
12. `quant-ph/0305088`, "Copenhagen Computation: How I Learned to Stop Worrying and Love Bohr," N. David Mermin.
13. `quant-ph/0305117`, "Why can states and measurement outcomes be represented as vectors?," Piero G. L. Mana.
14. `quant-ph/0307198`, "A de Finetti Representation Theorem for Quantum Process Tomography," Christopher A. Fuchs, Rüdiger Schack, Petra F. Scudo.
15. `quant-ph/0210017`, "Quantum theory from four of Hardy's axioms," Rüdiger Schack.
16. `quant-ph/0308114`, "The Bell-Kochen-Specker Theorem," D. M. Appleby.
17. `quant-ph/0311039`, "Multilinear Formulas and Skepticism of Quantum Computing," Scott Aaronson.

18. `quant-ph/0107151`, "Whose Knowledge?," N. David Mermin.

19. `quant-ph/0109041`, "How much state assignments can differ," Todd A. Brun, J. Finkelstein, N. David Mermin.

20. `quant-ph/0206110`, "Conditions for compatibility of quantum state assignments," Carlton M. Caves, Christopher A. Fuchs, Rüdiger Schack.

I'm sure I've missed a ton of things.
Skim and summarize!

07-01-04 *Four More* (to G. Brassard)

Let me give you four other papers that might be useful. None of these have appeared on the web yet.

1. Ari Duwell's "Quantum Information Does Not Exist" (appeared in the September 2003 issue of *Studies in History and Philosophy of Modern Physics*—a special issue edited by Bub and me on quantum information and foundations).

2. Jeff Bub's "Why the Quantum?". I think it will be his contribution for the Clifton memorial. Conceptually, it may do a better job than the earlier papers.

3. Piero Mana's "Probability Tables". This isn't quite the final version, but it must be quite close. It'll appear in our Växjö proceedings this year. If you want to mention it, you should get his permission. But, at the least, it may help you understand his previously posted paper.

4. Scott Aaronson's "Is Quantum Mechanics an Island in Theoryspace?" It'll appear in our Växjö proceedings this year. If you want to mention it, you should get his permission. It's a fun (and funny) paper.

OK, that exhausts my thoughts for the moment.

07-01-04 *A Really Important One* (to G. Brassard)

Forgot a really important one: Rob Spekkens's paper-in-the-writing, "In Defense of the Epistemic View of Quantum States: A Toy Theory." The last draft I saw of it was 65 pages. It's amazing the number of quantum-information style phenomena he nails with his toy theory.

You might ask him if he'd send you a copy of the draft to peruse, if you'd like to say a word or two about it.

Below is the abstract he used for his Caltech talk on the subject.

> Title: In defense of the view that quantum states are states of knowledge
>
> Abstract: I present a toy theory that is based on a simple information-theoretic principle, namely, that when one has maximal knowledge of a system, one's knowledge is quantitatively equal to one's ignorance. The object analogous to the quantum state in the theory is a uniform probability distribution over hidden states. Because the theory is, by construction, local and non-contextual, it does not reproduce quantum theory.

Nonetheless, a wide variety of quantum phenomena have analogues within the toy theory that admit simple and intuitive explanations. Such phenomena include: the noncommutativity of measurements, interference, no information gain without disturbance, the multiplicity of pure state decompositions of a mixed state, the distinction between two-way and intrinsic three-way entanglement, the monogamy of pure entanglement, no cloning, teleportation, dense coding, mutually unbiased bases, locally immeasurable product bases, unextendible product bases, the possibility of key distribution, the impossibility of bit commitment, and many others. The diversity and quality of these analogies provide compelling evidence for the view that quantum states are states of knowledge rather than states of reality, and that maximal knowledge is incomplete knowledge. A consideration of the phenomena that the toy theory fails to reproduce, notably, violations of Bell inequalities and the existence of a Kochen-Specker theorem, provides clues for how to proceed with a research program wherein the quantum state being a state of knowledge is the idea upon which one never compromises.

08-01-04 *Calls to Copenhagen* (to M. Pérez-Suárez)

It's too bad your plans had to change to a Jan 20 arrival. It turns out I will be gone Jan 23–27, for my mother's 75th birthday party in Texas. Sorry I didn't warn you of this before, but I just found out myself yesterday. I had to make a mad dash to get the tickets.

Beyond that, 20 minutes ago, I just got a call to Copenhagen! The Niels Bohr Institute has asked come for a job interview February 2. Thus you can probably count on my being gone Feb 1–3.

I hope you'll understand that in neither of these cases could I say "no". I realize that this will leave you a little guidanceless at the very beginning of your stay, but I'll try to think of ways to make things go as smoothly as possible in my absence.

08-01-04 *Partial Exchangeability* (to D. Poulin)

I'm glad to hear there was enough material in the paper to make it worth three readings!

Poulinism 14: *Is it possible to find, for example, a 3-qubit state which (i) CAN be obtained by tracing out the 4th qubit of a 4-qubit symmetric state but (ii) CANNOT be obtained by tracing out the 4th and 5th qubits of a 5-qubit symmetric state?*

Yes it is. Jaynes gives some good examples in

- E. T. Jaynes, "Some Applications and Extensions of the de Finetti Representation Theorem," in *Bayesian Inference and Decision Techniques*, edited by P. Goel and A. Zellner (Elsevier, Amsterdam, 1986), pp. 31–42.

for the case of classical probability distributions (i.e., commuting density operators) and gives some good intuitive explanation for what goes wrong.

There are similar results for partially exchangeable (entangled) quantum states. Joe Renes is the expert on that, and can probably give you some good examples in the noncommutative case.

09-01-04 *Where Did You Come From, Where Did You Go?* (to S. J. van Enk)

Where did you come from Cotton-Eyed Joe?

Where have you been? I never got a reply from you after I answered the note you sent to Kiki's account.

Anyway, I have a question in case you're listening. Have you seen Oliver Cohen's paper "Classical Teleportation of Classical States", `quant-ph/0310017`? I remember one day (two or three years ago) you and I were talking at the chalkboard, and we were toying with trying to write down a classical coin-toss "teleportation" scheme. Do you remember if we succeeded? I remember we were playing with something quite similar to this. (I can certainly dig up a lot of places in my samizdats where I've taken it for granted that such a kind of scheme would work.)

Anyway, I've got to decide whether this paper should be a PRL. I'll attach below the considerations I sent Bob Garisto this morning to help you see what I'm thinking.

09-01-04 *Christmas with The Pogues* (to D. B. L. Baker)

I didn't write you the letter I had hoped to during the Christmas holidays.

Instead, let me send you a song I learned this Christmas—a happenstance by being in Ireland. With your better knowledge of music than me you've probably already known it for a long time. But I'll place the words below and attach an mp3 file with the song. The words, especially near the end, have such a powerful effect on me. I haven't been able to get the song out of my head all this morning, and consequently the present note.

> **Fairytale of New York**
>
> by The Pogues
>
> I could have been someone
> Well so could anyone
> You took my dreams from me
> When I first found you
> I kept them with me babe
> I put them with my own
> Can't make it all alone
> I've built my dreams around you
>
> The boys of the NYPD choir
> Still singing "Galway Bay"
> And the bells are ringing out
> For Christmas day

10-01-04 *Disappointment* (to M. Pérez-Suárez)

About books, I brought Nielsen and Chuang with me and you are free to use it (and any of my books). I don't think I brought Peres with me, however. I will try to remember to check in my office Monday. As far as linear algebra, matrix analysis books go, I probably have anything you could need. For library use we have the Dublin Institute for Advanced Studies, about a 20 minute walk from our offices. They have a decent sized math/physics library. Also, I have use of the Trinity College mathematics library (quite large). I have a library of about 290 philosophy books (mostly about pragmatism, Wittgenstein, postmodern stuff, etc.) here in my own house. So, basically, just tell me about any books you were thinking of bringing, and I will tell you whether there is overlap with what you can borrow from any of these sources.

10-01-04 *Cohen Again* (to S. J. van Enk)

van Enkism 5: *I saw the Cohen paper you mention, I even read some part of it and decided it was nothing I didn't know. Moreover, I thought he missed something, but now I don't remember what that was. I'll check more carefully. I also remember vaguely we talked about this, and I thought we did have some essential difference between classical and quantum teleportation. Was it secrecy??*

I think maybe in the version we came up with, Alice could learn something about Victor's state (i.e., probability distribution). But in his version—where the 'Bell basis' measurement automatically randomizes first—he doesn't have that problem. Of course there could be the issue of a third party correlated with the 'entangled pair'—like in the version Collins and Popescu consider.

So, I'm kind of torn. Maybe it is too late for this paper. If it had just been written five years ago. (It is the sort of thing you and I should have written; but who would have guessed it could be turned into a whole PRL?) On the other hand, I like the way the guy makes a clean simple point of the lesson: quantum teleportation is simply not exciting or remarkable if one takes the epistemic view of quantum states. It's a point I want more people to appreciate—even if a few of us realized it long ago—and his paper could be a good vehicle for that.

Also there's the issue that Spekkens will soon release his toy model to the world. Buried within that far more ambitious work (it's a 65 page manuscript and counting) is a classical teleportation protocol. Should Cohen lose all credit, or all attention, in the blinding light of Spekkens's paper? Alternatively might I help bring attention to Spekkens's paper by letting Cohen into PRL at the same time as forcing him to cite Spekkens?

Cohen is not a power hitter. He's only had six papers since 1999. So I don't think I'm creating undue competition for us by letting a cheap paper past PRL, and I can see that it might actually help him hold onto a career he might otherwise be forced to drop out of.

I tell you, I turn more social democrat every day . . .

Anyway, all of this (especially Spekkens' toy model) is clarifying and food for thought. A good lot of quantum information theory is simply regular probability/information theory applied in ways that had not been deemed interesting before. It helps us realize that what is unique in quantum mechanics is not the probabilities but what the probabilities are applied to. There, I think, lies the essence of quantum mechanics: It is localized in the Kochen-Specker theorem. Unperformed measurements have no outcomes. It's just a question of putting that in a more useful form before something can really come of it.

Thanks for calling me a father. It helped a lot.

10-01-04 `quant-ph/0106166` (to G. Brassard)

Brassardisme 8: *Is* `quant-ph/0106166` *obsolete in the face of* `quant-ph/0205039`*?*

I think it is, and I try to sell it that way. But strangely, a lot of people choose to read it first nevertheless—thinking of it as a 'lite' version of `0205039`. Certainly the intros of the two papers have different jokes and allusions; maybe they're worth looking at separately because of that.

Still, it would be nice if you did mention `quant-ph/0106166` along with `quant-ph/0205039`, after all ... since its title coincides with the title of your talk.

More a little later this evening.

I realized I told you in one of my other notes this morning to keep breathing slowly. Don't breathe too slowly, though. That wouldn't be healthy ...

10-01-04 *More Help Please* (to G. Brassard)

Brassardisme 9: *But seriously, there is something else you can do to help. Please send me as much information as you can gather easily on the 3 meetings that took place so far, i.e. both here in Montréal and the one in Växjö.*

Four meetings so far, and at least two coming up. Though the fourth was really just a component in the larger Växjö meeting: This time, it was titled "Quantum Logic meets Quantum Information." And the idea was to get people together who had an interest in making a bridge between the two communities. So, one of the pre-requisites was that the participants from each community were supposed to have a little knowledge and sympathy of the other at the outset. ('Quantum Logic', in case you don't know, is a certain community in quantum foundations that thinks that what is going on behind quantum mechanics is literally a change of the rules of formal logic ... i.e., from Boolean algebra to something else.)

I'll compile the information for you, but I can't do it until about 8 hours from now.

11-01-04 *The First Montréal Meeting* (to G. Brassard)

Workshop on Quantum Foundations in the Light of Quantum Information

Centre de Recherches Mathématiques Université de Montrál

16 – 19 May 2000

Gilles Brassard and Christopher A. Fuchs, organizers

<u>17 May</u>

Gilles Brassard, Université de Montréal
Quantum Foundations in the Light of Quantum Cryptography

Christopher A. Fuchs, Los Alamos National Laboratory
Quantum Foundations in the Light of Quantum Information

William K. Wootters, Williams College
Quantum Mechanics from Distinguishability?

Benjamin W. Schumacher, Kenyon College
Doubting Everett

<u>18 May</u>

N. David Mermin, Cornell University
Pre-Gleason, Post-Peierls & Compumentarity

Herbert J. Bernstein, Hampshire College
Why Quantum Mechanics?

Richard Jozsa, University of Bristol

Foundations of an Interpretation of Quantum Mechanics in the Light of Quantum Computing

Charles H. Bennett, IBM Research at Yorktown Heights
Entanglement-Assisted Remote State Preparation

19 May

Rüdiger Schack, University of London – Royal Holloway
Quantum Gambling and Bayesian Probability in Quantum Mechanics

Patrick M. Hayden, Oxford University
Two Lessons from the Heisenberg Representation, or How I Learned to Stop Worrying & Love Non-Commutativity

Jeffrey Bub, University of Maryland
Some Reflections on Quantum Logic

11-01-04 *The Second Montréal Meeting* (to G. Brassard)

Be warned: Some of these titles are my own constructions! [See 10-09-02 note titled, "Tentative Talk Schedule for Commune."]

11-01-04 *The First Sweden Meeting* (to G. Brassard)

Officially titled:

Quantum Theory: Reconsideration of Foundations
Växjö University, Växjö, Sweden
17-21 June 2001
Organizers: Christopher A. Fuchs, Pekka Lahti, and Andrei Khrennikov.

however, a significant part of the meeting was a session titled:

"Shannon Meets Bohr: Quantum Foundations in the Light of Quantum Information"

The participants and talks in this session were:

1. Herbert J. Bernstein, "Observer Participancy and Law without Law (or something like that)"
2. Doug Bilodeau, "Real Time: How Quantum Mechanics Describes the World"
3. Jeffrey Bub, "Information and Objectivity in quantum Mechanics"
4. Carlton M. Caves, "Quantum Dynamics and Maximal Information"
5. Henry J. Folse, "Bohr's Conception of the Quantum Mechanical State of a System and Its Role in the Framework of Complementarity"
6. Christopher A. Fuchs, "Quantum Foundations in the Light of Quantum Information"
7. Daniel Greenberger, "The Inconsistency of the Galilean Transformation in Quantum Theory"
8. Lucien Hardy, "Quantum theory from Five Reasonable Axioms"

9. Peter Harremoës, “Bell’s Inequalities and Graphical Models of Independence”
10. Richard Jozsa, “Quantum Computation and Foundational issues”
11. N. David Mermin, “Whose Knowledge?”
12. Asher Peres, “Indiscrete Quantum Information”
13. Itamar Pitowsky, “Range Theorems for Quantum Probability”
14. Arkady Plotnitsky, “Spectro-Cryptography: Bohr, Heisenberg and Quantum Mechanics as an Information Theory”
15. Rüdiger Schack, “Bayesian Probability in Quantum Mechanics”
16. Ben Schumacher, “Doubting Everett”
17. John Smolin, “Quantum Nonlocality without Entanglement”
18. Joseph Renes, “(Bayesian) Probability in Quantum Mechanics”
19. Daniel Terno, “Quantum Information in Relativity Theory”

11-01-04 *The Second Sweden Meeting* (to G. Brassard)

Officially titled:

> **Quantum Theory: Reconsideration of Foundations – 2**
> Växjö University, Växjö, Sweden
> 1-6 June 2003
> Organizers: Howard Barnum, Christopher A. Fuchs, Robin Hudson, and Andrei Khrennikov

however, a significant part of the meeting was a session titled:

> “Quantum Logic Meets Quantum Information”

organized by Barnum and Fuchs. The participants and talks in this session were:

1. Scott Aaronson, “Quantum Computing and Dynamical Quantum Models”
2. Guido Bacciagaluppi, “Classical Extensions, Classical Representations and Bayesian Updating in Quantum Mechanics”
3. “Howard Barnum, Using Probabilistic Equivalence to Construct Algebraic Structures from Operational Theories”
4. “Stephen Bartlett, Restrictions to Quantum Information Processing”
5. Paul Busch, “Less (Precision) Is More (Information): Quantum Information in Fuzzy Probability Theory”
6. Bob Coecke, “Probability from Logic”

7. Christopher Fuchs, "What is the Difference between a Quantum Observer and a Weatherman?"

8. Alexei Grinbaum, "C. Rovelli's 'Relational Quantum Mechanics' and the Problem of Information Theoretic Derivation of Quantum Theory"

9. Hans Halvorson, "Tomita's Theorem and its Role in the Information-Theoretic Characterization of Quantum Theory"

10. Lucien Hardy, "Quantum Theory as a Probability Theory"

11. Piero Mana, "Why Can States and Measurement Outcomes Be Represented as Vectors?"

12. Marcos Pérez-Suárez, "Quantum Mechanics and Information Theory: Some Further Musings on a Fuchsian Proposal"

13. Rüdiger Schack, "On Unknown Quantum Operations"

14. John Smolin, "Can Quantum Cryptography Imply Quantum Mechanics?"

15. Rob Spekkens, "In Defense of the Epistemic View of Quantum States"

16. Alexander Wilce, "Compactness and Symmetry in Quantum Logic"

11-01-04 *Hardy Facts* (to G. Brassard)

By the way, a little factoid about Hardy. You might recall that he was invited to our first Montréal meeting but had to withdraw at the last minute because of an illness in his family or something. Anyway, his paper "Quantum Theory from Five Simple Axioms" was motivated directly—he tells me—by his invitation to our meeting.

More still to come, but I've got to get the kids to bed at the moment.

11-01-04 *Special Issue of SHPMP* (to G. Brassard)

Continuing. The September 2003 issue of the journal *Studies in History and Philosophy of Modern Physics* was devoted to "Quantum Information and Computation". The editors of the special issue were Jeff Bub and me. Below is a tabulation of the papers, and further below that is the introduction we wrote for the issue. N.B. there was a horribly serious omission in that introduction; pathetically we forgot to mention David Mermin's paper. I am still atoning for that sin!

1. Howard Barnum: 'Quantum information processing, operational quantum logic, convexity, and the foundations of physics'

2. Charles Bennett: 'Notes on Landauer's principle, reversible computation and Maxwell's demon'

3. Armond Duwell: 'Quantum information does not exist'

4. Lucien Hardy: 'Probability theories in general and quantum theory in particular'

5. David Mermin: 'Copenhagen computation'

6. Itamar Pitowsky: 'Betting on the outcomes of measurements: a Bayesian theory of quantum probability'
7. Andrew Steane: 'A quantum computer only needs one universe'
8. Chris Timpson: 'On the supposed conceptual inadequacy of the Shannon information'
9. David Wallace: 'Quantum probability and decision theory revisited'

12-01-04 *Upcoming Conferences* (to G. Brassard)

I'm sure this is only a partial list, but it includes all the ones that I am confident will carry our theme.

- Probability in Quantum Mechanics, Centre for Philosophy of Natural and Social Science London School of Economics and Political Science, Monday, February 16, 2004, Organizers: Stephan Hartmann and Roman Frigg
- Seven Pines Symposium VIII: "Quantum Mechanics, Quantum Information, and Quantum Computation," University of Minnesota, May 5–9, 2004, Organizer: Roger H. Stuewer
- Philosophy of Science Association, annual meeting 2004 (this is the biggest philosophy of science meeting) Austin, Texas, November 18–21, 2004 within it there will be a workshop titled 'Quantum Information Theory and the Foundations of Quantum Mechanics: Is Information the Way Forward?,' Organizer: Christopher G. Timpson
- This meeting should also have a significant component on quantum foundations in the light of quantum information: New Directions in the Foundations of Physics, American Institute of Physics, College Park, April 30 – May 2, 2004, Organizer: Jeff Bub

12-01-04 *Miscellania* (to G. Brassard)

Brassardisme 10: *Your polite silence on what you think of my slides worries me!*

Silent only because there wasn't much to say yet, and believe it or not, I am a busy man too. I like Michelangelo. And though I can imagine that the burning bush may have laid out "I am that I am" as fundamental principle (in constructing the universe), I agree with you that it is hard to imagine it declaring C^* algebras in the same breath.

12-01-04 *Diode Lasers* (to P. G. L. Mana)

Thanks for the final draft; I've forwarded it to Andrei Khrennikov.

Manalogue 7: *But I realise now, that I have not understood completely your "philosophy": roughly asking, do you consider a diode laser a sense impression? Do you prefer to speak of sense impressions rather than "(macroscopic) reality"?*

I consider a "diode laser" as very much akin to (or maybe even precisely) a prior. (As in, the kind of prior a Bayesian would use as the starting point of his probabilistic calculations.)

Manalogue 8: *What do you mean by 'the world'? Your position seems almost Leibnizian.*

I don't know what Leibnizian means. What I mean by 'the world' is everything external to the agent: the source of all the stimulations upon him.

Manalogue 9: *Apart from some possible differences in basic "philosophical" points of view (which concern something broader than quantum mechanics), ... and the fact that you believe in the ultimate validity of the quantum-mechanical formalism [...]*

I wouldn't say I believe the latter at all.

In any case, I'll attach a note that expresses aspects of my latest position, such as it is.

13-01-04 *Decisions* (to S. J. van Enk)

van Enkism 6: *I just read Cohen's paper, and I don't know what I found wrong about it before: I now agree! The only difference with quantum teleportation is, which I mentioned before, you could use quantum teleportation for key distribution, and you cannot use classical teleportation for that purpose. Of course, QKD without teleportation is perfectly possible too, so that argument doesn't really discredit Cohen's protocol.*

If you don't disagree harshly then, I guess I'm going to recommend that it be published (with changes), despite the existence of

```
quant-ph/9906105 [abs, ps, pdf, other] :
Title:  Classical Teleportation of a Quantum Bit

quant-ph/0107082 [abs, ps, pdf, other] :
Title:  A classical analogue of entanglement
Authors:  Daniel Collins, Sandu Popescu
Comments:  13 pages, references updated
```

and Spekkens' new paper. My support, as you know, is chiefly motivated by the moral he draws, which neither of the first two papers above seem compelled to.

I suspect I'm the only referee, because it was referred to me by "a Divisional Associate Editor" (had to be Bennett?). So it seems to hinge on me (and by proxy, if there is a lack of protest, you).

14-01-04 *Hello Kitty* (to H. Mabuchi)

I've been meaning to write you for a couple of days. Emma turned five on January 12, and in her pile of presents was a Hello Kitty watch, wrapped with a tag listing "Uncle Hideo" as the source. Emma asked, "Who's that?" Later I showed her a picture of you, and she said "Wow." (She says wow a lot.) Anyway, Kiki and I thank you! Emma was proud to sport her new watch along with her new dress, bought especially for the occasion of her date with her dad later that evening.

On less happy matters, you've probably heard by now that the Perimeter Institute decided I was too risky a proposition for their world fame and dominance. It seems that hidden-variables theories (or even sillier things) will carry the day.

You know my secret dream (and you know I've got a thousand secret dreams): That someone of unique talent at Caltech would convince their physics and humanities departments to throw in half and half on me. The possibilities! Courses on Bayesian foundations for probability theory, courses fleshing out comparisons and contrasts between Bayesianism and pragmatism, courses on Wittgenstein and the foundations of quantum mechanics, courses on James and Dewey and the foundations of science, courses on why we should take some of the postmodern thinkers seriously, courses connecting the interpretational issues for quantum states to the philosophy of language, courses on beginning quantum mechanics for undergraduates, courses on standard quantum information theory, courses on matrix analysis methods in quantum information, ... What possibilities! And what better place for such possibilities? ... Pipe dreams.

Actually Wittgenstein has become my latest addiction. In preparation for writing my new paper with Schack—one that we've been tentatively calling "On Quantum Certainty"—I thought I should read Wittgenstein's book "On Certainty" to see if, on the off chance, there was some overlap of ideas. I had some indication that there might be from things I had read in Richard Rorty. Well, what a pleasant surprise! Wittgenstein is much deeper than I ever imagined. It was just silly of me to be put off for so long by the style in which his books are written. Within the first five pages of that 90 page book, he already said all that Rüdiger and I ever wanted to say and just kept going. Here is a man who, 52 years ago, could have tackled the Penrose question head on: How a pure quantum state can be epistemic and yet still give probability one predictions for some measurements? Anyway, reading Wittgenstein is certainly taking me down a more solid and careful path on the issue than I thought I was prepared for.

And speaking of the fancy term "epistemic", I hope you've noticed that Rob Spekkens finally put his toy-model paper on `quant-ph`. It is a masterwork. You want to teach your first-year students what quantum mechanics is all about? Make this paper part of the curriculum. It is that simple, and it is that convincing. (That is, at least it gets half the answer. We wouldn't want them to think there's nothing left to do.)

OK, now I'm just procrastinating. Too many more official things to write, and too little desire to do it; email and gossip are always easier.

I hope things are going well for you and your family of 17. And many thanks again—this time from Emma—for the watch.

15-01-04 *Idealism* (to R. W. Spekkens)

I'm planning to write you two notes, one titled "Pragmatism" and one titled "Idealism." The one titled "Pragmatism" has to do with what I think I need for self-preservation at the moment, and not to do with my philosophy. The one titled "Idealism" has to do with my philosophy, which is pragmatism, but has nothing to do with my career.

On page 2 you write, "There is one case wherein the distinction between an ontic state and an epistemic state breaks down ... " You know I still disagree with you: epistemic is always epistemic, period. If I could just get the discipline to finish my paper with Schack, "On Quantum Certainty," maybe we could communicate better. In the mean time—though I doubt it will help—let me try to entice your soul not with my words, but Wittgenstein's. Here's something I wrote Mabuchi yesterday:

> Actually Wittgenstein has become my latest addiction. In preparation for writing

> my new paper with Schack—one that we've been tentatively calling "On Quantum Certainty"—I thought I should read Wittgenstein's book *On Certainty* to see if, on the off chance, there was some overlap of ideas. I had some indication that there might be from things I had read in Richard Rorty. Well, what a pleasant surprise! Wittgenstein is much deeper than I ever imagined. It was just silly of me to be put off for so long by the style in which his books are written. Within the first five pages of that 90 page book, he already said all that Rüdiger and I ever wanted to say and just kept going. Here is a man who, 52 years ago, could have tackled the Penrose question head on: How a pure quantum state can be epistemic and yet still give probability one predictions for some measurements? Anyway, reading Wittgenstein is certainly taking me down a more solid and careful path on the issue than I thought I was prepared for.

Here are a couple of paragraphs from *On Certainty* that I had the word "Spekkens" written by:

> 21. Moore's view really comes down to this: the concept 'know' is analogous to the concepts 'believe', 'surmise', 'doubt', 'be convinced' in that the statement "I know ..." can't be a mistake. And if that *is* so, then there can be an inference from such an utterance to the truth of an assertion. And here the form "I thought I knew" is being overlooked.—But if this latter is inadmissible, then a mistake in the *assertion* must be logically impossible too. And anyone who is acquainted with the language-game must realize this—an assurance from a reliable man that he *knows* cannot contribute anything.
> 22. It would surely be remarkable if we had to believe the reliable person who says "I can't be wrong"; or who says "I am not wrong."

There were many more than that, but I'm too lazy to copy them in at the moment!

I'd say that a Wittgenstein reading is hardly a substitute for reading Fuchs and Schack, but who knows, maybe his mortars will soften the front.

16-01-04 *Also Holevo* (to R. W. Spekkens)

I forget to mention in my previous notes the business about Chapter 1 in Holevo's book. You didn't mention the connection between that and your toy model in your paper. It's certainly of the same flavor, but it is hard (for me at least) to tell from his general theorem (7.1) whether one would get all the sorts of quantum behavior from it that you do. Maybe it's obvious though ... (And I'm starting to think it is as I write this sentence to you.)

16-01-04 *More Diodes* (to P. G. L. Mana)

Manalogue 10 :

> [CAF wrote:] I consider a "diode laser" as very much akin to (or maybe even precisely) a prior. (As in, the kind of prior a Bayesian would use as the starting point of his probabilistic calculations.)

Now I must really say that I'm confused.

I mean that within the framework of quantum mechanics "diode laser" is a name for a particular quantum operation (trace-preserving completely positive map) on the electromagnetic field. And from my point of view quantum operations are as sinfully subjective as quantum states. Their giveness just happens to be the starting point of most quantum mechanical problems, but it's nothing more than that. So, in that role, quantum operations play the role that the prior (or "statistical model") plays in most textbook problems in a probability course.

Most of my samizdat *Quantum States: What the Hell Are They?* (posted on my webpage) is devoted to this issue, but maybe pick up at the 19 September 2001 note "Practical Art" and then go to the 20 September 2001 note "Pots, Kettles, and Frying Pans." And then some of the subsequent notes. Maybe you'll find some of your wanted examples there. The phraseology I used with you came up when Caves and Schack and I were discussing those passages later in Australia. Caves said, "I call a beamsplitter an objective fact." I said, "I call it a prior."

Manalogue 11: *But on the following do we perhaps agree again: this not-quite-identified-yet something that makes the restriction – <u>this</u> must be the physical point, the trace – and hopefully trail – left by something we may call 'reality'!*

Yes, I suspect I agree with that.

19-01-04 *Shipbuilding, Part III* (to G. Brassard)

Brassardisme 11: *Wow! Had you ever mentioned this wild idea to me? This is getting more exciting by the minute.*

Actually, no I hadn't. But here's a slogan to go with it: I told it to Howard Burton when I was visiting PI. (So if you ever hear it re-surface, you'll know where it came from.)

> About some piece of matter:
>
> Question: How sensitive do you thing we can make this thing to eavesdropping in a quantum crypto protocol? What is its ultimate limit?
>
> Answer: I don't know; let's weigh it.

(To be taken somewhat poetically, not completely accurately.)

19-01-04 *NBI* (to G. Brassard)

Brassardisme 12: *But (I repeat) had you told me about an interview at the Bohr Institute? When? What? Why? (And please don't tell me that the B.I. is in fact at Caltech!)*

The Niels Bohr Institute is in Copenhagen. It was literally the birthplace of quantum mechanics: Heisenberg and Pauli were Bohr's postdocs at the time.

And, yes I told you about the application long ago. But I hadn't told you that it got to the stage of an interview.

There. That exhausts all my known interview information!

20-01-04 *Caltech and Peirce* (to A. Shimony)

Maybe in partial payment I should tell you that in the last couple of evenings I've been reading a fun piece by Susan Haack called "'We Pragmatists . . . ': Peirce and Rorty in Conversation".

It's a fictitious conversation between the two men built out of quotes from their various works. It makes it quite clear how sly Rorty is being when he continually invokes the phrase 'We pragmatists ...'. It'd be nice if someone were to put together a similar dialogue between Rorty and Dewey. I sometimes wonder if the two of them are as close to each other as Rorty portrays.

21-01-04 *The Ambiguity of Language* (to R. W. Spekkens)

Spekkensism 24: *Here is my response* [to 15-01-04 note "Idealism"]. *Physical theories involve idealizations, like fields upon which there is no back-reaction, point particles, isolated systems, etc. Quantum states are idealizations in the same sense. Quantum theory is a model of a world wherein observers do have certainty, even though our world may not admit such an idealization. You must admit something like this occurs when it comes to quantum state assignments that would, ideally, be adopted by an agent, but in practice are not because they involve solving some computationally difficult problem.*

We seem to be reading two very different things. Let's hold off discussion until Rüdiger and I write something that'll wallop you over the head.

21-01-04 *WJ for T?* (to H. Mabuchi)

Mabuchism 2: *What's your home address these days? I wanna send you a book!*

What could be an encore to a Hello Kitty watch? Did you manage to get a copy of *William James for Toddlers*?!?

More on other matters before the day is out ...

22-01-04 *Generalized Measurements* (to many)

Dear friends in the quantum information and foundations communities,

Many of you may not know it, but the concept of a generalized quantum measurement or positive-operator-valued measure was introduced in

- E. B. Davies and J. T. Lewis, "An Operational Approach to Quantum Probability," Communications in Mathematical Physics **17**, 239–260 (1970).

Last night, John Lewis passed away here in Dublin, his home of 28 years, from complications due to a recent surgery. He was a good man, honest and upright, and left us a deep legacy. He will be missed.

22-01-04 *Bekenstein, Bohr, and Bohr* (to A. Peres)

Your meeting sounds like it is going to be a great one. I would be particularly keen to get a report on Jacob Bekenstein's talk.

Asherism 41: *I am slowly browsing throught your book "Paulian Idea" in the evening, when I am too tired to do anything productive, and I have until now two minor remarks. The first use of entanglement was not by Schrödinger in 1935, but by Heitler and London, Zeits. Phys.* **44** *(1927) 455.*

Thank you for letting me know that. I hadn't heard of that paper before.

Asherism 42: *Bohr's key idea was that "classical" and "quantum" labeled ways of description, not properties of systems. Is this a Bayesian idea?*

Not properly, no. But what it does have in common with Bayesianism is that the quantum state (much like a probability distribution) is not a property of a system.

Asherism 43: *BTW, don't forget "my" Niels Bohr Medal (it's a medal, not a prize).*

I certainly will not! I had already searched on the web for information about nominations, but was not able to find it. I will be in Copenhagen Feb 2 however for my job interview, and I was planning to ask Ole Ulfbeck and Eugene Polzik anything they knew then. Do you have any leads on what the official procedure is? (If I can figure that much out, I can organize the behind the scenes thing myself.)

23-01-04 *Entropy?* (to P. Grangier)

Sorry to take a while to reply to you. I'm on my way to Texas as I am writing you this note. Unfortunately (or maybe fortunately) I don't have their paper here to look at, so I have to focus on the parts you've given me.

Grangierisme 19: *I wanted to know your opinion about a recent preprint (*`quant-ph/0401021`*) where the authors write on p1:*

> For a pure quantum mechanical state Ψ the Von-Neumann definition gives $S_H[\Psi] = 0$. This seems to imply that a pure quantum mechanical state is lacking a statistical nature. This is of course not correct. For a general measurement we have uncertainty.

There are many ways to define the von Neumann entropy of a density operator, and not simply by the raw formula. My favorite comes from Wehrl (I believe): the von Neumann entropy is defined to be the minimum Shannon entropy for the measurement outcomes of a fine-grained von Neumann measurement, where the minimum is taken over all such measurements. (See pages 31 and 32, starting at Eq. (77), of my `quant-ph/0205039` to see a little discussion of this and to see it formalized.)

The von Neumann entropy of a pure state being zero does not mean that the pure state has no statistical character. It only means that for some measurement it will give an outcome with certainty. For the vast majority of other measurements it will give uncertainty. (For the uncertainty on average, see Eq. (80) in my paper; it was a number first calculated by Bill Wootters.)

Grangierisme 20: *Then they define an "uncertainty-related" entropy, which is non-zero for a pure state.*

What do you think about such an approach? Clearly it has the major disadvantage of being in plain contradiction with the so-called "third principle of thermodynamics", stipulating that (in most cases) the statistical entropy is zero at zero temperature. Even worse, I wonder whether it might be self-contradictory in some sense (that I was not able to pin down), or at least contradictory with various points in statistical physics. Your opinion would be appreciated.

They can make any measure they want, say something like the Eq. (80) I've already referred to. But then it won't correspond to thermodynamic entropy. You're quite right. That number controls the free energy of a system—i.e., the energy that can actually be extracted once it is stored there—and there are already plenty of good arguments that it is the von Neumann entropy (going all the way back to von Neumann's book itself, but also detailed in Lindblad's book, and some of Jaynes's papers, etc.). If you have stored energy in a system, and you have maximal knowledge of it—i.e., a pure state for it—then you can use that knowledge to re-extract the energy you've stored there. That's what the von Neumann entropy being zero is about.

Now if one were to make a restriction on what operations can be done on a system, or a restriction on what measurements can be done on a system, that would change the flavor of everything. But I doubt they've done anything like that. It sounds to me like they're just confused.

Suggest that they read Wehrl's paper.

23-01-04 *Flying to Texas* (to N. D. Mermin)

I'm flying to Texas as I write this to you. I'm popping in for the weekend for my Mom's 75th birthday. I start heading back Monday morning. The following Sunday I'm off for a visit to the Niels Bohr Institute.

Mostly I'm working on a proposal in the background, but I'll stop for a minute to have some conversation with you.

Merminition 136: *Somewhere in Jaynes's book (but I haven't been able to find it again) he says that to assign something probability zero is, by Bayes's theorem, to commit yourself to never updating the assignment of zero on the basis of any new information. This, of course, would be bad news for your position.*

I don't understand why you are thinking it would be 'bad news'. In fact for our understanding it is actually good news, for it tells you how opinions actually change: By Darwinism. As de Finetti points out pretty strongly in his Probabilismo, applications of Bayes' rule are not changes of opinion at all, but rather following one's initial opinion through to its consequences.

In terms of a Dutch-book scenario, if one has certainty for some event, then one is willing to bet one's life savings on it. If that event then does not occur, one has lost everything: The whims of Darwinian evolution have taken one out. And one's beliefs then do not propagate.

Merminition 137: *But I believe what he has in mind is this:*

$$p(a|bx) = \frac{p(ab|x)}{p(b|x)} \leq \frac{p(a|x)}{p(b|x)}.$$

So if $p(a|x) = 0$, then $p(a|bx) = 0$ too, for any b.

What he appears to overlook is that this is only so if $p(b|x) \neq 0$. The correct statement should to be that if you assign something probability zero, then only the occurrence of something else to which you assign probability zero can lead you to update the first probability to a non-zero value (assuming you are behaving rationally — i.e. following the laws of thought.)

I was reminded of this when I read in paragraph 69 of "On Certainty":

> *... If I am wrong about this, I have no guarantee that anything I say is true ...*

In the context of the other paragraphs surrounding Wittgenstein's 69, Wittgenstein's point granted. But I don't understand your 'passing thought'. You can try again, but I think my point above already negates it: two deaths don't make a life.

Merminition 138: [Regarding Spekkens.] *Doesn't the fact that* [his toy model] *has both epistemic AND ontic states make it uninteresting?*

I think you're missing something big here. It is interesting precisely because he has ontic states. What his work helps argue is that so many of these effects we find interesting in quantum information—like teleportation, superdense coding, 'nonlocality without entanglement', the no-broadcasting theorem, entanglement monogamy, etc., etc.—come about *solely* from the epistemic nature of quantum states (including the less than full use of the probability simplex, i.e., his epistemic restriction, or knowledge-balance principle). And in that light they are not nearly as interesting as we once thought they were.

It's a question of refocusing yet again. What his work shows us is that the interesting questions lie elsewhere. In particular, it teaches us that the crucial question must be, 'Information About What?' A quantum state is epistemic alright—all these examples are meant to help you believe that—but epistemic about what? That is the great unanswered question. Of course, I myself say, epistemic about the outcomes of other interventions. But what is left to do is to make that sentence precise enough that, from it, we can rederive the structure of quantum theory. It is about formalizing THE Paulian Idea—that is where he has taught us to refocus. (Though he would likely disavow much that I've said, being one who deeply longs for nonlocal hidden variables or some such.)

Here's another way to put it. Does THE Paulian Idea (i.e., that the agent cannot be detached from the phenomena he helps bring about) find any crucial expression in the phenomena of teleportation, superdense coding, 'nonlocality without entanglement', the no-broadcasting theorem, entanglement monogamy, etc., etc.? Probably not. All those phenomena seem to have more to do with the epistemic nature of quantum states.

Instead, the Paulian Idea may well be localized solely in Kochen-Specker phenomena. (Which is something itself longing to be reexpressed in Bayesian terms, but I need to write you a separate note about that one day.)

I'll paste some related thoughts from a letter to Oliver Cohen below. [See 15-01-03 note "Memory Lane" to O. Cohen.]

Does any of this help you see why I am excited by Rob's work?

23-01-04 *The Wittgenstein Bug* (to R. Schack)

What a lovely Wittgensteinian reply to my little (and of course exaggerated) email! If you had only numbered the paragraphs …

I'm stuck in a snowy Chicago airport at the moment, trying to make my way to Texas. And I'm not thinking particularly clearly any more. I'll try to say something sensible of your email next week.

Rüdiger's Preply

> I own Wittgenstein's complete works (in German) and I had read a lot of it in my undergraduate days. Your email made me reread quite a sample of "On Certainty". Is your edition split in 676 paragraphs as mine is?
>
> My summary of the book: There are many intelligible ways of using the phrase '*I know x*', but Moore's is not one of them.
>
> The book may be relevant for our program by helping us clarify the differences between the following statements:

I know that $2 + 2 = 4$.
I know that $12 \times 12 = 144$.
I know that this is a chair.
I know that the earth existed 100 years ago.
I know that the ground state of the hydrogen atom is $|\psi\rangle$.
I know that the state of this hydrogen atom is $|\psi\rangle$.
I know that the outcome of this measurement will be 0.
I know that this is a beam splitter.

But then, it might not be relevant for our program. See par. 8, which states that in most contexts there is no difference between '*I know that x*' and '*I am certain that x*'. Here is another one-sentence summary of his book: '*I know that x*' is either meaningless or synonymous with '*I am certain that x*'. For our own program, we have the following:

> '*I know that the state is* $|\mathrm{up}\rangle$ *and the* Z *component of spin is measured*' is a reformulation of '*My state of belief is* $|\mathrm{up}\rangle$ *and* Z'. This reformulation is philosophically fraught and meaningless, exactly as the sentence '*I know this is a tree*' in Wittgenstein's text.
>
> '*I know the outcome will be up*' can be viewed as a careless way of saying '*I am certain that the outcome will be up*' which in turn is equivalent to saying '*I am willing to bet a lot of money on the outcome up*'.

I am rather puzzled by your sentence

> Within the first five pages of that 90 page book, he already said all that Rüdiger and I ever wanted to say and just kept going.

and the follow-up

> Here is a man who, 52 years ago, could have tackled the Penrose question head on: How a pure quantum state can be epistemic and yet still give probability one predictions for some measurements?

I am not sure he said all we ever wanted to say about certainty. He might even have doubted that the Penrose question as stated by you has any meaning. Wittgenstein says

(i) You can be certain about something ('*the earth was here 200 years ago*') without being able to prove it. To doubt the thing would mean leaving the boundaries of the Sprachspiel (language game?).

(ii) The sentence '*I know that this is a tree*' is usually meaningless. It is only meaningful if there could exist reasonable doubt about this being a tree (for instance, one biology student could use the sentence to try to convince another student that the plant in question is a tree and not a shrub).

(iii) The sentence '*I know that this is a tree*' does not imply that this is a tree. It is not a sentence about the tree, but about me.

Is (i) relevant to the Penrose question? Not directly, I think.

How about (ii)? Maybe (ii) is relevant in the sense that the distinction epistemic versus ontic is meaningless. You know (unobjectionable usage!) that I want to replace that distinction by the pair subjective versus nonsubjective.

Is (iii) relevant? No. Nobody claims that '*Mabuchi is certain that the outcome is 0*' implies that the outcome is 0. Mabuchi could be wrong.

What I think is that Wittgenstein is trying to tackle a different question.

Here is another attempt:

(A) I know the outcome is 0.

(B) I know the outcome will be 0.

Wittgenstein would have no objections at all to (B), I believe. But (A) is tricky. It could be that all I want to say is that the outcome is 0. In that case I should just say that. On the other hand, if the outcome is in plain view and everybody can see that it is 0, then uttering (A) should make people doubt my sanity.

For us, (B) is the tricky one.

Reading Wittgenstein certainly stimulates thought. Here is yet another version of our quantum question: How can we assign a pure state and at the same time grant that somebody else may legitimately assign another pure state? Or the extreme case: How can we assign a pure state and at the same time grant that somebody else may legitimately assign an orthogonal state? Translated into Wittgenstein's terms: How can I know x and at the same time grant that somebody else may know the negation of x? Wouldn't that mean that we play in different Sprachspiele? Which brings us back to my old and yet unanswered challenge to you: Give a satisfactory account of a crisis in a quantum measurement scenario.

I hope that some of all this makes sense. In any case, I KNOW that we are on the right track!

23-01-04 *I Married a Teenage de Finetti?* (to G. Bacciagaluppi)

Attack of the Giant de Finetti
The Bride of de Finetti
The Fearless de Finetti Killers (or Excuse Me but Your Dutch Book Is In My Neck) — produced and directed by Roman Polanski, introducing Sharon Tate
Plan de Finetti from Outer Space
Abbott and Costello Meet de Finetti
The de Finetti Rises
Attack of the Killer de Finettis
The Bride of de Finetti Returns!
The de Finetti of London
de de de Finetti: de Finetti 3D! (Just when you thought it was safe to read David Lewis again.)

28-01-04 *Merminizing* (to N. D. Mermin)

Just wondering how you're doing? Did you get my note in reply to your 'passing thoughts'? I seem to have had some email problems, with people not getting my messages again lately. I hope you weren't one of them.

My own favorite paragraph from *On Certainty* comes from #30:

> Certainty is as it were a tone of voice in which one declares how things are, but one does not infer from the tone of voice that one is justified.

31-01-04 *Just the Opposite* (to N. D. Mermin)

Merminition 139: *I read in today's NY Times:*

> *Mr. Bush no longer declares, as he once did, that he is certain that sooner or later unconventional weapons will be found in Iraq.*

Can Ludwig get him honorably off the hook?

It's just the opposite! That was the part of the point of my last long note to you. For the Bayesian, the only way to back away from certainty is death. I.e., it's Darwin to the rescue!

01-02-04 *Wilczek, Einstein, and Bohr* (to G. Brassard)

Brassardisme 13: *And do you feel that Copenhagen and Bohr's ghost are receptive?*

I was once at a conference where someone asked Frank Wilczek what it was like to live in Einstein's old house in Princeton. The fellow asked, "Have you ever felt Einstein's ghost?" Wilczek answered, "No, but every morning I wake up a little more dubious of quantum mechanics."

I'm going to bed now. I'll tell you if Bohr enters my dreams.

02-02-04 *Many Thanks* (to A. Shimony)

At the moment, I'm in Copenhagen, just finishing a visit to the Niels Bohr Institute. I think the talk only went so-so. But I did get to see Niels Bohr's office and desk! That was quite nice.

For my leisure reading, I brought Donald Davidson's book *Subjective, Intersubjective, Objective*. I'm not finding him nearly as hard to read as everyone has been warning me: It makes me worry that I'm missing something.

03-02-04 *The Land of Bohr* (to G. L. Comer)

I'm writing to you from Kastrup airport, just as I'm leaving the land of Bohr. Yesterday I walked into Bohr's old office and had a look at his desk. Thinking back on the moment, how I wish I had sat at it, even if only briefly. I could have; there was nothing to stop me. But it didn't dawn on me at the moment that there was an experience passing me by. It reminds me of a couple of lines in The Pogues' song, "Fairy Tale of New York." The man laments "I could have been someone," to which the woman cries out in reply, "Well so could anyone!"

When I visited you in Meudon that year [1992], I went into the Cathedral of Notre Dame and tried to imagine Napoleon taking the crown away from the Pope at the last minute of his coronation. "I crown myself Emperor," he said.

I hope I won't forget the lesson so quickly this time around.

03-02-04 *Napoleonic History* (to D. B. L. Baker)

Hey historian,

Can you point me toward a book where there's a good, vivid description of Napoleon crowning himself emperor?

Thanks (if you can),

05-02-04 *Facts, Values and Quanta* (to D. M. Appleby)

Wow! Thank you for the color-full and value-laden paper. I'm just printing it out now. I'll try to respond to you as soon as possible.

Will you be at the LSE meeting Monday February 16?

Most of the stuff in my talk you will have heard before (over and over and over), but there is one point that is new (and I think noteworthy). Plus there is a line-up of several other good-looking talks. It'd be great to see you there.

BTW, regardless of content, I love your title!

05-02-04 *Explain* (to H. Mabuchi)

Home from Copenhagen, and found a package waiting for me: It's the book by Richard Powers you sent me. Thanks! Now explain. Why did you send it? Because it's a good novel, and you know that I haven't read any fiction in a while? Or did you have something more specific in mind?

Hideo's Reply

> As for the book: it's a novel — read it! I suspect you'll sympathize with one of the characters. I declare it to be the best book I've ever read.

06-02-04 *Replies to Your Comments* (to N. D. Mermin)

Here goes something of a reply.

Merminition 140:

> [CAF wrote:] This is where quantum information (including the collateral fields of quantum cryptography, computing, and communication theory) has a unique role to play. Its tasks and protocols naturally isolate the parts of quantum theory that should be given the most foundational scrutiny. "Is such and such effect due simply to a quantum state being a state of information rather than a state of nature, or is it due to the deeper issue of what the information is about?"

Is superconductivity (a famous quantum effect) a state of nature or a state of information or is it due to .... I'm not trying to be nasty. Just suggesting thoughts that may occur to some readers.

That is precisely the sort of thing that I am asking that we examine—though I don't quite know where superconductivity fits into the quantum-informational classification scheme yet. How can I be faulted for asking the same question that your straw man is?

Merminition 141:

> [CAF wrote:] Recent investigations by several workers are starting to show that a plethora ...

Have even you succumbed to the use of "plethora" (which means excess, too much, etc.) simply to mean lots and lots without any negative connotations? Then the battle has been lost.

You forget that I did not know English before I started writing email in 1991, and even then I did not get a real boost in my grammar until I started corresponding with you in 1996. It is an ongoing process with me, and you have taught me the meaning of plethora. It's not a lost battle; thanks.

Merminition 142 :

> [CAF wrote:] On the other hand, other phenomena, such as the potential computational speed-up of quantum computing, seem to come from a more physical source: In particular, the answer to the question, "Information about what?"

Quantum computational speedup comes from the answer to the question, "Information about what?" Do you really mean that?

Yep, I mean that. What is the answer to "Information about what?"? I like to say, "the consequences of our interventions into nature." But that needs to be tightened up into a more formal statement. It has its base in Kochen-Specker, but I don't know how to carry the thought any further than that at the moment. Let me reiterate the point I made to you about Spekkens the other day: [See note titled "Flying to Texas," dated 23 January 2004.]

Merminition 143 :

> [CAF wrote:] When we finally delineate an answer to this physics will reach a profound juncture. We will for the first time see the exact nature of 'quantum reality' ...

By putting the term in quotes I assume you mean we will finally understand what the term means. But it can also be read as saying that there is a quantum reality that we will understand. Not sure what you want the reader to take from this.

Maybe both ideas.

Merminition 144 :

> [CAF wrote:] Trickle-down effects could be the solution to the black-hole information paradox and even the meshing together of quantum theory and gravitational physics—some of this can already be seen in broad outline.

Really!? Would you care to expand on this?

I was a little more careful in my formulation this time around. The 'broad outline' part really only attaches to the black-hole information paradox business. Who would have thought that it is a QM-foundational paradox on the order of all the usual ones, but I think that's all it is. In non-Bayesian approaches to quantum mechanics, when one has a mixed state, one usually gets all fuddled up either, a) trying to identify the REAL pure state underneath the mixed state, or b) trying to seek a purification of the state that is the REAL state of some bipartite system. From the Bayesian point of view that is a fruitless exercise: There is no demand that a mixed state be derivable from any REAL pure state. All those ancillas, environments, and purifications are generally factitious.

Similarly for the Bayesian point of view of quantum operations, à la Fuchs and Schack (but maybe not yet Caves). There is no demand that a proper trace-preserving quantum operation be derivable from some REAL unitary operation on a larger system. And that is all I think is going on with the black-hole information paradox. They can't find any natural bipartite system to pin a unitary dynamics on. But so what? It, like the EPR paradox, is a pseudo-problem. It can be good for clarifying concepts, but it is not a feature of nature.

Merminition 145 :

> [CAF wrote:] Since the beginning of quantum theory, much of what the enthusiasts have called 'foundational work' has been pseudoscience pure and simple. But the field can be made as respectable as quantum theory itself, if done right. Quantum information is the technique for the task.

Why get on the defensive? You're the one who disparaged foundational work. Why should these guys share this negative view?

Just pounding on the idea that my program is quantum foundations with that little something extra (i.e., legitimacy).

Anyway, why draw attention to it? Look at one question I got in Copenhagen the other day. A fellow said, "This is all very nice for 'Sunday physics,' but what do you do for the rest of the week?" I looked him straight in the eye and told him that this was the same kind of physics that went into my calculations for Kimble's teleportation experiment. Apparently he needed to be told that.

People have to get it in their heads that this is serious physics, as serious as anything else in the now vast edifice of quantum information and computing. They're drawing an imaginary line.

Merminition 146 :

> [CAF wrote:] With regard to quantum mechanics then, the Bayesian view of probability combined with Gleason's theorem on Hilbert-space measures leads ineluctably to the idea that a quantum state is a collection of gambling commitments and nothing more.

Ouch! You've been trying for 5 years to bring me around to this point of view and I'm still not there. Try to tell a solid state physicist that the BCS ground state of a superconductor is a set of gambling commitments. She'll kick you out of her office. Try to tell a chemist that a chemical bond is a gambling commitment. Who is your audience?

Position statement. But your point is well taken. Unfortunately, I can't help it that a probability distribution is not a solid object (as we've all been led to believe from our early educations), but I can't lie about it either. That point is the core of my research program. What one sentence could I write that would either a) soften the blow, or b) make it all seem more reasonable? One sentence alone?

Merminition 147 :

> [CAF wrote:] What is already clear enough, nonetheless, is that from a Bayesian approach the formal structure of quantum theory represents not so much physical reality itself, but rather a behavior change from standard Bayesianism for gambling agents *immersed* within a quantum world. The trace of a 'quantum reality' (which we would so dearly love to formalize) must be found in the difference.

I've missed the punch line. The difference between what and what? Between behavior as described by standard Bayesianism and behavior of gambling agents immersed in a quantum world? It sounds like you're saying that there is no reality for standard Bayesians but a little bit emerges when quantum phenomena enter the story. Is this really what you mean?

Something like that. Standard Bayesianism makes no reference to anything about reality. Quantum mechanics seems to: It is a layer on top of Bayesianism that has to do with setting priors, and modifying the update rule when there is physical contact between the agent and the system he is stimulating (in old language, measuring).

Merminition 148 :

> [CAF wrote:] Quantum mechanics holds the promise of drastically changing our world view.

That happened a long time ago. Before even I was born, if you can believe it.

I don't think so. It changed physical practice long ago, but it has yet to change our world view in a widespread way. That's why there is still so much effort to make Everett, decoherence (einselection), consistent histories, Bohmian mechanics, modal interpretations, etc., etc., work.

None of those wimps have had the nerve to embrace the Paulian idea (whatever it is).

OK, that's my response to all your comments.

Now, all that said, I am a little disappointed in what I've been able to muster for this proposal. I tried to be inspiring and sober at the same time; I suspect I failed.

Writing is not an easy profession, is it?

06-02-04 *For Your Amusement* (to H. J. Kimble)

I just wrote a note to David Mermin regarding some quantum foundational stuff we've been talking about, and the passage below came out. I thought you might find some amusement in it. When I said, "looked him straight in the eye," I was imagining what you would do in a similar situation! Probably make my actions look like cheesecake in comparison.

> Look at one question I got in Copenhagen the other day. A fellow said, "This is all very nice for 'Sunday physics,' but what do you do for the rest of the week?" I looked him straight in the eye and told him that this was the same kind of physics that went into my calculations for Kimble's teleportation experiment. Apparently he needed to be told that.
>
> People have to get it in their heads that this is serious physics, as serious as anything else in the now vast edifice of quantum information and computing. They're drawing an imaginary line.

12-02-04 *The House Philosopher* (to J. Preskill & H. Mabuchi)

This morning I finally completed all the requirements for the IST faculty-search application. As you'll see, I followed John's suggestion full stop:

Preskillism 9 : *I also think you are right that to have a chance of success you need to emphasize what makes you unique: your passion for and productive contributions to the foundations of quantum theory.*

It felt good.

Attached for the heck of it are my teaching and research proposals. It may not come through in the documents, but I gave quite a bit of thought to how I might actually pull off these course suggestions.

Thanks for giving me the incentive to go down this path, whatever the outcome: It was a very good exercise.

The Structure of Quantum Mechanical Information

Quantum Foundations in the Light of Quantum Information. Nothing has done more to revitalize the idea that quantum mechanics can be understood at a deep intuitive level—with the concomitant benefits to physics this could bring—than the development of quantum information. There is a reason for this. Quantum mechanics is predominantly about information—plain, ordinary Shannon information or uncertainty. Embracing this idea is the starting point of my research program.

But it is not the end point: No physicist would be doing his job if he did not strive to map reality itself—that is, reality as it is independently of any information processing agents. The issue is one of separating the wheat from the chaff: Quantum mechanics may be predominantly about information, but it cannot *only* be about information. Which part is which? The usual way of formulating the theory is a thoroughly mixed soup of physical and informational ingredients.

This is where quantum information (including the collateral fields of quantum cryptography, computing, and communication theory) has a unique role to play. Its tasks and protocols naturally isolate the parts of quantum theory that should be given the most foundational scrutiny. "Is such and such effect due simply to a quantum state being a state of information rather than a state of nature, or is it due to the deeper issue of what the information is about?" Recent investigations by several workers are starting to show that many of the previously-thought 'fantastic' phenomena of quantum information—like quantum teleportation, the no-cloning theorem, superdense coding, and nonlocality without entanglement—come about simply because of the epistemic nature of the quantum state. On the other hand, other phenomena, such as the potential computational speed-up of quantum computing, seem to come from a more physical source: In particular, the answer to the question, "Information about what?"

When we finally delineate a satisfying answer to this, physics will reach a profound juncture. We will for the first time see the exact nature of 'quantum reality' and know what to do with it to achieve the next great stage of physics. Trickle-down effects could be the solution to the black-hole information paradox—perhaps already seen in broad outline—and even the meshing together of quantum theory and gravitational physics. In the meantime the approach proposed here is a conservative and careful one; the work to be done is large. The effort aims not to say first what 'quantum reality' is, but what it is not and gather insights all along the way.

Since the beginning of quantum theory, much of what the enthusiasts have called 'foundational work' has been pseudoscience pure and simple. But the field can be made as respectable as quantum theory itself, if done right. Quantum information is the technique for the task.

Being Bayesian in a Quantum World. But what is information? The Bayesian approach to the idea is that it has to do with our individual expectations, however they might come about. In particular, a probability distribution is a property of one's head, not of what is outside it: Its existence is manifested only in the betting behavior of the agent who uses it. With regard to quantum mechanics then, the Bayesian view of probability combined with Gleason's theorem on Hilbert-space measures leads ineluctably to the idea that a quantum state is a collection of gambling commitments and nothing more.

There are, however, technical differences between quantum theory and straight up Bayesianism. For one thing, when one updates a probability after gathering data, one uses Bayes' rule for the transition. But, when one updates a quantum state, one uses the formal apparatus of quantum collapse. The two transition rules, though similar, are not identical. What this (as only one example) means is that the foundations of the Bayesian approach to probability need to be carefully rethought when probabilities are brought to bear on quantum phenomena. If Bayes' rule is not to be used directly in the quantum regime, something about the usual arguments for it must fail to apply there. And so too, with all of Bayesian decision theory. The work to be done will fill a book. In fact, the finished project should compare in scope and magnitude to the content of Bernardo and Smith's magisterial *Bayesian Theory* and have the same impact on practice, *e.g.* quantum feedback and control.

What is already clear enough, nonetheless, is that from a Bayesian approach the formal structure of quantum theory represents not so much physical reality itself, but rather a behavior change (from standard Bayesianism) for gambling agents *immersed* within a quantum world. The trace of this 'quantum reality' we are striving to formalize must be found in the difference.

Quantum Mechanics as a Powerful Hint. In my opinion, the most profound statement yet to come out of quantum theory is the Kochen-Specker theorem. For it licenses the slogan, "Unperformed measurements have no outcomes." This is just a beginning. If one canvasses the philosophic traditions for one that has significantly developed this slogan, one will find the now mostly-forgotten tradition of pragmatism fathered by William James and John Dewey. As a source of ideas for what quantum mechanics can more rigorously justify, no block of literature is more relevant: The connections between the two fields cry out for systematic study. Quantum mechanics holds the promise of drastically changing our worldview on the wide scale. It is time to let that happen.

Teaching Proposal for Caltech

A good summary of my last 11 years would be that I have lived and breathed quantum mechanics. I tried to let it and the worldview it suggests infuse every aspect of my life. What I find most attractive about Caltech is that it is an institution with enough resource, foresight, and intellectual talent to play the role of a seed for something like that on the grand scale.

The course suggestions proposed here are based on such an idea. Proposed are five courses I would like to develop *over the next few years*. They all mutually interlock, and the insights from the students' reactions to each are meant to play a significant role in the development of the others.

Quantum Foundations in the Light of Quantum Information. This course, for graduate students and high-level undergraduates, would be the torch bearer for the curriculum. There are deep rumbles in the foundations of quantum mechanics, and enough technical material has amassed to make a full survey course viable and certainly desirable. The lectures would highlight papers by Scott Aaronson, Marcus Appleby, Howard Barnum, Hans Briegel, Jeffrey Bub, Paul Busch, Adán Cabello, Ignacio Cirac, Rob Clifton, Carlton Caves, Giacomo D'Ariano, myself, Nicolas Gisin, Hans Halvorson, Lucien Hardy, Alexander Holevo, Piero Mana, David Mermin, David Meyer, Itamar Pitowsky, Sandu Popescu, Robert Raussendorf, Rüdiger Schack, Robert Spekkens, Guifre Vidal, David Wallace, William Wootters, and a few others. The continuous thread running through the lectures would be how each paper implicates the others. The goals are 1) to leave the students with a palpable sense that real progress is finally being made on this seemingly timeless problem, and 2) to promote a clear vision of how they might use the techniques and ideas explored in the course to good effect in their everyday research—be it quantum information and computing, condensed matter theory, or theoretical astrophysics.

The lecture notes in this course will be a crucial component in its construction. The plan is to put together a seamless-enough and thorough-enough document to avail of a recent proposition for a book of the same name by Springer-Verlag. The point is to leave a lasting and developable mark in the practice and applications of quantum mechanics. Quantum foundations work is worth little if it cannot leave that.

Innovative Undergraduate Quantum Mechanics. I once wrote these words as a battle cry in one of my quantum foundational papers,

> The task is not to make sense of the quantum axioms by heaping more structure, more definitions, more science-fiction imagery on top of them, but to throw them away wholesale and start afresh. We should be relentless in asking ourselves: From what deep *physical* principles might we *derive* this exquisite mathematical structure? Those principles should be crisp; they should be compelling. They should stir the soul. When I was in junior high school, I sat down with Martin Gardner's book *Relativity for the Million* and came away with an understanding of the subject that sustains me today: The concepts were strange, but they were clear enough that I could get a grasp on them knowing little more mathematics than simple arithmetic. One should expect no less for a proper foundation to quantum theory. Until we can explain quantum theory's *essence* to a junior-high-school or high-school student and have them walk away with a deep, lasting memory, we will have not understood a thing about the quantum foundations.

We are certainly far from that dreamy ideal today, but a soberer version of the lesson is the same: The only meter for progress in quantum foundations is the ease of quantum practice and the ease with which students absorb the subject.

To that end, quantum information has already taught us several lessons at the methodological level that can be made use of today. What I envision is developing a course that takes its base in Hideo Mabuchi's previously successful Ph125 and trying to tweak it to perfection. The great lesson of quantum information is how much of the meaning and mystery of quantum mechanics can be isolated in two and three-level systems and their interactions. Therefore it is useful to spend a solid amount of time sussing out that regime as thoroughly as possible. Simple quantum information effects like the no-cloning theorem, quantum cryptography, Bell inequalities, entanglement monogamy, quantum teleportation, and the Kochen-Specker theorem are not 'Sunday physics', but the very heart of the matter. More than anything, they give an intuition for the necessity of the Hilbert-space formalism.

The trick is in pushing that intuition deep into the students' psyche, while at the same time not losing sight of the need to get through a semi-standard curriculum of harmonic oscillators, perturbation theory, hydrogen atoms, the Zeeman effect, etc., as efficiently as possible. How to do it? Some of physics is just roll-your-sleeves-up hard work, but it is a good gamble that as the course develops much of the method will lead its own way. Inconsistencies in thought and method have a way of declaring themselves—it is that system of checks and balances which has tugged research in 'quantum mechanics as quantum information' in a uniform direction ever since the beginning anyway. In all seriousness, this is a case where basic quantum theory stands to gain as much from the reaction of the undergraduate as any amount of cloistered introspection.

Bayesian Theory. Bayesian Theory is an approach to probability theory and statistical decision-making that is quickly gaining traction in all aspects of science. José Bernardo and Adrian Smith characterize it this way in their masterwork on the subject:

> The theory and practice of Statistics span a range of diverse activities .... What is the nature and scope of Bayesian Statistics within this spectrum of activity? Bayesian Statistics offers a rationalist theory of personalistic beliefs in contexts of uncertainty, with the central aim of characterizing how an individual should act in order to avoid certain kinds of undesirable behavioral inconsistencies. The theory establishes that expected utility maximization provides the basis for rational decision making and that Bayes' theorem provides the key to the ways in which beliefs should fit together in the light of changing evidence. The goal, in effect, is to establish rules and procedures for individuals concerned with disciplined uncertainty accounting. The theory is not descriptive, in the sense of claiming to model actual behavior. Rather, it is prescriptive, in the sense of saying "if you wish to avoid the possibility of these undesirable consequences you must act in the following way."

My own interest in Bayesianism sprouts from the sensibleness it helps bring to quantum mechanics: For, one might consider much of the formal structure of quantum theory as a prescriptive set of rules for uncertainty accounting in the light of some (yet to be fleshed out) more basic features of the world. In other words, quantum theory is not so much about physics itself, but rather decision theory in the *presence* of physics. This is the research program of 'Being Bayesian in a Quantum World.'

It is crucial for this research program, however, that the physics community gain a proficiency and comfort with the subject long previous to that. This motivates me to try to introduce and maintain a top-notch, Bayesian theory course for graduate students and high-level undergraduates. The course, based initially on Bernardo and Smith's text *Bayesian Theory*, would have a university-wide appeal, being applicable to all the sciences and some fields in the humanities. Covering both foundational topics and rigorous technicalities in statistical modelling, it should be particularly relevant to those students associated with the IST Center for the Mathematics of Information.

Quantum Mechanics and Anti-representationalist Philosophies. There are various threads connecting the quantum research program proposed here to a wider philosophical tradition, which to my knowledge has never been greatly examined in this context. The tradition comes under the rubric of what Richard Rorty calls 'anti-representationalist philosophies.' This tradition, spearheaded by the pragmatism of William James and John Dewey, also includes thoughts of (the later) Ludwig Wittgenstein, Martin Heidegger, Donald Davidson, Hilary Putnam, Rorty himself, and several others. How else can one understand the implications of the Kochen-Specker theorem than by realizing it hints at something like James' analysis of the concept of 'truth'? How else can one make sense of a Bayesian take on pure quantum states than to explore the same paths as Wittgenstein in his book *On Certainty*?

Since becoming immersed in the subject, I have found nothing more exciting than these trains of thought. For they indicate the extent to which quantum foundations research may be the tip of an iceberg—indeed, something with the potential to drastically change our worldview, even outside the realm of physical practice. William James once said this of the method of pragmatism,

> [Within it] theories ... become instruments, not answers to enigmas, in which we can rest. We don't lie back upon them, we move forward, and, on occasion, make nature over again by their aid.

Two thousand years hence, this may be the greatest, most lasting legacy of quantum theory.

Within the humanities division, or possibly shared between physics and the humanities, I would like to develop a course for graduates and undergraduates that would meditate on these threads and tie them together as much as possible. The lectures and discussions would focus on a selection of materials drawn from my personal library of nearly 300 books on the subject. The goal with respect to interested philosophy of science graduate students would be to introduce them to enough material and provide them with enough guidance for a solid thesis topic in the subject.

Writing Physics. The greatest physics laboratory for me has always been my keyboard. With the practice of almost 17,000 emails since my first notebook computer in 1997 (a plethora of which are long and detailed), I believe I have taught myself a skill worth passing on to physics students in general: It is in line with what David Mermin has called *writing physics*,

> Physicists traditionally replace talk about physics by a mathematical formalism that gets it right by producing a state of compact nonverbal comprehension. The most fascinating part of writing physics is searching for ways to go directly to the necessary modifications of ordinary language, without passing through the intermediate nonverbal mathematical structure. This is essential if you want to have any hope of explaining physics to nonspecialists. And my own view is that it's essential if you want to understand the subject yourself.

My trick has been to never write for my own mind, but always for someone else's. That is why email has been essential to me. (Some of my best papers, technical and nontechnical, have been cut and pastes from old emails.) Indeed, email provides a kind of immediate feedback that no other kind of writing can.

Based on these ideas, and Mermin's own from his paper of the same name, I would like to create an innovative technical writing course for undergraduates within IST. The goal is to have better papers, and better scientists because of better papers. The goal is to have IST writing physics.

13-02-04 *Anniversary Cheer* (to J. Preskill)

NOTE: With hindsight, this letter seems to represent the first time I had incorporated William James's "will to believe" doctrine into my palette of thinking.

What welcome news to wake up to this morning, and what a great day to receive it on! Ten years ago today, I worked up the nerve to trot across a neighborhood park and asked Kiki to dinner. It was our first date. (You can read about the weeks leading up to it in the story of our dog Wizzy, in "Quantum States: W.H.A.T.?" on my webpage, pages 142–143.) [See 16-02-02 note "Some Things Should Not Pass."] Lesson learned: Without nerve first, there isn't hope second.

15-02-04 *Step Forward* (to G. Brassard)

Let me attach the proposals I finally sent off to Caltech last week. [See 12-02-04 note "The House Philosopher" to J. Preskill and H. Mabuchi.] I hope you enjoy them.

Today I fly out for the LSE meeting on Probability and Quantum Mechanics, and to give the "Popper Colloquium" the next day. I think I need to do a particularly good job here, as we stand to gain a lot of interest from the philosophers.

I've gotta, gotta, gotta get to work on the Asher paper for us. Let's hope that starts up in about a week: In any case, I'm sure the editor of the special issue will wait for us. I know him personally!

17-02-04 *From London* (to A. Fine)

Sorry to take so long to reply: I'm at the LSE now and going to give my first colloquium ever to a philosophy department. (Look in the obituary column tomorrow.)

Fine-ism 2: *I think we have some serious disagreements about how to think about QM, the role of pragmatic considerations, etc. But, then, choose any two folks who work in this area and you'll find the same sort of thing!*

Interesting. I hope you'll explain as you get a chance. In particular, it would be useful to me if you can pinpoint where you already disagree with my `quant-ph/0205039` "QM as QI (and only a little more)". Following that, I'd like to hear about the disagreements with my later thoughts (for instance, the ones in the proposals) after pragmatism sunk more deeply into my soul.

21-02-04 *Philosophical Training* (to A. Shimony)

I am just back in Dublin from a (mentally) long week in London at the LSE and then at All Souls College in Oxford. It was my first extended engagement with full-fledged philosophy departments. I tell you, I felt like I was in the frying pan the whole time! It was defense, defense, defense; they made me earn my travel expenses. But—no doubt—I got some good training in the process.

21-02-04 *My Visit* (to S. Savitt)

I am just back in Dublin from an exhaustingly long week at the LSE in London and All Souls College in Oxford. It was my first real engagement with philosophy departments. I tell you, I felt like I was in the frying pan the whole time! It was defense, defense, defense. What does not kill you makes you stronger? ... Actually, except for the constant effort I had to put into keeping from being bushwhacked, I think I fared pretty well. Even picked up a convert or two ...

Looking forward to seeing you.

22-02-04 *Fidelities* (to S. L. Braunstein)

Braunsteinism 3: *I have a question, you may know the answer to. What is the fidelity one needs to surpass to demonstrate teleportation of a qubit from an alphabet $|0\rangle$, $|1\rangle$, $|0\rangle \pm |1\rangle$, $|0\rangle \pm i|1\rangle$? Presumably it's higher than 2/3. Do you know of any reference which has calculated this?*

No, it's actually precisely 2/3. In fact, in d dimensions, if one uses the $d(d+1)$ vectors drawn from a complete set of mutually unbiased bases, the breaking point fidelity one needs is $2/(d+1)$.

I'll attach the draft of a paper that I sorely need to finish which contains these calculations. (It's a paper for the Holevo festschrift, and now the editors are really bothering me for it.) The bit about MUBs in particular can be found around equations 43 through 46.

I hope things are going well for you. For myself, I've been traveling far, far, far too much to get any work done. I doubt the viewers of `quant-ph` even remember me anymore.

24-02-04 *Weird Forms of Realism* (to K. Brading)

Thanks for the note; I very much appreciate it. I wish I had met you at Oxford.

I think the best answer I can give to your question at the moment is recorded in Sections 4 and 5 of my paper, "The Anti-Växjö Interpretation of Quantum Mechanics." (You can find the paper at my website; there is a link below.) Since then, I have developed those thoughts somewhat, but I think the gist of what I'm striving for is already expressed in a fairly easy-to-read form in that older paper (or, I should say two emails). Reading over the sections again, I think they answer you quite directly.

I did a Google search on your name a little while ago to try to figure out who I'm talking to. It didn't help much. But I did learn that you've just obtained a faculty position at U. Notre Dame. ... Wait! I did meet you: It was at the tea before the talk, wasn't it? Right. Well anyway, congratulations on your new position! Carry out some great work there.

Katherine's Preply

> I was at your talk last Thurs at the Phil of Physics seminar in Oxford, and wanted to drop you a line to say how much I enjoyed it. I don't know whether you knew that you were coming into a group dominated by committed realists — of various stripes, but realists nonetheless — and I thought you did a great job. Personally, I found your approach very congenial indeed, but I wondered whether you wanted to put your position concerning scientific realism as strongly as it appeared. You seemed to resist any temptation to talk about 'The World', and yet one motivation you were giving for your approach is that we may hope that it will lead us to a new route 'back to the world'.
>
> Would you find the following way of expressing things acceptable, or is there a reason why you feel you need to go further:
>
>> The world is such that if I update my beliefs according to these rules (QM...) then I will be successful in getting around. But there is no inference from this to realist claims about 'how the world is in itself', and without relation to my activity of going around in it. So when I make some claim, such as 'The photons in this beam are vertically polarized', that's shorthand for 'The world is such that if I believe that the photons in this beam are vertically polarized (and if I act accordingly) then I am likely to be successful in my further related activities'. Usually this shorthand doesn't get us into trouble ('There's a tree over there'), but sometimes it does.
>
> How I understood the message of your talk was that, rightly understood, QM forces us to move to the epistemically modest longhand, rather than the naively realist shorthand, BUT that there are clues as to how we might then go forwards into approaching 'the

world in itself' again. I very much liked the suggestive discussion of disturbance at the end of your talk.

Anyway, whatever you think of the above — if anything — all I really wanted to do was to write a brief line saying that there were at least two not-so-realist bodies in the audience — myself and Peter Morgan — and that I for one like very much what you're doing.

25-02-04 *Promised Message* (to N. D. Mermin)

Merminition 149: *The following true story will appeal to nobody but you and maybe not to you either, but here it is.*

Do you remember my funny way of solving Bernstein-Vazirani (that I spoke on at the Bennett symposium)? You want to determine an n-bit number a, and are given a U that acts on a n-bit input register containing x to shift the one bit output register by the bit-wise modulo-2 inner product of a and x. My solution starts by replacing U by a bunch of cNOT gates — one for each non-zero bit of a controlled by the corresponding bit of x, all of them targeted on the output register.

Anyway I showed this to my class of physicists and computer scientists, and somebody remarked that it was pretty clumsy having to reconfigure the hardware every time you wanted to do it for a different value of a.

Instantly one of the CS students said no, that wasn't necessary. All you needed was an additional n-bit register into which you put a. The hardware was then fixed, consisting of n doubly controlled NOTS (i.e. Toffoli gates) all targeted on the output register and controlled by pairs of corresponding bits of x and a.

Thinking back on this a few days later it struck me that the way I presented it the choice of Hamiltonian (in the form of U) associated with the different possible a's was objective — different arrangements of the classical hardware. But the way the sharp CS student suggested doing it changed that choice of Hamiltonian to a specification of the state of the additional register. The selection of the Hamiltonian from among all possible Hamiltonians in his scheme was on exactly the same footing as (and in fact was identical to) the specification of a state vector.

That's all. Sounds less entertaining now that I've written it out.

Nope, a very deep point I would say ... Sounds worthy of a slogan. How about, "A quantum operation is just a quantum state in disguise." ??

26-02-04 *Thanks* (to A. Peres)

Thanks for writing me back; I really had started to worry.

Asherism 44: *Please remind me where you have written "there are no quantum states (the ghost of Bruno de Finetti)". My question is related to Netanel's PhD work on quantum gravity. In some spacetimes, there are obviously no quantum states.*

The place where I made the most to-do of the phrase "quantum states do not exist" was in `quant-ph/0205039`, "Quantum Mechanics as Quantum Information (and only a little more)". However the phrase made its first public appearance in `quant-ph/0105039`, *Notes on a Paulian Idea*. In fact, it comes from a letter I wrote to you dated 1 December 1998:

Letter to Asher Peres, 1 December 1998, "Here Comes the Judge"

Asherism 45: *The measuring process is an external intervention in the dynamics of a quantum system.*

I know that I've already expressed what I'm about to say several times, but let me just set things off to a good start again: I really like this turn of phrase! For years now, I have believed exactly what you say, namely,

Asherism 46: *[I]t is preferable not to use the word "measurement" which suggests that there exists in the real world some unknown property that we are measuring.*

but I had never invented such a clever phrase to express it. For a long time instead I made use of the word "creation" in my tract-like emails on the subject. In some ways, I still think—taking my cue from John Wheeler—that that word captures a certain central truth of quantum theory, but your word is more encompassing. I think it captures better the idea that quantum measurement is a double-edged sword, learning *and* creating.

But I wouldn't be doing my scholarly duty, if I didn't remind you of some passages of Niels Bohr, whose words you seem to have so much respect for. In Bohr's 1949 article "Discussion with Einstein on Epistemological Problems in Atomic Physics," he wrote:

> [At the Solvay meeting in 1927] an interesting discussion arose about how to speak of the appearance of phenomena for which only predictions of statistical character can be made. The question was whether, as to the occurrence of individual effects, we should adopt a terminology proposed by Dirac, that we were concerned with a choice on the part of 'nature,' or, as suggested by Heisenberg, we should say that we have to do with a choice on the part of the 'observer' constructing the measuring instruments and reading their recording. Any such terminology would, however, appear dubious since, on the one hand, it is hardly reasonable to endow nature with volition in the ordinary sense, while, on the other hand, it is certainly not possible for the observer to influence the events which may appear under the conditions he has arranged. To my mind, there is no other alternative than to admit that, in this field of experience, we are dealing with individual phenomena and that our possibilities of handling the measuring instruments allow us only to make a choice between the different complementary types of phenomena we want to study.

And, more to the point, in his 1958 article "Quantum Physics and Philosophy: Causality and Complementarity," he wrote:

> In the treatment of atomic problems, actual calculations are most conveniently carried out with the help of a Schrödinger state function, from which the statistical laws governing observations obtainable under specified conditions can be deduced by definite mathematical operations. It must be recognized, however, that we are here dealing with a purely symbolic procedure, the unambiguous physical interpretation of which in the last resort requires a reference to a complete experimental arrangement. Disregard of this point has sometimes led to confusion, and in particular the use of phrases like "disturbance of phenomena by observation" or "creation of physical attributes of objects by measurements" is hardly compatible with common language and practical definition.

> In this connection, the question has even been raised whether recourse to multivalued logics is needed for a more appropriate representation of the situation. From the preceding argumentation it will appear, however, that all departures from common language and ordinary logic are entirely avoided by reserving the word 'phenomenon' solely for reference to unambiguously communicable information, in the account of which the word 'measurement' is used in its plain meaning of standardized comparison.

Do you see these passages as meshing well with your new terminology? I don't really, but then again I don't feel that Bohr was all that right when he came to these points. I think it might be useful for your ultimate reader to add some words about your opinion on this.

Asherism 47: *As a concrete example, consider the quantum teleportation scenario. The first intervention is performed by Alice: she has two spin-$\frac{1}{2}$ particles and she tests in which Bell state these particles are.*

In which state they *are*?!?! There's got to be a better way of putting this ... especially one more consistent with your whole view of the measurement process.

Asherism 48: *I do not want to use the word "histories," which has acquired a different meaning in the writings of some quantum theorists.*

What happened to your nice word "chronicle"? I liked it a lot. Can't you find some way to reinstate it? I guess I liked it because it always reminded me of a passage that I like to quote from Pauli. In a letter to Markus Fierz in 1947, he wrote:

> Something only really happens when an observation is being made .... Between the observations nothing at all happens, only time has, 'in the interval,' irreversibly progressed on the mathematical papers!

Asherism 49: *Quantum mechanics is fundamentally statistical, and any experiment has to be repeated many times (in a theoretical discussion, we shall imagine many replicas of our gedankenexperiment).*

Asherism 50: *Each one of these records has a definite probability, which is experimentally observed as its relative frequency among all the records that were obtained.*

Asherism 51: *Note that the "detector clicks" are the only real thing we have to consider. Their probabilities are objective numbers and are Lorentz invariant.*

As a disciple of the Reverend Bayes, you should know that I strongly dislike all these expressions. A good Bayesian would say that probability quantifies a state of knowledge. It is that and that alone, meeting an operational verification *only* through a subject's betting behavior. In particular, probability has no *a priori* connection to the frequency of outcomes in a repeated experiment. It matters not whether that repetition is real or, instead, imaginary and virtual.

Let me just try to drive this home with two of the simplest possible examples.

(1) Consider a coin for which you have no reason to believe that a head will occur over a tail in a toss. Now imagine that you flip that coin an infinite number of times,

tabulating the number of heads and tails. Do you really believe that a frequency of precisely 1/2 *must* occur in the infinite limit? Answer this question to yourself very honestly. What is to bar you from getting a head as the outcome in literally every single toss? What is there in the coin to favor a random-looking sequence to a nonrandom one? Nothing. To say something like, "Well the nonrandom-looking sequences have probability zero" is just to beg the question. For one thing, you have to invoke the concept of probability again to even say it. For another, even if you allow yourself that, it still carries no force: just take the set of nonrandom-looking sequences and add to it any sequence that you would consider a valid random one (i.e., one that you believe could be generated by a repeated coin toss). That set still has probability-measure zero, but now you would have to say that that means the random-looking sequence could not be generated by your imaginary coin. The point: probability has no direct connection to frequency.

(2) Consider now the case where I toss a coin repeatedly for you. I assure you strongly that the coin is weighted 80–20 heads vs. tails *or* 20–80, but I steadfastly refuse to tell you which way it goes. What probability would you ascribe to the outcome of a head upon my first toss? Fifty-percent of course. The point is, my probability ascription is not your probability ascription. As I toss the coin ever more, if you are rational, your probability ascription will *very likely* approach mine, but there are no absolute assurances. The point: again probability has no direct connection to frequency. But also, two perfectly rational people can make different probability assignments to the same experiment without being inconsistent with each other. There is nothing objective about a probability assignment per se.

If you'd like to understand better this point of view, then I'd strongly suggest the wonderful collection of essays, "Studies in Subjective Probability," edited by Henry E. Kyburg, Jr., and Howard E. Smokler (Wiley, NY, 1964). Also there is a later edition of the book with a few other essays. For a much more in-depth study I couldn't recommend anything more than Ed Jaynes' book, "Probability Theory: The Logic of Science." It unfortunately may never be published properly, but preprints of the parts that were written can be found at the "Probability Theory as Extended Logic" web page, `http://bayes.wustl.edu/`.

Asherism 52: *[P]robabilities are objective numbers .... On the other hand, wave functions and operators are nothing more than abstract symbols. They are convenient mathematical concepts, useful for computing quantum probabilities, but they have no real existence in Nature.*

I think it is really cute the way you cite Stapp here!

But again I want to come back to the last point above. A good Bayesian already knows that probabilities cannot be taken to be objective numbers, existent "out there" in nature. And a good quantum physicist similarly knows that the wave function is *not* something "out there" existent in nature. The similarity of these two points of view is not an accident: it had to be the case! For, from one point of view, the wave function is nothing more than a compendium of probabilities. It may be the case that "unperformed measurements have no outcomes," but it is not the case that unperformed measurements have no probabilities! If we specify the probabilities of the outcomes for every *potential* measurement, then we have specified the wave function. There cannot be a difference in the objectivity levels of these two mathematical objects: they are both abstract symbols that summarize our states of knowledge. Their empirical meaning comes about precisely in how a rational being would behave in the light of that knowledge.

There is a famous quote in Bayesian probability theory due to Bruno de Finetti. It starts out the two volumes of his book.

> My thesis, paradoxically, and a little provocatively, but nonetheless genuinely, is simply this:
>
> PROBABILITY DOES NOT EXIST.
>
> The abandonment of superstitious beliefs about the existence of Phlogiston, the Cosmic Ether, Absolute Space and Time, ..., or Fairies and Witches, was an essential step along the road to scientific thinking. Probability, too, if regarded as something endowed with some kind of objective existence, is no less a misleading conception, an illusory attempt to exteriorize or materialize our true probabilistic beliefs.

In contrast, my paper "Bayesian Probability in Quantum Mechanics" with Caves and Schack, opens up with the following lines:

> My thesis, paradoxically, and a little provocatively, but nonetheless genuinely, is simply this:
>
> QUANTUM STATES DO NOT EXIST.
>
> The abandonment of superstitious beliefs about the existence of Phlogiston, the Cosmic Ether, Absolute Space and Time, ..., or Fairies and Witches, was an essential step along the road to scientific thinking. The quantum state, too, if regarded as something endowed with some kind of objective existence, is no less a misleading conception, an illusory attempt to exteriorize or materialize the information we possess.
>
> — *the ghost of Bruno de de Finetti*

I don't know of any better way to express it than this.

Asherism 53: *The physical evolution that leads to Eq. (1) is the following. The intervener receives a quantum system in state ρ and adjoins to it an auxiliary system (an ancilla) in a known state ρ_a. The composite system, in state $\rho \otimes \rho_a$, is subjected to a unitary transformation ...*

In my present way of speaking, I like to make this sound much less absolute. I usually say that this is only one *representation* of a superoperator. It is the superoperator that is the only thing that need be given; anything else is just one way or another of thinking about it. I guess the point is I see no reason to give unitary evolutions and von Neumann measurements a special status in the axiomatics of the theory. POVMs and superoperators are perfectly good (and much less specific) starting points for the theory. You can certainly do as you please, but it seems to me that there is a lot to be gained from this point of view. For instance, it seems to me to de-emphasize the point of view that Charlie Bennett labels "the Church of the Larger Hilbert Space" (which is, as he admits, a euphemism for the many-worlds interpretation).

Asherism 54: *If we wish to consider only the states just before and after the intervention, without entering into the detailed dynamics of the intervention, the result appears as a discontinuous jump of the wave function (often called a "collapse"). Clearly, this jump is not a dynamical process. It results from the introduction of an ancilla, followed* *by its deletion, or that of another subsystem. The jump is solely due to abrupt changes in our way of delimiting what we consider as the quantum system under study.*

I agree with you to some extent here, but not the whole way. The abrupt change that comes about when we conceptually delete a subsystem from a larger composite system corresponds to a *partial trace*. Where does the *random* jump come from that corresponds to the measurement outcome label k? I've heard you say things like this many times, i.e., that the statistics in quantum mechanics comes about because of a mismatch in two languages, the quantum and the classical—your talk at QCM was just one example—but how does one see that you're not just talking about a partial trace here? I am perfectly willing to take measurement/intervention as a primitive of the theory—it's the very thing that gives the theory meaning—but you seem to want to go further, to have it fall out of something more primitive, namely the act of drawing a conceptual line in an overall unitary dynamics. I guess I still don't see it.

Asherism 55: *Summing over them is like saying that peas and peanuts contain on the average 42% of water, instead of saying that peas have 78% and peanuts 6% [25].*

I loved the citation here! You don't think there might be a connection between Stapp and the USDA, do you?

Asherism 56: *Between these two events, there is a "free" (that is, deterministic) evolution of the state of the quantum system. What distinguishes such a free evolution from an intervention is that the latter has unpredictable output parameters, for example which one of the detectors "clicks," thereby starting a new chapter in the history of the quantum system. As long as there is not such a branching, the evolution will be called free, even though it may depend on external classical fields, that are specified by the classical parameters of the preceding interventions.*

I like this distinction, but I cannot completely agree with it. Take any trace-preserving completely positive map that is not unitary, i.e., most any quantum channel like the amplitude damping channel or the depolarizing channel will do. It gives rise to no "branching" changes in the quantum state, but I think one would be hard pressed to call it a "free" evolution.

I overheard Herb Bernstein once say something like, "Of course there are two kinds of evolution in quantum mechanics; there are the times when we learn something and then there are the times when we learn nothing." The line struck me. I know that this is something like what you're trying to get at, but the cut isn't between unitary and nonunitary then.

Asherism 57: *Quantum mechanics asserts that during a free evolution the quantum state undergoes a unitary transformation.*

This needs cleaning up exactly because of the point above. By the way, note that there is a typo in the sentence following Eq. (7).

Asherism 58: *Note that* $\mathrm{Tr}(\rho_f) = \mathrm{Tr}(\rho'_f)$ *is the joint probability of occurrence of the records k and μ. This is the only observable quantity in this experiment. ... Einstein's principle of relativity asserts that both descriptions given above are equally valid. Formally, the states ρ_f (at time t_f) and the state ρ'_f (at time t'_f) have to be Lorentz transforms of each other.*

I am afraid that this might be construed to mean that the only way the equality of the traces can be satisfied is if ρ_f and ρ'_f are "Lorentz transforms" of each other. Surely that's not true and that's not what you mean. Maybe you could clarify this a bit.

Asherism 59 : *As a further simplification, let all the U and V operators be unit matrices, so that the two particles are really free, except at the intervention events.*

What do you mean by the phrase "really free" here? Is it a joke?

Asherism 60 : *We thus have to accept that unit matrices of any order may also be legitimate Lorentz transforms of each other.*

So I guess what you're meaning is that you want this problem to partially define what is meant by the very term "Lorentz transform?" I'm looking forward to understanding the business about Green's functions much better. After that I'll come back for some more substantial comments on everything in this section following Eq. (10).

Asherism 61 : *Quantum nonlocality has led some authors to suggest the possibility of superluminal communication.*

Notice the correction to *your* spelling mistake ... ahem. Grin. Anyway, in this connection let me point you to a very nice article by a philosopher: J. B. Kennedy, "On the Empirical Foundations of the Quantum No-Signalling Proofs," Phil. Sci. **62**, 543–560 (1995). The point he makes—and I think validly so—is that any so-called "proof" that quantum mechanics cannot support superluminal signalling by using entanglement is essentially circular. It's not that the "proofs" are invalid, but essentially that there was no use in doing them in the first place: no-signalling is much more of an *axiom* than a result of the standard structure of quantum mechanics. Kennedy argued by way of digging into the historical references, finding for instance von Neumann's original motivation for introducing the tensor product rule for combining Hilbert spaces—it was essentially to block the possibility of superluminal signalling! You might enjoy reading the paper.

Asherism 62 : *The classical-quantum analogy becomes complete if we use statistical mechanics for treating the classical case. The distribution of the bomb fragments is given by a Liouville function in phase space. When Alice measures $\mathbf{J}_1$, the Liouville function for $\mathbf{J}_2$ is instantly altered, however far Bob is from Alice. No one would find this surprising, since it is universally agreed that a Liouville function is only a mathematical tool representing our statistical knowledge. Likewise, the wave function ψ, or the Wigner function, which is the quantum analogue of a Liouville function, are only mathematical tools for computing probabilities. It is only when they are considered as physical objects that superluminal paradoxes arise.*

Indeed you have captured the point here. Part of this, i.e., that the proper comparison is between state vectors and Liouville distributions, is what Carl and I were striving to convey in our paper for Nathan Rosen's festschrift—so I'm already very sympathetic to this. (Of course I know that you already made this point long ago in your paper "What is a State Vector?") More particularly, though, this is one thing that Steven van Enk and I had planned to write in a silly little paper—titled "Entanglement is Super

... but not Superluminal!"—for our contribution to a book on superluminal signaling! I hope you won't mind the overlap.

The thing that holds so many up from immediately grasping this point of view is the *difference* between the quantum and classical states of knowledge (i.e., those things that are changing instantaneously as you say). Classically, the probability is attached to an existent property. "The particle has a position; I just don't know it. I capture what little bit I do know with a probability assignment." Quantumly, the probability is attached to *potential* measurement outcomes and nothing more. How is it that my probability assignment for some potential measurement outcome can change from 50-50 to complete certainty when there is no sense in which that measurement outcome can already be said to be "out there" without the performance of a measurement? That's the thing that has people perplexed and, I think, is the source of their confusion about using entanglement for communication.

Asherism 63: *In our approach, there is no 'delayed choice' paradox. It is indeed quite surprising that JAW, who is a hard core positivist, introduced this 'delayed choice' idea.*

Sometimes it's pretty hard to figure out what precisely it is that John is trying to say. Perhaps you shouldn't be overly harsh on him. In some of his discussions of "delayed choice" he makes it very clear that he is not talking about affecting the "past" itself (whatever that might mean) but instead "what we have the right to say about it." Combine that with one of the phrases he is fond of saying, i.e., "The past exists only insofar as it is recorded in the present," and I think you will have to position him closer than not to the positivist you used to think of him as.

01-03-03 *Wither Entanglement!* (to T. Siegfried)

Thanks for the letter. I'm glad you're enjoying parts of *Notes on a Paulian Idea* (even if some other parts rankle you). Kluwer has picked it up to make for a more official-looking (even if ridiculously expensive) second edition this summer. But that means I've got to get off my duff and get the thing re-edited by June. I couldn't be a journalist for sure: I'm so bad with deadlines. I envy you.

Siegfriedism 1: *At the moment, I'm trying to work out a way of doing something on quantum entanglement as a foundation for 21st century technologies (based on a symposium at the recent AAAS meeting). Any suggestions of non-obvious angles to pursue, or particularly significant papers you've seen lately?*

It'd be hard for me to suggest an angle to pursue, as I don't really think entanglement is ultimately at the base of what is interesting in quantum information and computing. I think entanglement is an auxiliary effect that is sometimes useful, but there is something deeper going on. What the deeper thing is, now that's harder to say, but my feeling is that it has something to do with the particular structure of quantum measurements (which in turn capture something about the zing, zip, verve, pizzazz of the world).

But seriously, there are plenty of things in quantum information that don't derive their power from entanglement. Simple BB84 and B92 quantum cryptography are two examples. Or the stuff we called "quantum nonlocality without entanglement" (an old paper by Bennett and several of us, `quant-ph/9804053`) which makes use of the tensor product structure for combining systems, but not quantum entanglement in particular.

Also, in fact, one can see how the tensor product structure (and with it entanglement) arises in a simple way as a byproduct of the structure of measurements and a simple locality condition. The argument is in the "Wither Entanglement?" section of my `quant-ph/0205039`. So, there is some substance to my speculation above.

Finally, let me just mention my favorite paper of the year: Rob Spekkens', "In defense of the epistemic view of quantum states: a toy theory," `quant-ph/0401052`. In that paper, Rob shows how a load of (what were once thought to be) 'fantastic' quantum information effects can come about—qualitatively at least—even in a local hidden variable theory, as long as one is talking about the epistemic states of the theory. Among these are things like teleportation, superdense coding, an analogue of entanglement monogamy, secure key distribution, and the list is quite a bit larger than that. The point is, entanglement in the proper sense powers none of those effects—for his toy theory can have no entanglement; it is a local hidden variable theory. The paper is quite easy to understand; in fact it contains almost no physics at all, just elementary combinatorics. You ought to have a look at it. It's the sort of thing that leaves you with a warm, fuzzy feeling that you've understood something quite deep.

Siegfriedism 2: *Also, any comments on Bub's recent paper?:* `quant-ph/0402149`

It's a pretty good paper until he flubs it up by still thinking that decoherence is of any importance for quantum foundational issues. In general the work by Clifton, Bub, and Halvorson is some nice stuff and a suggestive hint of the kinds of efforts we should keep striving at. I think taking C^* algebras as a starting point is far too advanced a starting point to get at the real nub of the matter, but what we're all doing is chipping away at an iceberg ... and I think their work contains a legitimate insight.

01-03-04 *Midnight Murmurs* (to R. W. Spekkens)

Good to hear from you. I enjoyed your story about the Bielefeld meeting. It sounds like the same meeting where I first concocted the image of a Holy City. It was on the island of Ischia, near Naples, and I'm pretty sure a lot of the same people were there. (The story is recorded in the letter spanning pages 450 and 451 of *Notes on a Paulian Idea*, VUP edition.) You didn't describe how your talk went though. Did it make some impact?

Spekkensism 25: *Thanks for promoting my paper.*

It's hard for me to keep my mouth shut about the paper. [...] For instance, I just wrote this to Tom Siegfried (who writes the science column for the *Dallas Morning News*):

> Finally, let me just mention my favorite paper of the year: Rob Spekkens's, "In defense of the epistemic view of quantum states: a toy theory," `quant-ph/0401052`. In that paper, Rob shows how a load of (what were once thought to be) 'fantastic' quantum information effects can come about—qualitatively at least—even in a local hidden variable theory, as long as one is talking about the epistemic states of the theory. Among these are things like teleportation, superdense coding, an analogue of entanglement monogamy, secure key distribution, and the list is quite a bit larger than that. The point is, entanglement in the proper sense powers none of those effects—for his toy theory can have no entanglement; it is a local hidden variable theory. The paper is quite easy to understand; in fact it contains almost no physics at all, just elementary combinatorics. You ought to have a look at it. It's the sort of thing that leaves you with a warm, fuzzy feeling that you've understood something quite deep.

It is hard for me to keep my mouth shut.

Spekkensism 26: *Most recently, I needed to prepare a talk for the quantum gravity meets quantum information workshop at PI. (It's too bad you were unable to make it to the workshop. We needed a talk on how mass is nothing but Hilbert space dimension. How is that coming along anyway?)*

Basically, I'm not thinking at all. And I don't foresee that I will again until I have the job issue settled and have a place to plant the family. Mentally I'm empty, outside of those basic urges. (Before you ask: Yes, I could go back to Bell Labs. But I think it would signal the end of all that I really love.)

Spekkensism 27: *How was the response to your talk at Oxford? I would expect there to be animosity towards your views there. Did you manage to shake the convictions of any of the Everettians?*

It felt like it was quite successful in some ways actually: At the very least I did some of the best sparring I've done in a while, and I felt like it made an effect, though it was quite exhausting. I got, I think, four emails, maybe five, afterward from people I didn't know expressing various kinds of interest. For instance, I got this from Katherine Brading (never met her before):

> I was at your talk last Thurs at the Phil of Physics seminar in Oxford, and wanted to drop you a line to say how much I enjoyed it. I don't know whether you knew that you were coming into a group dominated by committed realists – of various stripes, but realists nonetheless – and I thought you did a great job. Personally, I found your approach very congenial indeed ...

That's what it's all about: Chipping away at an iceberg, getting people to rethink.

01-03-04 *Thinking Out Loud, As Usual* (to H. Halvorson)

Thanks for the note. I guess we *have* never met; I've certainly seen you in the distance.

Halvorsonism 1: *In some of my current work, I'm picking up a question that has been close to your heart over the past few years — viz., how much of QM is just "laws of thought"? I'm going to have occasion to talk to some general philosophical audiences about the topic, and I'd like to give them an accurate representation of your position. So, I was wondering if I could ask you a favor: Could you point me to what you take to be the two or three (or more, if you have time!) most significant passages or results in your corpus that discuss, or bear on, this topic? In other words, where should one look first if one wants to quickly learn the correct answer to the question?*

It's a phrase I stole from Boole, you know. (See pages 527–529 and 351 in *Notes on a Paulian Idea*, Växjö U Press edition. I did send a copy of that to you, didn't I?)

It would be hard to tell you the "correct" answer because all of these thoughts are in constant transition. It's just been something I've been groping for, for the last eight or nine years. (I think I invented the phrase at a bar in Albuquerque, Jack's Liquor and Lounge, in the Fall of 1995.)

Be warned that by the phrase I don't mean something like a Kantian a priori category, i.e., a position like von Weizsäcker's in his book *The Unity of Nature*. I don't mean something like, "an understanding using the terms of quantum mechanics is the precondition for possible experience." Rather I have started to toy rather strongly with a Darwinian kind of idea: Using the rules of quantum mechanics for manipulating and updating our expectations (i.e., as a "law of thought") is the presently best known means for survival, given that we are immersed in the particular world we are. That is, I want to view quantum theory as a branch of decision theory that is contingent upon properties of the world we live in ... and it is something we locked into only in our most recent turn in evolutionary development.

Also, I should try to make it clear that, in this light, I view quantum mechanics as a normative theory in a sense akin to the one Bernardo and Smith use to describe Bayesian probability theory:

> Bayesian Statistics offers a rationalist theory of personalistic beliefs in contexts of uncertainty, with the central aim of characterising how an individual should act in order to avoid certain kinds of undesirable behavioural inconsistencies. The theory establishes that expected utility maximization provides the basis for rational decision making and that Bayes' theorem provides the key to the ways in which beliefs should fit together in the light of changing evidence. The goal, in effect, is to establish rules and procedures for individuals concerned with disciplined uncertainty accounting. The theory is not descriptive, in the sense of claiming to model actual behaviour. Rather, it is prescriptive, in the sense of saying "if you wish to avoid the possibility of these undesirable consequences you must act in the following way."

That's the short of it.

The best reference for the long story at the moment is my samizdat *Quantum States: What the Hell Are They?*,—unfortunately the whole of it—posted at my webpage in pdf format. But that's too much material (and too loosely organized) for you. So within that, let me point you more specifically to: pages 49–50 "Note on Terminology," pages 83–85 "Replies on Practical Art," pages 144–147 "Psychology 101," and pages 150–155 "A Wonderful Life." Maybe also pages 35–38, "Identity Crisis." That might do for first pass.

Ultimately, I'd like to synthesize (and "consistify") these 235 pages of email into a single paper of 20 or 30 pages, but unfortunately that hasn't happened yet. If anything looks like sheer nonsense, or the writing is detractingly ambiguous, let me know, and I'll try to clarify for you.

Good luck. If the stuff provokes any thoughts in you, I'd love to hear them. Also, I'd love to know the sorts of things you're already thinking (that your note above alluded to).

03-03-04 *Title and Abstract* (to UBC)

Below is the title and abstract for my talk next week. If there's anything else I've neglected to send you, let me know.

> Title: Two Strangely Similar Problems in Quantum Information
>
> Abstract: The deepest question one can ask in quantum information and computing is what makes it tick, what gives it its power? The field is still new enough that no one really knows the answer—speculations range across the board, from quantum coherence to quantum entanglement to parallel worlds, and to stranger things still. My own hunch is that the source of the power comes from the particular structure of quantum mechanical measurements, with entanglement being a secondary effect that derives from this source. In this talk, I will demonstrate a few tools for exploring that hunch. One is a representation of quantum measurements from the standpoint of probability theory. Another one is connected to a question that first arose in the context of developing criteria for certifying the success and failure of quantum teleportation experiments.

> Strangely enough, two open questions with regard to these tools seem to have the same answer.

04-03-04 *Curl Activator* (to N. D. Mermin)

Merminition 150: *Don't know if you wanted comments on the opening serenade of your paper with Rüdiger, but here are a few:*

- (a) The Bayesian view of quantum states is that it is not: The quantum state is not something the system itself possesses.
- (b) What distinguishes this view from a more traditional "Copenhagen-interpretation style" view is that there is no pretense that a quantum state represents a physical fact.

"this view" in (b) seems to refer to (a). But it's a non-trivial jump from not being something the system itself possesses, to not representing a physical fact. E.g. the state of a quantum computer represents the initialize procedure (measure all the qubits and apply NOT to those that register 1) and the sequence of gates that have been applied. While this history is not "possessed by" the qubits (since it can't be recovered from them) it's a big step to say that the history (and the quantum state it gives rise to) is not a physical fact. (Namely your denial that gates [hamiltonians] are objective, or that what has been measured [as opposed to the measurement outcome] is objective.)

> It is the outcomes of quantum measurements that represent physical facts within quantum theory, not the quantum states.

Repeating myself, shouldn't you acknowledge here that although the outcomes of measurements represent physical facts, what it is that has been measured is not, in your view, a physical fact.

> In particular, there is no fact of nature to prohibit two different agents from using distinct pure states for a single system. [Footnote: Contrast this to the treatment of Refs. Mermin2001 and Brun2001b.]

Please cite Mermin2002 (J. Math. Phys., **43***, 4560-66) where the argument is (in response to you guys) at least explicitly made contingent on the assumption that probability 0 means objective impossibility (and, I believe, no other assumption).*

So, my words did curl your hair! Makes me proud.

Thanks for the comments. Rüdiger and I had a nice time on the phone discussing them this evening. The main thing it helped us realize is that we've gotta, gotta, gotta get that "On Quantum Certainty" paper written for you.

Anyway, the first main comment didn't cause us to make a change in the draft: The introduction wasn't the place to defend the view; we just wanted to state the view.

About Mermin2002, I've included it in the citations. I've never actually read the paper though (the dangers of not putting something on `quant-ph`). Could you send me the file?

Concerning this one:

Merminition 151:

> In any case, this does not imply that a single agent can believe willy-nilly in anything he wishes. To quote D. M. Appleby, "You know, it is *really* hard to believe something you don't actually believe." Difficult though this may be to accept for someone trained in the traditional presentation of quantum mechanics, the only thing it demonstrates is a careful distinction between the terms *belief* and *fact*.

It's not clear what "this" refers to. From the syntax alone it would appear to be Appleby's remarks. This is reinforced by the "believe" (Appleby) and "belief" (you). But I assume you have in mind some or all of what you have to say before Appleby appeared on the scene.

I think you got confused by not noticing that the "Difficult though this ..." sentence, was outside of the footnote. If you ignore the footnote it works fine. Still though I did adjust the words slightly, just in case the reader loses track after a diversion to the footnote.

Just in case you're curious, in the next email, I'll send you the completed paper. I'll have to send it as a pdf file though, so that you get the figures. As I told you before, it's pretty much a throw-away paper, using as it does nothing but old technical material.

Still, you might enjoy the Introduction, the Concluding Remarks, and Section VI on "Subjectivity of Quantum Operations." They package the story in a way you may not have seen before.

Of use to me would be to know how the "stimulus-response" imagery at the end strikes you.

> Is there something in nature even when there are no observers or agents about? At the practical level, it would seem hard to deny this, and neither of the authors wish to be viewed as doing so. The world persists without the observer—there is no doubt in either of our minds about that. But then, does that require that two of the most celebrated elements (namely, quantum states and operations) in quantum theory—our best, most all-encompassing scientific theory to date—must be viewed as objective, agent-independent constructs? There is no reason to do so, we say. In fact, we think there is everything to be gained from carefully delineating which part of the structure of quantum theory is about the world and which part is about the agent's interface with the world.
>
> From this perspective, much—*but not all*—of quantum mechanics is about disciplined uncertainty accounting, just as Bayesian probability theory in general. Bernardo and Smith write this of Bayesian theory,
>
>> What is the nature and scope of Bayesian Statistics ... ?
>>
>> Bayesian Statistics offers a rationalist theory of personalistic beliefs in contexts of uncertainty, with the central aim of characterising how an individual should act in order to avoid certain kinds of undesirable behavioural inconsistencies. The theory establishes that expected utility maximization provides the basis for rational decision making and that Bayes' theorem provides the key to the ways in which beliefs should fit together in the light of changing evidence. The goal, in effect, is to establish rules and procedures for individuals concerned with disciplined uncertainty accounting. The theory is not descriptive, in the sense of claiming to model actual behaviour. Rather, it is prescriptive, in the sense of saying "if you wish to avoid the possibility of these undesirable consequences you must act in the following way."
>
> In fact, one might go further and say of quantum theory, that in those cases where it is not just Bayesian probability theory full stop, it is a theory of stimulation and response. The agent, through the process of quantum measurement stimulates the world external to himself. The world, in return, stimulates a response in the agent that is quantified by a change in his beliefs—i.e., by a change from a prior to a posterior quantum state. Somewhere in the structure of those belief changes lies quantum theory's most direct statement about what we believe of the world as it is without agents.

I think it's a particularly crisp way of expressing the program. Anyway, it's all perfectly tame as written down, but the phrases arose out of a discussion during my recent visit to the Oxford philosophy department, where I was extolling the virtues of the "sexual interpretation of quantum mechanics." Caught up in the moment, I said something like: "Mermin's got this thing about 'correlation without correlata', but what I'm looking for in my quantum foundations program is 'stimulation without stimulata'!" It was nonsense and didn't fit, but we had a good laugh … and the word 'stimulate' stuck with me, waiting to rise again on a more legitimate occasion.

04-03-04 *Catalog of Probabilities* (to J. N. Butterfield)

I can't quite remember if it was you that I was talking to after Michael Redhead's talk at LSE about this. … But in any case, I'll get these quotes into my computer this way.

In Michael's talk, he implied (or rather said outright) that he introduced the term "catalog of probabilities" for quantum states. I thought it was a much older term, probably going back to Pauli, but I haven't been able to confirm that. Anyway, I just ran across these quotes of Schrödinger in a Brukner/Zeilinger paper; they were taken from S's 1935 papers on entanglement. They quote the German and offer these as translations. I'm not sure if these are their translations or, rather, they are the translations in the Wheeler/Zurek book.

> For each measurement one is required to ascribe to the ψ-function (= the prediction catalog) a characteristic, quite sudden change, which depends on the measurement result obtained, and so cannot be foreseen; from which alone it is already quite clear that this second kind of change of the ψ-function has nothing whatever in common with its orderly development between two measurements. The abrupt change by measurement … is the most interesting point of the entire theory. It is precisely the point that demands the break with naive realism. For this reason one cannot put the ψ-function directly in place of the model or of the physical thing. And indeed not because one might never dare impute abrupt unforeseen changes to a physical thing or to a model, but because in the realism point of view observation is a natural process like any other and cannot per se bring about an interruption of the orderly flow of natural events.

and

> Whenever one has a complete expectation-catalog — a maximum total knowledge — a psi-function — for two completely separated bodies …

These don't explicitly contradict Michael, as they don't use the word "probability," but they certainly convey the idea that a quantum state is catalog of something.

Anyway, words, just words — not something particularly important. But I like to get the history of QM straight when I can.

06-03-04 *Receipt* (to G. Bacciagaluppi)

Thanks for the long detailed note! Now that's the kind of note I like to see!!

I hope to get back to you with something of substance before my physical arrival in Freiburg.

Since you brought up de Finetti, let me attach our latest concoction on the man. Rüdiger and I just sent it off yesterday for a review book on quantum-state estimation. It's mostly a throw-away paper with no new technical work, but I did use some new forms of expression in the Introduction and Conclusion sections, and also Section VI on the subjectivity of quantum operations. In particular, I managed to clean up "stimulation without stimulata" enough, as to make it usable in the public forum. Hope you enjoy.

06-03-04 *Lost Cousins of de Finetti* (to G. Bacciagaluppi)

Actually, I need to cite your paper "Classical Extensions, Classical Representations and Bayesian Updating in Quantum Mechanics" in the paper I just sent you. Can you send me the citation information on that? I didn't find it posted anywhere on `quant-ph`. Did you post it somewhere else? Anyway, I'll get a chance to fix things up when the proofs come back to me next week.

You really should post it on `quant-ph`! (If you can post it fast enough, I'll get a chance to cite it in a way that people can find it.)

06-03-04 *Cutting the Umbilical* (to A. Plotnitsky)

Please allow me to attach a paper that Rüdiger and I have just finished. [See C. A. Fuchs and R. Schack, "Unknown Quantum States and Operations, a Bayesian View," `quant-ph/0404156`.] It's mostly a regurgitation of old material—it was put together for a review volume on quantum-state estimation—but there are some new means of expression that may strike your sensibilities, or at least put you in a better position to contrast us with Bohr, Heisenberg, and even Pauli. I'm thinking in particular here about the Introduction and Conclusion sections, and also Section VI on the subjectivity of quantum operations. You'll understand why I titled this note "Cutting the Umbilical" when you read the first sentence of the second paragraph in the paper. I don't know whether Ref. 23 still expresses Asher's point of view today—he has probably backed off on that slightly—but given your interest in the term "quantum state", and how it should be best used, I thought it might be worthwhile to point you in the direction.

06-03-04 *Darwinism Down* (to M. Pérez-Suárez)

Attached is the samizdat "Darwinism All the Way Down" to the extent that it's been put together—a lot of material is still missing.

Anyway, the great mistake is recorded on page 9. The especially sad thing was how it contradicted what I was saying as early as the note "Identity Crisis" of 22 August 2001 (in "Phase Transition"), where I had already pretty much sorted everything out. It was as if I had forgotten everything of the previous year. Anyway, it was the solution to this problem which effectively forced me to a Wittgensteinian notion of certainty. (Though I only started reading Wittgenstein this January.)

07-03-04 *All Kinds of Veils* (to A. Peres)

Asherism 64: *I am absolutely elated by "my" discovery that there are no quantum states (and therefore no "problem of time" in quantum gravity, etc.). Heisenberg et al. used only algebras of operators to compute observable quantities. Then Schrödinger came and "stole the show"—and completely messed it up. He did that after Einstein called his attention to de Broglie's thesis, and wrote "he has partly lifted the great veil" or something like that. You are an inexhaustible source of references. Where is that "great veil" mentioned?*

I will look for the "great veil" reference tomorrow at the office, where I have a copy of Jammer's *The Philosophy of Quantum Mechanics*. It is a very thorough historical reference. Another place where you are likely to find it, and other interesting things, is a little book titled *Letters on Wave Mechanics*, edited by Karl Przibram, with letters by Einstein, Schrödinger, Lorentz, and maybe a couple of others. Your library might have it. I remember finding one letter particularly amazing within it. It was a letter written by Einstein to Schrödinger, in great excitement, after Einstein's first quick reading of Schrödinger's paper on the time independent Schrödinger equation. Einstein says something like "what a great insight!" but then he quotes Schrödinger's equation *incorrectly* and complains something like, "You will note that this equation has this and this and this undesirable property. On the other hand, if you had considered this equation [where Einstein now writes the correct Schrödinger equation as if he had never seen it], all of these problems will be fixed." But then the really lovely thing that Einstein says next is something like, "However, for the life of me, I can't think of a physical interpretation for the wave function that appears in this equation."

Unfortunately, my copy of the book was burned up in the fire, and I haven't replaced it since. It's a nice little book.

08-03-04 *The Great Veil* (to A. Peres)

Asherism 65: *Then Schrödinger came and "stole the show"—and completely messed it up. He did that after Einstein called his attention to de Broglie's thesis, and wrote "he has partly lifted the great veil" or something like that. You are an inexhaustible source of references. Where is that "great veil" mentioned?*

Apparently the quote is "lifted a corner of the great veil." However, I haven't been able to pin down the exact origin of it yet. You can at least read it here:

`http://www.aip.org/history/einstein/quantum1.htm`.

Jammer's book wasn't as much help as I thought it would be. For instance, I'm discovering how bad the index is. My method of looking was to cross-reference a) Einstein and de Broglie, and b) Einstein and Schrödinger. There are quite a few places where I found the names within the text, but no cataloguing within the index.

Actually, I just found this story:[76]

> Working on his doctorate in 1909, a young aristocrat, Prince Louis-Victor de Broglie, discovered a mathematical relationship between Planck's Constant and a yet to be observed wavelike property of moving masses. His examiners were of a mind to reject the paper, and wanting an outside opinion, sent a copy to Einstein who replied: "He has lifted the corner of a great veil." The dissertation was accepted—fifteen years later it earned de Broglie a Nobel Prize, the first ever awarded for an academic thesis.

08-03-04 *IC-POVM Entropies* (to A. H. Jaffe)

Thanks for the letter.

Jaffe-ism 1: *I hope you'll remember me — we met briefly in London and then Oxford — I asked you about the Shannon entropy of an informationally complete POVM but then had to go.*

I do remember talking to you in London right after my talk; you were to the left of the seat I was sitting in and wanted to know something about one of my transparencies. Unfortunately, though, I can't visualize your face. And I don't remember talking to you again in Oxford: Everything about that trip is a big blur!

[76] See H. A. Medicus, "Fifty Years of Matter Waves," Phys. Tod. **27**(2), 38 (1974) for more details.

Jaffe-ism 2: *My "Bayesian bona fides" can be indicated (I hope) by the fact that I reviewed Jaynes' book for* Science *last year.*

I'd very much like to read that. Could you send me an electronic copy of the article?

Jaffe-ism 3: *Anyway, on to something more specific. I've been thinking about the entropy of the probabilities related to a set of informationally complete POVMs. Obviously, it depends on the detailed set of POVMs chosen. But it seems that there are 'better' and 'worse' choices here — related, I wouldn't be surprised, but have not yet worked out — to the shape/volume of the accessible area of the probability simplex.*

There are probably a load of interesting questions one can ask here. For instance, given a density operator ρ, what is the minimum Shannon entropy a measurement can generate, subject only to the condition that the measurement be an IC-POVM. I suspect the answer is $S(\rho) + \log D$, where D is the Hilbert-space dimension, but I don't have a proof of this. In other words, the optimal POVM is just an infinitesimal variation of the basis that diagonalizes ρ, but having D^2 linearly independent outcome operators, rather than D.

Maybe a more interesting question is: What is the *largest* Shannon entropy, subject only to the constraint that the POVM be a minimal IC-POVM (i.e., it have precisely D^2 outcomes)? Again I don't know the answer, but I would bet it has something to with using *symmetric* IC-POVMs (at least if ρ is a pure state). (Actually it's probably obvious in the pure state case that the thing to do is align one of the outcomes of the SIC-POVM with the pure state.)

In general, the SIC-POVMs are the most interesting ones of the lot I think. You can read about them here:

> `quant-ph/0310075`:
> Title: Symmetric Informationally Complete Quantum Measurements
> Authors: Joseph M. Renes, Robin Blume-Kohout, A. J. Scott, Carlton M. Caves

It'd be an interesting project to say everything that can be said about the entropies such things can generate.

Jaffe-ism 4: *Of course, you can also use the entropy to assign distributions in the face of less-minimal information — i.e., known averages, as usual. But in this case we would expect that the results should depend on POVM, since that's what determines what the averages correspond to. Thinking about it a bit further, I imagine there's a further subtlety: there must be something subjective about the POVM itself. So if two different agents use maxent to assign a density matrix, under what circumstances will they get 'compatible' assignments (to use the language of your work).*

Over the last couple or three years, Caves, Schack and I have been steadily moving further away from our Jaynesian roots to a more Bernardo and Smith kind of Bayesianism. One of the upshots of this is a recognition that POVMs, too, have a subjective component (if they are not wholly subjective in the same way as any probability assignment – which is what I personally believe).

For your fun, let me attach the draft of a new paper by Schack and me. [See "Unknown Quantum States and Operations, a Bayesian View," `http://arxiv.org/abs/quant-ph/0404156`.] (It's effectively complete, except that we'll add a couple of footnotes and references at proof time.) Mostly it's a throw-away paper in that it has almost no new technical results; it was put together for a review volume on quantum-state estimation. However, the Introduction, Concluding Remarks, and Section VI on the subjectivity of quantum operations, may give you some insight on where this program is going.

Good luck in your work, and I'm very happy to meet you. There are so many things that need to be done to complete this Bayesian view of QM.

09-03-04 *Alchemy Quote* (to M. Pérez-Suárez)

Thanks for the quote. See you later today.

Marcos's Preply

I should be writing equations, but I find myself writing only numbers. I'll take this exhaustingly boring exercise as a excuse for making a remark on my not well articulated answer to your question about the alchemists' psycho-physical parallelism. One of the leading ideas (I'd say, that THE core of the subject) in alchemy, leading back to the (mythological?) Hermes Trismegistus (three times magister), is precisely this (translated from the supposedly original):

> It is true without lie, certain and most veritable, that what is below is like what is above and that what is above is like what is below, [...]

I have fortunately included this as a quote in one of the chapters for those Lecture Notes I have been writing. I'm afraid that most alchemical texts are so full of symbolism and esoteric that only an "initiate" (that is, someone already acquainted with this imagery, like Jung, for instance) can make any sense of them. But this is "the point" here: The Macrocosm (the Universe, if you want) is "in a likeness" (well, more than that, I'd say) to the Microcosm (the psyche), and they are intimately related to each other so that processes in one of the two domains have their correspondences in the other.

Hope that this provides further insight in Pauli's involvement with alchemical notions.

09-03-04 *Reality of Wives, Part 2* (to J. Preskill)

I remember how much you seemed to enjoy my story a couple of years ago about the reality of wives (in a note to you and Landahl). [See 21-07-01 note "The Reality of Wives" to A. J. Landahl and J. Preskill.] Attached is a throw-away paper that Rüdiger and I just sent off for a collection of review papers on quantum-state estimation—they wanted one from a Bayesian too. I say it's throw-away because there are no new technical results, outside of a little foundational argument; predominantly it's a cut and paste job. (We probably won't post it on `quant-ph`.) Nevertheless I send it because you might still get something out of reading the Introduction, Conclusions, and Section VI on the subjectivity of quantum operations. They indicate a little of what I've been on about when I previously mentioned the issue in connection to the black-hole information problem. The main point is that, to us, a quantum operation is to a conditional probability distribution what a quantum state is to an unconditioned distribution. To the extent that a Bayesian does not demand a mechanical or dynamical explanation for a quantum state assignment, he need not (should not) demand one for a quantum operation either.

09-03-04 *Bitbol* (to A. Plotnitsky)

Plotnitskyism 13: *I know Bitbol's work—he has a book on Schrödinger. I doubt I'd have a chance to see him this time (too tight and too late to arrange), but I am back to France in May/June for a longer time, and perhaps I should write him, mentioning that you suggested this (with your permission, of course).*

Sure, no problem. Bitbol's later work has turned, I would say, toward more Copenhagenian styles of interpreting quantum mechanics. Here's his web page:

`http://perso.wanadoo.fr/michel.bitbol/page.garde.liste.html`.

Most of his papers are in French, but a few are in English. I particularly enjoyed his "Non-representationalist theories of knowledge and quantum mechanics."

12-03-04 *Your Post-Partum* (to G. Brassard)

I had a chance to read your report on our meetings. It was great and to the point.

Let me attach my own latest concoction: It is a contribution (quickly) pasted together for a review volume on quantum state estimation. They wanted one article from a Bayesian point of view. So, there's not a lot of new technical material there, but I think you might enjoy reading the Introduction, Conclusions, and Section VI on the subjectivity of quantum operations. Particularly, I hope you enjoy the concluding remarks. It's the closest I've come yet to declaring the "sexual interpretation of quantum mechanics" in the public forum. The choice of the word "stimulation" in that section shouldn't be lost on you! (Key point to notice: In opposition to Mermin's desire for 'correlation without correlata', there's no use to talk about the 'stimulation' unless you're also going to talk about the 'stimulata'!)

So the queue to the construction of our joint paper is getting shorter. Upon my return to Dublin from Vancouver, I've got five days to put something together for the Holevo festschrift (I'm 3/4 way there already). And then I'll get to work on our project. As I say, the editor seems to be particularly tolerant on us ...

12-03-04 *Putting It Sharply* (to W. G. Unruh)

I'm afraid I wasn't very clear yesterday about why I consider measurement the crucial component of quantum theory. Let me attach an article Rüdiger Schack and I just put together for a review volume on quantum state estimation. I think the first three or four paragraphs in the introduction, plus the 'concluding remarks' section, make our crispest statement yet of the interpretation of quantum mechanics we're shooting for (and distinguishes it from a certain thread in all the various 'Copenhagen interpretations' I know).

Stimulation and response, and maybe a little creation in the process. Let me know if the paragraphs clarify anything. (And one day soon, I'll tell you more about how Section VI on the subjectivity of quantum operations impinges on the black-hole information problem.)

14-03-04 *The House Philosopher, 2* (to S. Savitt)

Thanks again for dinner, the nice visit to your home, and the pleasant conversation about Goodman. (I'll definitely plunge more carefully into Goodman.)

For the heck of it, let me go ahead and attach the proposals I wrote for Caltech. (I'll just forward an old letter.) [See 12-02-04 note "The House Philosopher" to J. Preskill and H. Mabuchi.] The proposals had to be short (one and two pages), but maybe they still give a glimpse of the kind of program I'd put together if I lived in the best of all possible worlds. But I'm not fooling myself: The dice have only a very, very slim chance of falling in that direction.

I'll keep in touch with you about things. Have a great trip to merry old England.

15-03-04 *Via Alaska Airlines* (to D. M. Appleby)

I apologize for the long delay, but I've finally read your paper on probability. It happened on my flight from Vancouver to Los Angeles the last few hours. Now I'm in the Aer Lingus lounge in LAX, waiting to make the rest of my way home to Dublin.

It's a good paper! What parts were you afraid I would disagree with? I think you did the community a great service with the paper, and I'll try to advertise it as best I can. I particularly enjoyed your argumentation in Section 6 on retrodictive inferences.

A few very minor remarks.

1. Of the paragraph in Section 1 starting, "Hume famously argued that one ... ", I wrote, "Good way of saying it."

2. Of the sentence in the same section, "On the face of it, taking an epistemic view of the state vector amounts to giving up on the idea of physical reality altogether," I wrote, "Yuck." Rather than "on the face of it" you might have written "ostensibly" or "at first pass". I guess "on the face of it" conveys the idea somewhat, but I fear the reader may not immediately see that you're being rhetorical. You do, in fact, recover with:

3. "However, I feel it may be consistent with a much more subtle and interesting kind of realism ... " to which I wrote "Better."

4. In Section 4, where you say, "For instance half-lives are typically tabulated next to masses, as if they were just one more physical property," I wrote "Interesting!" That is a good point. However,

5. from that point onward, all the way to the end of the section, I could not understand what you were getting at.

6. At section 9, I wrote "Utilities!!" I think you could do a lot better in general in that discussion.

7. Finally Section 12 was far too abrupt! You had me licking my lips and then left me hanging. (It looks a little like you were exhausted by the time you got to the last section and, so, wrapped it up pretty quickly.) I was tantalized by this comparison of probabilities to qualia—I had never seen that before—and I wanted to see how you developed the point. Also, despite the mention of Bohr in the last two paragraphs, you never did come back to the point of a "much more subtle and interesting kind of realism."

All very minor points.

In an earlier note, you wrote me,

Applebyism 7: *It is all about classical probability—coins, and the like. I do appreciate that quantum probabilities are fascinatingly and intriguingly different. And that is what I am going to start thinking about now.*

I don't think you'll find any consideration in your paper that is changed in the quantum setting. ("Where did you make use of the difference between classical and quantum?," I ask rhetorically.) At least as long as you are talking about actually performed trials—rather than counterfactually performed trials (as in my bureau of standards)—I think everything will be OK. In particular if we look at things in the right way, I suspect the only difference between classical and quantum will be in their notions of event, not in their notions of probability. In the quantum case, the events are direct consequences of the agent himself (via his conjugal relations with the external world)—stimulandum, stimulation, stimulata. (Correlation without correlata? No! Rather, no stimulation without stimulata! No stimulation in the agent without a corresponding stimulation to the external world.) Somehow, taking that into account in the agent's reasoning leads to an apparent modification of the probability calculus with respect to counterfactual measurements (i.e., how he updates his beliefs about the bureau of standards).

By the way, concerning,

Applebyism 8: *Matthew thinks that he cannot pick up a glass of wine. Only an American pragmatist could be so simple-minded—so horribly unsophisticated—as to imagine that it is possible to genuinely do anything.*

thank you! It's been a long time since I've been proud to be an American!

All the best, and it really is a fine paper. Thanks for writing it.

PS. Let me attach the latest concoction Schack and I brewed; it's something we haven't posted yet. There's not much new in it—it was a quickly pasted together article for a review volume on quantum state estimation—however you might still enjoy reading the introduction, conclusion, and Section 6 on the subjectivity of quantum operations. In particular, I'm kind of proud of the language choices I made in the first three paragraphs or so, and also in the concluding section. I really want to rearrange how we think of quantum theory—from a big theory of everything to a little theory from the inside. A theory of stimulation and response, and maybe a little creation in the process. It's the latter part of that sentence that gives me the will to keep working at this.

15-03-04 *Via Aer Lingus* (to D. M. Appleby)

I also reread your note "Poetry, subjectivity, mirroring and algorithms" of 11/19/2002, which has been sitting in the "must reply to" box in my email program since then. It's a great note, and I loved its construction, but I still don't know how to reply. Hence, I think I'm going to file it into the regular "Appleby, Marcus" box at this point.

In your "Facts, Values and Quanta" you say "a probability statement cannot be identified with a fact about the world, as it exists independently of us." I think that is all I have ever meant by "subjective." But, then again, maybe that's just hindsight playing a trick on me.

16-03-04 *Bayes or Bust* (to A. H. Jaffe)

Thanks for sending your review. It went down well with my coffee this morning. It's quite nice.

Jaffe-ism 5: *Conversely I suppose I share some of Jaynes's suspicion of the fundamental status of Dutch book-type arguments, although I do think they tell you something — but perhaps not everything — about the meaning of probability assignments once you've derived the rules by, for example, the Cox derivation.*

I hope I haven't given the impression in my writings (or the writings with Caves and Schack) that I think the Dutch-book argument is the end-all and be-all of probability theory. I'm quite a bit more liberal than that. The better go at it, I think, is given by a decision theoretic derivation, say, like the one in Bernardo and Smith. Cox, on the other hand, is nice, but I personally have never found it nearly as convincing as decision theoretic ideas. . . . Well, that's not true: I did once, but somewhere in 1994 I got suspicious of it and started to think its assumptions aren't nearly as compelling as Jaynes finds them. (If I can recall my particular arguments, eventually I'll write them up and send them to you.) Maybe my opinion is more like Earman's in his book *Bayes or Bust*: No single Bayesian style argument for the probability calculus is completely compelling, but the whole package taken together lends quite some evidence that everything is on the right track.

16-03-04 *The IQSA Meeting* (to F. E. Schroeck)

Thanks for the invitation to the IQSA meeting. I wish I could be there, but I think now I'm so over-committed that I ought to make a decision not to get myself in any deeper. I'll have just gotten home from a meeting in Waterloo at the time your meeting starts up: My semi-constant absence is pretty tough on the family.

But good luck to you; it sounds like a great meeting. Beside Barnum, another few people you might try out of the quantum information community are Jeff Bub (`jbub@carnap.umd.edu`), Lucien Hardy (`lhardy@perimeterinstitute.ca`), and Rob Spekkens (`rspekkens@perimeterinstitute.ca`). Spekkens in particular has done some really exciting work lately, which you can find on `quant-ph`.

18-03-04 *Hubert Space* (to R. Schack)

Damned editors. They are so very worthless. I'll look at the proofs in the next couple of days. Did you notice they changed one of our Hilbert spaces to a Hubert space!

18-03-04 *ABL, Appleby, and Grue* (to S. Savitt)

Savittism 7: *Second, it raises a question in my mind. Bill (Unruh) insists that the right way to think of QM, to say what the theory is, is the time-symmetric ABL formalism. Might it not be interesting to figure out whether Paul Humphrey's criticism of the propensity view would or would not apply to the probabilities needed for ABL if you tried to think of them as propensities?*

Good question. Off the cuff, though, I'd bet the same criticism applies: the main issue, I think, is about the difference (or whether there should be no difference) between predictive probabilities and inferential probabilities. One might think of the ABL rule as giving propensities, but then one has to account for what one might mean by an "unknown ABL probability." At that point, one invokes inferential probabilities, which are clearly epistemic. So, one either ends up with a mixed theory (propensities and epistemic probabilities, which by a miracle obey the same formalism), or one says, "this is good evidence once again for a purely epistemic view of probabilities."

But that's off the cuff, and I'll certainly think about the issue further.

By the way, interesting coincidence. On my flight home from Vancouver, I fulfilled an obligation to read Marcus Appleby's paper "Facts, Values and Quanta," which is really mostly devoted to the interpretation of probability (outside of quantum issues). Here's the link: `http://www.arxiv.org/abs/quant-ph/0402015`. If you can get past the sickly sweet introduction (praising some guy named Fuchs), it's not a bad paper. There are some novel arguments in there that I liked. In particular—and the reason I say "interesting coincidence"—at one point he uses a modification of Goodman's grue to discredit frequency interpretations. Given a couple of your remarks in our conversation the other night about "predicted frequencies being seen," you might find reading the paper useful, at least as some food for thought.

24-03-04 *Give Me Fungible* (to C. H. Bennett)

Can you give me a citation to the first time where you called quantum information fungible? Better yet, can you *also* send me the text of the paper?

25-03-04 *Reining in My Life* (to G. Brassard)

I'm finally beginning to rein my life back in. I finally finished the Holevo festschrift and sent it off. [See "On the Quantumness of a Hilbert Space," `http://arxiv.org/abs/quant-ph/0404122`.] If you can, let me know what you think about the Introduction, Conclusions, and Eqs. (13) and (14). More importantly, can you think of anything in quantum computing that would bolster the vision (or the hope) expressed in Paragraph 5 of Section 1.

Now, I finally start the process of writing our joint paper. It is brewing. I'll send you the thoughts as they come next week. Part of it will certainly have to do with the content of the Holevo paper: It is quantum crypto that powers quantum computation! (I like pipe dreams.)

By the way, when are you going to take me to that Greek seafood place in Montréal again?

25-03-04 *Hot Off the Presses* (to P. C. E. Stamp & W. G. Unruh)

Attached is a paper I just sent off to the editors of the Holevo festschrift. [See "On the Quantumness of a Hilbert Space," `http://arxiv.org/abs/quant-ph/0404122`.] It contains the material I was hoping to get to for the second part of my talk in Vancouver. The fifth paragraph of the introduction, in particular, tries to say (in a sentence) what I think all of this has to do with the source of power of quantum computing—something I was hoping to play up even further with you guys, but I ran out of time.

Anyway, I hope you enjoy the verbiage, if not the equations.

26-03-04 *So Slow Chris* (to A. Peres)

I apologize for being so slow to reply. I have been hurriedly trying to finish my paper for the Holevo festschrift, and I pretty much dropped all else to get it done. I will attach the LaTeX file to the present note: Perhaps the introduction and conclusion sections will amuse you. (I haven't posted it yet on `quant-ph`; I'll probably do so Monday before departing for Germany myself.)

Asherism 66: *I have read again your* `quant-ph/0205039`*, and figures 1 and 2 reminded me of my paper "Convex probability domain ..." with Danny Terno, JPA* **31** *(1998) L671 [*`quant-ph/9806024`*]. Is there any relation?*

Yes, there absolutely is. It was quite an oversight on my part not to cite your paper there. (In fact, I thought I had until I received this from you.) It was because of your paper with Danny that I decided to make the "bureau of standards" measurement have precisely D^2 outcomes. If the measurement had any more than D^2 outcomes, say N, then the allowed region would have zero volume in the N-simplex, as you and Danny show. I have been meaning to repost that paper with various fix-ups. This will surely be one of them. (There, I just fixed it actually.)

What I think is the next important step is to say more about the geometric properties of these convex sets. For instance, with regard to qubits, the convex region is actually always an ellipsoid (no matter what the bureau-of-standards measurement). The ellipsoid varies from measurement to measurement, but it is always an ellipsoid. One question is, what is the proper characterization of the region in higher dimensions? What are the invariant geometrical features? And I can think of several questions beyond that. Would you be interested in collaborating on this?

I am glad to hear you survived your voyage back to Germany and did not come back with a renewed bitter taste. I very much enjoyed reading the (partial) autobiography you sent me. You have had a stirring and very impressive life.

26-03-04 *Nonuniqueness from Nonexistence* (to A. Peres)

By the way, I've been meaning to tell you how pleased I am of your embracing the point that "quantum states do not exist" in your quantum gravitational research.

To that end, let me attach another paper of mine—this one with Schack. There is not a lot new in it by way of technicality. It was effectively pasted together from old publications for the purpose of a review volume on "quantum state estimation," however, we reworked the language in the old articles significantly to take into account the more consistent view that we now have. The main parts that will be relevant to you are the introduction, the conclusions, and Section 6 on "The Subjectivity of Quantum Operations."

If quantum states do not exist (even pure states), then they surely cannot be unique (even pure states).

You will note how I used your 1984 paper "What Is a State Vector?" as a point of contrast for our present view. I hope you will not think that I was picking on you. The reason I singled out your paper is because it is the very clearest statement on the subject. If you think, however, that I should change any of the language before posting it, please let me know. For instance, I did not attempt to contrast your 2004 view with your 1984 view—they may be significantly different!! (And I would guess they are.) Unfortunately, it may be too late for the version appearing in the volume: I was in such a rush sending off the draft—and returning the proofs—that the possible sensitivity of my statement didn't dawn on me at the time. But it will not be too late for `quant-ph`; please let me know.

26-03-04 *Hot Off the Press; Closing My File* (to J. Preskill)

Attached is a paper I just sent off to the editor of the Holevo festschrift. [See `http://arxiv.org/abs/quant-ph/0404122`.] I thought I might send it to you too. It's the last remaining thing on my CV that's not publicly available. With it you can close my ITS file . . .

I remember your asking me during my visit to Caltech in October, "Remind me why this symmetric POVM is interesting?" The present paper is an attempt to answer that. I.e., it's because I think these structures lie closer to the heart of what Hilbert space is than do orthogonal sets. In particular, I'm banking that "No" will be the answer to the open question in Section 6, and that the SIC ensembles will be the only minimal sets giving Q_d. But I could be wrong.

If you want to throw in on the open question, I'd be grateful for any ideas (or even the flat-out solution). Chris King and I spent a solid couple of weeks on it last summer, but didn't make any great progress.

26-03-04 *Thanks* (to M. Pérez-Suárez)

I just wanted to say quickly (before I start to enjoy my Friday night beer) that I enjoyed our session together today. It was stimulating. Great to see you asking questions like that that are on the edge: I.e., what can we glean from this Bayesian program? How does this piece link with that piece? So forth. Keep it up! That's what a researcher is: A big bundle of questions.

05-04-04 *Elevator Stories* (to W. K. Wootters)

I'm glad you are following through with a contribution to Asher's festschrift. I'm still waiting on three other people too, so you're not the last one. ... But the faster you can get it to me, the better! (There are always further uncertainties with referees, etc., etc.)

I'm in Munich at the moment, taking a little holiday with Kiki and the kids at Kiki's parents' place. A couple of days before that, however, I was in Freiburg visiting Guido Bacciagaluppi and Harald Atmanspacher and was lucky enough to run across a recent issue of Foundations of Physics at their institute: It had your paper "Why Things Fall" in it, which I had not heard of before! Very nice. I got a chance to read it this morning.

In that regard, maybe let me attach two of my own papers that haven't made their way onto `quant-ph` yet. The first, "Unknown States and Operations, a Bayesian View," is a kind of throw-away in that it doesn't contain really any new technical results—it was pasted together for a review volume on quantum tomography—but you might get something out of the introduction, conclusions, and Section 6 on the "subjectivity of operations" (which are new) that I haven't yet been able to adequately express to you. In particular, I hope the choice of words there will better help you see how I am starting to view quantum mechanics as a whole—i.e., as predominantly a theory "from the inside." As I see it, it is a theory that helps us gamble on our little parts in the act of creation. But I also hope the argument in Section 6 will help you appreciate why I am starting to take such an austere position about what is "real of a quantum system"—little more (and maybe no more) than its dimensionality.

In the tradeoff though, I hope this austerity provokes an image of another austerity in physics for you: The equivalence principle. And that's where the elevator stories come in, and my pleasure this morning in having read your article. With "elevator stories," I'm referring to my second attached article, "On the Quantumness of a Hilbert Space." You'll see what I'm talking about if you open it up.

What I didn't go so far as to mention there is that I am starting to wonder if Hilbert-space dimension is not so unlike gravitational mass as to actually BE gravitational mass. It's a wacky thought—almost surely wrong in detail, but maybe evocative of a fruitful direction of thought. At least I hope so. Q: "What's the ultimate limit to this system's sensitivity to quantum eavesdropping?" A: "I don't know, let's weigh it." Wouldn't something like that be cool?

Anyway, part of this thinking is motivated by Bekenstein-entropy-bound kinds of things. From a Bayesian point of view of QM, I can't see what the entropy bound could possibly mean but that: If one posits an E and an R for a system, at the same time as positing a Hilbert-space dimension above that allowed by the bound (assuming a completely mixed density operator), one is living in a state of sin—i.e., one is being incoherent in one way or the other. But part of the thinking is just motivated by a desire for even more austerity, full stop.

If you have any comments on the quantumness paper, let me know: It's still at a stage where it can be modified before posting.

05-04-04 *Gambling on Creation* (to W. K. Wootters)

Looking back over the note I just wrote you, I doubt you could understand what I meant by, "As I see it, it is a theory that helps us gamble on our little parts in the act of creation." Let me try to make some sense of that by attaching a couple of old emails. Both are written in a polemical style, but if you can ignore that they might help draw a picture.

06-04-04 *Participatory Universe* (to Z. D. Walton & T. Toffoli)

I'm just starting to understand your paper. I hope you'll forgive me if it takes a while. I am certainly sympathetic to your goal: "Derive quantum mechanics from the premise that we live in a participatory universe." What a great thing it would be!

In the meantime, maybe you guys would enjoy (as a little "bathroom reading") something I put together a while ago: It's titled *Notes on a Paulian Idea*, `quant-ph/0105039`. The thing I call "the Paulian idea" is the idea that the (quantum) observer cannot be detached from the phenomena he *helps* bring about. If you'd like the file bound as a (paperback) book, let me know, and I'll have a copy (or copies) of the Växjö University Press edition sent to you.

I also have a semi-historical document I'm putting together: "The Activating Observer: Resource Material for a Paulian-Wheelerish Conception of Nature". Presently, it stands at 124 pages of quotes drawn from (some fraction of) the 459 references it cites. I'm hoping to post it next spring, but I've still got quite a lot of work to do to get it into shape before then. (It'll probably double, if not triple in size before then.) In any case, though, if you're interested in seeing it as it stands, I'll send you a PDF file of the draft. (As payment, I only request that you compile and point out to me any typos you find in it.)

15-04-04 *Slowly Coming Back* (to S. Hartmann)

Slowly I'm coming back to speed on my backlog of work. I decided to stay in Munich until the 14th (yesterday) and after Freiburg, I almost didn't do a thing work-wise. In an impromptu way, I decided to take a real vacation (not something I do very often)—I neither read nor wrote almost any email!

Tomorrow I'll write Caves and Schack about your proposal of pitching in on the "Being Bayesian in a Quantum World" conference. I'm quite thrilled about the idea. In the meantime, let me paste in the list I had drawn up of potential participants to give you a firmer idea of the sort of thing I had been having in mind.

By the way, I looked at Hagar's paper to the level of being able to find the part you told me about: "Motivated in this way Fuchs then goes on to 'trash' (Fuchs' own description of his attempt to understand QM) about as much of QM as he can . . . " I thought he could only be talking about my lines in `quant-ph/0205039` where I say:

> The task is not to make sense of the quantum axioms by heaping more structure, more definitions, more science-fiction imagery on top of them, but to throw them away wholesale and start afresh. We should be relentless in asking ourselves: From what deep *physical* principles might we *derive* this exquisite mathematical structure? Those principles should be crisp; they should be compelling. They should stir the soul. When I was in junior high school, I sat down with Martin Gardner's book *Relativity for the Million* and came away with an understanding of the subject that sustains me today: The concepts were strange, but they were clear enough that I could get a grasp on them knowing little more mathematics than simple arithmetic. One should expect no less for a proper foundation to quantum theory. Until we can explain quantum theory's *essence* to a junior-high-school or high-school student and have them walk away with a deep, lasting memory, we will have not understood a thing about the quantum foundations.

> So, throw the existing axioms of quantum mechanics away and start afresh! But how to proceed? I myself see no alternative but to contemplate deep and hard the tasks, the techniques, and the implications of quantum information theory. The reason is simple, and I think inescapable. Quantum mechanics has always been about information. It is just that the physics community has somehow forgotten this.

But indeed he was right. At the beginning of the "Intermission" section, I write:

> Let us take a deep breath. Up until now I have tried to trash about as much quantum mechanics as I could, and I know that takes a toll—it has taken one on me. Section 3 argued that quantum states—whatever they are—cannot be objective entities. Section 4 argued that there is nothing sacred about the quantum probability rule and that the best way to think of a quantum state is as a state of belief about what *would* happen if one were to ever approach a standard measurement device locked away in a vault in Paris. Section 5 argued that even our hallowed quantum entanglement is a secondary and subjective effect. ...
>
> Subjective. Subjective! Subjective!! It is a word that will not go away. But subjectivity is not something to be worshipped for its own sake. There are limits: The last thing we need is a bloodbath of deconstruction. At the end of the day, there had better be some term, some element in quantum theory that stands for the objective, or we might as well melt away and call this all a dream.
>
> I turn now to a more constructive phase.

It's good to have people out there watching you: they set you straight from time to time when you forget what you've written.

16-04-04 *What is the Difference between a Quantum Observer and a Weatherman?* (to A. J. R. Parker)

Thanks for your interest. You can find most of what I've written on quantum foundations posted at my website (link below). Further materials can be found at the `quant-ph` archive.

With regard to your query about a link between theories of consciousness and quantum foundations, I don't have any answers. The only tangential link I see between my own quantum foundational program and such things is that I see some affinity between the direction I'm turning toward and the American pragmatist tradition (particularly James, Dewey, and Schiller). In that connection, I bring up something the quantum computer scientist Scott Aaronson wrote me a while ago:

> PS. I remember you talked about William James in the samizdat ... Have you read the *Principles of Psychology*? I'm working through it now. I've decided to recommend it to people as "the most up-to-date, state-of-the-art book about consciousness" (without telling them the publication date).

Scott is a serious scientist (much more serious than I am). Thus it might be worth your while.

Good luck.

Andrew's Preply

> I note that you recently gave the above paper at All Soul's College Oxford.

I am a psychiatrist, but also studying for an MA in philosophy of mind. My interest is the nature of consciousness and whether quantum mechanics has serious implications for current neuroscientific and philosophical theories of consciousness. My current position is that it does … that is, it seems, if my understanding of what it is to be an "observer" is broadly correct.

The latter issue seems to be addressed head on by very few people in the field — although I have to admit, I have to skip over the equations given my non-physics/maths background. Perhaps there is an understanding growing which I am not aware of?

I wonder if your paper above may help, and whether it is available to send by e-mail.

19-04-04 *Part 2.1* (to D. M. Appleby)

I'm sorry; you've caught me at one of those times when I am in "bad correspondent" mode. (At the moment it looks like this is going to continue for a while—at least until I get my post-sabbatical plans settled.)

Presently, I guess I don't have much to say about your note except that I still don't like propensity, even as a view from somewhere. For it would mean—as far as I understand the term—that from my (or your or his or her, etc.) point of view nature has a certain tendency to this or that (quantifiable by the probability distribution each of us happens to use). I just think that terminology is misleading, attempting as it does to once again materialize probabilities, rather than let them stand for sheer ignorance or opinion. The only direction I see forward is for all of us to recognize starkly that the world owes us nothing. Regardless of our probability assignments, the world owes us nothing.

Beyond that, I also don't think I'm happy with the conception of physics as a *view* from somewhere. The term I protest is "view." Presently, I think it's all about survival, period, with the last bit of representationalism banished. I agree with the "somewhere-centeredness" you are striving for—though in my terms, for each of us, it is about MY survival (remember the note I sent you titled "Me, Me, Me"?)—but I would be hesitant to call that a "view." Do have a read of Rorty's "philosophical papers," Volume 1—I think he does a pretty good job of what I'm shooting for (what I'm shooting for in QM particularly, where I think the evidence is greater than what he's got to work with). But that's about all I can say at the moment.

Or maybe I can swipe a few (relevant) words from a recent note that Michel Bitbol wrote me. I'll place them below. Maybe they add a little gloss to what I'd like to say myself (if it were a better world with fewer time constraints).

Anyway, really, thanks for your long note. I hope I'm not offending with this short reply, but you're not alone: I've only been replying to small fraction (the most urgent) of my emails lately.

21-04-04 *From Glub to Snowflakes, Creation, and Construction* (to M. Bitbol)

Thanks for your thoughtful letter. I have very much enjoyed reading it (maybe five times now).

Bitbolism 1: *At this stage, I have to state my major point of disagreement with you: I suspect the remark you made about the "many-worlds interpretation" applies quite well to some of what you say. Let me explain this.*

You write: "What I find egocentric about the Everett point of view is the way it purports to be a means for us little finite beings to get outside the universe and imagine what it is doing as a whole." I deeply agree with you.

But, then, you begin to do essentially the same as the naive Everettian. You try to describe our situation in the world from a sort of vantage point. Here is the sentence in your paper that made me suspicious: "I think the solution is in nothing other than holding firmly—absolutely firmly—-to the belief that we, the scientific agents, are physical systems in essence and composition no different than much of the rest of the world. But if we do hold firmly to that—in a way that I do not see the Everettist as holding to it—we have to recognize that what we're doing in the game of science is swimming in the thick middle of things."

Of course, once again, I am delighted by the Pascalian metaphor of "swimming in the thick middle of things". But you seem to take it as more than a metaphor: a definite belief about (not to say a faithful description of) the world and our position in it. You write seriously that "we, the scientific agents, are *physical systems in essence and composition no different than much of the rest of the world". Isn't this a way of extrapolating one of our pragmatic-adaptative concepts, one of the concepts we need to swim with some success in the midst of the "glub" (here, the concept of a "physical system"), in order to describe everything including us as if it were seen from outside? I hear you saying something like "the world as I see it from my cosmic exile is made of physical systems and each one of us is one of these physical systems". But if we are "swimming" in the deep ocean of whatever we call "reality", we have absolutely no context-independent concept at our disposal, not even the very general meta-concept of "physical system". We must say that we ignore* everything *of the "thing in itself", including whether it is organized or not in a plurality of "physical systems". And we must therefore content ourselves with stating the formal conditions of our cognitive aptitudes (within it). This latter attitude is typical of the Kantian and neo-Kantian lineage of philosophy (when one gets rid of the foundational aspect of Kant himself and holds a pragmatic variety of Kantianism, as I do). I hope you'll recognize it as a radical variety of your view... I wonder whether you'll become a member of our radical club or rather decide to stick to your position as it stands.*

I don't know that I have an answer for you at the moment. (I hope you understand that all my efforts, all my writings, are of the groping variety—I have no final answers to anything. Nor do I hold any pretense of being consistent from one email or paper to the next. The only thing I can promise is that I do strive for consistency, and I welcome exercises like the one you've presented me.)

To make a start of an answer though, I think my usage of the term "physical system" is considerably more nuanced than you probably guess. (Though, it may not have been so nuanced at the time of my writing the anti-Växjö paper. Alternatively, I may have simply lapsed while I was writing those notes.) I say that it is nuanced, because I often toy with the idea that "physical systems" are agent-defined. You will find this idea probably first appearing in my writings in the chart on page 292 of *Notes on a Paulian Idea*. There I ask, "What is a quantum system?" And I reply to myself, "A line drawn in the sand." (It goes back to a 1995 letter to Greg Comer.)

Maybe I can do a better job of what I am thinking, though, by attaching a couple of other emails that I've been promoting recently. They're attached to this letter in a file titled `ForMarcus.pdf`. In the letter "Me, Me, Me" to Mermin and Schack within that collection, I give a definition of what I mean by "system." I hope that definition will make you think twice about the characterization of my views you gave above.

In general lately, I'm not even sure what I can make of the idea of "thing in itself"—it now sounds too static for what I'm trying to get at. To that end, let me attach another little compilation—this one titled `ForSlusher.pdf`. In particular, I hope the note within that titled "The World Is Under Construction" will help you better see what I am talking about.

Finally, let me paste below still another note to help muddy the waters. It is a string of earlier notes culminating in a few remarks to Jeff Bub; so in reading it linearly you will be traveling backward in time. Its relevance here is that I think you think when I utter the words "physical system" I am doing it in the sense that William James describes below as a case of "nothing but." But I sincerely hope that is not what I am doing.

Anyway, all of this is probably not the sort of thing you were expecting as a reply: It is quite roundabout. But I am trying to put three lines of thought (as expressed in the three collections mentioned above) into a consistent whole. If I can do that, I think it will count as something of a direct answer to your query.

Does any of this make sense to you? Or does it all look more like the ramblings of a crazy man?

21-04-04 *Essential Incompleteness* (to W. G. Demopoulos)

Thanks for sending me your paper "Some Remarks on Elementary Propositions and Partial Boolean Algebras." I've taken a shot at understanding it—i.e., I've read it by some measure—but I probably didn't fare as well as I should have.

As you argued in your earlier letter to me (one from last year sometime), our views—or maybe just our languages—may not be so incompatible as one might think. However, I am left with the feeling that this is only a contingent feature of the particular stages of the game we happen to be at, at the moment. In particular, from my own view, I think it is quite important that we strive to stop thinking of quantum states as states of knowledge about the TRUTH VALUE of this or that proposition (even if truth value is not invariant with respect to 'experimental arrangement'—the idea you are toying with). My feeling is that the imagery of measurement outcomes mapping to truth values (in this context anyway) will only cloud our vision for how to take the next big step.

What is the next big step? I think it is a deeper understanding of how—very literally—the world "is in the making" (to use a Jamesian phrase). To try to make that idea at least graspable (if not either clear or consistent yet), and to try to show you quantum theory's role in all this, let me attach four letters I've written recently. They're contained within the attached files `ForMarcus.pdf` and `ForSlusher.pdf`. I think they are my best statements to date of what I am shooting for; and I think that goal fundamentally conflicts with the idea of "measurement" propositions having truth values in the conventional sense.

That is not to say, however, that I am yet ready to give up on the idea of physical systems having autonomous properties. The question is, what can still be pinned down as a property in the conventional sense?

In the letter you wrote me way back you said,

Demopoulosism 1: *What I've tried to address in my paper is the question whether there is anything in the quantum theory's conceptual framework that plays a role analogous to that played by a classical state. My suggestion is that the closest analog of this is given by the elementary physical propositions that are true of the system. They, rather than the quantum state, expresses the underlying reality that the theory purports to describe.*

As I said above, that's where I don't want to go. Instead, at least at the moment, the only thing I am willing to think of in quantum theory that "plays a role analogous to that played by a classical state" is a system's dimensionality. [Question: What is this system's ontic state? Answer: D, just D.] Here's the way I put it in the paper "On the Quantumness of a Hilbert Space" which will be appearing on `quant-ph` tomorrow:

> In this paper, I present some results that take their *motivation* (though not necessarily their interpretation) in a different point of view about the meaning of a system's dimensionality. From this view, dimensionality may be the raw, irreducible concept—the single *property* of a quantum system—from which other consequences are derived (for instance, the maximum number of distinguishable preparations which can be imparted to a system in a communication setting). The best I can put my finger on it is that dimensionality should have something to do with a quantum system's "sensitivity to the touch," its ability to be modified with respect to the external world due to the interventions of that world upon its natural course. Thus, for instance, in quantum computing each little push or computational step has the chance of counting for more than in the classical world.

This language is definitely not completely consistent with the vision I outline in the attached letters but it is the best I can do at the moment. ("Modification without modificata?!?," I hear you asking. "What could it mean?")

In any case, I have looked at your new paper, and I have re-looked at the paper you gave me last year, and I will be bringing both of them with me to Maryland. It would be a pleasure to talk further about all this—how we differ, or even how I missed something and the gaps may be erasable after all. (The latter would be very nice if it is the case.)

21-04-04 *Can Your Toy Model Do This?* (to R. W. Spekkens)

Attached is an old set of notes that I finally glossed up into a paper and sent off to quant-ph today. [See `arXiv:quant-ph/0404122`.] It dawned on me that one ought to ask a similar question of your toy model: I'm thinking of the part of my paper surrounding Eqs. (13) and (14). There one sees that quantum systems' sensitivity to eavesdropping scales supermultiplicatively in the number of systems making up a composite system. Does a similar effect arise for your toy model? I don't have a strong feeling one way or the other which way the answer will go.

22-04-04 *Language Games* (to N. D. Mermin)

Correlation without Correlata … Modification without Modificata … No Stimulation without Stimulata!

I actually have found a way to make sense of the last one, "no stimulation without stimulata," within my budding point of view about quantum mechanics. Have I told you? No stimulation to the agent (in old language "the observer"), without simultaneously recognizing that the world must be stimulated in return. No stimulation to the agent without the external world being stimulata—i.e., that which is stimulated—in its own right.

Language games.

23-04-04 *Demonizing Bayesians* (to J. D. Norton & J. Earman)

Nortonism 1: *As you may know, I've been commissioned to speak on Maxwell's demon at this year's offering of New Directions and give my response to Charles Bennett's reply. Last year I had only a visceral sense that something was wrong. Since I've got to stand and speak, I tried to make these concerns more precise and now I think they are very precise. The result can be downloaded (in draft form) at: …*

Of course with any paper like this there is always a nagging worry that I have missed something obvious or not so obvious. So, if you do look at the paper, I'd be grateful for any reactions.

I've started to absorb a bit of your paper now and am enjoying it. I'm looking forward to overhearing the discussions in Maryland. (My only advice at this stage is that you might find a way to make the title a little less belligerent—but that's your business. I've got no room to talk given some of the introductions to my own papers. See for instance, `quant-ph/0106166` where I demonized the Zurekians.)

In the meantime, could one or the other of you send me electronic versions of your 1998 and 1999 exorcist papers? I don't have that journal easily available where I am.

It is good for me to think about these demon problems again, as I haven't really thought about them since long before my transformation to (some flavor of) personalistic Bayesianism. The justification for Landauer's principle that I had used in my own mind previously always involved considering the erasure from two points of view: 1) what happens from the demon's view, and 2) what happens from a "view from nowhere" that includes the system the demon is acting upon and the demon himself. Matching inside-view to outside-view probability distributions obtains (or, at least, so I had thought at the time) the result. But a personalistic Bayesian has no *a priori* reason to match those distributions—for they must be attached to some agents if they exist at all, and there can be nothing that automatically requires the agents to have compatible assignments.

Anyway, it's a good opportunity for me to rethink all these things. Now I am inclined to wonder whether something like a Dutch-book argument might not banish the demon forever. Namely, could one show that an agent (i.e., a demon) who claims 1) to be ignorant of the molecule's position after removing the partition in a Szilárd piston, and 2) to be able to extract work ad infinitum, is simply incoherent (in something like a Dutch-book sense)? Or something like that ...

Looking forward to seeing John N. again and meeting John E. for the first time.

24-04-04 *Trees for the Woods* (to R. Schack)

I read `t.tex` with breakfast this morning, and I don't quite know what to tell you at this stage. When we last talked about it, I thought you were going to make a clean simple point in the paper: That when one generates a 50/50 distribution via a quantum measurement on a pure state, one has much more than simply the 50/50 state of belief about the outcome. One also has the belief that no further part of the world can have any insider information about the outcome. And it is that that makes a quantum random number generator interesting. But at least in the present draft I don't yet see that idea cropping up (or even presented in the bold way that it ought to be). I.e., at this stage it's hard to see the forest for the trees.

26-04-04 *Batting Eyes and Smiling Faces* (to L. Henderson)

Hendersonism 3: *There is no option to photocopy it, except if they do it for you, and in this case that would cost $113.75, since the thesis is 455 pages long (it is a Long thesis, ho ho). If you still want it I can order it for you, but it will take about 5–7 days so I wouldn't be able to bring it to the conference.*

To show you how weird I am (read devoted), I'll take it! (They'll regret it though: I'll just post the damned thing to the internet once I get it and then they'll never get their $113.75 again.) Can I pay you back in Maryland this weekend? (Cash.) Also, maybe if you'll bat your eyes and give a big smile, they'll be compelled to give it to you before Thursday. I'll pay for your extra trouble there too: beer, dinner, fantastic ideas, ... some combination of all three.

See you soon! And thanks again ...

27-04-04 *Jeffrey Knew Certainty* (to R. Schack)

- R. C. Jeffrey, "De Finetti's Radical Probabilism," *Probabilità e Induzione—Induction and Probability*, edited by P. Monari and D. Cocchi, (Biblioteca di Statistica, CLUEB, Bologna, 1993), pp. 263–275.

27-04-04 *At It Again: Delirium Quantum* (to H. M. Wiseman)

I'm at it again with my 'samizdatery': I put together a little collection of emails that may be relevant for a meeting on the philosophy and history of science I'm attending next week. And I am flirting with the idea of posting it on `quant-ph` (though I haven't made a decision yet). The document is attached: `DeliriumQuantum.pdf`. [See "Delirium Quantum" `arXiv:0906.1968v1`.]

The reason I'm writing is to make sure the document doesn't offend you. The first two letters contain direct quotes of yours, and Section 4 mentions you both at the beginning and at the end. Let me know if I have your approval to post as is.

There is one little bit of new stuff in the paper that you may not have seen before (or at least a combination of words that you may not have seen before): Footnote #2 on page 7. I dream that I might have finally hit the sweet spot of clarity with those words, but I probably haven't.

27-04-04 *At It Again: Delirium Quantum* (to A. Sudbery)

I'm at it again with my 'samizdatery': I put together a little collection of emails that may be relevant for a meeting on the philosophy and history of science I'm attending next week. And I am flirting with the idea of posting it on `quant-ph` (though I haven't made a decision yet). The document is attached: `DeliriumQuantum.pdf`. [See "Delirium Quantum" `arXiv:0906.1968v1`.]

The reason I'm writing is to make sure the document doesn't offend you at a personal level. Section 5 in particular quotes you directly. Let me know if I have your approval to post the document as is, or whether you would suggest some changes.

There is one little bit of new stuff in the paper that you may not have seen before (or at least a combination of words that you may not have seen before): Footnote #2 on page 7. I dream that I might have finally hit the sweet spot of clarity with those words, but I probably haven't.

28-04-04 *Darwin, Qubit, Butterfield* (to C. G. Timpson)

Timpsonism 1: *Here's a question for you: Do you have any idea of when the phrase 'quantum information' might have begun to appear in print? It's in Peres and Wootters' 1991 PRL, anything earlier do you think?*

Good question! I wish I knew the answer. Looking through my own database, the earliest paper I could find with "Quantum Information" in the title was:

- Masanori Ohya, "On Compound State and Mutual Information in Quantum Information Theory," *IEEE Transactions on Information Theory*, **IT-29**(5), 770–774 (1983).

But I also seemed to recall an early paper by Roman Ingarden titled "Quantum Information Theory". So I Googled it and found a nice paper by Barbara Terhal that references it. It was a 1976 paper. (Barbara's paper is on `quant-ph`, titled "Is Entanglement Monogamous?") As Barbara stresses though, what those people (as well as Holevo) were concerned with in the early days was using quantum states and quantum channels for transmitting classical information.

The idea of transmitting quantum states for the sheer beauty of sending intact quantum states was something that only arose with the Bennett, Schumacher, Wootters club. I wonder if maybe the phrase appeared in Ben's PhD thesis:

- Benjamin Wade Schumacher, *Communication, Correlation and Complementarity*, Ph.D. thesis, The University of Texas at Austin, 1990.

The word "qubit," by the way, was invented by Schumacher. And, as opposed to what Artur Ekert's webpage says, I believe it was in a private conversation between Schumacher and Wootters somewhere in New England, not at the Broadway meeting in the UK.

Maybe I'll check with Schumacher and Wootters on these things.

Timpsonism 2: *Enjoy the Seven Pines, I believe Jeremy B and Olly Pooley are going.*

I didn't know Jeremy would be there! That's great. Even more fun now. (Don't know the other fellow though.)

28-04-04 *Quantum History* (to B. W. Schumacher & W. K. Wootters)

Since I'm turning into the amateur historian of the field, could I get either or both of you to record your earliest recollections of the words "qubit" and "quantum information"?

I know that Ben produced "qubit," but where and when? (Ekert has a webpage that says the word was coined at the Broadway meeting in 1993, but I thought it came earlier than that.)

Concerning the idea of calling a quantum state "quantum information," where did that come from? Do either of you know?

Ben's Reply

OK, here is the whole story as I remember it. I'm not sure that I've ever written it down.

In the spring of 1990 at the Santa Fe Institute, Bill (Wootters) and I discussed the idea that, by using suitable code words and decoding observables, you could reach the Holevo bound for classical information transfer over a quantum channel. I don't think I knew that Holevo had previously conjectured this; Bill will have to speak for himself. We worked on this for a couple of years. The problem proved to be horribly difficult.

In 1991–92 I had a student named Eric Nielsen who was doing a senior honors project on Maxwell's demon. I arranged to have Bill come to Kenyon for a couple of days in May of 1992 as an "outside examiner" for Eric. He did, and we also spent a day or two trying everything we could think of to find our way into the Holevo capacity problem. We didn't get anywhere.

After a couple of years of struggling with the problem, I was pretty discouraged. I drove Bill back to the airport in Columbus, which takes about an hour. As often happens when nothing is working, the talk turned a little crazy. Maybe, we said, we are asking the wrong questions. Maybe in quantum mechanics, the old ideas of information are just not appropriate. Maybe we need a new idea of "quantum information". And we could measure it in "qubits"! The idea of measuring something in "qubits" (like Noah's ark) struck us as immensely funny, and we laughed a good deal.

(Who made the joke? Honestly, I do not remember for sure. I think that I was the one who made the "quantum information" remark, but the joke sounds like Bill. Don't know, though.)

Then I dropped Bill off at the airport and drove back. During the drive back, I started thinking about our joke. It occurred to me that it was not a bad idea, actually. I understood several things immediately – such as the fact that "quantum coding" could not be a copying process because of the no-cloning theorem, and the fact that the qubit would be a generic two-level system. When I got back to Gambier, I spent the summer cooking up the data compression theorem.

Interestingly, I later ran across one of my notebooks from graduate school, circa 1985. I had proved the theorem about typical subspaces then, so this was undoubtedly in the back of my mind somewhere, though I did not remember it and actually proved it a second time. (I think it is also implicit in Ohya and Petz, but their book did not come out till 1993, I think, and I did not read that till much later.) What was new in 1992 was the physical picture.

This was first presented at the IEEE meeting on the Physics of Computation in Dallas in October of 1992. This was about a 12-minute talk, as I recall, so it went by pretty quick. But Charlie Bennett was in the audience and thought that "qubits" were cool. (I knew Charlie from previous meetings in various locales. He had explained superdense coding to me in the fall of 1991 in Spain.)

At the time, I definitely talked about quantum information as a distinct concept – in fact, the paragraph at the end of my 1995 data compression paper (which was written in 1993) is pretty much a verbatim quotation of end of my 1992 talk – a paragraph I had carefully composed in advance to put my idea across in the brief time I had in Dallas. I was quite consciously suggesting that there was a new field to be explored.

The Broadway meeting in 1993 was undoubtedly when lots of people who cared heard about this, and when Richard Jozsa made his suggestion for improving the proof. I think that my talk in Broadway tracked the Dallas talk closely, except for being longer.

BTW, I never considered another spelling for "qubit". So what Mermin says is "orthographically preposterous" seemed obvious to me.

Later, of course, we returned to the Holevo capacity problem and were more successful, thanks to Bill's persistence and a few tidbits from the data compression paper. So the story has a very happy ending.

So the whole thing started for me more or less as a really funny joke. There's a moral there somewhere. I will be interested to hear if Bill's recollection matches mine.

Bill's Reply

Ben's recollections sound entirely right to me. In the course of our discussion in the car, Ben suggested that maybe we needed to think about a new kind of information that is fundamentally quantum mechanical. And I remember very clearly that he is the one who came up with "qubit" as a unit of this information. "And we could measure it in qubits!" were very likely his exact words, including the exclamation point!

29-04-04 *More Reading* (to G. Musser)

I'm at the Dublin airport waiting for my departure, but I've got a moment to write.

Musserism 1: *I've been reading your "only a little more" paper, actually. I do not pretend to understand all, or much, of it, but it is fascinating, and engagingly written. It almost seems that the role of information theory is not to explain the quantum per se, but to peel away the subjective aspects of the theory and see whether some ontological nugget remains.*

Thanks, I'm flattered. And, yep, that's it. Here's the way I put it in a recent proposal:

> Quantum Foundations in the Light of Quantum Information.
>
> Nothing has done more to revitalize the idea that quantum mechanics can be understood at a deep intuitive level—with the concomitant benefits to physics this could bring—than the development of quantum information. There is a reason for this. Quantum mechanics is predominantly about information—plain, ordinary Shannon information or uncertainty. Embracing this idea is the starting point of my research program.
>
> But it is not the end point: No physicist would be doing his job if he did not strive to map reality itself—that is, reality as it is independently of any information processing agents. The issue is one of separating the wheat from the chaff: Quantum mechanics may be predominantly about information, but it cannot ONLY be about information. Which part is which? The usual way of formulating the theory is a thoroughly mixed soup of physical and informational ingredients.
>
> This is where quantum information (including the collateral fields of quantum cryptography, computing, and communication theory) has a unique role to play. Its tasks and protocols naturally isolate the parts of quantum theory that should be given the most foundational scrutiny. "Is such and such effect due simply to a quantum state being a state of information rather than a state of nature, or is it due to the deeper issue of what the information is about?" Recent investigations by several workers are starting to show that many of the previously-thought 'fantastic' phenomena of quantum information—like quantum teleportation, the no-cloning theorem, superdense coding, and nonlocality without entanglement—come about simply because of the epistemic nature of the quantum state. On the other hand, other phenomena, such as the potential computational speed-up of quantum computing, seem to come from a more physical source: In particular, the answer to the question, "Information about what?"
>
> When we finally delineate a satisfying answer to this, physics will reach a profound juncture. We will for the first time see the exact nature of 'quantum reality' and know what to do with it to achieve the next great stage of physics. Trickle-down effects could be the solution to the black-hole information paradox—perhaps already seen in broad outline—and even the meshing together of quantum theory and gravitational physics. In the meantime the approach proposed here is a conservative and careful one; the work to be done is large. The effort aims not to say first what 'quantum reality' is, but what it is not and gather insights all along the way.

Anyway, you know what you're talking about: You got the central idea.

Maybe I could recommend another thing you might enjoy reading (at least parts of): a paper of mine titled, "The Anti-Växjö Interpretation of Quantum Mechanics," `quant-ph/0204146`. Particularly I'm thinking of the two ending sections (built from letters to Preskill and to Wootters); ignore the other parts. They try to build a picture of quantum theory as a "theory from the inside."

In addition to that, let me give what I think is my present best compact description of the idea. It comes from a paper Schack and I posted on `quant-ph` a couple of days ago:

> Is there something in nature even when there are no observers or agents about? At the practical level, it would seem hard to deny this, and neither of the authors wish to be viewed as doing so. The world persists without the observer—there is no doubt in either of our minds about that. But then, does that require that two of the most celebrated elements (namely, quantum states and operations) in quantum theory—our best, most all-encompassing scientific theory to date—must be viewed as objective, agent-independent constructs? There is no reason to do so, we say. In fact, we think there is everything to be gained from carefully delineating which part of the structure of quantum theory is about the world and which part is about the agent's interface with the world.
>
> From this perspective, much—*but not all*—of quantum mechanics is about disciplined uncertainty accounting, just as is Bayesian probability in general. Bernardo and Smith write this of Bayesian theory,
>
> > What is the nature and scope of Bayesian Statistics … ?
> >
> > Bayesian Statistics offers a rationalist theory of personalistic beliefs in contexts of uncertainty, with the central aim of characterising how an individual should act in order to avoid certain kinds of undesirable behavioural inconsistencies. The theory establishes that expected utility maximization provides the basis for rational decision making and that Bayes' theorem provides the key to the ways in which beliefs should fit together in the light of changing evidence. The goal, in effect, is to establish rules and procedures for individuals concerned with disciplined uncertainty accounting. The theory is not descriptive, in the sense of claiming to model actual behaviour. Rather, it is prescriptive, in the sense of saying "if you wish to avoid the possibility of these undesirable consequences you must act in the following way.
>
> In fact, one might go further and say of quantum theory, that in those cases where it is not just Bayesian probability theory full stop, it is a theory of stimulation and response. The agent, through the process of quantum measurement stimulates the world external to himself. The world, in return, stimulates a response in the agent that is quantified by a change in his beliefs—i.e., by a change from a prior to a posterior quantum state. Somewhere in the structure of those belief changes lies quantum theory's most direct statement about what we believe of the world as it is without agents.

Finally, for more on the "golden nuggets," have a look at another new paper of mine (just the intro and conclusions): "On the Quantmness of a Hilbert Space," `quant-ph/0404122`.

I'll write more about arranging a discussion once I'm in the States. Gotta run now.

Musserism 2: *We should get you to write for us someday!*

Never thought of that. But now that you mention it, if *Scientific American* would ever like an article on "progress in information-based interpretations of quantum mechanics" or an article on "Being Bayesian in a Quantum World," let me know and I'll drop everything else (well, almost) to get it done.

I'll be back in less than 48 hours.

29-04-04 *Turgidity* (to H. M. Wiseman)

> **turgid** (tûr'jîd) adjective
> 1. Excessively ornate or complex in style or language; grandiloquent.
> 2. Swollen or distended, as from a fluid; bloated.

Which definition?

Wisemanism 33 : *I read the footnote and it seemed clear enough. However the last sentence was a bit turgid: Somewhere in the structure of those belief changes lies quantum theory's most direct statement about what we believe of the world as it is without agents.*

Just to pick this sentence apart, you have a theory of our beliefs about the world (quantum mechanics) making a statement about our beliefs about the world. Is this circular, or are we talking about different sorts of beliefs? Or maybe in the "what we believe of the world as it is", "we" is the authors of this paper. In this case I suggest it would be much punchier if you replaced the above phrase by "the world".

Lovely that you say that! After I wrote the said passage for our paper, I wrote to Rüdiger:

> I'm pretty pliable with a lot of the writing. But I've got to admit I'm pretty proud of the first two and the last two pages (before references, that is). So I'll pray that you spare the knife on those, especially on the concluding remarks—my pride-and-joys. In the words of John Wheeler at his 83rd birthday conference, "Give the old man his firecrackers!"

To which he replied:

> I am surprisingly happy with your intro and conclusion. Just one thing. The paradox in the penultimate sentence in the Concluding Remarks, starting "Somewhere. . . ", is clearly intended. I am not too sure it makes sense, though. I am not sure at the moment if I really believe this sentence.

Yes, I was intentionally slightly mystical with that sentence: I like to end my papers that way—probably a bad habit, but I have this secret dream that it'll help draw people into the program if the whole thing doesn't look too dry. Have a look at the introductory and concluding sections of my paper "On the Quantumness of a Hilbert Space" (just posted a few days ago). They're maybe my most mystical passages yet . . . or at least I hope so!! (If they're not, I've really been fooling myself!)

However, you do point out an ambiguity that I had not intended. By "we" I meant "we physicists," or maybe more particularly the community of those physicists who wish to squeeze some statement about (our beliefs about) reality out of quantum mechanics—not "we authors." Being something of a budding pragmatist (in the philosophical sense), I have to add for myself the reminder that *at best* a physical theory is always a statement of belief about reality. In its own way it is a gambling commitment. That's why I wrote "about what we believe of the world as it is without agents" rather than simply "about the world as it is without agents" (i.e., more along the lines of your suggestion).

Beyond that, however, you were right that I was talking of two different sorts of belief in the sentence. One can talk about accepting a quantum state ρ and one can talk about accepting the very structure of quantum theory. In both cases, I would say, one is accepting a state of belief. However the objects of those beliefs are very different. In the first case, I would say one is not at all accepting a belief about reality as it exists independently of the agent. The quantum state, for me, is only my state of belief about how nature will react back upon me consequent to one of my potential stimulations upon it. On the other hand, accepting the very structure of quantum theory is—I am banking—a hidden statement of what we believe of nature as it is without agents. There is a hierarchy here: At one level we cannot get rid of the agent in any convincing way, at the other level we might be able to. That's the idea. Finally, the question is how to unlock the hidden statement. I am banking that the best place to look is in the structure of how the former types of belief (i.e., quantum states) are changed consequent to the acquisition of a measurement outcome. (I.e., in the deviation from Bayes' rule encoded by the Kraus collapse rules.)

Hope that was worth reading. (Now I return back down to 35,000 feet where the airplane is situated.)

29-04-04 *Ontic Elements for Quantum Systems* (to H. Atmanspacher)

Thanks once again for your hospitality during my visit to IGPP. And more than that, thanks for sending me your paper with Primas, "Epistemic and Ontic Quantum Realities." I finally got a chance to give it a go today. (I'm flying to the States as I write this. It's a 10 day visit, three separate meetings, so I plan to have a few good days to let your ideas rattle around in my head before I have to return to my more usual world.)

You know of course how committed I am to making the ontic/epistemic split absolutely clear within quantum theory. And I am very happy that it looks like (at least in some instances) we would be compelled to make the split at the same place. For instance, for me, as for you, a density operator should be classified as an epistemic element. (A radical Bayesian about probability must go further—as Schack and I argue in our latest paper on `quant-ph`—and also classify quantum operations (i.e., quantum channels) as epistemic, but that is not so important to me at the moment.)

What I am having difficulty understanding on this first reading, however, is what you are taking to be the ontic elements within quantum theory? What is a quantum system's "mode of being at a given instant" (as you say)? In my own case, the only thing I am willing to relegate to the ontic realm (at this stage in my thought) is the quantum system's Hilbert-space dimension (in the finite-dimensional case)—it signifies something about the system's "sensitivity to the touch". (See my new paper, "On the Quantumness of a Hilbert Space," `quant-ph/0404122`, to make that remark maybe epsilon clearer.) Maybe I would be willing to relegate more than stark dimensionality to the ontic realm upon further reflection (and maybe that's where your paper will lead me), but that's where I stand at the moment.

In the hope of making some intellectual progress on these issues during this week of freedom, could I ask you to drop the C^* language for the moment and consider a very simple case so that I might see how your view fares with regard to my pre-established prejudices. Consider a simple qubit or qutrit, i.e., a 2-state or 3-state quantum system. What would you identify as the potential ontic states for those systems. Can you identify them in Hilbert-space language for me? What are such a system's properties? I should be in email contact almost every day despite my travels; if you could answer these questions in a language that I can hope to understand quickly, that would be most helpful for getting the ball rolling.

After that, I can see there may be some disagreements between the two of us that may not be so easily erasable. But I think that is at a further step down the line and we shouldn't quite go there yet. (For instance, I am thinking of your invoking systems with infinite degrees of freedom for a "solution" to the measurement problem. In my own mind, recognizing that quantum states are epistemic already DISsolves the measurement problem enough. That was part of the picture I tried to present when I spoke at your institute.)

On the other hand, I was very much intrigued by your idea of relative onticity. Something feels very right about that, and I can see myself plunging into the idea and trying to adapt it to my own purposes.

Thus I hope you can see that my respect for your work is very strong. There are points to be hammered out, but I am definitely adding your thoughts to my toolbox.

02-05-04 *Precision* (to A. Wilce)

Do you still remember the precise quote of what David Albert said at the end of my talk? If you do, I'd like to get it recorded into my records.

Alex's Reply

> "I think we can pretty exactly quantify the interpretational progress made here – and it's zero."

06-05-04 *SIC-POVMs* (to F. E. Schroeck)

Schroeckism 1: *I was reading "On the Quantumness of a Hilbert Space" (given to me by Stan Gudder) and I wanted to look up Carlton Caves' paper "Symmetric Informationally Complete POVMs". It wasn't online. In particular, I wanted to know why the factor* $1/(d+1)$ *occurs in your eqn 15. Can you give me either a hint, or Cave's e-mail address (or both)?*

By the way, the first half of the paper is great, and the other half is to be read.

Wow, thanks!

It's a simple consequence of the definition of a SIC-POVM. The definition is that the POVM consists of d^2 rank-1 elements, all of equal trace, and such that the pairwise inner products of nonindentical elements are constant.

Using the fact that the d^2 elements form a resolution of the identity, and taking the trace of the identity, you get that the trace of each element must be $1/d$.

Now to get the values of the pairwise inner products, you just square the identity (and consequently square the resolution of the identity) and pull the same trick: Namely taking the trace of the consequent.

Hope that makes it clear enough.

I'm kind of surprised you couldn't find Carl's notes at his webpage, but maybe he removed them.

06-05-04 *Section 4.1* (to W. G. Demopoulos)

I'm on the plane now. I guess, at this stage, I don't have much to add to what I wrote you earlier after all. The "snowflakes" bit captures most of what I had wanted to say. The only other thing I can recommend to have a look at is Section 4.1 (trying to justify noncontextuality for our probability assignments in QM) in `quant-ph/0205039` (i.e., "QM as QI (and only a little more)"). I'll be curious to know how that argument meshes with your own.

What I would like to go into further eventually is the similarity and differences between 1) your point of view of the underlying events in QM as being preexistent (but maybe unique) realities, and 2) my point of view that they are best supposed as (unique) creations. I also get the feeling that your view collides with another one of my favorite doctrines: Namely, that we should take POVMs as just as basic as standard quantum measurements (because they so prettily match Bayes' rule). But I'll have to think about that.

06-05-04 *Middle of the Meeting* (to A. Peres)

Asherism 67: *I finished to read (many parts of)* No time to be brief*, Pauli's biography by Enz. The book is overcomplete, with plenty of irrelevant gossip on other physicists. Yet, there are many interesting things in it. I never imagined that Pauli had such a tortured soul and needed help from Jung and similar crooks. Why did you call your future book* Notes on a Paulian idea*?*

Because most of the notes in there were deeply influenced by the collection of Pauli's more-philosophical papers *Writings on Physics and Philosophy* that I had read in 1995. Also the letters from Pauli to Fierz (that I had found in one of Laurikainen's books) made a similar effect.

Anyway, in particular, the phrase "Paulian idea" is meant to capture the two explicit quotes of Pauli's that I placed at the very beginning of the book.

I agree with your remark about Jung. I had a fun time recently reading the Jung/Pauli correspondence volume. There was a lot of trash from both sides, but on the other hand, at least there were several letters on Pauli's side that were quite interesting—and said, I think, some deep physics. But with regard to Jung's side of the conversation, I really could not make heads from tails—I think it was very likely total nonsense.

Now I should probably return to listening in on the present talk.

11-05-04 *The Late, Late, Late Show* (to A. Sudbery)

I'm at it again with my 'samizdatery': I put together a little collection of emails that may be relevant for a meeting on the philosophy and history of science I'm attending next week.

There is one little bit of new stuff in the paper that you may not have seen before (or at least a combination of words that you may not have seen before): Footnote #2 on page 7. I dream that I might have finally hit the sweet spot of clarity with those words, but I probably haven't.

Sudberyism 12: *The footnote on p. 7 is very clear, though I personally have problems with the notion that quantum mechanics is all about your (my, our) interventions in the world and its response. I know that's what the textbooks say – you only get a prediction for the result of a measurement – but I don't think that's an accurate description of the theory (as it actually exists in the practice of working scientists).*

You mean after all this technical work (of mine and so many others), and all my attempts to find the best English yet to tell the story (of "measurement" ... better yet "intervention" ... or still better "stimulation"), I still haven't gotten any further than what the textbooks say?

One more round, Delia's gone, one more round. ☺

Sudberyism 13: *I was sorry not to get to the LSE meeting on probability. Was it good? Lots of elevated blood pressure? You know about our Foundations meeting in York in September, don't you? No invited speakers, just a free-for-all. I'd like to incorporate a round table or two, maybe one on Everettism and one on Bayesianism, or even just one on both, face to face.*

Yeah, the LSE meeting was pretty good. I enjoyed it. And even more than that I enjoyed sparring with Butterfield, Saunders, Brown, and a few others in Oxford afterward.

I didn't know about the September meeting. Is there a website? I ought to try to come to that if I can.

12-05-04 *Pragmatism, Quantum, Bayes, and pragmatism (no capital)* (to J. Woodward)

I had a look at your profile on your Caltech webpage this morning, and then I worked my way to your Stanford Encyclopedia article. It was a nice experience reading parts of it—I'll give it a more serious consideration over the next couple of days—for it looks like there is some real overlap in our concerns. In particular, one might almost describe what I'm shooting for in rewriting the notion of quantum measurement is something like a manipulationist account of it. In place of "measurement", I think it is firmer ground to think of a quantum measurement click as a system's *response* to an external intervention ... that is, rather than think of it as the *revelation* of some pre-existent value. My latest ways of putting these things are detailed in "Delirium Quantum", particularly in the section "Me, Me, Me". Also, there's plenty to read about it scattered throughout my book *Notes on a Paulian Idea* (I gave Jed a copy that you can borrow, or I can have one sent to you), for instance on pages 394 or 509–510. What I have written is surely cloudy thinking in comparison to your corpus, but maybe it's enough to show that my heart is in the right place and that our interactions could be mutually beneficial.

Anyway, that's just a taste of things, and an attempt to put all the issues on the table.

12-05-04 *Does Hilbert-Space Dimension Gravitate?* (to J. Preskill)

Preskillism 10: *In my view, you were the most cogent of the "philosophers" I talked to in Stillwater.*

That's because I'm a physicist in disguise.

"Philosophy is too important to leave to the philosophers." – J.A.W.

13-05-04 *Epistemic Pure States* (to H. Atmanspacher)

Thanks for the note. I apologize for not getting back to you sooner, but the conferences I was at knocked me for more of a loop than I had expected. I'm still recovering, and now my backlog of tardy work is piled even higher!

Let me just say a very short word at the moment. With your note and the attached paper, you confirmed what I feared: That you take a pure quantum state to be an ontic state. This contrasts with our Bayesian approach where all quantum states (pure or mixed) are epistemic.

Let me attach two papers and one pseudo-paper that say something about this approach. One paper is one of my own with Schack which talks about a Bayesian view of quantum states in general. The other is due to Rob Spekkens. In it, he gives the most compelling case I've ever seen that pure quantum states should be viewed epistemically. He does this by getting to the core of the matter in a toy model (that is not quantum mechanics). His model lacks a lot—for instance, his observers are still detached in that it is a hidden variable model—but I still think it is a strong argument for the epistemicity of the quantum state. Finally the pseudo-paper is something I threw together for the

Seven Pines meeting in Minnesota. The relevant sections are the last two, "Me, Me, Me" and "The Big IF". What they try to give a hint of is a view in which quantum theory is not taken so much as a "theory of the world," but rather as a theory of decision-making for agents *immersed* in and *interactive* with the quantum world. Making that change in point of view is a crucial component in what we are after.

Atmanspacherism 1: *It could be that this provides a bridge between your and our approaches. In my view and Primas', there is no absolutely ontic description anyway (one cannot even speak without a context). In this sense, our ontic states are already relative to a context which, however, is unspecified.*

I hope so. I will think about it.

13-05-04 *10 Lines and MaxEnt* (to R. Schack)

One of the meetings I'm back from is the Seven Pines meeting in Minnesota. A few philosophers were there including John Earman and a guy named Geoffrey Hellman (a student of Hilary Putnam's). In Hellman's (short) talk, he briefly mentioned that the interpretation of probability was important for quantum foundational issues. He mentioned frequency interpretations, propensity interpretations, and our approach. He very nicely complimented us by calling it a "radical move" (though of course, in private, he said that he didn't believe that it could be the "right move"). Earman said in one of our discussion sessions: "You mean $\psi^*\psi$ as a Bayesian degree of belief? Could not be."

So it goes: Even the Bayesians won't believe us!

13-05-04 *LNP Volume* (to M. G. A. Paris)

Just use the abstract we already wrote. It's only six sentences:

> The classical de Finetti theorem provides an operational definition of the concept of an unknown probability in Bayesian probability theory, where probabilities are taken to be degrees of belief instead of objective states of nature. In this paper, we motivate and review two results that generalize de Finetti's theorem to the quantum mechanical setting: Namely a de Finetti theorem for quantum states and a de Finetti theorem for quantum operations. The quantum-state theorem, in a closely analogous fashion to the original de Finetti theorem, deals with exchangeable density-operator assignments and provides an operational definition of the concept of an "unknown quantum state" in quantum-state tomography. Similarly, the quantum-operation theorem gives an operational definition of an "unknown quantum operation" in quantum-process tomography. These results are especially important for a Bayesian interpretation of quantum mechanics, where quantum states and (at least some) quantum operations are taken to be states of belief rather than states of nature.

17-05-04 *Big Bang 1910* (to G. L. Comer)

The following passage comes from William James's posthumous book, *Some Problems of Philosophy*—started in March 1909 and worked upon until his death in August 1910.

> It is a common belief that all particular beings have one origin and source, either in God, or in atoms all equally old. There is no real novelty, it is believed, in the universe, the new things that appear having either been eternally prefigured in the absolute, or being results of the same *primordia rerum*, atoms, or monads, getting into new mixtures. But the question of being is so obscure anyhow, that whether realities have burst into existence all at once, by a single 'bang,' as it were; or whether they came piecemeal, and have different ages (so that real novelties may be leaking into our universe all the time), may here be left an open question, though it is undoubtedly intellectually economical to suppose that all things are equally old, and that no novelties leak in.

17-05-04 *Jamesian Exchangeability* (to R. Schack)

[[The quote below comes from William James's book *Some Problems of Philosophy*. There was no further text in this note beyond the quote.]]

> A concept, it was said above, means always the same thing: Change means always change, white always white, a circle always a circle. On this self-sameness of conceptual objects the static and 'eternal' character of our systems of ideal truth is based; for a relation, once perceived to obtain, must obtain always, between terms that do not alter. But many persons find difficulty in admitting that a concept used in different contexts can be intrinsically the same. When we call both snow and paper 'white' it is supposed by these thinkers that there must be two predicates in the field. As James Mill says: 'Every colour is an individual colour, every size is an individual size, every shape is an individual shape. But things have no individual colour in common, no individual shape in common; no individual size in common; that is to say, they have neither shape, colour, nor size in common. What, then, is it which they have in common which the mind can take into view? Those who affirmed that it was something, could by no means tell. They substituted words for things; using vague and mystical phrases, which, when examined, meant nothing.' The truth, according to this nominalist author, is that the only thing that can be possessed in common by two objects is the same *name*. Black in the coat and black in the shoe are the same in so far forth as both shoe and coat are called black—the fact that on this view the name can never twice be the 'same' being quite overlooked. What now does the concept 'same' signify? Applying, as usual, the pragmatic rule, we find that when we call two objects the same we mean either (a) that no difference can be found between them when compared, or (b) that we can substitute the one for the other in certain operations without changing the result. If we are to discuss sameness profitably we must bear these pragmatic meanings in mind.
>
> Do then the snow and the paper show no difference in color? And can we use them indifferently in operations? They may certainly replace each other for reflecting light, or be used indifferently as backgrounds to set off anything dark, or serve as equally good samples of what the word 'white' signifies. But the snow may be dirty, and the paper pinkish or yellowish without ceasing to be called 'white'; or both snow and paper in one light may differ from their own selves in another and still be 'white,'—so the no-difference criterion seems to be at fault. This physical difficulty (which all house painters know) of matching two tints so exactly as to show no difference seems to be the sort of fact that nominalists have in mind when they say that our ideal meanings are never twice the same. Must we therefore admit that such a concept as 'white' can never keep exactly the same meaning?

It would be absurd to say so, for we know that under all the modifications wrought by changing light, dirt, impurity in pigment, etc., there is an element of color-quality, different from other color-qualities, which we mean that our word *shall* inalterably signify. The impossibility of isolating and fixing this quality physically is irrelevant, so long as we can isolate and fix it mentally, and decide that whenever we say 'white,' that identical quality, whether applied rightly or wrongly, is what we shall be held to mean. Our meanings can be the same as often as we intend to have them so, quite irrespective of whether what is meant be a physical possibility or not. Half the ideas we make use of are of impossible or problematic things,—zeros, infinites, fourth dimensions, limits of ideal perfection, forces, relations sundered from their terms, or terms defined only conceptually, by their relations to other terms which may be equally fictitious. 'White' means a color quality of which the mind appoints the standard, and which it can decree to be there under all physical disguises. *That* white is always the same white. What sense can there be in insisting that although we ourselves have fixed it as the same, it cannot be the same twice over? It works perfectly for us on the supposition that it is there self-identically; so the nominalist doctrine is false of things of that conceptual sort, and true only of things in the perceptual flux.

What I am affirming here is the platonic doctrine that concepts are singulars, that concept-stuff is inalterable, and that physical realities are constituted by the various concept-stuffs of which they 'partake.' It is known as 'logical realism' in the history of philosophy; and has usually been more favored by rationalistic than by empiricist minds. For rationalism, concept-stuff is primordial and perceptual things are secondary in nature. The present book, which treats concrete percepts as primordial and concepts as of secondary origin, may be regarded as somewhat eccentric in its attempt to combine logical realism with an otherwise empiricist mode of thought.

18-05-04 *Agents, Interventions, and Surgical Removal* (to J. Woodward)

(I'll drop the "Professor Woodward" bit and act like I know you, now that this is a second contact.)

I had time over the weekend to better digest your Stanford Encyclopedia article, "Causation and Manipulability." Per my first guess, we do indeed use a lot of words in common—intervention, manipulation, agent—though your concern is causation and my concern is the elicitation of "quantum measurement outcomes." As evidence of this, see for instance Section 4 of my paper "Quantum Mechanics as Quantum Information (and only a little more)" posted at my website (link below).

But there are also more than words in common. There is the common concern of exorcising the (anthropomorphic) agent if possible from each of our domains. Can it be done? My suspicion about quantum mechanics is that there is a level at which it can be done and a level of which it can't. Both levels are needed, however, for an explication of what the theory is about.

What I liked in learning from your paper is the similarity of our strategies. (Rüdiger Schack tells me I'm a cherry-picker when it comes to extracting content from papers; sorry if I'm doing that here.) Anyway, the way I see it is we both start from rather firm starting points—though they necessarily involve the notion of an agent—and only then, make a step toward de-anthropomorphizing the picture. In your case, it's to start with a manipulationist account of causation and then to move to an interventionist one. The ultimate goal is to talk of causes in a way that makes no reference to human action.

In my case, I try first to make sense of a quantum measurement outcome as a birthy sort of event that happens when two pieces of the world metaphorically bump into each other *in the case that* one of the pieces is an active agent (who is equipped with subjective probabilities, etc., etc.). Of course, after that I'd like to go the next step—to imbed these anthropocentric "births" in a larger account of a world in continuous creation, in analogy to your strategy of imbedding humanly manipulations within a larger (de-anthropocentrized) interventionist account. At present, I only have a glimpse of how to do that. About the only thing I feel confident of is that, if it's going to be done, the project is going to have to be carried out in a relatively oblique manner—namely, one that stops talking about the births themselves and transfers attention to systems' capacities to take part in these kinds of mini-creations. (This is the stuff I call "Zing!" in footnote 10 of the paper mentioned above.)

Why must the strategy be oblique? Your paper gave me a nice metaphor for that:

> Human beings cannot at present alter the attractive force exerted by the moon on the tides (e.g., by altering its orbit). More interestingly, it may well be that there is no physically possible process that will meet the conditions for an intervention on the moon's position with respect to the tides – all possible processes that would alter the gravitational force exerted by the moon may be insufficiently "surgical". For example, it may very well be that any possible process that alters the position of the moon by altering the position of some other massive object will have an independent impact on the tides in violation of condition (M2) for an intervention.

You see, as opposed to classical gravitational phenomena, I believe quantum mechanics puts us in a new situation. The world appears to be wired together so intricately that every attempt to extricate or "surgically remove" the agent from the quantum measurement process leaves a conceptually empty structure (I'm thinking of Everettian and Bohmian quantum mechanics, etc., here). What quantum mechanics is mostly about is making-do in light of that.

That's on the negative side of things. On the positive side of things, knowing that the world is made of a "stuff" that causes us to "make-do" in this way is something I find tremendously exciting. I.e., it's not the making-do that's exciting, but the stuff that gives rise to it that is. This is because I think it leads to a far more interesting and creative world than we might have imagined otherwise. In the next note, I'll attach a historical/philosophical document I've been working on that tries to convey some of this. The title is, "The Activating Observer: Resource Material for a Paulian-Wheelerish Conception of Nature," and it's fairly large (922K) ... so don't get frightened that something has gone wrong with your email. The thing is still far from complete, but I hope it conveys a flavor of the kinds of thoughts I'm up to in my most philosophical moments.

How do I live with such a crucial piece of quantum theory (and the next stage of physics it hints at) being so anthropocentric? Here's the way I put it in that document: "Observers, a necessary part of reality? No. But do they tend to change things once they are on the scene? Yes. If quantum mechanics can tell us something deep about nature, I think it is that." And it is that idea that I'm working my tail off to formalize.

Anyway, a long letter just to say I got a lot out of reading your paper and to reiterate that I think we have plenty of potential for fruitful interaction. [For instance—on a different subject—my radically Bayesian nose smells the agent remaining, despite your efforts, in your account of nondeterministic causation (right after equation CD). That is because, for such a Bayesian, the probabilities in the difference you consider still make crucial reference to an agent for their very existence.]

18-05-04 *Striving for Consistency* (to A. Grinbaum)

Grinbaumism 1: *I am still thinking what to respond to your* quant-ph/0404122*. Frankly, I was slightly unhappy to read that "sensitivity to the touch" means "ability to be modified with respect to the external world due to the interventions of that world upon its natural course". This sounds so realist, and the sentence is so different from the rest of your article. I know that you had acknowledged that the dimension of the Hilbert space is for you the only remaining element of physical reality, but I certainly see no need to come to realism from "sensitivity to the touch". Why put accent on touch rather than sensitivity?*

You are right about that, and the only thing I can do for the moment is plead guilty. I strive for consistency, but I don't always achieve it—worse yet, sometimes my repertoire for proper expression runs limp. (You'll see in the first letter below how I made fun of myself on just this issue.) [See 21-04-04 note "Essential Incompleteness" to W. G. Demopoulos.]

Anyway, let me try to make up for it—or make the matters worse!, I don't know which—by sending you some further expressions of what I'm trying to get at. For one thing, see the attached pseudo-paper (which I haven't yet decided whether I will submit it to the archive or not, your vote would count). [See "Delirium Quantum" arXiv:0906.1968v1.] For another, see the further letter below that I wrote to Jim Woodward this morning. [See 18-05-04 note "Agents, Interventions, and Surgical Removal" to J. Woodward.]

To answer your question, it's very unlikely that I'll be in Europe in the Autumn. I'm now scheduled to return to Bell Labs in mid-August, and the Fall is likely to be a quite hectic time with us getting settled into our new house, etc. Sorry; I would have liked to have been at your defense. But I know you'll do well.

Glad you enjoyed Dublin.

19-05-04 *The Barbecue Quest* (to G. Musser)

Sorry for the slow reply.

Musserism 3: *To follow up our conversation regarding entanglement, I looked at the "Wither Entanglement" section of* quant-ph/0205039*. If I follow, the idea that entanglement is a statement about our knowledge, rather than about a system, is demonstrated by the derivation of the tensor-product rule. What is the physical meaning of that rule?*

I'm not sure what to say beyond what I said in the paper. The point is simply that the tensor-product rule for generating a Hilbert space to describe composite systems is a consequence of a) the structure of localized quantum measurements, augmented solely with b) classical, subluminal communication between observers at each site.

Maybe I should put the point this way: If one is looking for a mystery in quantum mechanics, one need look no further the structure of (local) measurements on single systems. That's where the real mystery is. Why is the structure of quantum measurements such that it can power a Kochen-Specker no-coloring theorem? If we had a stick-to-your-ribs answer for that, I think we'd finally be at the end of the quest.

Musserism 4: *I was also told to think of QM as nondeterminstic. More recently I was told (cf. John Earman), no, it is completely deterministic, because the Schrödinger equation uniquely maps a wave function at t_0 to another at t_1. Now Griffiths tells me to think of it as nondeterministic* *again: "The successive events of a history are, in general, not related to one another through the Schrödinger equation." Help.*

I'm sure all three of us have very different reasons for saying what we say. Here's the way I would put it. You cannot forget the distinction between a) states of knowledge/expectation/belief, on the one hand, and b) what *is* or what *is happening* in the world, or more particularly what an agent can provoke of it, on the other. Neither has an implication on the other. Quantum time evolution—which is smooth and deterministic—is about how an agent's state of knowledge changes over time. The singular, unpredictable, event-like "measurement outcomes" are about the response an agent's stimulation to a system external to himself will provoke. Those events or responses seem to come out of the blue. It is they that are (among) the real things of the world. The quantum state is just a fancy way of organizing the agent's expectations—thus it is not among the real things of the world. The only time there is a nonsmooth (indeterministic) change in a quantum state is when the agent holding it incorporates a new piece of *data* into his expectations.

I thought I had said this much better in *Notes on a Paulian Idea* somewhere, but if I did, I couldn't find the place with a quick perusal. The closest thing I could find was in the notes surrounding "The Evolution of Thought", pages 163-168 (in my website version). Still, you might get something useful out of reading the note titled "A Non-Randy Non-Bugger" on page 163 nonetheless.

By the way, I had the secretary in Sweden send you a copy of the Växjö University Press cut of *Notes on a Paulian Idea*. (Kluwer is publishing it later this year too.) I hope it doesn't take too long to arrive. The way to treat the book is as bathroom reading (i.e., not systematically)—think of it as a kind of snippet book on information-based interpretations of quantum mechanics. It's main purpose is to inspire. If you want to find my insults on various people, use the name index in the back.

Musserism 5: *If after returning NJ you ever teach a senior-level or first-year graduate-level course in QM, please let me know. I took such a course in grad school but the knowledge evidently has a short exponential decay timescale. I need to work through the math again.*

Flattery. (Thanks.) Better flattery would be to tell me that *Scientific American* wants a full article on this stuff.

19-05-04 *Bathroom Reading* (to P. C. E. Stamp)

Per your request, I just had the secretary in Sweden send you a copy of the Växjö University Press cut of *Notes on a Paulian Idea*. I'm sure I don't need to say it, but the way to treat the book is as bathroom reading (i.e., not systematically, to put it mildly)—think of it as a kind of snippet book on information-based interpretations of quantum mechanics. Its main purpose is to inspire.

Particularly, something relevant to our last conversation (in the wrap-up session) can be found in two notes in the Barnum chapter, titled "It's All About Schmoz" and "New Schmoz Cola". The best part is after Barnumism 5.

The main point I was trying to make to you—when I thought I could do it better than Aspelmeyer—is that in an information-based interpretation of quantum mechanics (like the one Caves, Schack, Mermin, Peres, Hardy, and few others of us are trying to put together) is that: Though we take the wavefunction to be information, we never take it to be information about "what is existent" in the quantum system, or "what is happening in the quantum system." That it cannot be information about something like that is what I take to be the great lesson of the

Bell-Kochen-Specker theorem. Rather it is always information about how a system will *respond* to an external stimulation (i.e., in usual language, a measurement ... but I want to get away from the usual language because it carries the wrong imagery). This is the way to think of it when the wave function is about a single system and the way to think of it when the wave function is about a composite system—it doesn't matter.

So, what I am asking—among other things—is that the notion of "measurement" be replaced with the idea of "stimulation and response." We only use wave functions to calculate our expectations with regard to how a system will respond to one or another of our possible stimulations upon it. In this light, there is no contradiction between an "inside view" of a measurement where an unpredictable click really happens and an "outside view" (encompassing both the original system and the first observer), where a wave function for the composite system undergoes a smooth and deterministic transition. This is because the "outside view" wave function refers again to *nothing more than* the outside observer's expectations for how that composite system will respond to external stimulations upon it.

Hope that helps clarify at least what I was trying to say.

24-05-04 *Admissions* (to H. Mabuchi)

Mabuchism 3: *Did you find time to read the Richard Powers novel I sent you?*

I've got to admit that I haven't read it yet. But because of my upcoming visit, it's hittin' high priority. You should be doubly honored, it'll be the first fiction book I've read in over 10 years. (Unless you think I ought to count David Deutsch's book *The Fabric of Reality* ...)

25-05-04 *Bathroom Reading* (to G. Hellman)

It was good meeting you at the Seven Pines meeting. I was particularly impressed with your fairness, balance, and patience in taking in a wide range of viewpoints. If you could send me some of your "relation without relata" philosophy-of-mathematics papers, I would enjoy reading them. (The best format is to send them electronically if you can, but snail-mail will do as well.)

I just had the secretary in Sweden send you a copy of the Växjö University Press cut of *Notes on a Paulian Idea*. I'm sure I don't need to say it, but the way to treat the book is as bathroom reading (i.e., not systematically, to put it mildly)—think of it as a kind of snippet book on information-based interpretations of quantum mechanics. Its main purpose is to inspire; I hope it fits the bill at least a little. The name index at the back is hopefully a handy way to look up one or another point of view. You might be particularly interested in the early discussions with Jeff Bub.

I intend to write a lengthy note to John Earman to reply to his take, "Psi-star-Psi, a Bayesian degree of belief? Cannot be!", from the wrap-up session. If you're interested, I'll forward it to you too once it's constructed.

25-05-04 *Bathroom Reading* (to A. Duwell)

It was good seeing you again a couple of weeks ago. (Get that paper on `quant-ph`, young man!)

I just had the secretary in Sweden send you a copy of the Växjö University Press cut of *Notes on a Paulian Idea*. I'm sure I don't need to say it, but the way to treat the book is as bathroom reading (i.e., not systematically, to put it mildly)—think of it as a kind of snippet book on information-based interpretations of quantum mechanics. Its main purpose is to inspire. I hope it fits the bill at least a little.

Concerning the little discussion we had on noncontextuality for quantum probability assignments, the section I was talking about was 4.1 in `quant-ph/0205039`. If you have any thoughts on the argument (except for the sentence where I used a little circularity for rhetorical purposes), I'd like to hear them.

Finally, the paper with a discussion on the classical analogue(s) to Schumacher compression that I was telling you about is: `quant-ph/0008024`. Don't know if it's as clear as I remember it to be, but maybe it's a start.

25-05-04 *Bathroom Reading* (to A. J. Leggett)

It was good seeing you again at the Seven Pines workshop. I particularly enjoyed the question you asked me at the end of my talk because I thought it got at the heart of the matter. It is the laboratory procedures that refine our predictability that come first in defining the very notion of the (bad word) "measurement." It is only post facto that a set of operators from the quantum mechanical formalism is associated with such a procedure. Without the idea that knowledge is being refined, somewhere, somehow, the word measurement should never be used.

Anyway, I know you didn't request it, but I decided to have the secretary in Sweden send you a copy of the Växjö University Press cut of my *Notes on a Paulian Idea*, since I was already sending it to several others anyway. I guess if anything, all I really want out of this is to present a convincing case to you that the stance I am taking on the wave-function is not giving up on realism (which is roughly the way you put it). It's the opposite, as I see it—it's just recognizing a spade for a spade and trying to divert our attention to the parts of quantum theory that stand a chance of being realistically construed. I try to make the case in several places in the book, but the parts you might be particularly interested in are the early discussions with David Mermin, Jeff Bub, and Rolf Landauer. Maybe some of the stuff to John Preskill too. (Mermin, by the way, wrote the foreword, if that'll help you get past the first page.)

Regarding the book as a whole, I'm sure I don't need to say it, but the way to treat it is as bathroom reading (i.e., not systematically, to put it mildly)—think of it as a kind of snippet book on information-based interpretations of quantum mechanics. Its main purpose is to inspire if it can. The name index at the back is the best bet for looking up one or another point of view; unfortunately I didn't have a subject index made for the initial publication.

If—in the end—you're interested in any of the more technical results needed to prop up these goals (and there is a lot of technical work to be done), most of my papers can be found at `arXiv.org` in the `quant-ph` listings (`quant-ph/0205039` being the most comprehensive). In the one titled, "Quantum States and Operations, a Bayesian View," you'll find extensive references to everyone else's work along the same lines as well.

25-05-04 *Bathroom Reading* (to M. Janssen)

It was good meeting you at the Seven Pines workshop. I particularly enjoyed the little discussion we had near the end. I learned a lot from what you saw as a difference between Jeff Bub's and my approaches/goals.

I know you didn't request it, but thinking about this, I decided to have the secretary in Sweden send you a copy of the Växjö University Press cut of *Notes on a Paulian Idea*. Anyway, I'm sure I don't need to say it, but the way to treat the book is as bathroom reading (i.e., not systematically, to put it mildly)—think of it as a kind of snippet book on information-based interpretations of quantum mechanics. Its main purpose is to inspire; I hope it fits the bill at least a little. The name index at the back is maybe the best bet to look up one or another point of view; sorry I didn't have a subject index prepared at the time. Anyway, you might be particularly interested in the early discussions with Jeff Bub (which in turn was mostly based on Jeff's reading of the notes to Mermin).

If—in the end—you're interested in any of my more technical results toward these goals, most of my papers can be found at `arXiv.org` in the `quant-ph` listings.

25-05-04 *Cathy and Erwin, the Movie* (to C. G. Timpson)

You're not being dim-witted at all. Instead, thanks for giving me a new opportunity to clarify things still further. I'll take the task seriously if you can wait a day or two for my reply: I want to do it right (certainly righter than before).

The central issue is to never forget that a quantum state is a state of belief *about* how a system will **respond** to an external stimulation. Or better yet—and maybe necessarily so—as I put it in `quant-ph/0404156`, "The agent, through the process of quantum measurement, stimulates the world external to himself. The world, in return, stimulates a response in the agent that is quantified by a change in his beliefs—i.e., by a change from a prior to a posterior quantum state." In particular, the state should never be construed as being about "what is existent" or "what is happening" in the quantum system.

Aside: From this point of view, the quantum system is a "philosopher's stone" that brings about a transformation in the agent. (I just wanted to record that while I was thinking it.)

But anyway, I'll try to say all this more clearly and at length—and particularize it to the context of your two questions—as I get a chance to compose something.

26-05-04 *Rorty, Delirium* (to A. Fine)

Hey, did you know that Richard Rorty calls you his favorite philosopher of science? I read that a while ago, and I've been meaning to tell you. What kind of reaction does it elicit from you? I'm a great fan of some of Rorty's (more tempered) writings. (But I'm a cherry-picker when it comes to papers: I absorb the parts I think I can use, and try to hold no ill will for the parts I simply ignore.)

Anyway, I was thinking of that when I was sending the attached cheerleading paper to a friend yesterday. [See "Delirium Quantum" `arXiv:0906.1968v1`.] (The first and second sections lean heavily on Rorty.) So while you're on my mind, I'll send it to you too. I haven't quite decided whether I'm going to post it yet, or whether it's a little too delirious for the moment.

26-05-04 *Bathroom Reading and Subliminal Suggestions* (to D. Howard)

It was good meeting you at the Seven Pines workshop.

Per your request, I had the secretary in Sweden send you a copy of the Växjö University Press cut of my *Notes on a Paulian Idea* a couple of days ago. It shouldn't take too long to get there. I'm sure I don't need to say it, but the way to treat the book is as bathroom reading (i.e., not systematically, to put it mildly)—think of it more as a kind of snippet book on information-based interpretations of quantum mechanics. Its main purpose is to inspire if it can. The name index at the back is the best thing presently for looking up one or another point of view; unfortunately I didn't have a subject index made for the initial publication. Thinking of our discussions in Minnesota, you might particularly enjoy reading the correspondence with Mermin, Peres, Bub, and Landauer; they're maybe the most relevant things to start off with.

The quote I read aloud after your talk, showing that Pauli clearly understood the concept of entanglement as early as 1927, can be found on page 334 in a note titled "Pauli Understood Entanglement." You'll find the Rosenfeld quote that you're fond of on pages 299–301 in a note titled "How Do I Sleep?"

Concerning the other quotes I promised to send you (from the Bohr-Pauli correspondence), they'll come in the next email in a big attachment—a little over 1MB—titled `PauliProject.pdf`. Let me know if you have any trouble opening the file; if necessary I'll seek another means to send it to you.

Sorry for the delay, but I was tweaking the document and resisted sending it until it found a new plateau of semi-stability. In general the thing is a mess and very, very far from complete. But I haven't given up hope that I might get it posted on `quant-ph` by December. It's mainly a question of getting a load of (pre-marked) material out of my file cabinet and into the computer, and then getting a useful indexing system made. The introduction has a long way to go too, but that pales in comparison to the former task.

Definitely, if you have any suggestions for further materials that I should include in the thing (from your own work or anyone else's), or you catch any typos, please let me know.

26-05-04 *The Pauli Program* (to D. Howard)

I forgot to mention in my last long note a couple of references that might interest you. These concern what you called "The Pauli Program" (I think)—namely, the idea of taking how subsystems combine into composite systems as one of the basic pillars of quantum mechanics.

Two things to read:

1) Lucien Hardy's axiom-system paper. You can find it here: `http://www.arxiv.org/abs/quant-ph/0101012`. Hardy's paper is one of the few—maybe the only one—I can think of where an axiom for combining systems plays such a prominent role. (I would say his system is too positivistic/instrumentalistic for my taste, but nevertheless he makes wonderful mathematical progress.)

2) Section 5, "Wither Entanglement?," of my paper `http://www.arxiv.org/abs/quant-ph/0205039`. There I show how the tensor-product structure can be gotten out of a Gleason-type theorem. It's not clear to me how such a result would fit into a Pauli program—it may be antithetical to it—but it might provide some food for thought nevertheless. I myself certainly remain sympathetic to some aspects of the Pauli program. (You can see by looking at pages 548–554 of the book I'm sending you that I've long had an interest in the idea.)

By the way, don't forget to send me the papers you promised.

27-05-04 *Conflict* (to K. R. Duffy)

The unrelenting external world smites me again: Kiki just told me that Emma's school performance is next Tuesday night. So the Pub is out.

01-06-04 *Bathroom Reading, 2* (to M. Janssen)

Thanks for the great Slater quote. I love collecting things like that.

Thanks also for the encouraging words about our research program. After writing you, I used the same letter as a template and extended it a bit more in writing to Tony Leggett. Let me paste that in below, as it might give you a little more orientation for where to seek out further information (for instance papers by Bub, Hardy, Mermin, Spekkens, etc., that I think are great steps forward in the effort).

Michel's Preply

> For your amusement I quote from a letter of July 27, 1924 from John C. Slater to Minnesota's own John H. Van Vleck with Slater's impression of Copenhagen from which he is just returning (the letter is written as he sails along the coast of New England):
>
>> Don't remember just how much I told you about my stay in Copenhagen. The paper with Bohr and Kramers was got out of the way the first six weeks or so—written entirely by Bohr and Kramers. That was very nearly the only paper that came from the institute at all the time I was there; there seemed to be very little doing. Bohr does very little and is chronically overworked by it. The paper that was all written last Fall still hasn't been revised and printed, and I don't know when it will be. Bohr had to go on several vacations in the spring, and came back worse from each one. Kramers hasn't got much done, either. You perhaps noticed his letter to *Nature* on dispersion; the formulas that he had before I came, although he didn't see the exact application; and except for that he hasn't done anything, so far as I know. They seem to have too much administrative work to do. Even at that, I don't see what they do all the time. Bohr hasn't been teaching at all, Kramers has been giving one or two courses.
>>
>> There were visits from both Pauli and Heisenberg in the course of the spring. I don't know whether you have met either one. Heisenberg is a very nice red haired unassuming young chap, talks a little English, and everybody likes him. Pauli is as different as he could be, a big fat Jew, with a very good opinion of himself and a great liking to hear himself talk. Still, he is a good natured and accommodating person, and well liked.

01-06-04 *Dreams* (to A. Sudbery)

Thanks for keeping me apprised of the Foundations meeting in September. I really feel like I should be there—I want to be there—but I don't think I can get back so soon after my move back to the States. Also there's the little issue that Bell Labs has dried up as far as travel funds are concerned now, and I don't have any other grants.

On a different matter, strangely I had a dream about you the other night. We were, of course, debating quantum foundations. (To set the scene, you had had some more dental work done, so your mouth was bleeding again; I think we were in an empty conference room.) And for some reason in the dream, I thought it was really important for you to read some passages I had scanned into my computer the night before—that is, passages that I had really scanned in, and not just in the dream. I'm not making this up. Anyway, upon waking, I couldn't figure out why it was so all-fired important that you read the passages, but still I'll send them to you. They're attached [from William James's essay, "The Sentiment of Rationality"].

> A completed theoretic philosophy can thus never be anything more than a completed classification of the world's ingredients; and its results must always be abstract, since the basis of every classification is the abstract essence embedded in the living fact—the rest of the living fact being for the time ignored by the classifier. This means that none of our explanations are complete. They subsume things under heads wider or more familiar; but the last heads, whether of things or of their connections, are mere abstract genera, data which we just find in things and write down.
>
> When, for example, we think that we have rationally explained the connection of the facts A and B by classing both under their common attribute x, it is obvious that we have really explained only so much of these items as *is* x. To explain the connection of choke-damp and suffocation by the lack of oxygen is to leave untouched all the other peculiarities both of choke-damp and of suffocation—such as convulsions and agony on the one hand, density and explosibility on the other. In a word, so far as A and B contain l, m, n, and o, p, q, respectively, in addition to x, they are not explained by x. Each additional particularity makes its distinct appeal. A single explanation of a fact only explains it from a single point of view. The entire fact is not accounted for until each and all of its characters have been classed with their likes elsewhere. To apply this now to the case of the universe, we see that the explanation of the world by molecular movements explains it only so far as it actually *is* such movements. To invoke the "Unknowable" explains only so much as is unknowable, "Thought" only so much as is thought, "God" only so much as is God. *Which* thought? *Which* God?—are questions that have to be answered by bringing in again the residual data from which the general term was abstracted. All those data that cannot be analytically identified with the attribute invoked as universal principle, remain as independent kinds or natures, associated empirically with the said attribute but devoid of rational kinship with it.
>
> Hence the unsatisfactoriness of all our speculations. On the one hand, so far as they retain any multiplicity in their terms, they fail to get us out of the empirical sand-heap world; on the other, so far as they eliminate multiplicity, the practical man despises their empty barrenness. The most they can say is that the elements of the world are such and such, and that each is identical with itself wherever found; but the question Where is it found? the practical man is left to answer by his own wit. Which, of all the essences, shall here and now be held the essence of this concrete thing, the fundamental philosophy never attempts to decide. We are thus led to the conclusion that the simple classification of things is, on the one hand, the best possible theoretic philosophy, but is, on the other, a most miserable and inadequate substitute for the fulness of the truth. It is a monstrous abridgment of life, which, like all abridgments, is got by the absolute loss and casting out of real matter. This is why so few human beings truly care for philosophy. The particular determinations which she ignores are the real matter exciting needs, quite as potent and authoritative as hers. What does the moral enthusiast care for philosophical ethics? Why does the *Æsthetik* of every German philosopher appear to the artist an abomination of desolation?
>
> Grau, teurer Freund, ist alle Theorie
> Und grün des Lebens goldner Baum.
>
> The entire man, who feels all needs by turns, will take nothing as an equivalent for life but the fulness of living itself. Since the essences of things are as a matter of fact

disseminated through the whole extent of time and space, it is in their spread-outness and alternation that he will enjoy them. When weary of the concrete clash and dust and pettiness, he will refresh himself by a bath in the eternal springs, or fortify himself by a look at the immutable natures. But he will only be a visitor, not a dweller, in the region; he will never carry the philosophic yoke upon his shoulders, and when tired of the gray monotony of her problems and insipid spaciousness of her results, will always escape gleefully into the teeming and dramatic richness of the concrete world.

So our study turns back here to its beginning. Every way of classifying a thing is but a way of handling it for some particular purpose. Conceptions, "kinds," are teleological instruments. No abstract concept can be a valid substitute for a concrete reality except with reference to a particular interest in the conceiver. The interest of theoretic rationality, the relief of identification, is but one of a thousand human purposes. When others rear their heads, it must pack up its little bundle and retire till its turn recurs. The exaggerated dignity and value that philosophers have claimed for their solutions is thus greatly reduced. The only virtue their theoretic conception need have is simplicity, and a simple conception is an equivalent for the world only so far as the world is simple—the world meanwhile, whatever simplicity it may harbor, being also a mightily complex affair. Enough simplicity remains, however, and enough urgency in our craving to reach it, to make the theoretic function one of the most invincible of human impulses. The quest of the fewest elements of things is an ideal that some will follow, as long as there are men to think at all.

But suppose the goal attained. Suppose that at last we have a system unified in the sense that has been explained. Our world can now be conceived simply, and our mind enjoys the relief. Our universal concept has made the concrete chaos rational. But now I ask, Can that which is the ground of rationality in all else be itself properly called rational? It would seem at first sight that it might. One is tempted at any rate to say that, since the craving for rationality is appeased by the identification of one thing with another, a datum which left nothing else outstanding might quench that craving definitively, or be rational *in se.* No otherness being left to annoy us, we should sit down at peace. In other words, as the theoretic tranquillity of the boor results from his spinning no further considerations about his chaotic universe, so any datum whatever (provided it were simple, clear, and ultimate) ought to banish puzzle from the universe of the philosopher and confer peace, inasmuch as there would then be for him absolutely no further considerations to spin.

This in fact is what some persons think. Professor Bain says —

> A difficulty is solved, a mystery unriddled, when it can be shown to resemble something else; to be an example of a fact already known. Mystery is isolation, exception, or it may be apparent contradiction: the resolution of the mystery is found in assimilation, identity, fraternity. When all things are assimilated, so far as assimilation can go, so far as likeness holds, there is an end to explanation; there is an end to what the mind can do, or can intelligently desire .... The path of science as exhibited in modern ages is toward generality, wider and wider, until we reach the highest, the widest laws of every department of things; there explanation is finished, mystery ends, perfect vision is gained.

But, unfortunately, this first answer will not hold. Our mind is so wedded to the process of seeing an *other* beside every item of its experience, that when the notion of an absolute datum is presented to it, it goes through, its usual procedure and remains pointing at the void beyond, as if in that lay further matter for contemplation. In short, it spins for itself the further positive consideration of a nonentity enveloping the being of its datum; and as that leads nowhere, back recoils the thought toward its datum again. But there is no natural bridge between nonentity and this particular datum, and the thought stands oscillating to and fro, wondering "Why was there anything but nonentity; why just this universal datum and not another?" and finds no end, in wandering mazes lost. Indeed, Bain's words are so untrue that in reflecting men it is just when the attempt to fuse the manifold into a single totality has been most successful, when the conception of the universe as a unique fact is nearest its perfection, that the craving for further explanation, the ontological wonder-sickness, arises in its extremest form. As Schopenhauer says, "The uneasiness which keeps the never-resting clock of metaphysics in motion, is the consciousness that the non-existence of this world is just as possible as its existence."

The notion of nonentity may thus be called the parent of the philosophic craving in its subtilest and profoundest sense. Absolute existence is absolute mystery, for its relations with the nothing remain unmediated to our understanding. One philosopher only has pretended to throw a logical bridge over this chasm. Hegel, by trying to show that nonentity and concrete being are linked together by a series of identities of a synthetic kind, binds everything conceivable into a unity, with no outlying notion to disturb the free rotary circulation of the mind within its bounds. Since such unchecked movement gives the feeling of rationality, he must be held, if he has succeeded, to have eternally and absolutely quenched all rational demands.

But for those who deem Hegel's heroic effort to have failed, nought remains but to confess that when all things have been unified to the supreme degree, the notion of a possible other than the actual may still haunt our imagination and prey upon our system. The bottom of being is left logically opaque to us, as something which we simply come upon and find, and about which (if we wish to act) we should pause and wonder as little as possible. The philosopher's logical tranquillity is thus in essence no other than the boor's. They differ only as to the point at which each refuses to let further considerations upset the absoluteness of the data he assumes. The boor does so immediately, and is liable at any moment to the ravages of many kinds of doubt. The philosopher does not do so till unity has been reached, and is warranted against the inroads of those considerations, but only practically, not essentially, secure from the blighting breath of the ultimate Why? If he cannot exorcize this question, he must ignore or blink it, and, assuming the data of his system as something given, and the gift as ultimate, simply proceed to a life of contemplation or of action based on it.

01-06-04 *Shielding the Mathematics* (to I. Pitowsky)

I thought of you the other day as I was reading a passage in one of Quine's books. In particular I thought of the conversation we had on the plane to New Jersey, where you told me your thoughts on how a frequentist account of probability might be salvaged. It struck me that the move you're toying with is in no longer "shielding the mathematics" in Quine's sense.

Anyway, I'll place the passage below for your enjoyment.

- W. V. Quine, *Pursuit of Truth*, revised edition (Harvard U. Press, Cambridge, MA, 1992).

Let us recall that the hypothesis regarding the chemical composition of litholite did not imply its observation categorical single-handed. It implied it with the help of a backlog of accepted scientific theory. In order to deduce an observation categorical from a given hypothesis, we may have to enlist the aid of other theoretical sentences and of many common-sense platitudes that go without saying, and perhaps the aid even of arithmetic and other parts of mathematics.

In that situation, the falsity of the observation categorical does not conclusively refute the hypothesis. What it refutes is the conjunction of sentences that was needed to imply the observation categorical. In order to retract that conjunction we do not have to retract the hypothesis in question; we could retract some other sentence of the conjunction instead. This is the important insight called *holism*. Pierre Duhem made much of it early in this century, but not too much.

The scientist thinks of his experiment as a test specifically of his new hypothesis, but only because this was the sentence he was wondering about and is prepared to reject. Moreover, there are also the situations where he has no preconceived hypothesis, but just happens upon an anomalous phenomenon. It is a case of his happening upon a counter-instance of an observation categorical which, according to his current theory as a whole, ought to have been true. So he looks to his theory with a critical eye.

Over-logicizing, we may picture the accommodation of a failed observation categorical as follows. We have before us some set S of purported truths that was found jointly to imply the false categorical. Implication may be taken here simply as deducibility by the logic of truth functions, quantification, and identity. (We can always provide for more substantial consequences by incorporating appropriate premises explicitly into S.) Now some one or more of the sentences in S are going to have to be rescinded. We exempt some members of S from this threat on determining that the fateful implication still holds without their help. Any purely logical truth is thus exempted, since it adds nothing to what S would logically imply anyway; and sundry irrelevant sentences in S will be exempted as well. Of the remaining members of S, we rescind one that seems most suspect, or least crucial to our overall theory. We heed a maxim of minimum mutilation. If the remaining members of S still conspire to imply the false categorical, we try rescinding another and restoring the first. If the false categorical is still implied, we try rescinding both. We continue thus until the implication is defused.

But this is only the beginning. We must also track down sets of sentences elsewhere, in our overall theory, that imply these newly rescinded beliefs; for those must be defused too. We continue thus until consistency seems to be restored. Such is the mutilation that the maxim of minimum mutilation is meant to minimize.

In particular the maxim constrains us, in our choice of what sentences of S to rescind, to safeguard any purely mathematical truth; for mathematics infiltrates all branches of our system of the world, and its disruption would reverberate intolerably. If asked why he spares mathematics, the scientist will perhaps say that its laws are necessarily true; but I think we have here an explanation, rather, of mathematical necessity itself. It resides in our unstated policy of shielding mathematics by exercising our freedom to reject other beliefs instead.

01-06-04 *ReAktivation* (to M. Pérez-Suárez)

Pérez-Suárezism 6: *Great, my copy of 'The Activating Observer' includes 113 pages, 455 references.*

It's now at 187 pages, 513 references. Mainly I've significantly beefed up the pragmatism references—James is quoted extensively now. Also I've added a fair amount from the Jung-Pauli correspondence (Pauli's side). If you want it at this stage, I can send you the pdf; I don't think I'll be working on it again for a while.

Pérez-Suárezism 7: *Btw, I have found a very interesting letter (at the very least, its opening paragraph) from Pauli to Bohm, which is item 1313 (a nice number) in the PWB collection, vol. 1950–1952. I think that is one of his clearest statements on the "attached observer". I'll take the book and copy it for you (the paragraph I referred to, not the whole thing) later on.*

I should peruse those volumes. Are many of the letters in English? Thanks for the offer. Please try to include as much of the letter as possible.

01-06-04 *Quantum System as Philosopher's Stone* (to M. Pérez-Suárez)

First a joke: Notice the similarity between the symbol drawn near the top of this page

`http://www.starchamber.com/1997/09/the-rewards-of-the-infinite.html`

and a modern quantum circuit. Archetypes everywhere!

(I'll cc this note to David Mermin; he might enjoy the joke too.)

More seriously, the phrase in the title of this note is something I've toyed with as a title for a paper I'd like to write one day. It's been on my mind ever since I wrote these words for `quant-ph/0404156`:

> In fact, one might go further and say of quantum theory, that in those cases where it is not just Bayesian probability theory full stop, it is a theory of stimulation and response. The agent, through the process of quantum measurement stimulates the world external to himself. The world, in return, stimulates a response in the agent that is quantified by a change in his beliefs—i.e., by a change from a prior to a posterior quantum state.

With the aid of a quantum system—and only with its aid—a transmutation takes place in the agent. Of course, these ideas flow directly from Pauli; I'm just trying to give them more rigorous substance. (See for instance, the Heisenberg entry "Wolfgang Pauli's Philosophical Outlook" in my compendium. Or more generally, any number of entries under Pauli himself.)

Pérez-Suárezism 8: *As I promised, here you have the paragraph I told you from Pauli's letter to Bohm, dated December 3, 1951:*

> "Since Descartes, it was the ideal of natural philosophy to conceive a system of laws in which an entirely loose and untied observer is looking from outside at a part of the world completely determined by these laws. For me, however, it is much more satisfactory if the laws of nature themselves exclude in principle the possibility even to *conceive* the disturbances in the observer's own body and own brain connected with his own observations."

Well, it didn't turn out to be either the opening paragraph of the letter or his clearest statement on the rejection of the ideal of the "detached observer". Actually, I am not sure as to what he means by his last sentence (I have my own guess, though).

I think he means "quantum system as philosopher's stone."

02-06-04 *Dreams, 2* (to A. Sudbery)

Sudberyism 14: *We Everettians must be getting to you.* ☺

Keep in mind that I (like most people) also have dreams about snakes and rats too.

02-06-04 *The Chemical Wedding* (to M. Pérez-Suárez)

I promise to write more tomorrow. Thanks for the references. I have to admit that I'm getting more interested in the alchemical aspects of the whole issue again. Maybe it's your dangerous influence upon me!

Marcos's Preply 1

Thanks for your note. As soon as I read your words under the heading "Subject", I found myself thinking that it would make for a great title!

Yes, the similarity is really amazing, much more than I was expecting it to be while downloading the webpage. But let me suggest to you two books, namely,

- A. Roob: *Alchemy and Mysticism* (Taschen) (unbelievably INexpensive given its contents),
- S. Klossowski de Rola: *Alchemy. The Secret Art* (Thames and Hudson) (A tougher nut than the previous one. Sometimes it is not even that easy to discern whether what you are reading is the main text or paragraphs quoted from alchemical writings.)

and a website: `http://www.levity.com/alchemy/`.

The three of them are quite interesting if only for the huge amount of (enrapturing, breathtaking, amazing ...) images from many ages (although Middle Ages and Renaissance take most of them, for sure) that they include. But to me they are interesting in more than that.

I'll think harder on Pauli's sentence in that letter, but he writes:

> [...] much more satisfactory if the laws of nature themselves exclude in principle the possibility even to *conceive* the disturbances in the observer's own body and own brain connected with his own observations.

I mean, he says "excludes". This is where I get lost.

Marcos's Preply 2

Take a look at this (included in one of the books I told you about in a previous note). This is my own translation from the Spanish (the edition I own):

> At the microphysical level there is a tight ontological [imbrication?] between the subject and the object under observation. It has been necessary to admit that subjectivity is an active agent in the development of natural processes, processes that some alchemists define as the permanent inversion of the inner and the outer.

And later on, he quotes Whitehead after making (the author) some reference to the "mercurial" character of physics: "Exactness is a fake".

I insist that this is a wonderful book, if only for its pictorial reproductions. If only it were larger ...

02-06-04 *Leggett* (to G. Brassard)

Thanks for the note. I'm just about to go out for a "good-bye" pub meeting with my friend Ken Duffy. (When John Lewis died, he got reassigned to Maynooth; today was his last day here.)

Your note is cherished. I'll send you that longer reply tomorrow.

In the meantime:

Brassardisme 14: *You may be interested to know that I gave our talk on QFLQI (with your name explicitly as coauthor on the title slide) a few days ago in front of 2003 Physics Nobel Prize laureate Tony Leggett. He showed interest with several questions, but in the end I don't think he bought the project.*

Pasted below is my own recent letter to Leggett. [See 25-05-04 note "Bathroom Reading" to A. J. Leggett.] Like with you, I saw him have little flashes of understanding, but ultimately he didn't buy it. But that's OK, with concerted efforts, we'll eventually get there.

I did get this recently from a Minnesota professor (Michel Janssen) who was at the same meeting as Leggett:

Janssenism 1: *Anyways, may this serve as a surrogate for a substantial response to your work. I too am glad that we had that chat. Without it, I'm afraid, I would have just dismissed your stuff as crackpot physics. Now I see it as the one serious contender to my favorite scheme—Everett + decoherence.*

These kinds of reactions keep rolling in ... just no job market for me.

03-06-04 *Your Address and Six or So Books Coming* (to H. Mabuchi)

If you don't mind, I might have some books from Amazon or Powell's shipped to your house to await my arrival. That'll save me quite a bit in shipping. ...

I think in total I ordered six books and had them shipped to your home address. Thanks for letting me do this. The books are all on Schiller, Boutroux, and pragmatism. Feel free to dig into them if you want.

04-06-04 *Earwax* (to P. C. E. Stamp)

Stampede 1: *Thanks for sending the copy of your book – and I will put it in the bathroom, where it will be a useful antidote to the fashion magazines that my wife leaves there.*

Quoting you:

Stampede 2: *Regarding the information theory programme – I have indeed got the message that you are trying to do something analogous to, e.g., Skinner and Watson, with your black box (ie., stimulus-response) approach. However I have several remarks to make on this*

(i) Like many people I find the black box approach scientifically sterile – and I didn't need, e.g., Chomsky to tell me why, it has been understood to be sterile for a long time now (from this perspective Skinner-Watson was apparently just an ephemeral aberration). The problem with a black box approach is that it ignores what may be going on inside or outside the box, which exists without the stimuli and may not be completely characterised by the responses. Of course hidden variable theories have been toasted so far, most generally by Bell-Kochen-Specker, but that is no reason to cease looking for something more than a "measurement calculus" (which is essentially what the information approach is doing as far as I can see). This is what physicists do, and they have ended up with quite a dazzling display of objects ranging from non-Abelian gauge fields to macroscopic order parameters and 'wave-functions' to topological quantum fluids to complex spin nets, etc. The attempt to strip this down to nothing but stimulus and response, in a measurement or information theoretic calculus, is very much like the attempt by Skinner and Watson to take all the colour out of psychology – at least in my opinion. This is something of a gut reaction, but I suspect it is shared by many physicists.

If you can say this, you haven't listened to me very carefully. It seems to me that you're just rather offhandedly drawing associations with things you have a distaste for because of little more than a similarity of words.

For instance, how can you make your characterization above mesh with these words that I wrote in `quant-ph/0205039`? (I hope you'll read the passage all the way to the end; the average listener doesn't seem to hear anything beyond the first paragraph.):

> So, throw the existing axioms of quantum mechanics away and start afresh! But how to proceed? I myself see no alternative but to contemplate deep and hard the tasks, the techniques, and the implications of quantum information theory. The reason is simple, and I think inescapable. Quantum mechanics has always been about information. It is just that the physics community has somehow forgotten this.
>
> This, I see as the line of attack we should pursue with relentless consistency: The quantum system represents something real and independent of us; the quantum state represents a collection of subjective degrees of belief about *something* to do with that system (even if only in connection with our experimental kicks to it). The structure called quantum mechanics is about the interplay of these two things—the subjective and the objective. The task before us is to separate the wheat from the chaff. If the quantum state represents subjective information, then how much of its mathematical support structure might be of that same character? Some of it, maybe most of it, but surely not all of it.
>
> Our foremost task should be to go to each and every axiom of quantum theory and give it an information theoretic justification if we can. Only when we are finished picking off all the terms (or combinations of terms) that can be interpreted as subjective information will we be in a position to make real progress in quantum foundations. The raw distillate left behind—minuscule though it may be with respect to the full-blown theory—will be our first glimpse of what quantum mechanics is trying to tell us about nature itself.

> Let me try to give a better way to think about this by making use of Einstein again. What might have been his greatest achievement in building general relativity? I would say it was in his recognizing that the "gravitational field" one feels in an accelerating elevator is a coordinate effect. That is, the "field" in that case is something induced purely with respect to the description of an observer. In this light, the program of trying to develop general relativity boiled down to recognizing all the things within gravitational and motional phenomena that should be viewed as consequences of our coordinate choices. It was in identifying all the things that are "numerically additional" to the observer-free situation—i.e., those things that come about purely by bringing the observer (scientific agent, coordinate system, etc.) back into the picture.
>
> This was a true breakthrough. For in weeding out all the things that can be interpreted as coordinate effects, the fruit left behind finally becomes clear to sight: It is the Riemannian manifold we call spacetime—a mathematical object, the study of which one can hope will tell us something about nature itself, not merely about the observer in nature.
>
> The dream I see for quantum mechanics is just this. Weed out all the terms that have to do with gambling commitments, information, knowledge, and belief, and what is left behind will play the role of Einstein's manifold. That is our goal. When we find it, it may be little more than a minuscule part of quantum *theory*. But being a clear window into nature, we may start to see sights through it we could hardly imagine before.[77]

The very point of the whole program is to see quantum systems as MORE than just black boxes. But to do that, a lot of crud to do with observers or agents has to first be excised from the theory—or, at least, that's what the program I'm working on is about: Getting to the physical kernel of quantum mechanics. Here's the way I put it in a recent proposal:

> No physicist would be doing his job if he did not strive to map reality itself—that is, reality as it is independently of any information processing agents. The issue is one of separating the wheat from the chaff: Quantum mechanics may be predominantly about information, but it cannot *only* be about information. Which part is which? The usual way of formulating the theory is a thoroughly mixed soup of physical and informational ingredients.
>
> This is where quantum information (including the collateral fields of quantum cryptography, computing, and communication theory) has a unique role to play. Its tasks and protocols naturally isolate the parts of quantum theory that should be given the most foundational scrutiny. "Is such and such effect due simply to a quantum state being a state of information rather than a state of nature, or is it due to the deeper issue of what the information is about?" Recent investigations by several workers are starting to show that many of the previously-thought 'fantastic' phenomena of quantum information—like quantum teleportation, the no-cloning theorem, superdense coding,

[77]I should point out to the reader that in opposition to the picture of general relativity, where reintroducing the coordinate system—i.e., reintroducing the observer—changes nothing about the manifold (it only tells us what kind of sensations the observer will pick up), I do not suspect the same for the quantum world. Here I suspect that reintroducing the observer will be more like introducing matter into pure spacetime, rather than simply gridding it off with a coordinate system. "Matter tells spacetime how to curve (when matter is there), and spacetime tells matter how to move (when matter is there)." Observers, scientific agents, a necessary part of reality? No. But do they tend to change things once they are on the scene? Yes. If quantum mechanics can tell us something truly deep about nature, I think it is this.

and nonlocality without entanglement—come about simply because of the epistemic nature of the quantum state. On the other hand, other phenomena, such as the potential computational speed-up of quantum computing, seem to come from a more physical source: In particular, the answer to the question, "Information about what?"

When we finally delineate a satisfying answer to this, physics will reach a profound juncture. We will for the first time see the exact nature of 'quantum reality' and know what to do with it to achieve the next great stage of physics. Trickle-down effects could be the solution to the black-hole information paradox—perhaps already seen in broad outline—and even the meshing together of quantum theory and gravitational physics. In the meantime the approach proposed here is a conservative and careful one; the work to be done is large. The effort aims not to say first what 'quantum reality' is, but what it is not and gather insights all along the way.

The last thing I want to do is view quantum theory as a species of a rather sterile positivism, or as you put it, as no more than a "measurement calculus". It is clearly more than that.

Where you misread me is in thinking that taking an epistemic view of the quantum state—epistemic, in particular, about the potential results of measurements and nothing more—is necessarily throwing out the baby with the bathwater. It is not. It is instead a strategy for getting around all the nasty foundational problems of a realistically construed "wave-function collapse" while not going so far as the emptiness of Everett or Bohm (or the unchecked and little-motivated speculation of GRW). The point is to salvage realism by looking for it at a *higher level* than the level of quantum states and their equations of motion.

For one can ask, and one should ask: Why this "measurement calculus" rather than another? There is some *property* of the stuff of the world, or of physical systems, that forces the particular calculus we use upon us—it is not arbitrary, and to that extent, it tells us something about the world as it is without the gambling agent.

Here's yet another way I've put the program recently, in a letter to Jim Woodward: [See note dated 18-05-04, and titled "Agents, Interventions, and Surgical Removal."]

There, I hope that's enough to defend myself from your accusation of being to quantum mechanics what Skinner and Watson were to psychology. Or, at least, to show you that my heart is not where you think it is.

You want color? Then let me tell you about the actual origin of my use of the phrase "stimulation and response"—it was not Skinner or Watson or the like. Instead, the words comes from the palette of imagery I've been building up ever since I started calling my view "the sexual interpretation of quantum mechanics". (See *Quantum States: What the Hell Are They?* posted on my webpage, last paragraph page 49. See also the note to Mermin below.) Put yourself in a lascivious mindframe, and then once again approach the word "stimulation." I hope it leaves an indelible mark on you.

14-06-04 *RMTTR,BOWEAL* (to H. Mabuchi)

The title to the note would have been "Reality Modifiable To the Roots, But Only with Effort and Luck," but it looked too long, and so I shortened it.

Our conversation this morning emboldened me; I rather enjoyed the part about the Upanishads, etc. In that regard, let me attach two of my pseudo-papers, "Delirium Quantum" and "The Activating Observer". You might enjoy perusing parts of both. Discussions like the one with you this morning make me feel like maybe I'm not going too far after all. Indeed, maybe I'm not going far enough!

OK, the last sentence was a little of a joke . . . but maybe ultimately not. Still, if I use quantum mechanics as the firmest place I can start, I don't think it yet countenances a move that far, i.e., that that which is without is actually within (Brahman = Atman). But I think QM does move somewhat in the direction, by making that which is without to be somewhat malleable. And to that extent, that which is without looks to be somewhat within. (It's kind of fun writing like this.) Anyway, true enough, the effort does remain with the distinction without/within—which I am presently comfortable with. It doesn't completely erase it.

If you enjoy anything in these writings, give me feedback.

14-06-04 *The Toy Intro* (to H. Mabuchi)

Finally, I'll share with you the toy intro I wrote for the basic quantum mechanics talk. Since I almost surely won't say it out loud (or at least in such detail), I might as well share it with somebody. [See 17-06-04 note, "Preamble," to H. Mabuchi.]

14-06-04 *Concrescence?* (to W. K. Wootters)

BTW, on my flight yesterday, I sketched out the following little introduction for my summer school lectures here at Caltech. I don't know if I'll actually say those things. But does any of it sound like the Whiteheadian ideas—I think you called it concrescence—you told us about in Montréal two Falls ago? [See 17-06-04 note, "Preamble," to H. Mabuchi.]

Bill's Reply

> Yes, it seemed to me when I was reading Whitehead that the emergence of a definite fact, out of quantum potentialities, should count as an example (maybe the only example) of concrescence. It is the process of becoming concrete.
>
> I don't have my Whitehead with me here, but from a couple of webpages I got the following definitions:
>
> concrescence – a dipolar process involving an interplay between physical feelings and mental valuations (PR 108) in which prehensions of early phases are contrasted in later phases. In short, it is the production of novel togetherness (PR 21.)
>
> Whitehead defines 'concrescence' as a process in which prehensions are integrated into a fully determinate feeling or satisfaction. A 'satisfaction' is a unity of physical or mental operation attained by an actual entity.

17-06-04 *Preamble* (to H. Mabuchi)

I think I would like you to also post the little text file below along with my other suggested readings for my "Intro to QM" lecture. You can give it the title "Preamble". It was something I sketched out on my flight over here, and reading over it again, I kind of like it.

> A lecturer faces a dilemma when teaching a course at a farsighted summer school like this one. This is because, when it comes to research, there is often a fine line between what one thinks and what is demonstrable fact. More than that, conveying to the students what one thinks—in other words, one's hopes, one's desires, the potentest of one's premises—can be just as empowering to the students' research lives (even if the

ideas are not quite right) as the bare tabulation of any amount of demonstrable fact. So I want to use one percent of this lecture to tell you what I think—the potentest of all my premises—and use the remaining ninety-nine to tell you about the mathematical structure from which that premise arises.

I think the greatest lesson quantum theory holds for us is that when two pieces of the world come together, they give birth. [Bring two fists together and then open them to imply an explosion.] They give birth to FACTS in a way not so unlike the romantic notion of parenthood: that a child is more than the sum total of her parents, an entity unto herself with untold potential for reshaping the world. Add a new piece to a puzzle—not to its beginning or end or edges, but somewhere deep in its middle—and all the extant pieces must be rejiggled or recut to make a new, but different, whole. That is the great lesson.

But quantum mechanics is only a glimpse into this profound feature of nature; it is only a part of the story. For its focus is exclusively upon a very special case of this phenomenon: The case where one piece of the world is a highly-developed decision-making agent—an experimentalist—and the other piece is some fraction of the world that captures his attention or interest.

When an experimentalist reaches out and touches a quantum system—the process usually called quantum 'measurement'—that process gives rise to a birth. It gives rise to a little act of creation. And it is how those births or acts of creation impact the agent's *expectations* for other such births that is the subject matter of quantum theory. That is to say, quantum theory is a calculus for aiding us in our decisions and adjusting our expectations in a QUANTUM WORLD. Ultimately, as physicists, it is the quantum world for which we would like to say as much as we can, but that is not our starting point. Quantum theory rests at a level higher than that.

To put it starkly, quantum theory is just the start of our adventure. The quantum world is still ahead of us. So let us learn about quantum theory.

Hideo's Reply

From *Three Farmers on Their Way to a Dance*, Richard Powers' first novel:

> "Sander," a German photographer of the early 1900's, "at the same time as those working in physics, psychology, political science, and other disciplines, blundered against and inadvertently helped uncover the principle truth of this century: viewer and viewed are fused into an indivisible whole. To see an object from a distance is already to act on it, to change it, to be changed."

18-06-04 *Retracing Thoughts* (to J. Woodward)

Retracing yesterday's conversation in my head (I've got nothing better to do; my lectures being over), I realized I didn't quite adequately respond to one of your questions near the end. It was just before we arose from the table. You asked something like, "Then what are the random variables in these probability distributions?" I replied, "Measurement outcomes." But I don't want to leave you with the impression that such an empiricist or positivist take is the end of the story. Indeed the bit below, which I wrote for the research proposal John Preskill gave you and others, addresses the very issue with the phrase, "Information about what?"

No physicist would be doing his job if he did not strive to map reality itself—that is, reality as it is independently of any information processing agents. The issue is one of separating the wheat from the chaff: Quantum mechanics may be predominantly about information, but it cannot *only* be about information. Which part is which? The usual way of formulating the theory is a thoroughly mixed soup of physical and informational ingredients.

This is where quantum information (including the collateral fields of quantum cryptography, computing, and communication theory) has a unique role to play. Its tasks and protocols naturally isolate the parts of quantum theory that should be given the most foundational scrutiny. "Is such and such effect due simply to a quantum state being a state of information rather than a state of nature, or is it due to the deeper issue of what the information is about?" Recent investigations by several workers are starting to show that many of the previously-thought 'fantastic' phenomena of quantum information—like quantum teleportation, the no-cloning theorem, superdense coding, and nonlocality without entanglement—come about simply because of the epistemic nature of the quantum state. On the other hand, other phenomena, such as the potential computational speed-up of quantum computing, seem to come from a more physical source: In particular, the answer to the question, "Information about what?"

When we finally delineate a satisfying answer to this, physics will reach a profound juncture. We will for the first time see the exact nature of 'quantum reality' and know what to do with it to achieve the next great stage of physics. Trickle-down effects could be the solution to the black-hole information paradox—perhaps already seen in broad outline—and even the meshing together of quantum theory and gravitational physics. In the meantime the approach proposed here is a conservative and careful one; the work to be done is large. The effort aims not to say first what 'quantum reality' is, but what it is not and gather insights all along the way.

What these paragraphs are not detailed enough convey is that the issue boils down to the need for a much better understanding of the implications of the Kochen-Specker theorem: That is, the theorem that blocks measurement outcomes from being preexistent realities in the usual quantum description (i.e., without the supplementation of nonlocal hidden variables, etc.). My own feeling is that it is this part of quantum theory which gives rise to the computational speed-up in quantum computation. So, these things are intimately related I believe.

Thus, as much as I endorse taking "measurement" (or "intervention" as Asher Peres and I have called it in our articles; see pages 99, 146, 336, 384, 394, etc., and most notably page 417) as the very foundation of what the theory is about—those little acts of creation I always talk about—there is still so much work to be done to get this clarified. Part of it hinges on clarifying the particular form of "noncontextuality" for the quantum probability assignment, but also more philosophically I think it is an opportunity to rethink variations on James and Dewey's notion of truth. (Maybe I wouldn't want to apply that notion to everything in the world, as a true pragmatist (say Richard Rorty) would, but it does strike me as an appropriate concept for these particular quantum mechanical issues.)

Anyway, I hope that tells you a little more.

I've also been thinking a little more about "Making Things Happen" in the context of quantum computing. I think there's a lot of thought one could give that. I haven't yet decided if I would count a quantum measurement as an example of "making things happen". However, one most certainly should count the enacting of a quantum computational algorithm—let's say, factoring a large composite number—as an example: The number goes in the quantum computer, the factors come out. What is interesting is that there are some new models of quantum computation that involve solely the action of quantum measurement, and make no use of time evolution at all. How do these ideas mesh together? Don't know at the moment.

I'm sitting in Steel, Rm. 305, till the end of the stay, by the way. The phone number on my desk is 4493.

For the fun of it, I'll paste below the intro to my first lecture for the CBSSS summer school that I told you about. I didn't do it quite so William-Jamesy when I did it in real life, but it conveys the idea. (These were the notes I wrote myself on the flight the other day.) The second lecture—the one I gave after we parted—went fabulously. You must've put me in the right mood. The students here are like eager sponges!

21-06-04 *Teleportation* (to G. Musser)

Musserism 6: *P.S. How do you interpret teleportation?*

Below is an outtake from a letter I wrote to Oliver Cohen a while ago; I think it answers your question. [See 15-01-03 note "Memory Lane" to O. Cohen.] I decided to be lazy and not change the page numbers for *Notes On a Paulian Idea* listed below: They refer to the web edition—which can be downloaded at my webpage—rather than the VUP edition which I had sent to you. (Did you get it?) If you have trouble downloading it, let me know and if worse comes to worst, I'll fix the page numbers up for you.

28-06-04 *Decisions, Decisions* (to J. Woodward & C. R. Hitchcock)

There's no doubt I think the time is ripe to meld philosophy of science and honest-to-god quantum information physics—both physics and philosophy will greatly benefit from the marriage—but finding a place that'll share this belief with me is mostly beyond my control. Of course I'll try to turn the tide by writing more papers (and hopefully ever more convincing papers), but that will take some time in the coming. In any case, I hope I have sufficiently piqued your interest in the subject that you might follow it a little and use your accumulated body of work on causality to make a contribution to it. Vice versa, I hope the field will give you something to think about from a fresh perspective and maybe lead to something new in your own work.

In case you're interested, you can read about the quantum de Finetti theorems I told you about in my paper with Schack, "Unknown Quantum States and Operations, a Bayesian View," posted here: `http://www.arxiv.org/abs/quant-ph/0404156`. In the time-evolution version of the theorem (as it stands), we only imagine a dynamics imposed upon our quantum systems from the outside—say, by some "device." If we were to try to prove a version of the theorem sufficient for an account of an internal dynamics—i.e., like the stuff I was telling you about at the Red Door—then I am sure we would have to take into account something like the conditions for your "interventions" to make it fly. Anyway, food for thought and some work for the future.

29-06-04 *Late, Sorry* (to G. Musser)

I'm sorry I'm late. The travel and flu took a big toll on me, and I forgot about email for a while . . . despite my promises. Bad behavior.

Anyway, let me zoom in on the paragraphs where you mention me.

Musserism 7: *... Many of those struggling to grok quantum mechanics say Einstein's mistrust [of QM] was well-founded. "This guy saw more deeply and more quickly into the problems that plague us today," says Christopher Fuchs of Bell Labs ....*

Did I really say that? It's kind of a strange construction. But maybe it's only a question of intonation. Does something like this more capture the moment: "This guy saw more deeply—and actually more quickly—into ..." (emphasizing quickly maybe)? Also, I am a bit reluctant to say that he saw into the "problems that plague us today," because I'd rather not think of them as such horrible problems. But if I said it that way, then I said it, and it's your property now. But, given the chance, I think I would say it this way if I could: "This guy saw more deeply—and actually more quickly—into the central issues of quantum mechanics than many give him credit for." I say this because he so quickly gave such a clean argument for the idea that the quantum mechanical wave function represents a "state of knowledge" rather than a "state of nature." And I think that realization quashes over half of the mysteries already. See, for instance, Section 3 of my "only a little more" paper.

The only thing that differentiates Einstein from our little effort at this juncture is that he thought physics should ultimately be about the "states" of nature, whereas the guys in my camp think that the great lesson of quantum mechanics is that physics must be about something else.

Musserism 8: *If hidden variables have a fatal flaw, it is that any attempt to reconstruct quantum mechanics from something deeper is limited by physicists' imagination.*

I'm not sure I understand this. What do you mean?

Musserism 9: *Rather than try to build the theory from the bottom up, the most respected efforts to explain the quantum work from the top down. Fuchs, a leader in this area, says that so much of quantum mechanics pertains to our information about a system rather than the system itself. As Einstein argued, it is a theory of hearsay rather than of direct knowledge. Fuchs is trying to strip away these subjective aspects so that the objective properties of nature can stand out.*

Our information about a system. More accurately, our (statistical) information about how the system will evoke a response in us—i.e., the thing usually called a "result" of a measurement. (Asher Peres likes to say, "Unperformed measurements have no results.")

Musserism 10: *Physicists had long assumed, for example, that measuring a quantum system causes it to "collapse" from a range of possibilities into a single actuality. Fuchs argues it is just our uncertainty about the system that collapses. Uncertainty about a quantum system is very different from uncertainty about a classical one, because the process of measurement cannot help but disturb a quantum system. And this sensitivity to disturbance is a clue to what a quantum system really is. Quantum mechanics may prove to be more complex than either its inventors or detractors ever envisioned ....*

This is the paragraph that particularly troubles me. For it makes this position of mine look like that of a closet hidden-variablist (i.e., one that hasn't had the intellectual honesty to see what he really stands for).

There are two issues to try to separate, and I'm not sure what's the best way to do it so that the paragraph is both accurate and pithy at the same time. In a quantum measurement, I would say two things happen: 1) something is created that was not there before, the measurement "click"—this idea bars hidden variables—and 2) something changes, this is the observer's wave function for the system, i.e., his knowledge. Physicists often get in the bad habit of muddling the two things, the creation ("the measurement result coming out of nowhere") and the change due to the creation. The "collapse" properly only refers to the change of the wave function and, thus, to knowledge. But what is the knowledge about? It is not really about the system alone, or what is there, i.e., what properties it has—if it were, then we would be talking about hidden variables ultimately—but rather about what will come about the next time the observer touches it.

Think of a quantum system as a kind of philosopher's stone. Its power is in transmuting an observer's state of knowledge. And presumably it is transmuted too in the process. Interestingly, quantum theory is predominantly about the observer's side of this state of affairs. Think about how much two parents are transformed by the process of giving birth. One parent is the quantum system, one parent is the observer; the child is the click. Quantum theory effectively only interrogates one of the parents—the observer—and, to the extent that we get some characterization of the other parent from this interrogation, it is only second-hand.

I doubt these words are helpful to you, but I'm trying.

On another point, I know that I've used the word "disturb" before, but I have been trying to get away from it because of all the incorrect imagery it evokes—it just calls out for one to think of hidden variables being disturbed. Thus, I would like to keep the idea of "sensitivity," but I hope I never say "sensitivity to disturbance" anymore (if I ever did). In the past, rather than the parenting imagery I used above, I have used the imagery of an oyster, a grain of sand, and a pearl to try to capture the idea of system, observer, and click respectively. And it was in that context that I started to speak of a "quantum system's sensitivity to the touch." No oyster, no pearl. No sand grain, no pearl. The pearl is a manifestation of the oyster's sensitivity to the touch in the presence of a sand grain.

"And the shape of this sensitivity is a clue to what a quantum system really is." — For some reason I like that sentence, but I don't know how you would fit it into what you write.

If you need more help, I should be pretty steady on my email now that I'm back in Dublin. (Though I'm flying out to house-hunt in NJ as of July 6, and you can expect an almost total shutdown until that's over with July 16 or 17.)

Sorry if I'm causing you more trouble than I'm worth.

30-06-04 *Fancy Words First* (to M. Janssen)

Janssenism 2: *[L]et me just ask you what I should read to get over the next hurdle I'll have to take before this information stuff has a prayer of dislodging Everett. The hurdle is simply this: how is your information approach different from the old ignorance interpretation of QM. And I'm sure you won't mind me spelling this out a bit to make sure you know what I mean. I take the ignorance interpretation to be saying things like this: of course, an electron has a definite position (as well as definite whatever) at all times, it's just that typically we don't know what that is. That's why we can only describe the electron in terms of a superposition of it being in all places it could possibly be. When we perform a measurement we find out what its real position is. So QM is just like classical statistical mechanics basically: it gives us probability distributions over values of variables we don't know the exact value of. The only difference is that QM tells us that we can't ever know all values of all variables at the same time, because typically the measurement of the value of one variable disturbs the value of others. I buy (what I take to be) the standard line against this view: the probability distributions generated by state vectors in Hilbert space cannot be reduced to classical probability distributions.*

From talking to Christoph Lehner, who witnessed your exchange with David Albert at this year's

Ryno-Bub fest, I understand that Albert's criticism was along these same lines (but maybe Christoph was just reading that into the exchange: it's certainly Christoph's first line of defense when I told him my Everettian faith had been tested). I'll be seeing Christoph in a week and a half and I'd appreciate it if you provide me with some target-specific ammunition.

Thanks for the note, and thanks for the alert to the *Science* article. I hope I can retrieve it.

Thanks also for the question. I'll do my best to clarify things for you; give me a couple of days to work something up specific to your question. The short story is that I am about as far away from the ignorance interpretation you speak of as one can imagine: Quantum measurement is—for me—not a case of revealing, but a case of making (making something that was explicitly not there before). That I take to be the significance of the Bell and Kochen-Specker theorems.

Particularly, you've got to understand that I draw a distinction between the quantum world (i.e., the world presumably as it really is) and the quantum formalism. The latter is not a reflection of the former in any exact-correspondence sense. That is to say, quantum theory is not a story of the world as it is completely independent of decision-making agents. Rather it is—from this point of view—a normative theory for the optimal survival of agents immersed in this kind of world. To the extent that we are using *this* normative theory of survival (i.e., this theory of decision-making and gambling) rather than *that* normative theory, we are saying something about the world as it is independent of the agent. But the strategy for saying something about the world is necessarily more oblique than one thought one could obtain in classical times.

All of this is much too subtle of stuff for David Albert to have absorbed in my talk . . . predominantly because he does not listen. His actions (at my talk and every other one I have ever seen him attend) make it clear that his purpose for attending talks is not to listen, but to have a good spit.

Anyway, I will try to write you (or direct you to) something of detail within a couple of days. In the meantime, let me attach a little poetic piece I wrote for my summer-school lectures at Caltech last week. It says a little more about the point of view above. Feel free to share any of these notes with your friend. [See 17-06-04 note, "Preamble," to H. Mabuchi.]

30-06-04 *Quail and Pheasant?* (to J. B. Lentz & S. J. Lentz)

> *Leggett, Preskill, and 22 other physicists, philosophers, and historians have gathered here for the Seven Pines Symposium. Packed into a slightly ramshackle lodge in a wooded state park, the scholars—all of them men—will share their insights, suites of rooms without telephones, and meals of roast quail and pheasant at a long communal table. Perhaps not since the famous Solvay Conferences of the early 20th century, at which Niels Bohr and Albert Einstein debated the meaning of quantum theory in their free time, has physics seemed so genteel.*

I thought you might enjoy this article from *Science* [A. Cho, "Elite Retreat Takes the Measure of a Weirdly Ordinary World," Science **304**, 1896 (2004)], which one of my acquaintances from the same meeting just sent me. I learned from it that I was eating quail and pheasant! I myself never imagined I was eating anything but chicken.

Anyway, I was particularly pleased to see the napkin pictured in the article: It means someone was taking notes at my lecture or explaining it to someone else. The fellow in the blue shirt looking down at me is the Mercedes man.

The atmosphere the author builds in the story is basically the sort of thing Kiki envisions when we dream of opening an institute in the New Hampshire countryside. Scientists eating good food because someone has put it in front of them, and happy for it ... even if they don't quite know what it is.

30-06-04 *Memory Lane* (to D. B. L. Baker)

Just ran across this on the web and it reminded me of the time we both happened to see Vampire Circus and reported it to each other one Monday morning in about 1979/80.

> Things weren't as complex in 1972 when the Spanish film *La Noche de Walpurgis* was released in the grindhouses and drive-ins of America as *The Werewolf vs. The Vampire Woman*. A big hit in Europe, cementing Paul Naschy's position as Spain's preeminent horror film star, it came to America with all the fanfare and bluster of a dusty, ratty, moth-eaten circus. I saw it as a young teenager one gummy-eyed late night in the '70's on San Antonio's KENS-TV's *Project Terror* program ("Where the scientific and the mystifying merge ..."). *Project Terror*'s programming consisted mainly of European horror at the time, and although some were heavily edited, one could see a glimpse of a bare breast once in a while and some cool but cheap gross-out gore. Ah, adolescence! I don't remember either actively liking or disliking it, but I do remember thinking that the werewolf makeup looked cheap and that the vampire woman (played by Patty Shepard) looked pretty hot, so much that I rooted for her in the climactic battle with the good guy wolfman Waldemar Daninsky played by Paul Naschy. A silly diversion, nothing more, nothing less. I hadn't thought about the movie since I saw it over 25 years ago. I've seen some other Naschy horror titles on video since then (*House of Psychotic Women* is one that immediately comes to mind), and they're certainly fun to watch if you don't mind the fast, cheap, and out of control nature of the movies, but they contain none of the cruel poetry and transgressive power of the best of '70's Euro-horror (de Ossorio's *Blind Dead* series, Rollin's vampire films, Argento's Suspiria, even a couple of Franco's films). Naschy's work is a throwback to the Universal horrors of the '30's and '40's, albeit with nudity and gore, but unfortunately adds nothing new to the mix.

30-06-04 *Writing Physics* (to G. Musser)

Musserism 11: *Another issue that I'm struggling with is this business of separating states of knowledge from states of nature. Isn't a state of knowledge a state of nature where "nature" includes the observer? The wavefunction is a statement about me, but I'm part of nature, right?*

Honestly, I am quite intrigued by your question. It's perceptive and a good one—you articulated it well. I hope to use this as an opportunity to "write physics" in Mermin's sense. If you haven't looked at it yet, read David's article "Writing Physics":

`http://www.lassp.cornell.edu/mermin/KnightLecture.html`.

01-07-04 *Friends and Enemies* (to S. Hartmann)

Wow! Thanks for the letter. After reading your letter, I wanted to hire the guy you were talking about; I hope I get a chance to meet him some day.

Anyway, in reading it, it dawned on me that I ought to contrast my emotions with the old phrase, "With a friend like that, who needs enemies?" After reading your letter, I thought, "Wow, with a friend like that, maybe I can afford even a few more enemies!"

Which brings me to Amit. I'd be more than happy to look at your student's paper! . . . Ahh, don't get me wrong, Amit and I actually have a very friendly relationship—he is truly a nice guy, and we've had a lot of personal conversations. It's just that he didn't read me nearly as thoroughly or carefully as he thought he had. I found his paper pretty annoying. For instance, all this talk about "decoherence" and "for all practical purposes" in one of the sections had nothing to do with me: I've even gone out of my way to disavow that decoherence has anything whatsoever to do with quantum foundational issues. (See for instance the introduction to my `quant-ph/0106166`. That's probably the strongest statement, but there are many places beyond that, and in more technical detail.) Also, in his paper it keeps coming through that he had never grasped what I take the quantum state to be knowledge (now belief) about. Else, when talking about me, he would have never talked about the wave function being "knowledge of the state." That's a phrase I would never use. Here's the way I explained it most recently to Philip Stamp.

> The main point I was trying to make to you . . . is that in an information-based interpretation of quantum mechanics (like the one Caves, Schack, Mermin, Peres, Hardy, and few others of us are trying to put together) is that: Though we take the wavefunction to be information, we never take it to be information about "what is existent" in the quantum system, or "what is happening in the quantum system." That it cannot be information about something like that is what I take to be the great lesson of the Bell-Kochen-Specker theorem. Rather it is always information about how a system will *respond* to an external stimulation (i.e., in usual language, a measurement . . . but I want to get away from the usual language because it carries the wrong imagery). This is the way to think of it when the wave function is about a single system and the way to think of it when the wave function is about a composite system—it doesn't matter.
>
> So, what I am asking—among other things—is that the notion of "measurement" be replaced with the idea of "stimulation and response." We only use wave functions to calculate our expectations with regard to how a system will respond to one or another of our possible stimulations upon it. In this light, there is no contradiction between an "inside view" of a measurement where an unpredictable click really happens and an "outside view" (encompassing both the original system and the first observer), where a wave function for the composite system undergoes a smooth and deterministic transition. This is because the "outside view" wave function refers again to NOTHING MORE THAN the outside observer's expectations for how that composite system will respond to external stimulations upon it.

If Amit had understood that properly, he would not have misapplied Hemmo's argument to this context.

But they say in the Hollywood circles, no advertisement is bad advertisement. (And Caltech is close to Hollywood.) So, I'm keen to hear about your student's paper. Certainly, feel free to share any of the technical parts of my emails with him (like some of the stuff in here) that you wish. And I can certainly give pointers to other relevant materials after reading the draft if that would be useful to you guys.

I suppose I'm hard on the philosopher, being such a moving target to attack or analyze—i.e., the fact that my position is evolving rather than being settled yet (maybe it'll never be settled). But all I'm shooting for is airtight clarity, and that can be a tough process. Reading other's perceptions of the program is quite useful in that regard.

01-07-04 *Quail and Pheasant?, 2* (to S. Hartmann)

You might enjoy this and the story below too. [See 30-06-04 note "Quail and Pheasant?" to J. B. Lentz & S. J. Lentz.] It was nice to see (*what I hope will eventually be*) a quantum-Bayesian trademark—i.e., a probability simplex with a restricted area—making an appearance in such a prominent place.

05-07-04 *Your Friend Philip* (to M. Janssen)

Let me come back to your question now:

Janssenism 3 : *[L]et me just ask you what I should read to get over the next hurdle I'll have to take before this information stuff has a prayer of dislodging Everett. The hurdle is simply this: how is your information approach different from the old ignorance interpretation of QM. And I'm sure you won't mind me spelling this out a bit to make sure you know what I mean. I take the ignorance interpretation to be saying things like this: of course, an electron has a definite position (as well as definite whatever) at all times, it's just that typically we don't know what that is. That's why we can only describe the electron in terms of a superposition of it being in all places it could possibly be. When we perform a measurement we find out what its real position is. So QM is just like classical statistical mechanics basically: it gives us probability distributions over values of variables we don't know the exact value of. The only difference is that QM tells us that we can't ever know all values of all variables at the same time, because typically the measurement of the value of one variable disturbs the value of others. I buy (what I take to be) the standard line against this view: the probability distributions generated by state vectors in Hilbert space cannot be reduced to classical probability distributions.*

As I've already told you, as I see it, my view is pretty diametrically opposed to the "ignorance interpretation" you describe. You can find some early and very direct discussion of this in my paper with Kurt Jacobs, "Information Tradeoff Relations for Finite-Strength Quantum Measurements." Here's a link to the version sitting on the archive: `quant-ph/0009101`.

The part relevant for you is the introduction. Reading over this again for the first time in almost four years, it doesn't strike me as half bad (even though I've become more metaphysical since then). Anyway, read that, and see how it moves you. Don't forget footnote 27.

It's hard to tell you where the very "best" thing to read is, as my view has been evolving (and I think becoming much more consistent) over the last few years. The view will never be completely consistent until we get a full-fledged derivation of quantum mechanics from it (and I hope you'll contribute to it eventually). But I'm still relatively proud of my paper "Quantum Mechanics as Quantum Information (and only a little more)." I think I gave you a copy of that, but in case you threw it out, get the version on my web page.

(The version on `quant-ph` has more typos.) The relevant parts for a first, philosophical reading are: Section 3, "Why Information?", and Section 4, "Information about What?". I think they answer your question pretty directly. You might want to also look at Section 10, "The Oyster and the Quantum." I'm not completely sure how that section fits in with the stuff I've been thinking most recently, but I think there's still a significant overlap.

Finally, let me supplement all that with some recent words that I recorded for Philip Stamp. They're placed below. I think that's about as complete a picture I can give you at the moment without getting into the project of writing a new paper. [See 19-05-04 and 04-06-04 notes, "Bathroom Reading" and "Earwax," to P. C. E. Stamp.]

05-07-04 *Flavors of Realism* (to M. Janssen)

Let me finally send you two more supplements to what I've already sent you before you face your friend. These things address the ways in which I see this foundational program for quantum mechanics as a flavor of realism (and a result of Darwinism).

The most important among these is Sections 4 and 5 in my paper "The Anti-Växjö Interpretation of Quantum Mechanics" posted at `quant-ph/0204146`.

Second to that, though, let me also attach the handout I put together for the Seven Pines meeting, "Delirium Quantum." (There was no particular reason that it needed putting together for Seven Pines per se; I just needed some event as a catalyst, and Seven Pines was it.) The most relevant sections for your particular question are Sections 4 and 5 (again).

06-07-04 *World and Observer Intertwined* (to G. Musser)

I'm planted in Munich now for the evening, and it's two and a half hours until beer-thirty with my in-laws. So, let me see what I can work up for you between now and then. As I've already expressed, your main question is a good one, and I had hopes of writing you a little essay in reply. But as usual, I wasn't being realistic with myself about my duties and my distractions. Thus, the stuff below will have to do for the moment.

First off:

Musserism 12: *... most physicists still regard hidden variables as a long shot. Quantum mechanics is such a rainforest of a theory, filled with indescribably weird animals and endlessly explorable byways, that seeking to reduce it to classical physics seems like trying to grow the Amazon from a rock garden. Instead of attempting to reconstruct the theory from scratch, why not take it apart and find out what makes it tick? That is the approach of Fuchs and others in the mainstream of studying the foundations of quantum mechanics.*

They have discovered that much of the theory is subjective. It does not describe the objective properties of a physical system, but rather the state of knowledge of the observer who probes it. Einstein argued as much when he critiqued the concept of quantum entanglement–the "spooky" connection between two far-flung particles. [The following is presumably the problematic sentence.] Fuchs argues that what looks like a physical connection is actually an intertwining of the observer's knowledge about the two particles. After all, if there really were a connection, physicists should be able to use it to send faster-than-light signals, and they can't.

I like all of that quite a bit. The only thing I would change is your sentence, "They have discovered that much of the theory is subjective." I'm not sure a reader would quite get what you mean. If you came upon this sentence cold, not preconditioned by my idiosyncrasies, would you know what it means for a theory to be subjective (or even have a guess at it)? Your sentence immediately following it wards off quite a bit of the trouble, but you might be a little more preemptive. Maybe I'd say something like this:

> They have discovered that, though conditioned by the peculiarities of nature, much of the theory concerns not nature itself but the observer's interface with nature. In other words, the theory does not primarily describe the objective properties of physical systems, but rather the possible states of knowledge of the observers who probe them.

That's probably a bit long for you, but I'm sure it's shortenable with a little work (and can made to sound more in your own style), but most importantly I think it's more on the right track.

Now to the next paragraph. Even up to here, I'm OK with it:

Musserism 13 : *Physicists had long assumed that measuring a quantum system causes it to "collapse" from a range of possibilities into a single actuality. Fuchs argues it is just our uncertainty about the system that collapses.*

The only way I might amend the first sentence if I were writing it myself would be to make it something like this:

> Physicists had long assumed that measuring a quantum system causes it to literally 'collapse' from a range of possibilities to a single actuality. Fuchs argues it is just our uncertainty about the system that collapses.

The trouble only really starts with the next sentences:

Musserism 14 : *Uncertainty about a quantum system is very different from uncertainty about a classical one, because the process of measurement inevitably disturbs a quantum system. And this sensitivity to disturbance is a clue to what a quantum system really is.*

So, let's focus on them. Maybe I would change them to something like this:

> It is only that the uncertainty is about a very different beast in the quantum case than in the classical one. Classically when one speaks of uncertainty, one assumes that it is always uncertainty about a some preexisting property that has nothing to do with the act of observation. In the quantum case the uncertainty is about something at the interface between the system in the observer—the result that comes about through the very act of probing the system. Like Einstein's entangled particles, the world and the observers within it are wired together so tightly that the theory cannot be about the one without also being about the other.

I know it probably doesn't sound like something you yourself would compose—I get truly pissed off any time someone tries to change my own writing—but maybe it gives you something to work with that starts off a little closer to what's inside my head.

Here's the whole lot pasted together:

> . . . most physicists still regard hidden variables as a long shot. Quantum mechanics is such a rainforest of a theory, filled with indescribably weird animals and endlessly explorable byways, that seeking to reduce it to classical physics seems like trying to grow the Amazon from a rock garden. Instead of attempting to reconstruct the theory from scratch, why not take it apart and find out what makes it tick? That is the approach of Fuchs and others in the mainstream of studying the foundations of quantum mechanics.
>
> They have discovered that, though conditioned by the peculiarities of nature, much of the theory concerns not nature itself but the observer's interface with nature. In other words, the theory does not primarily describe the objective properties of physical systems, but rather the possible states of knowledge of the observers who probe them. Einstein argued as much when he critiqued the concept of quantum entanglement—the "spooky" connection between two far-flung particles. Fuchs argues that what looks like a physical connection is actually an intertwining of the observer's knowledge about the two particles. After all, if there really were a connection, physicists should be able to use it to send faster-than-light signals, and they can't.
>
> Physicists had long assumed that measuring a quantum system causes it to literally 'collapse' from a range of possibilities to a single actuality. Fuchs argues it is just our uncertainty about the system that collapses. It is only that the uncertainty is about a

> very different beast in the quantum case than in the classical one. Classically when one speaks of uncertainty, one assumes that it is always uncertainty about a some preexisting property that has nothing to do with the act of observation. In the quantum case the uncertainty is about something at the interface between the system and the observer—the result that comes about through the very act of probing the system. Like Einstein's entangled particles, the world and the observers within it are wired together so tightly that the theory cannot be about the one without also being about the other.

I hope that's helpful and not just annoying. I might (repeat *might*) get a chance to write a little more, but let's start with this.

My wife and I are just in Munich for the night to drop off the kids with the grandparents while we're house hunting. We fly out for NJ at 7:00 tomorrow morning.

06-07-04 *A Little More* (to G. Musser)

Back again. It's beer-thirty now, but the family's still shopping. Still no proper essay, but let me come back to that set of questions of yours.

Musserism 15 : [CAF wrote:]

> The only thing that differentiates Einstein from our little effort at this juncture is that he thought physics should ultimately be about the "states" of nature, whereas the guys in my camp think that the great lesson of quantum mechanics is that physics must be about something else.

What is it about, then? Also, are you agreeing with Bohr that physics isn't about nature but what we can say about nature?

I hope the reworking of your old paragraphs that I just sent you, along with the opening of my Caltech lectures, already answers this question. I don't think Aage Petersen's rendition of Bohr—"There is no quantum world. There is only an abstract quantum physical description. It is wrong to think that the task of physics is to find out how nature *is*. Physics concerns what we can say about nature."—gets it quite right. Instead, the model of QM is predominantly about something arising between the world external to the observer and the observer himself. Don't you see the difference of tone? It is not as if we are talking about something from afar (as Petersen makes it sound like), but something we are deep within the middle of and intimately involved with. A quantum mechanical measurement result has its source as much in the system as it does with the observer—that is an ontological statement and not just an epistemological one. After all these years, there's probably still no better picture of the process than in John Wheeler's story of the game of twenty questions (surprise version):

> The Universe can't be Laplacean. It may be higgledy-piggledy. But have hope. Surely someday we will see the necessity of the quantum in its construction. Would you like a little story along this line?
>
> Of course! About what?
>
> About the game of twenty questions. You recall how it goes—one of the after-dinner party sent out of the living room, the others agreeing on a word, the one fated to be a questioner returning and starting his questions. "Is it a living object?" "No." "Is it here on earth?" "Yes." So the questions go from respondent to respondent around

the room until at length the word emerges: victory if in twenty tries or less; otherwise, defeat.

Then comes the moment when we are fourth to be sent from the room. We are locked out unbelievably long. On finally being readmitted, we find a smile on everyone's face, sign of a joke or a plot. We innocently start our questions. At first the answers come quickly. Then each question begins to take longer in the answering—strange, when the answer itself is only a simple "yes" or "no." At length, feeling hot on the trail, we ask, "Is the word 'cloud'?" "Yes," comes the reply, and everyone bursts out laughing. When we were out of the room, they explain, they had agreed not to agree in advance on any word at all. Each one around the circle could respond "yes" or "no" as he pleased to whatever question we put to him. But however he replied he had to have a word in mind compatible with his own reply—and with all the replies that went before. No wonder some of those decisions between "yes" and "no" proved so hard!

And the point of your story?

Compare the game in its two versions with physics in its two formulations, classical and quantum. First, we thought the word already existed "out there" as physics once thought that the position and momentum of the electron existed "out there," independent of any act of observation. Second, in actuality the information about the word was brought into being step by step through the questions we raised, as the information about the electron is brought into being, step by step, by the experiments that the observer chooses to make. Third, if we had chosen to ask different questions we would have ended up with a different word—as the experimenter would have ended up with a different story for the doings of the electron if he had measured different quantities or the same quantities in a different order. Fourth, whatever power we had in bringing the particular word "cloud" into being was partial only. A major part of the selection—unknowing selection—lay in the "yes" or "no" replies of the colleagues around the room. Similarly, the experimenter has some substantial influence on what will happen to the electron by the choice of experiments he will do on it; but he knows there is much impredictability about what any given one of his measurements will disclose. Fifth, there was a "rule of the game" that required of every participator that his choice of yes or no should be compatible with *some* word. Similarly, there is a consistency about the observations made in physics. One person must be able to tell another in plain language what he finds and the second person must be able to verify the observation.

Musserism 16: *But ultimately don't you suggest that there is more to nature than is captured in the quantum formalism?*

Yes I do. Here's how I put it in the "Delirium Quantum" thing I sent you:

The whole subject matter of my *Notes on a Paulian Idea* is in toying with the idea that the cleanest expression of quantum mechanics will come about once one realizes that its overwhelming message is that the observer cannot be detached from the phenomena he *helps* bring about. I italicize the word *helps* because I want you to take it seriously; the world is not solely a social construction, or at least I cannot imagine it so. For my own part, I imagine the world as a seething orgy of creation. It was in that orgy before there were any agents to practice quantum mechanics and will be in the same orgy long after the Bush administration wipes the planet clean. Both of you have probably heard me joke of my view as the "sexual interpretation of quantum mechanics." There is no one way the world is because the world is still in creation,

> still being hammered out. It is still in birth and always will be—that's the idea. What quantum mechanics is about—I toy with—is each agent's little part in the creation (as gambled upon from his own perspective). It is a theory about a very small part of the world. In fact, I see it as a theory that is trying to tell us that there is much, much more to the world than it can say. I hear it pleading, "Please don't try to view me as a theory of everything; you take away my creative power, my very promise, when you do that! I am only a little theory of how to gamble in the light of a far more interesting world! Don't shut your eyes to it."
>
> The question is, how to get one's head around this idea and make it precise? And then, once it is precise, what new, wonderful, wild conclusions can we draw from it? That is the research program I am trying to define.

And in another part:

> But, you should remember that these quantum states we speak of are not perspectives. They are personal possessions. To modify Tilgher's quote at the beginning of de Finetti's "Probabilismo" for our own purposes,
>
>> A quantum state is not a mirror in which a reality external to us is faithfully reflected; it is simply a biological function, a means of orientation in life, of preserving and enriching it, of enabling and facilitating action, of taking account of reality and dominating it.

Musserism 17: *That there is a there, there?*

Are you a fan of Gertrude Stein? Carl Caves and I wrote this in a 1996 paper:

> The information gathered from repeated measurements on quantum systems is indeed drawn from an inexhaustible well, but it is a well of potentialities, not actualities. Asked where all this information resides, we reply, with apologies to Gertrude Stein "There is no where there."

I wouldn't use that language anymore (i.e., talking about measurement results as information unqualified), but I still like the idea of using Stein when possible.

Musserism 18: *Or at least, you seem to suggest that there are "buried" variables – they're not hidden, because they do appear in the formalism, but they're so entangled with subjective elements that they are hard to tease out.*

I still don't know quite how to respond to this one. The language of "variables" is on the wrong track. But this is why I wanted to write a little essay for you. (These things are never for free by the way: You're the muse and the laboratory. If the explanation turned out good enough, I'd find a way to incorporate it into a paper.)

Similarly I'd love to give you an extended explanation of this:

Musserism 19: *Another issue that I'm struggling with is this business of separating states of knowledge from states of nature. Isn't a state of knowledge a state of nature where "nature" includes the observer? The wavefunction is a statement about me, but I'm part of nature, right?*

The root of this one goes even deeper, all the way back to Bayesian probability. Quantum mechanics just adds an extra layer (or reinforcement) to it. The best I can do is give you a hint of an answer that comes from a little piece of an exchange with Marcus Appleby after his paper `http://www.arxiv.org/abs/quant-ph/0402015` (definitely recommend reading it if you want to go a little more deeply into this). You are right: The observer is certainly part of nature. Here's the exchange:

> In your "Facts, Values and Quanta" you say "a probability statement cannot be identified with a fact about the world, as it exists independently of us." I think that is all I have ever meant by "subjective." But, then again, maybe that's just hindsight playing a trick on me.

But I need to write so much more on the subject.

06-07-04 *Preliminary Yes* (to G. Musser)

I might use "pertains to" rather than "describes", but otherwise I think the paragraph is accurate. The only other thing is whether "sexual interpretation" is too risqué for *Scientific American*: If it's not, I guess I'm OK with it.

Gotta run for the flight. I'll think about the rest of your note over the Atlantic, and may possibly reply.

George's Preply

> This is all very helpful. I've tinkered with the first two paragraphs of that passage, but as you said, the real issues concern the third paragraph. Here is my latest attempt:
>
> > Physicists had long assumed that measuring a quantum system causes it to "collapse" from a range of possibilities into a single actuality. Fuchs argues that it is just our uncertainty about the system that collapses. Uncertainty about a quantum system is very different from uncertainty about a classical one, and this difference is a clue to the objective world. In the classical case, a particle has some velocity; uncertainty means that observers do not know this velocity until they measure it. In the quantum case, the velocity does not even exist until observers go to look for it. The concept of velocity describes the interface between system and observer. Fuchs calls this idea the "sexual interpretation of quantum mechanics." He has written: "There is no one way the world is, because the world is still in creation, still being hammered out." The same thing can be said of our understanding of quantum reality.
>
> Please let me know asap if this works or not.

07-07-04 *A* (to G. Musser)

Stuck on the runway at Heathrow with the threat of an equipment change! Arrggh!

Musserism 20: *How literally should I take Wheeler's game of 20 Questions? There is a rhyme and a reason behind the answers I get to my 20 questions – namely the (pre-existing!) agreement among the participants. There is an objective reality.*

You should read that passage much more carefully! (Second Arrggh!!) It is not about the "game of 20 questions" but the "game of 20 questions (surprise version)". The whole point of the story is exactly the opposite of what you took from it. [But, see 12-08-04 note "Background Noise" to G. Musser.]

07-07-04 *A.5* (to G. Musser)

B and C still coming, but now I'm stuck in Heathrow for five hours (at least) and not in a particularly good mood. I'll probably return to complete them in NJ somewhere in the middle of some night.

07-07-04 *B* (to G. Musser)

Musserism 21 : [CAF wrote:] *"It is a theory about a very small part of the world ... a theory that is trying to tell us that there is much, much more to the world than it can say." How is this not hidden variables?*

Sure, they may not be hidden variables in the pre-existing sense – i.e. in the sense that a properly designed experiment can come asymptotically close to ascertaining their pre-experiment value. But does not "more to the world" imply something hidden?

Take a break from me for a moment and ask yourself how the Everett interpretation is not a hidden-variable theory? (It almost seems you would have asked the Everettian the same thing you asked me.) A hidden-variable theory is a very specific thing: If one were to know the value (even if only hypothetically and not operationally) of all the variables (including possibly the ones on the inside of the observer), then one can predict the outcome of all measurements with certainty. It is a fancy way of saying measurement outcomes pre-exist, even if nothing one would ever call a measurement is actually performed.

The determination or setting of specific measurement outcomes (in any quantum mechanical experiment) has always been outside of the quantum mechanical formalism. There is nothing in the formalism that determines whether one will get this click or whether one will get that click in some measurement device. But that does not make it a hidden-variable theory. What is hidden?

Here is the way Pauli put it:

> Like an ultimate fact without any cause, the individual outcome of a measurement is ... in general not comprehended by laws. This must necessarily be the case ...
>
> In the new pattern of thought we do not assume any longer the detached observer, occurring in the idealizations of this classical type of theory, but an observer who by his indeterminable effects creates a new situation, theoretically described as a new state of the observed system. In this way every observation is a singling out of a particular factual result, here and now, from the theoretical possibilities, thereby making obvious the discontinuous aspect of the physical phenomena.
>
> Nevertheless, there remains still in the new kind of theory an objective reality, inasmuch as these theories deny any possibility for the observer to influence the results of a measurement, once the experimental arrangement is chosen.

(The conjunction of these thoughts is what I call "the Paulian idea"—hence the name of my book.) "Like an ultimate fact without any cause, the individual outcome of a measurement is not comprehended by laws."

The way I see it, quantum measurement outcomes are ultimate facts without specific call for further explanation. And indeed the quantum formalism supplies none. Thus there is more to the world than the quantum formalism can supply. Nothing to do with hidden variables.

But more specifically, regarding your point:

Musserism 22: *"It is a theory about a very small part of the world... a theory that is trying to tell us that there is much, much more to the world than it can say." How is this not hidden variables?*

How does the theory tell us that there is much more to the world than it can say? It tells us that *facts* can be made to come into existence, and not just at some time in the remote past called the "big bang" but here and now, all the time, whenever an observer sets out to perform (in antiquated language) a quantum measurement. I find that fantastic! And it hints that facts are being created all the time all around us. But that now steps out of the domain of what the quantum formalism is about, and so is the subject of future research. At the present—as a first step—I want rather to make the interpretation of the quantum formalism along these lines absolutely airtight. And then from there we'll better know how to go further.

Doesn't that just make you tingle? That (metaphorically, or maybe not so metaphorically) the big bang is, in part, right here all around us? And that the actions we take are *part* of that creation! At least for me, it makes my life count in a way that I didn't dare dream before I stumbled upon Wheeler, Pauli, and Bell-Kochen-Specker.

But let me get away from this speculation and rope myself back in on your particular question: How is this not some hidden variables account? Simple: If there are any extra facts being created around us, they nevertheless do not impinge on the individual quantum measurement outcome.

When I say that QM is a theory about a very small part of the world, you should literally think of a map of the United States in relation to the rest of the globe. The map of the US is certainly incomplete in the sense that it is obviously not a map of the whole globe. But on the other hand it is as complete as it can be (by definition) as a representation of the US. There are no hidden variables that one can add to the US map that will magically turn into a map of the whole globe after all. The US map is what it is and need be nothing more.

Does that help any?

I think a good bit of the problem comes from something that was beat into most of us at an early age. It is this idea: Whatever else it is, quantum theory should be construed as a theory of the world. The formalism and the terms within the formalism somehow reflect what is out there in the world. Thus, if there is more to the world than quantum theory holds out for, the theory must be incomplete. And we should seek to find what will complete it.

But my tack has been to say that that is a false image or a false expectation. Quantum theory from my view is not so much a law of nature (as the usual view takes), but rather a law of thought. In a slogan: Quantum mechanics is a law of thought. It is a way of plagiarizing George Boole who called probability theory a law of thought. (Look at the first couple of entries in the Rüdiger Schack chapter of *Notes on a Paulian Idea*.) Try to think of it in these terms, and let's see if this helps.

Let us take a simple term from probability theory, namely a probability distribution over some hypothesis $P(h)$. This function represents a gambling agent's expectations about which value of h will obtain in an observation or experiment. Suppose now the agent gathers a separate piece of data d from some other observation or experiment and uses it to conditionalize his expectations for h; i.e., he readjusts his expectations for h to some new function $P(h|d)$ by using Bayes' rule. Now here's a question for you. Is there anything within abstract probability theory that will allow the agent to predict precisely which value of d he will find when he gathers his data? Of course not. It's almost silly to pose the question. Abstract probability theory has nothing to do with the actual facts of the world. But then, doesn't that mean that probability theory is an incomplete theory? It can't, for instance, explain its own transitions $P(h) \longrightarrow P(h|d)$ since probability theory alone can't tell us why this d rather than that d. Moreover if probability is incomplete in this way, shouldn't we be striving to complete it? Both silly questions, and I hope for obvious reasons.

So:

1. There is no particular mystery in the transition $P(h) \longrightarrow P(h|d)$.
2. We would never expect probability theory to provide a mechanism to determine which value of d is found or produced in the experiment. The value d represents a fact of the world, and probability theory is *only* a theory about how to manipulate expectations once facts are given.
3. But also no one would be compelled to call probability theory incomplete because of this.
4. In particular, admitting this does not amount to having a hidden-variable explanation of probability theory.

So I say with quantum mechanics. The story is almost one-to-one the same: You just replace probability distributions with quantum states. ... But then you reply, "But there's a difference; quantum theory is a theory of physics, it is not simply a calculus of thought." And I say, "That's where you err." Quantum theory retains a trace of something about the real, physical world but predominantly it is a law of thought that agents should use when navigating in the (real, physical) world. In particular, just like with probability theory, we should not think of quantum theory as incomplete in the usual sense. If it is incomplete in any way, it is only incomplete in the way that the US map is incomplete with respect to the globe: There's a lot more land and ocean out there.

Teasing out (your words) the trace of the physical world in the formalism—i.e., the part of the theory that compels the rest of it as a useful law of thought—is the only way I see to get a solid handle on what quantum mechanics is trying to tell us about nature itself.

With this let me now go back to the US map for one final analogy. I said that there is a sense in which the US map is as complete as it can be. However there is also a sense in which it tells us something about the wider world: If we tabulate the distances between cities, we can't help but notice that the map is probably best drawn on the surface of a globe. I.e., the US already reveals a good guess on the curvature of the world as a whole—it hints that the world is not flat. And that's a great addition to our knowledge! For it tells a would-be Columbus that he can safely go out and explore new territories. Exploring those new territories won't make the US map any more complete, but it still means that there is a great adventure in front of him.

OK, with that, I'm going to call this discussion to an end. If you still think of me as a hidden variableist, I've either failed in my explanatory powers or my view is simply inconsistent. (I would bank on the former rather than the latter.) Either way I'm going to call the discussion to an end.

Good luck finalizing your article (if you haven't already finalized it).

07-07-04 C (to G. Musser)

Musserism 23: *I hate to say it, but if you write for* Scientific American*, as I hope and expect you will, it will be very similar to the process we are now undergoing. You will come up with something, I or one of my colleagues will critique and perhaps rewrite it, and around and around we will go.*

The trick is to ensure that the writing converges before the pissedoffedness diverges.

I tend to be gentler when someone gains my trust ...

28-07-04 *Three, Two, One* (to G. Brassard)

I'm sorry for the absence: I apologize to everyone now, and constantly. What I really need is three months off to clean the palette and get a fresh start. . . . But I don't have that privilege.

Brassardisme 15: *I spent 4 out of 5 consecutive nights with 3 to 4 hour sleep per night last week+ for the purpose of finishing my survey of pseudo-telepathy, since I wanted to have something in the Asher special issue (having given up on you), and I was more than late with the submission. I would appreciate* at least *a word of acknowledgement-of-receipt! By the way, I'll be away (mostly vacation) all of August, and therefore unable to react quickly if you ask me for an urgent and/or a version typeset according to* Foundations of Physics *nonsense (such as double-spaced).*

Great paper, the part I've read. Please make sure to add the authors' affiliations, fix any typos, and email me the original TEX/LATEX/whatever. Also, yes, please do make it double-spaced.

Little point of history: Podolsky actually wrote the EPR paper. Einstein was not particularly pleased with it, but reluctantly agreed to publish it as it was. He thought it obscured the cleaner argument he had—the one he reports in several letters (to Schrödinger, Born, Besso, and others). A good/fun place to read about all this is in the first couple of chapters of Arthur Fine's book *The Shaky Game*.

Brassardisme 16: *My talk on QFLQI in Toronto last Friday went extremely well. Well over one hundred people in attendance (something never seen in summer time) and by far the liveliest crowd I've ever seen! They kept me with questions for 90 MINUTES after the end of the talk. Wonderful, except that I almost missed my flight back! Of particular interest among the attendance was Marlan Scully from Texas A & M University. Do you know him?*

That is great news! I wish I could have been there to hear it. It's nice to see this program getting so much enthusiasm. Yes, I know Marlan and have some good stories to tell about him. What has his reaction? Did he say anything interesting?

02-08-04 *My Own Apology* (to C. G. Timpson)

I enjoyed your envoi and am thankful you wrote it: Your willingness to take the program seriously is already a great compliment—in fact, it's its only toehold in the Oxford community.

I liked the way you made it clear that even if one adopts a kind of instrumentalism for the quantum state, one can still ask, "Why this instrumentalism, rather than that instrumentalism?" And to the extent that one can provide reasons for the choice, one is going beyond instrumentalism. While I'm here, let me paste in something I wrote up for a reporter at *Scientific American* that addresses the same issue. I used a metaphor I hadn't used before that maybe better captures the idea: It's how an accurate map of an isolated country can already reveal that there's a larger world out there (through the curvature required to make sense of the distances between cities). Yet it's no sin of the map that it doesn't cover the whole world. Likewise, I think of quantum theory.

12-08-04 *Background Noise* (to G. Musser)

I'm coming back intermittently. My wife, kids and I are presently in Texas, visiting my mom, and soon to start driving our mini-van back to New Jersey. (We had it stored here, because we had to drive down our ailing old dog before taking off for Ireland.)

You had a point about the pre-agreement in Wheeler's game of twenty questions. That is one part of the image that I'd like to not take too seriously. I'd rather have Darwinism all the way down, if the world will support it.

If you haven't read it yet, read Louis Menand's *The Metaphysical Club*. (Menand also writes for the *New Yorker*, I'm told.) It's an easy in into the idea that the world is Darwinism all the way down. Very enjoyable book; I loved it.

Yeah, there's a lot about your note below that I like. But I've got too much to do to parse it at the moment.

George's Preply

> You write: "If you still think of me as a hidden variableist, I've either failed in my explanatory powers or my view is simply inconsistent." I'm not seeking to label your ideas as an "ism". I realize that the term "hidden variables" is a loaded one within the foundations-of-QM community, but I have been using it simply as a foil to try to understand your work. I'm not an antagonist but a persistent student.
>
> Let me see whether I understand your vision of a world in continuous creation. Ernst has bequeathed me his cat; it arrives in a box. I open it to find the cat is ... alive. Before I do, the cat is neither alive nor dead; it is not even in a purgatorial superposition. In fact, the categories of cat alive and cat dead don't even exist yet. When I open the box, I create the fact of a live cat. That fact had to come into existence *sometime*. In the classical deterministic universe, it came into existence when the universe did. All the arbitrariness was in the ICs. The quantum universe makes up facts as it goes along. The arbitrariness is spread out over time. It's the distinction between my wife, who makes plans and carries them out, and me, who decides step by step on the fly.
>
> If we're talking about, say, particle spin, I play an even more active role in the creation, by virtue of how I conduct my experiment. I tell the particle: You are spinning up toward the ceiling of my lab or down toward the floor; now choose.
>
> Is that the general idea? There are lots of issues in there, but I want to get this down.

12-08-04 *The Fruit* (to G. Musser)

By the way, let me show you the fruit of my extended absence—it hasn't been an easy few weeks. We got a nice house in Cranford, the second town closer to NYC on the Raritan Valley Line than Westfield. (I don't know if you're familiar with the towns around there.) Now I'm 8 miles from Bell Labs, 10 miles from Newark Airport, and 19 from the WTC. Anyway, an 1890 house in great shape, three levels, three fire places, 0.4 acre yard, a nice patio, etc. I think it's going to be a good place for thought. Drop by some time.

03-09-04 *The Fruit of Someone Else's Imagination* (to D. Poulin)

Poulinism 15: *You seem to be comfortable with this situation, but I'm not. In particular, I'm not very happy being the fruit of someone else's imagination, specially knowing that this person is the fruit of my imagination. What's your response to this? Did I take a wrong turn or do you agree with my conclusion? Is there any way out of this?*

Oh student! Yes, you took a wrong turn: You're not the fruit of anyone's imagination. (You've always been beyond my imagination anyway.)

But there's no time for email this week. Maybe next week. (In any case, what could I say differently this time than I've said before?) Instead, let me let another French speaker—Michel Bitbol—talk to you for the time being. He captures much of my position in the letter below. [See 10-12-03 note "First Meeting" to M. Bitbol.] Does it help any?

PS. You should come visit us sometime: We now have the best house we've ever had: about 400 square meters (three levels plus basement) on a .43 acre park-like yard, quiet street, walking distance to train station (.5 mile), and only 45 from New York thereafter. The guest room is the biggest in the house.

David's Preply

> It appears to me that there is no way around the fact that quantum states are not real, they represent our knowledge about systems. At first, I thought that one could get away with a "mild flavored" notion of subjectivity: the type discussed by Rovelli in his "Relational Quantum Mechanics". But I have been re-reading this lately, and I think that deep inside he is a many-world guy, but doesn't want to admit it. He talks about certain consistency conditions and other imposed relations between distinct observers. He never says so clearly, but in the back of his head there is a God's eye point of view from which all observers' "subjective" state assignments only reflect the bits and pieces of the "real" wave function of which they have only partial access (they are "stuck in a branch"). (Note that he rejects this in his paper ... but there is no way around it.)
>
> But once you recognize that states represent your knowledge, you get caught in a spiral that leads you to the unavoidable conclusion that there is nothing real. I guess that this was the point of your Phys. Today letter: if you believe that quantum theory is right (and believe in causality), then there is no room in it for an objective reality. Of course, there is room for inter-subjective agreement among several independent observers (emergent objectivity), but this is not fundamental. A more profound theory might eventually admit elements of reality, but not quantum theory the way it is today.
>
> You seem to be comfortable with this situation, but I'm not. In particular, I'm not very happy being the fruit of someone else's imagination, specially knowing that this person is the fruit of my imagination. What's your response to this? Did I take a wrong turn or do you agree with my conclusion? Is there any way out of this?

03-09-04 *Newer, Newish Thoughts* (to D. Poulin)

I'll also paste in one of my more recent smears on "reality". It's a PDF file.
Have a good weekend.

03-09-04 *Reach of the Black Cow* (to C. H. Bennett)

I thought fondly of you as I drove to work this morning: The radio announcer on JAZZ 88.3 said that the music set he just played was sponsored by the Black Cow in Croton.

Anyway, I'm back at Bell Labs now. My new addresses and phone numbers are listed below. We ought to have a good work weekend in Wendel some time. Or alternatively, you and Theo should come visit us: We've got a great house now in a great area. (If you've got a broadband connection, I'll send you some pictures.)

07-09-04 *Targeted Answer* (to D. Poulin)

When I wrote you the other day, I had forgotten about the little piece of literature below. It's much more of a direct answer to what you were asking:

Poulinism 16: *But once you recognize that states represent your knowledge, you get caught in a spiral that leads you to the unavoidable conclusion that there is nothing real. I guess that this was the point of your Phys. Today letter: if you believe that quantum theory is right (and believe in causality), then there is no room in it for an objective reality. Of course, there is room for an inter-subjective agreement among several independent observers (emergent objectivity), but this is not fundamental. A more profound theory might eventually admit elements of reality, but not quantum theory the way it is today.*

You seem to be comfortable with this situation, but I'm not.

The outcome of a quantum measurement is not the fruit of the measurer's imagination, for he cannot predict it. It is first-class evidence of a reality (at least partly) independent of himself. The "identity of the outcome" is something in the world that quantum theory cannot capture. But I don't see that as a blemish on the theory that is waiting to be *fixed* by a more "profound theory." The way I explain this is below; it is something I wrote for a *Scientific American* reporter. [See 07-07-04 note titled "B" to G. Musser.]

07-09-04 *Summer-School Words* (to D. Poulin)

Poulinism 17: *Now, I should probably read the papers ten times before asking these dumb questions, (I don't have much time to do this these days) but what gets to provoke reality? You say many times that it is our interventions into the world (measurements) that forces reality into existence. Does this require consciousness?*

I'll only comment with the words I wrote for the intro to my summer-school lectures at Caltech this summer. They're below. [See 17-06-04 note "Preamble" to H. Mabuchi.]

07-09-04 *Realism* (to H. Barnum)

Barnumism 9: *I would like to be realistic about, say, electrons, if not about the wavefunction. Can you think of a way to do that? The problem is, one is led to say things like "Yeah, there really are electrons, and there are some right here in this box". The latter statement seems to be about their wavefunction, however. Maybe that's not a problem.*

For the heck of it, while we're on the subject of realism, let me place below three recent letters/compositions that plead again that I'm really a realist. I think I used some new modes of expression that might be useful. I particularly like the analogy that makes use of a U.S. map and a globe that I explain near the end.

Barnumism 10: *I don't think it's just the dimension of their Hilbert space, though. Maybe it's a little bit more: a Hilbert space with a particular group action on it...? Wavefunctions aren't* *real, but maybe the place where they live, equipped with its observables and their group-theoretic structure, is. . . ?)*

Oh well. . .

Yeah, it is something more like that—I think in my more democratic moments. Bill Unruh spent a good amount of time at the Minnesota meeting this summer trying to suggest something like that to me too.

08-09-04 *Fuchsian Pick List* (to S. Hartmann, C. M. Caves & R. Schack)

I'm trying to make up for lost time before Rüdiger arrives in New Mexico. Attached is my reworking of Stephan's last list of potential invitees.

You'll see I blithely rearranged according to my tastes. I hope I won't cause any offense. I did try to annotate pretty thoroughly. And definitely, I'm not above bargaining on any of these positions: Anyone I moved into the "waiting list" can certainly be moved back out of it and vice versa. The main thing I am shooting for is a happy, productive, mutually-respectful crew. With the exception of Price, Fitelson, and Ismael, I know everyone in the present invitee list personally, and I think they will work well together . . . providing a little friction, but not too much friction. You'll see, I was pretty negative on Bohmians and other exotic sorts. The main thing I personally want to see at this meeting is a sense of progress, rather than a continuing sense of standstill (which is what I see every time I see a confirmed Bohmian in the room).

If we could open the floodgates, I would love to see everyone in the present list plus the waiting lists all together hashing it out. It would be a grand get-together. But there is no doubt that it'd be much too large for the present meeting.

10-09-04 *Soul's Return* (to S. Hartmann, C. M. Caves & R. Schack)

After 37 days of crossing the ocean and (mostly) sitting in US customs, my household goods finally made their way to Cranford today. That includes my 331 books on James, pragmatism, Wittgenstein, and Rorty: It's almost as if my soul was returned to me!

Perhaps I'll be a more creative writer next week.

13-09-04 *Blurb* (to Princeton University Press)

Here's the blurb.[78] Two points: 1) If you decide to use it, you have to keep the bad with the good, i.e., use the whole thing. I.e., you can't just cut the positive part from the review. My integrity is at stake. And 2) my affiliation "Bell Labs, Lucent Technologies" must be used along with my name. Blurb below.

> Roland Omnès has a knack for writing in at least three of the world's major languages: English, French, and Science. I have at times found a lifetime's worth of insight from a single paragraph of his. The present work is no exception. For though I disagreed

[78] For R. Omnès, *Converging Realities: Toward a Common Philosophy of Physics and Mathematics*, (Princeton University Press, Princeton, 2005).

with whole swaths of the book, I learned much from it and had to fight every inch of the way to shore up my position against its onslaught. No discussion of reality should ignore this powerful and novel exposition.

13-09-04 *Silence from the Podium Is Sometimes Golden* (to S. Hartmann, C. M. Caves & R. Schack)

Hartmannism 1: *I think that it is important that we come up with a structure of the conference very soon. We need this before we write the speakers to give them instructions.*

I actually think it preferable if not all invitees are allotted a formal speaking spot. I'm thinking particularly of the format of the Seven Pines meeting in Minnesota this spring. Maybe only a little over half the participants actually spoke. The ones that did would speak in pairs (with somewhat related subjects), then we would take a coffee break, and come back for discussion. The two speakers would be placed in chairs in front of the audience and the discussion would go for about as long as the talks. The discussions were often more riveting than the talks.

Also, myself, I'm all for longer talks generally. It is just too hard to convey one's point and the flavor of one's thinking in 30 minutes ... especially when a subject is not mature. Thus, I would suggest strict 45 minute talks (two at a time), then break, and readjourn for one hour of discussion/debate. Or something like that kind of scheduling.

Like I say, I think it worked quite well at Seven Pines.

How to weed out speakers from pure discussants? As a first round, I would suggest something like the call that was made for the Banff meeting next week. Here are the exact words:

> It is time to begin the process of scheduling of talks for the workshop. If you would like to speak, please reply to this message with a short description of what you would like to present.
>
> Also feel free to suggest a topic that someone else from the list of participants might speak about.
>
> We hope to follow a relaxed model for the workshop that will allow us to have ample time to talk and work with one another ...
>
> For this reason, please do not volunteer to give a talk out of any sense of duty or obligation, or if you would give a talk that many people have already heard. Ideally less than half of the participants should give scheduled talks.

After we see what kind of response we get from that, then we could cajole as many people as we need to fill the gaps.

In the end, at Seven Pines everyone participated in just about the right way.

Any thoughts or counterpoints?

I'll write that blurb before you wake up in the morning. I guess Rüdiger should be in Albuquerque by now.

14-09-04 *Assessment Letter* (to whom it may concern)

To whom it may concern:

I have been asked to assess the International Center for Mathematical Modelling in Physics, Engineering, and Cognitive Sciences at the University of Växjö, Sweden. I gladly take on this task, as I have nothing but positive things to say about the Center. It has been a driving force in world-wide quantum mechanical research, bringing researchers together from every corner of that specialty for a kind of symbiosis I have seen nowhere else in the world (even in my dealings with the Newton Mathematical Institute at Cambridge University, the Perimeter Institute for Theoretical Physics in Waterloo, Canada, or the Aspen Center for Theoretical Physics in the United States).

I first became involved with the ICMM in December 2000 when Andrei Khrennikov invited me to organize a conference with him for the following year (apparently at the suggestion of Jeffrey Bub of the University of Maryland). The meeting was titled *Quantum Theory: Reconsideration of Foundations*. What an experience and what a meeting that was! Andrei gave me a pleasant budget of "seed money," and with it—along with significant matching funds from the various researcher's own grants—I was able to attract 15 world-class physicists from the field of quantum information and computing, a few of whom were actually founding fathers of the field, for a special session on "Shannon Meets Bohr: Quantum Foundations in the Light of Quantum Information." That meeting was a watershed moment for the field: For the first time it became internationally recognized that quantum information and computing have very deep things to say about quantum foundations, and more importantly, vice versa. Progress was seen all around, and a real sense of unity came of it. The conference proceedings emanating from the meeting, published by Växjö University Press, have come to be a standard reference on the subject.

Since then I have had several encounters with Professor Khrennikov, organized another conference with him in Växjö (a conference just as successful as the first one), joined the advisory board of the ICMM, and published a book in Växjö University Press's series on Mathematical Modelling in Physics, Engineering, and Cognitive Sciences—all wonderful experiences. In particular, the VUP publication of my book *Notes on a Paulian Idea* has led to an outpouring of research in these directions and gained enough recognition that Kluwer Academic Publishers has picked up the book for a second-edition printing in their series Fundamental Theories of Physics. In all, I have had more email traffic and praise about this book than all of my other publications combined (and that is not a skimpy record, with over 1500 citations recorded in the ISI Web of Science, Science Citation Index). All of this goes to show the important role that the ICMM has come to take in our community, through the meetings it has funded, the conference proceedings and books it has disseminated, and the collaborations it has spawned.

And this is just my personal experience with the ICMM. Since its founding, literally hundreds of researchers have been affected by or participated in ICMM events. Moreover, with the conference proceedings being widely read, the prestige of the ICMM conferences is taking on a life of its own. For instance, I recently received this request from a respected Italian professor in quantum optics and quantum information: "I am very interested in the Växjö conferences. I presume there will be one next year in June, right? Can you put me in the mailing list? I'm currently working extensively on the convex structure of quantum mechanics (states, POVM's, channels, and their relative connections), on which with my group, we are writing a set of 4–5 papers ...." Evidence like this cannot be ignored. I can attest from my interactions with so many in the community that you would hear a similar stories all around.

The ICMM is a gem in the world of fundamental quantum mechanical research. I hope similar levels of activity will be funded for years to come.

Sincerely,

Christopher A. Fuchs

14-09-04 *Barbecue Blurb, First Draft* (to S. Hartmann, C. M. Caves & R. Schack)

Being Bayesian in a Quantum World
1-6 August 2005, Konstanz, Germany

To be a Bayesian about probability theory is to accept that probabilities, whenever used, represent degrees of belief. This is in distinction to the idea that probabilities represent long-term frequencies or intrinsic, chancy propensities "out there" in nature itself. But, how well does this mesh with the existence of quantum mechanics? To accept quantum mechanics as a physical theory is to accept the calculational apparatus of quantum states and the Born rule for determining probabilities in measurement situations: "These probabilities are given by fundamental physical law!" one might eject. Does this dilemma spell the death of Bayesianism? Or does it rather give us an opportunity to rethink what quantum mechanics is actually about?

There is no doubt that we live in a quantum world. From transistors to lasers to nuclear warheads, the evidence is all around us. One might take from this that the quantum formalism ideally represents a mirror image of the world: That is, the wave function is so successful as a calculational tool precisely because it represents an element of reality. A more Bayesian (or, at least, Bayesian-like) perspective is that, if a wave function generates probabilities, then they too must be Bayesian degrees of belief, with all that that entails. In particular, quantum probabilities have no firmer hold on reality than the word "belief" in "degrees of belief" already indicates. From this perspective, the only sense in which the quantum formalism mirrors nature is through the normative constraints it places on gambling agents doing their best to navigate within such a quantum world. To the extent that an agent should use *this* structure (i.e., quantum mechanics) for his uncertainty accounting rather than *that* structure (i.e., some foil theory) tells us something about the world itself—i.e., the world independent of the agent and his particular beliefs at any moment. The task of the quantum Bayesian is to make this argument explicit and rigorous and to reap any benefit this can give to philosophy and physical practice.

Hogwash or deep idea? The time is ripe for a debate. At the present meeting, in the beautiful surroundings of Lake Konstanz, we envision a fifty-fifty mix of philosophers (who have thought long and hard about probability and quantum foundations) and quantum-information physicists (who have developed an impressive box of mathematical tools for prying apart the probabilistic structure of quantum mechanics) to set the tone. The goal is make real progress on these issues through a unique complementation of talents. All proposed participants have been hand picked for their registered interest in the debate and their known ability to "talk to the other side."

The format for the meeting will be . . .

At present we can commit to the following funding . . .

We look forward to seeing you in Konstanz!

— — — — — — —

> This day is called the feast of Being Bayesian in a Quantum World:
> He that outlives this day, and comes safe home,
> Will stand a tip-toe when the day is named,
> And rouse him at the name of BBQW.
> He that shall live this day, and see old age,
> Will yearly on the vigil feast his neighbours,
> And say 'To-morrow is Saint de Finetti:'

Then will he strip his sleeve and show his scars.
And say 'These wounds I had on de Finetti's day.'
Old men forget: yet all shall be forgot,
But he'll remember with advantages
What feats he did that day: then shall our names.
Familiar in his mouth as household words
Rüdiger the king, Hartmann and Fuchs,
Caves and Poulin, Barnum and Timpson,
Be in their flowing cups freshly remember'd.
This story shall the good man teach his son;
And BBQ BBQWian shall ne'er go by,
From this day to the ending of the world,
But we in it shall be remember'd;
We few, we happy few, we band of brothers;
For he to-day that sheds his blood with me
Shall be my brother; be he ne'er so vile,
This day shall gentle his condition:
And gentlemen in Germany now a-bed
Shall think themselves accursed they were not here,
And hold their manhoods cheap whiles any speaks
That fought with us upon Saint de Finetti's day.

15-09-04 *Quanta of Rain* (to H. J. Folse)

I'm quite concerned about you, your family, and your house. I will keep my fingers crossed that things don't go too badly for you—at this point it's fairly clear that you're going to get at least some troubles from the storm. In any case, you're in my thoughts.

... for that and another reason actually. Caves, Schack, Stephan Hartmann, and I are organizing a meeting to be held in Konstanz next August, titled "Being Bayesian in a Quantum World" — we're hoping for roughly 17 (quantum-information) physicists and 17 philosophers. The theme is about hashing out how well Bayesian probability fits with quantum mechanics. And we figure we ought to have one resident expert on Bohr and/or "the" Copenhagen interpretation around for part of the discussion. As it stands, you're top on the list if we do indeed go that route. We'll let you know something soon.

15-09-04 *Certain Epiphanies* (to M. Pérez-Suárez)

Pérez-Suárezism 9: *On certainty: Now I am certain (and not* just *in the sense of assigning probability one) that an assignment of probability one to an event does not make of it a certain event and that, in much the same way, probability zero for an event does not make of it an impossible event. At least, this is definitely what follows from the measure-theoretic approach to probability, and both Dutch-book coherence and probability theory in the more general framework of decision theory (as in Bernardo and Smith's book) may be seen as "just" providing the former (axiomatic) approach with an operational meaning, thus keeping intact those conclusions.*

I'm glad for this epiphany. When I had it, it may have been the most important transition in my life.

18-09-04 *Caves and Schack* (to M. Pérez-Suárez)

I'm writing you from a wireless connection for my laptop in the American Airlines Admirals Club in Chicago, as I'm making my way to the Banff meeting. It is kind of exciting; I've never done this before.

I think either Caves or Schack would be fine for you. I don't think you can go wrong with either of them. Carl has the better track record under his belt of nurturing many students, but Rüdiger has his own strengths and might have more personal time for you (though beware). Caves group would help fill in the gaps though, and probably prove far more stimulating.

Only one comment about something you wrote:

Pérez-Suárezism 10: *The only problem as for me is that I'm not sure how much I could get involved in the work he and his group are doing, mostly due to his not being a "full fledged" subjectivist, which might cause me some trouble I use the verb "might" for a good reason: I simply don't know if it would). On the other hand, his work on issues related in one way or another to QKD is of course pertinent to me. But ...*

You shouldn't underestimate Carl's breadth and versatility. And he is often willing to travel where his students lead him researchwise. He will be a full fledged subjectivist one day, if he's not already (and he might be already) ... simply because logic will ultimately lead him there.

I will write both Caves and Schack now preparing the way for your proposal. Thereafter it's up to you.

18-09-04 *Quantum Foundations in Sci Am* (to G. Musser)

Musserism 24: *Now that I've shaken the monkey of our Einstein special issue off my back, perhaps we can return to the idea of your writing an article for us. The first step would be to prepare a proposal that I could circulate among my colleagues for their formal approval. The ulterior motive of such a proposal is to get you (and me and our high-energy editor, to whom I would probably hand the baton) thinking about what the article would say, how it might be structured, and how the topic might be motivated for the nonphysicist.*

I think the article would be a service not just to the lay person but also to the foundations-of-QM community. The preparation of a nontechnical account is often an excellent excuse to think through issues. Then again, I don't need to convince you of that, since you're the one who referred me to Mermin's essay.

Let me now apologize for my latest extended absence: You wrote that to me over five weeks ago! This relocation and getting resettled in Bell Labs has just been a bear. Anyway, don't think that I've lost interest!

I've put a marker in my calendar to come back to the matter Nov 15. Unfortunately, I've got a big presentation to give to the president of Bell Labs Nov 11 on our efforts in quantum info, and between that and the conferences I'm attending in the meantime, I know that I won't honestly be able to do anything for you before then. But I'm hoping to hit the project with a vengeance soon after that.

BTW, I was prompted to finally reply to you by seeing your article at a newsstand in Chicago. (I'm on the way to Banff.) And I would have bought the issue too! But there was a tear in the cover and it was the only one they had left. Anyway, I'll get it soon, as I have a chance. I look forward to reading what you've written.

04-10-04 *Bush and Reality* (to me)

From Bob Herbert, "Bush and Reality," *New York Times*, 4 October 2004:

> For 90 minutes, at least, democracy seemed to be working. The two men in dark suits took their places at the lecterns. The analysts, the handlers, the spinmeisters and the hangers-on had been cleared out of the way. With no commercial interruptions, more than 60 million Americans got a rare, unedited, close-up look at the candidates in one of the most important presidential elections in the nation's history.
>
> John Kerry got the better of President Bush in last Thursday's debate in Coral Gables, Fla. The president seemed listless, defensive and not particularly well prepared. His facial expressions and body language at times were odd. Some of his strongest supporters were dismayed by his performance, and polls are showing they had reason to be concerned.
>
> There undoubtedly were many reasons for Mr. Bush's lackluster effort. But I think there was one factor, above all, that undermined the president in last week's debate, and will continue to plague him throughout the campaign. And that was his problematic relationship with reality.
>
> Mr. Bush is a man who will frequently tell you – and may even believe – that up is down, or square is round, when logic and all the available evidence say otherwise. During the debate, this was most clearly displayed when, in response to a question about the war in Iraq, Mr. Bush told the moderator, Jim Lehrer, "The enemy attacked us, Jim, and I have a solemn duty to protect the American people, to do everything I can to protect us."
>
> Moments later Senator Kerry clarified, for the audience and the president, just who had attacked the United States. "Saddam Hussein didn't attack us," said Mr. Kerry. "Osama bin Laden attacked us. Al Qaeda attacked us."
>
> Given a chance to respond, Mr. Bush flashed an unappreciative look at Senator Kerry and said, "Of course I know Osama bin Laden attacked us – I know that."

06-10-04 *Incompleteness* (to H. Price)

By the way,

Pricey Quote 1: *I'm fascinated to hear that you've been reading stuff written under what I usually think of as my other hat, such as "Truth as convenient friction". Somewhere I've got a rough piece I wrote about 20 years ago, trying to argue that there were two attractive avenues to explore in QM (in the light of the difficulties with either answer to the question whether the wave function is a complete description): first, backward causation HV approaches, and second, a view which rejects the question, on the grounds that the very notion of complete description is suspect. I was reminded of it when I read the attachments you sent before.*

could you send me that draft as you get a chance (if it is in electronic form, that is). I would enjoy reading it.

Regarding on my own take on the "incompleteness" of wave functions, let me paste in a note I wrote a little while ago to a reporter at *Scientific American*. He kept hammering on how I could say that the wave function is not a complete description of a quantum system (actually, I would say it's not even a description … at least in a correspondence sense) and yet not be a (closet) supporter of hidden variables extensions. In my frustration, the note below resulted. In writing it, I became quite keen on the metaphor of the map (especially the bit about curvature at the end). [See 07-07-04 note to Musser, titled "B".]

08-10-04 *Krugman, Reality* (to me)

From Paul Krugman, "Ignorance Isn't Strength," *New York Times*, 8 October 2004:

> I first used the word "Orwellian" to describe the Bush team in October 2000. Even then it was obvious that George W. Bush surrounds himself with people who insist that up is down, and ignorance is strength. But the full costs of his denial of reality are only now becoming clear.
>
> President Bush and Vice President Dick Cheney have an unparalleled ability to insulate themselves from inconvenient facts. They lead a party that controls all three branches of government, and face news media that in some cases are partisan supporters, and in other cases are reluctant to state plainly that officials aren't telling the truth. They also still enjoy the residue of the faith placed in them after 9/11.
>
> This has allowed them to engage in what Orwell called "reality control." In the world according to the Bush administration, our leaders are infallible, and their policies always succeed. If the facts don't fit that assumption, they just deny the facts.
>
> As a political strategy, reality control has worked very well. But as a strategy for governing, it has led to predictable disaster. When leaders live in an invented reality, they do a bad job of dealing with real reality.

08-10-04 *Emerson* (to M. Pérez-Suárez)

Emerson. I don't have much to tell you, because I don't know that much about Emerson yet. But I do know that Cornell West has argued that pragmatism has its roots in Emerson. You can read about that in his book, *The American Evasion of Philosophy: A Genealogy of Pragmatism*. I read a couple of chapters of this book—the parts on Emerson in fact—but then stopped reading because his writing style drove me to distraction. Unfortunately, I don't remember much of what West said.

Here's another source that you might look at: David Jacobson's book, *Emerson's Pragmatic Vision: The Dance of the Eye*. I've got it in my collection, but a) I haven't read it, and b) it's still packed up in a box somewhere (until I get some new bookshelves), so I can't look at it. However, here's a blurb on the book: `http://www.psupress.org/books/titles/0-271-00896-2.html`. Also, I can tell you that William James knew Emerson personally; Emerson was a friend of the James family, in fact, when William was a child. Beyond that, though, you're left to your own research.

Don't ask me questions about LSE and Kluwer. Some things I'm too ashamed to talk about . . .

08-10-04 *Aage Bohr* (to G. Musser)

Musserism 25: *What do you think of Aage Bohr et al.'s letter in the October* Physics Today*?*

I haven't been able to see that article, because a) unfortunately the Bell Labs electronic library does not carry the most recent three months of the magazine (that would cost the library more), and b) my own subscription seems to have ended in August (or at least the September and October issues were not in my mail pile). Maybe I'm behind in my APS membership.

Anyway, if you've got the article in electronic form, please send it to me. If you don't, can you tell me what it said?

12-10-04 *Reality, Cohen, Christopher Reeve* (to me)

From Richard Cohen, "The Dreams and Realities of a Superman," *New York Times*, 12 October 2004:

> As she aged, Marlene Dietrich became a recluse. She was seen by a few people, but never by the public nor in public. She was determined to stay as she had been – a striking beauty. Her decline and death would remain her own business. The myth would endure.
>
> Christopher Reeve took a different tack. After considering and rejecting suicide, he thrust himself back into public life. In the words of the writer Roger Rosenblatt, who got to know Reeve when he worked on the actor's biography, Reeve had to choose between a "horizontal and a vertical life. He aggressively chose the vertical life."
>
> This does not mean that Reeve ever stood again after being thrown from a horse in 1995. It did mean that he avoided becoming a recluse. It did mean that he made public appearances, was interviewed several times by Barbara Walters, appeared before Congress and at the 1996 Oscar awards ceremony, returned to film and even became a director. He refused to become invisible.
>
> Death often rebukes, and this is one of those occasions. Reeve's insistence that he would someday walk again was proved sadly false – as some always said it would be. He was criticized by knowledgeable people for what they characterized as his ignorant or opportunistic optimism – he appeared in a TV ad promoting spinal cord research – that gave false hope to others in his condition. What these people needed above all, Reeve's critics said, was the determination to face reality – not the bogus dream that the past could somehow become the future. [. . .]
>
> There always was a kind of lie to the life of Christopher Reeve. His faith that he would walk again, his optimism in the face of insurmountable bleakness – all of this was belied by what we all sensed was a dismal truth. But he kept at it – kept us at it – and made us think about what had become of him and others like him. "It was his way of standing up," Rosenblatt said.
>
> R.I.P., Christopher Reeve. You always stood tall.

12-10-04 *Three Children* (to D. B. L. Baker)

Thinking of Child #3, there is something else I had wanted to send you in addition to the little note I wrote commemorating Elizabeth's birth ... but until now had forgotten. It's the introduction to my first lecture at a summer school at Caltech a couple months back. I'll paste it in below. It is along the lines of something I wrote for Madelynn's birth: Some themes die hard with me. Please keep it for all three of your girls. I had them all in mind along with my two as I wrote it. [See 17-06-04 note "Preamble" to H. Mabuchi.]

12-10-04 *Being Bayesian in a Quantum World* (to W. T. Grandy, Jr.)

Thanks for the nice note; I'm flattered. And most importantly, I'm glad you're enjoying my paper. There's a lot of work to be done, but more and more people are taking note of the sensibility of (at least the broad outline of) the program, and that leaves me hope that we'll see some real progress in quantum foundations in the next few years.

In case you're not aware of some of the other papers melding elements of Bayesianism with quantum mechanics, let me put a list below for you.

First, some of my own (with colleagues):

- Quantum information: How much information in a state vector?
  `http://www.arxiv.org/abs/quant-ph/9601025`
- Quantum Probability from Decision Theory?
  `http://www.arxiv.org/abs/quant-ph/9907024`
- Information Tradeoff Relations for Finite-Strength Quantum Measurements
  `http://www.arxiv.org/abs/quant-ph/0009101`
- Unknown Quantum States: The Quantum de Finetti Representation
  `http://www.arxiv.org/abs/quant-ph/0104088`
- Notes on a Paulian Idea: Foundational, Historical, Anecdotal and Forward-Looking Thoughts on the Quantum
  `http://www.arxiv.org/abs/quant-ph/0105039`
- Quantum Probabilities as Bayesian probabilities
  `http://www.arxiv.org/abs/quant-ph/0106133`
- Quantum Foundations in the Light of Quantum Information
  `http://www.arxiv.org/abs/quant-ph/0106166`
- The Anti-Växjö Interpretation of Quantum Mechanics
  `http://www.arxiv.org/abs/quant-ph/0204146`
- Quantum Mechanics as Quantum Information (and only a little more)
  `http://www.arxiv.org/abs/quant-ph/0205039`
- Conditions for compatibility of quantum state assignments
  `http://www.arxiv.org/abs/quant-ph/0206110`
- Gleason-Type Derivations of the Quantum Probability Rule for Generalized Measurements
  `http://www.arxiv.org/abs/quant-ph/0306179`
- A de Finetti Representation Theorem for Quantum Process Tomography
  `http://www.arxiv.org/abs/quant-ph/0307198`
- On the Quantumness of a Hilbert Space
  `http://www.arxiv.org/abs/quant-ph/0404122`
- Unknown Quantum States and Operations, a Bayesian View
  `http://www.arxiv.org/abs/quant-ph/0404156`

Secondly, some from my colleagues:

- C. M. Caves and R. Schack, "Properties of the frequency operator do not imply the quantum probability postulate"
  `http://www.arxiv.org/abs/quant-ph/0409144`
- R. Schack, "Quantum theory from four of Hardy's axioms"
  `http://www.arxiv.org/abs/quant-ph/0210017`
- R. Schack, T. A. Brun, and C. M. Caves, "Quantum Bayes Rule"
  `http://www.arxiv.org/abs/quant-ph/0008113`
- R. W. Spekkens, "In defense of the epistemic view of quantum states: a toy theory." (This paper is not explicitly Bayesian in bent, but it is big a step in the right direction. I think this is the most important paper in quantum foundations in quite some time.)
  `http://www.arxiv.org/abs/quant-ph/0401052`
- R. W. Spekkens, "Contextuality for preparations, transformations, and unsharp measurements." (This paper is not explicitly Bayesian in bent, but it is big a step in the right direction.)
  `http://www.arxiv.org/abs/quant-ph/0406166`
- D. M. Appleby, "Facts, Values and Quanta"
  `http://www.arxiv.org/abs/quant-ph/0402015`
- D. M. Appleby, "Probabilities are single-case, or nothing"
  `http://www.arxiv.org/abs/quant-ph/0408058`
- D. M. Appleby, "The Bell-Kochen-Specker Theorem"
  `http://www.arxiv.org/abs/quant-ph/0308114`

There are several more that I could recommend, but since I suspect your main interest is in the Bayesian aspects of the program, I'll leave it at that for the moment.

Also, by the way, if you would like a copy of the Växjö University Press edition of my 700 page samizdat *Notes on a Paulian Idea* (which you can preview online in a 500 page format at the link above), let me know and I'll have a copy sent to you. All I'll need is your mailing address. You can find my eulogy to Ed Jaynes on page 49 of the VUP edition under the heading "Probability Does Not Exist," and general references to him throughout the book (by looking in the name index). Your name, in fact, is listed in the index five times.

Thanks again for writing. It makes me very happy to learn of people out there sharing in the spirit!

12-10-04 *Blowing in the Wind* (to G. L. Comer)

I thought about both of us as I was reading the article below yesterday. I particularly loved the line, "Half the people you knew believed that if only they could figure out what Bob Dylan was saying, the secrets of the universe would be revealed." I've certainly done that: With John Lennon, then Paul Simon, and then Bob Dylan, and before and after and in between with John Wheeler and John Coltrane, and now mostly with William James and Richard Rorty. I keep waiting for the secrets of the universe to be revealed, and it's usually in poetry and music and stirring prose. Or at least I used to. Now mostly I worry about getting a new roof on the house and getting the place rigged with central air and heat . . . and how much that's going to cost my pocket book.

12-10-04 *Endophysics Meeting* (to H. Atmanspacher)

Will you be going to this meeting:

> Endophysics, Time, Quantum and the Subjective
> January 17–22, 2005, Bielefeld, Germany

I saw your name listed in the invited speakers list (and that the meeting is invitation only). I think I would be interested in attending, and I think I could speak on aspects of quantum information that are probably little known to the audience. Do you think there is any room left? Do you know the organizers?

12-10-04 *Equiangular Lines* (to C. H. Bennett)

Bennettism 21: *Today I just noticed a dissertation* `quant-ph/0410071` *on your favorite subject.*

You mean on maximal sets of equiangular lines in Hilbert spaces of general finite dimension D?

Good to hear from you. When you get back, I'm hoping to drop in on you guys and get you fired up on this pesky question. I've told John we can call it the "SIC Project." (SIC is really for Symmetric Informationally Complete, but the overtones are clear.) I want to know everything I can about these sets of quantum states, abstract and applied. (Renes, for instance, now has a nice QKD protocol in terms of them.)

A much more important thing for you to look at (if, for instance, you've only got the stomach to look at one such thing this year) is Rob Spekkens' paper `quant-ph/0401052`. I like to think that's really a very important paper.

Tell Theo hello for me and send my congratulations on her retirement.

What was quantum about your cobwebs?

13-10-04 *The Incentive Program* (to G. Bacciagaluppi)

Thanks for the note, and it was great to hear your good news. I had such a wonderful time in Paris when I last visited (Grinbaum and Bitbol), that I can well see you might be in paradise. I stayed at some little hotel in the Latin Quarter and found, to my surprise, that my brain could still produce fresh thoughts: There is just something about even a simple walk in the streets there that is so promotional of thought. And Bitbol, particularly, was a great find: I like his style of philosophy and certainly have much in common with him when it comes to quantum foundations. I think there is something very deep in his phrase "the blinding closeness of reality."

But I write this note for another purpose. Thinking of our tripartite interests last night (i.e., yours, mine, and Jenni's), I decided it was time to finally unpack the box of single malts and get the bottles organized [...]

13-10-04 *The Free City* (to D. B. L. Baker)

I know that over the years you've heard me talk about the Copenhagen interpretation of quantum mechanics, the Bohmian interpretation (in Ischia in particular), the many-worlds interpretation, and so forth. There's quite a long list of such "interpretations" now; they come a dime a dozen. Well, to the list I've been trying to add my own—I call it the "sexual interpretation of quantum mechanics." I call it this because the name really captures the main idea I want to get across—that quantum mechanics hints of a world in constant creation. Moreover, that such creation comes about in an almost sexual way whenever two conceptual parts of the world "touch" each other. (The first written mention of this that I can find in my records is in a letter dated 3 September 2001 to Michael Nielsen, now posted in my *Quantum States: What the Hell Are They?* on the web; I'm not sure how long I had been talking about the idea before then. On the other hand, the phrase made its national debut in a little description in *Scientific American* last month, page 91.)

OK, that's the introduction; now for the story I wanted to record. A couple of years ago, a friend (who shall remain nameless) and I were in Copenhagen for a few days. As it goes, we found out that there is a little section in the city, called Christiania or "the Free City," that's something like a big hippie commune. There's over 900 people who live there, and marijuana and hash are sold freely in the streets. As long as you stay within Christiania's boundaries, the police won't bother you about possession and such. It's great: In one of the beer gardens, there was a huge banner proclaiming "JUST SAY NO to hard drugs." My friend, giddy like a school kid, wanted to go to the Free City for the purpose of buying a joint—something he hadn't done in years—and I thought, "Why not?" So, I accompanied him.

We went to the beer garden I just mentioned, and he lit it up. But here and there throughout the day we had been talking about the "sexual interpretation," and it was really getting under his skin. He would say, "You're only doing this for shock value, to bring attention to yourself. The name adds nothing substantial to our understanding of quantum mechanics." And I would say, "No, no, no; it really does capture an important idea. And it is one that needs to be made just as plain as it can be." We went round and round in argument. He took his first hit. Exhaled, and at the same time finally said in exasperation, "What are you really hoping to get out of this?!" In equal exasperation, I said, "I guess I just want to believe that with every quantum measurement I perform, I *please* nature just a little." He took his second hit. "So what? What good would that do!?" I couldn't help myself! "If I do it right, maybe she'd eventually gasp my name!"

You should have seen the guy's eyes! They lit up! He looked at me with complete conviction and said, "I get it. I get it." And for a moment you could tell he really did. ... And for a moment, I really got it too!

15-10-04 *Bohr, Mottelson, and Ulfbeck* (to G. Musser)

If you ever sent me the lost email again that I had requested, I never got it.

Anyway, I've seen the letter in *Physics Today* now:

Musserism 26: *What do you think of Aage Bohr et al.'s letter in the October* Physics Today*?*

But, I'm not sure what you want to know.

Once upon a time, I wrote a rather mean-spirited note to Mermin about Ulbeck and Bohr's "genuine fortuitousness." I'll dig that up and paste it below, but I doubt it answers whatever you had in mind. [See 25-09-02 note "Ulfbeck and Bohr" to N. D. Mermin.] But who knows, maybe it does. `\bdm` and `\edm` refer to the beginning and end of a David Mermin quote; `\bq` and `\eq` refer to the beginning and end of a more general quote. I later cleaned that letter up and used it in Section 3 of my pseudo-paper "Delirium Quantum" which I sent you a while back.

If your concern has to do with the phrase "quantum world," and contrasting their use of the phrase with mine (I say it exists, they say it doesn't)—they're quite likely very different uses of the phrase—then it would probably take me longer to answer you.

15-10-04 *Genuine Fortuitousness* (to O. C. Ulfbeck)

I noticed from reading your letter (with Bohr and Mottelson) in the October *Physics Today* that you three have a new article: *Foundations of Physics* **34**, (2004) p. 405. Would it be possible for you to send me an electronic version of the paper (TEX, LATEX, PDF, MS Word, etc.)—our library at Bell Labs no longer carries that journal.

21-10-04 *Dowd on Faith and Certainty* (to me)

From Maureen Dowd, "Casualties of Faith," *New York Times*, 21 October 2004:

> When I was little, I was very good at leaps of faith.
>
> A nun would tape up a picture of a snow-covered mountain peak on the blackboard and say that the first child to discern the face of Christ in the melting snow was the holiest. I was soon smugly showing the rest of the class the "miraculous" outline of that soulful, bearded face.
>
> But I never thought I'd see the day when leaps of faith would be national policy, when the fortunes of America hung on the possibility of a miracle.
>
> What does it tell you about a president that his grounds for war are so weak that the only way he can justify it is by believing God wants it? Or that his only Iraq policy now – as our troops fight a vicious insurgency and the dream of a stable democracy falls apart – is a belief in miracles? [. . .]
>
> W.'s willful blindness comes from mistakenly assuming that his desires are God's, as if he knows where God stands on everything from democracy in Iraq to capital-gains tax cuts.
>
> As Lincoln noted in his Second Inaugural Address about the Civil War, one can't speak for God: "The Almighty has His own purposes."

21-10-04 *Words Aiming to Inspire* (to R. E. Slusher)

Finally a note that has nothing to do with the performance review . . . Spurred by our conversations yesterday, let me send you the little introduction I wrote for my Caltech summer school lectures a few months ago. It's pasted below. [See 17-06-04 note "Preamble" to H. Mabuchi.] I think it touches on quite a few themes of our discussion yesterday—both on the points where we seem to agree and the points where we seem to disagree.

I hope it paints a fairly evocative picture of what I see quantum mechanics indicating at its core: That the world is in continued (everlasting) creation. And that this creation comes about in an almost "sexual" way—that is, it is something that happens whenever two pieces of matter get together. (This is what was being talked about when *Scientific American* said I call my view the "sexual interpretation of quantum mechanics".) But I am careful to say quantum mechanics *indicates* this: Because another part of the lesson is that quantum mechanics itself is not a low-level physical theory making direct statements about physical reality. Rather it is a very high-level theory whose main concern is about an agent's (i.e., a man, a computer, whatever it is that is needed to make an agent) making enlightened decisions in response these little acts of birth that it itself is involved in.

Anyway, that's what the note below is about. Read it and see if it stirs any sympathy. I think you might see some resemblance between my idea of "birth" and your attention to the discreteness of quantum measurement outcomes that you were mentioning yesterday.

Just waiting for Russo to begin to speak.

21-10-04 *More on the S Interpretation* (to R. E. Slusher)

If the Caltech intro did anything for you, you might also be interested in this little pseudo-paper "Delirium Quantum" that I distributed at the Minnesota meeting (but never posted on the `arXiv`). [See "Delirium Quantum" `arXiv:0906.1968v1`.]

21-10-04 *Books, Books, Books!* (to J. B. Lentz & S. J. Lentz)

Thank you both for the fabulous birthday present!!! You certainly shouldn't have ... but I'll certainly take it! Tomorrow I'm taking the whole day off to go book shopping, and I suspect I'll be in the Strand for about six hours of that. This is really the best birthday present I've had in ages.

I've been joking lately about how there's no better insulation for thin walls than a good collection of American pragmatism! (In case you want to know more about the philosophy, go here: `http://www.pragmatism.org/`. William James is my hero of heroes.) Anyway, let's see how the library grows tomorrow. At present, that section of the library has 331 books. I'll give you an update on what it looks like by the end of the weekend.

22-10-04 *More from NY Times about Reality* (to me)

From Bob Herbert, "Bush's Blinkers," *New York Times*, 22 October 2004:

> Does President Bush even tip his hat to reality as he goes breezing by?
>
> He often behaves as if he sees – or is in touch with – things that are inaccessible to those who are grounded in the reality most of us have come to know. For example, with more than 1,000 American troops and more than 10,000 Iraqi civilians dead, many people see the ongoing war in Iraq as a disaster, if not a catastrophe. Mr. Bush sees freedom on the march.
>
> Many thoughtful analysts see a fiscal disaster developing here at home, with the president's tax cuts being the primary contributor to the radical transformation of a $236 billion budget surplus into a $415 billion deficit. The president sees, incredibly, a need for still more tax cuts.
>
> The United States was attacked on Sept. 11, 2001, by Osama bin Laden and Al Qaeda. The president responded by turning most of the nation's firepower on Saddam Hussein and Iraq. When Mr. Bush was asked by the journalist Bob Woodward if he had consulted with former President Bush about the decision to invade Iraq, the president replied: "He is the wrong father to appeal to in terms of strength. There is a higher father that I appeal to." [...]
>
> There are consequences, often powerful consequences, to turning one's back on reality. The president may believe that freedom's on the march, and that freedom is God's gift to every man and woman in the world, and perhaps even that he is the vessel through which that gift is transmitted. But when he is crafting policy decisions that put people by the hundreds of thousands into harm's way, he needs to rely on more than the perceived good wishes of the Almighty. He needs to submit those policy decisions to a good hard reality check.

25-10-04 *Son of Samizdat* (to H. Price)

I'm pleased to hear that you're enjoying my samizdat! If that's whet your appetite, I hope you'll move on to Son of Samizdat as you get a chance. More officially, it's titled *Quantum States: What the Hell Are They?* and it's posted on my website. I consider it the best work of my life (though it still needs distilling into a paper). It's where I took my strong anti-representationalist turn. It was a very hard turn to take, but I think if we stick with it the rewards could be very big.

25-10-04 *Inventory* (to J. B. Lentz & S. J. Lentz)

OK, here's the monster you helped create! The list of Friday purchases is pasted in below. If you want to borrow any of the books you funded, let me know . . .

More seriously, get this title: Michael Magee, *Emancipating Pragmatism: Emerson, Jazz, and Experimental Writing*. I didn't buy it, but the blurb on Amazon says:

> *Emancipating Pragmatism* is a radical rereading of Emerson that posits African-American culture, literature, and jazz as the very continuation and embodiment of pragmatic thought and democratic tradition. It traces Emerson's philosophical legacy through the 19th and 20th centuries to discover how Emersonian thought continues to inform issues of race, aesthetics, and poetic discourse. Emerson's pragmatism derives from his abolitionism, Michael Magee argues, and any pragmatic thought that aspires toward democracy cannot ignore and must reckon with its racial roots. Magee looks at the ties between pragmatism and African-American culture as they manifest themselves in key texts and movements, such as William Carlos Williams's poetry; Ralph Ellison's discourse in *Invisible Man* and *Juneteenth* and his essays on jazz; the poetic works of Robert Creeley, Amiri Baraka, and Frank O'Hara; as well as the "new jazz" being forged at clubs like The Five Spot in New York. Ultimately, Magee calls into question traditional maps of pragmatist lineage and ties pragmatism to the avant-garde American tradition.

Maybe that explains why I've been drawn to jazz since meeting you guys!

Thanks again for the birthday present.

1. John Dewey, *Experience and Nature*, Second Edition, (Open Court, La Salle, IL, 1971), HC.
2. John Dewey, *John Dewey—The Later Works, 1925-1953. Volume 12: 1938*, editor Jo Ann Boydston, textual editor Kathleen Poulos, introduction by Ernest Nagel, (Southern Illinois University Press, Carbondale, IL, 1986), HC.

25-10-04 *Stages of Development* (to N. D. Mermin)

I went through a hernia operation in the winter of '94 and didn't much enjoy it. (Though, Carl Caves used to pride himself that it was his kids that likely caused the hernia—when I was playing with them one evening—and, by way of that, he could trace the cause of my meeting Kiki back to himself. You see, because of the operation, I actually stayed home for a while and stopped looking for a girl friend in the coffee shops and bars. And, lo and behold, in my boredom looking out the window, I first noticed this beautiful neighbor walking her dog. The rest is history ... and two kids.)

Which reminds me of something that I've been wanting to record. Lately when Katie (who is getting close to three years old) misplaces something, if I ask her where it is, she will reply, "anywhere." She doesn't say, "I don't know." Or "I can't remember," or indeed any other phrase that would put the blame on her incapacities. She just replies with "anywhere." What has struck me is how much this reminds me of some of the early expositions of the uncertainty principle that I was exposed to. Maybe in both cases, it's all about stages in our development.

25-10-04 *The Quantum and the Politic* (to N. D. Mermin)

By the way, as you can guess, I've been watching the presidential race with greater than usual interest this time around. Of course there's the issue of how our nation is in a quagmire now ... and my profound confusion about how so many Americans can still support Bush. But there's been an undercurrent that has interested me at the intellectual level: All the talk about belief, reality, and certainty. It's everywhere!

In the first presidential debate, I couldn't have gotten a better slogan for our own discussions of the last couple of years, than from a remark Kerry made to Bush: "But this issue of certainty: it's one thing to be certain, but you can be certain and be wrong."

Even in quantum mechanics.

25-10-04 *Ever More Interpretations* (to M. A. Nielsen)

Did you happen to read David Mermin's diatribe in the May issue of *Physics Today* about how he invented the "Shut Up and Calculate Interpretation" of QM? (I'm just getting caught up with my *Physics Todays*—they were all piled up in my Bell Labs mail box when I returned from Ireland.) Anyway, I faintly remember you and I having that very conversation a few years back at Caltech. We were in your office as I recall, and one of us said Feynman and one of us said Mermin. Or, at least I faintly remember that. Problem is, I don't remember which of us took which side! Do you remember this? I've been trying to replay this in my mind, and half the time I think I thought it was Feynman and half the time I think I thought it was Mermin! If you can help me out, I might be able to make up a good joke to play on Mermin.

Michael's Reply

> Funny, I remember having this discussion with someone, but I don't remember it being with you! Dave Bacon comes to mind. I'm not sure this helps you out in quite the way you hoped, although it does add to the story. So many cases of mistaken identity . . .

25-10-04 *More on Landauer* (to W. T. Grandy, Jr.)

Grandyism 1: *I was interested in the exchanges with Landauer, but his replies didn't reveal much. For a number of years now I've been wrestling with the definition of information – to paraphrase the title of one of your papers, "What the Hell Is It?" In contemplating Landauer's claim that "Information Is Physical" I've had the impression that he was not distinguishing between information and its representation, and was really talking about the latter, which is indeed physical.*

I'm inclined at this point to think that the concept of information – like randomness, probability, and entropy – is basically anthropomorphic, or at least brain dependent down to some level. But, then, anthropomorphic is certainly physical, though not in the sense usually envisioned by physicists, so maybe his characterization has something to it after all. This is a bit like punching a pillow, or wrestling with jello!

I am pleased to hear you are enjoying my samizdat. Better than the Landauer section, I think you might get more from the exchanges with Mermin and Peres—at least a lot more Bayesian flesh was put on my Copenhagen bones there.

You are right about Rolf confusing information with information carriers—I think that has caused quite a bit of trouble in our quantum-information community. I'll append a note below where I tell a little story about this. (This one comes from my second email samizdat "Quantum States: What the Hell Are They?" posted on my webpage.) [See 02-02-02 note to Timpson, titled "Colleague."]

26-10-04 *More "More on Landauer"* (to W. T. Grandy, Jr.)

Grandyism 2: *Thanks for your last note and the Bennett anecdote re: Landauer. Sometime, perhaps after a sufficient amount of wine, I'll have to share my copy of Ed Jaynes' rejection of Landauer's paper "Minimum Energy Dissipation in Logic." Other correspondence indicates that the editor was not at all happy with Ed's recommendation, but I'd guess the original still exists in the editorial archives of the IBM J. Research. It was published anyway, of course.*

I would very much like to see that, if you ever feel like divulging it! As you can see, I'm fashioning myself somewhat as a historian of quantum information. And your copy of the report sounds like it will ultimately be important historically.

Tom's Reply

> Upon reflection, and in the interests of history, I see no reason not to pass this on to you now, particularly since both Ed and Rolf are gone. I've attached a pdf file with both

the request and Ed's report. In connection with this you might also find interesting an excerpt from an email Ed sent to me on 7 July 1996: "Landauer just throws his readers off by insisting that erasing a memory requires a dissipation of energy of about kT per bit. It obviously requires NO dissipation of energy, because computer memories are never "erased"; they are just overwritten. Resetting every bit to zero does not destroy any information either – it merely moves it into correlations between the memory and its environment. It is when you fail to take note of the changed environment that information is lost; but still no energy is dissipated. I have been trying to explain this to Landauer for 35 years now (having refereed his first paper in which he said this and trying again whenever I meet him) without the slightest success."

An interesting point here is the discrepancy in dates in the above review and the "35 years", so there must be an earlier Landauer paper that Jaynes also refereed – unless Ed's memory here was faulty, but it usually was prodigious.

Letter from IBM Journal Editor to E. T. Jaynes

November 10, 1969

Professor E. T. Jaynes
Department of Physics
Washington University
St. Louis, Missouri 63130

Dear Professor Jaynes:

Thank you for agreeing to review the enclosed manuscript, ''Minimum Energy Dissipation in Logic'' by R. W. Keyes and R. Landauer. It has been submitted for publication in the *IBM Journal of Research and Development* and I would like to know your opinion of its originality, technical accuracy and general merit.

A list of suggested review criteria is enclosed, but these need not be followed on a one-for-one basis. I would also appreciate any comments or suggestions you think appropriate. Your report will be anonymous where the authors are concerned; may I hear from you by November 24?

There will be an honorarium and I have entered a complimentary subscription to the *Journal* in your name.

Sincerely,

R. J. Joenk
Associate Editor
IBM JOURNAL OF
RESEARCH AND DEVELOPMENT

E. T. Jaynes' Referee Report

REPORT OF REFEREE

R. W. Keyes and R. Landauer, ''Minimum Energy Dissipation in Logic''

I feel that the weakest aspect of this article is its lack of convincing power; after reading it over several times, I remain unconvinced that computer operations have anything to do with entropy, or that there is <u>any</u> fundamental minimal energy dissipation in logic steps.

This doubt stems from two causes, both of which should be correctible if the authors' conclusions are correct.

Firstly, they place a great burden on the reader, requiring him to have read about a dozen previous articles from which they merely quote the conclusions without giving any supporting arguments for them. Surely, if these matters have been discussed so much, there must exist by now some simple argument, requiring only a paragraph or two, indicating to the reader <u>why</u> any fundamental limitation must exist. Presentation of <u>one</u> such argument would accomplish more for the reader than citing any number of ''authorities.''

Secondly, their analysis of one particular model does not seem entirely air-tight, and in any event it gives no reason to think that the conclusions are general. A different model might lead to entirely different conclusions. I illustrate this by two counter-examples.

On the next to last page of the text, the authors say that removal of a thin barrier leads to ''an unavoidable non-equilibrium process'' with an entropy increase of k ln 2. But this does not follow from the laws of physics; there must be some hidden assumption involved. For example, before the barrier is removed the particle might be in a definite quantum state $\psi(0)$. Removal of the barrier then leads to a problem which can in principle be solved to give the state $\psi(t)$ at any later time, in which the wave function will in general be non-zero on both sides. But it was initially in a pure state with entropy zero, and it remains, according to the Schrödinger equation, in a pure state with entropy zero. The supposed ''irreversibility'' must be the result of some unstated limitation of how deeply we are permitted to analyze the situation.

A switching operation does not have to take place via adiabatic changes in a potential well. We can have simply two well-separated holes A and B, into which a particle may be put. We switch by lifting the particle bodily out of a hole A, and placing it in hole B. Whatever energy was required to lift it out of A is recovered when we lower it back into B. If one considers a thermal situation, with the energy in holes A and B fluctuating by kT, this conclusion remains true on the average, for we have just as much chance of gaining energy as losing it when the transfer is made.

If I were a computer engineer, I think I would simply ignore articles that try to tell me what I <u>cannot</u> do; and just go ahead and do them anyway. Almost all progress in technology has been made in the face of theoretical predictions that it can't be done; and unless some limitation is derived rigorously from some undoubted law of physics, such as energy conservation, the lessons of history lead one to place his bets on the clever inventor, to circumvent imaginary problems.

Subsequent Letter from IBM Journal to E. T. Jaynes

February 10, 1970

Professor E. T. Jaynes
Department of Physics
Washington University
St. Louis, Missouri

Dear Professor Jaynes:

Thank you again for your critique of the manuscript, ''Minimal Energy Dissipation in Logic'' by R. W. Keyes and R. Landauer. A copy of the current, revised manuscript is enclosed. There were two other reviews of the original manuscript in addition to yours; one of these is included for your information.

You will observe, of course, that the authors have not adopted the reasoning of your counterexamples. In their opinion, the first example is not appropriate because it is based on a conservative system whereas, in fact, fluctuating external forces must be included in a relevant model of machine manipulations. The second example is thought to be incomplete due to neglect of ''prior information,'' or testing of information states, which is necessar for a realizable computer operation. Both the requirement of energy dissipation and that of testing states are described in Landauer's original paper, which is also enclosed.

If you would like to comment further on this manuscript, I would appreciate receiving your reply by February 18.

```
Sincerely,

R. J. Joenk
Associate Editor

27-10-04 *NY Times on Reality* (to me)

From Nicholas D. Kristoff, "Pants on Fire?," *New York Times*, 27 October 2004:

> Whenever I say that President Bush isn't a liar, Democrats hurl thunderbolts at me. And when I say Mr. Bush isn't truthful, Republicans erupt like Mount St. Helens.
>
> So what do I mean?
>
> Let me offer an example – not from Iraq but from Mr. Bush's autobiography. In it, he tells a charming little story involving his daughters in 1988, on the eve of the presidential debate between his father and Michael Dukakis:
>
>> "One night, Laura and I were out of town campaigning, and Barbara and Jenna spent the night at the vice presidential mansion. Dad had spent the day preparing for a debate with Michael Dukakis. Unfortunately, Barbara lost her sleeping companion, Spikey, her favorite stuffed dog. She complained loudly that she could not sleep without Spikey, so 'Gampy,' better known as Vice President Bush, spent much of the night before his debate searching the house and grounds of the vice presidential residence, flashlight in hand, on a mission to find Spikey. Finally, he did, and Barbara slept soundly. I don't know if my dad ever went to sleep that night."
>
> It's a heartwarming tale of family values. And while it's not malicious enough to count as a lie, it's laced with falsehoods.
>
> We know that because Mr. Bush's mother wrote about the same incident much earlier, in 1990, in *Millie's Book*, nominally written by her dog. For starters, the episode occurred when the girls were five and a half, in 1987, a year before the presidential debate.
>
> What's more, *Millie's Book* says that Spikey was a cat, not a dog. And instead of searching all night and finally finding Spikey, Vice President Bush gave up, grumbling: "I have work to do. What am I doing searching for a stuffed animal outdoors in the dark?" Anyway, little Barbara had already fallen asleep with another stuffed animal. Spikey turned up the next day behind the curtains. [...]
>
> The current president's hyped version of the incident reflects his casual relationship with truth. Like President Ronald Reagan, reality to him is not about facts, but about higher meta-truths: Mom and Dad are loving grandparents, Saddam Hussein is an evil man, and so on. To clarify those overarching realities, Mr. Bush harnesses "facts," both true and false.

28-10-04 *Enjoyed and No* (to M. Pérez-Suárez)

I read your paper and enjoyed it. And I think it is a great effort in getting out "the word." Also the discussion on probability is top-notch and makes a much better effort than I ever have personally to explain why we adopt the Bayesian notion of probability (even for quantum states).

But this paper really is your production, and you should de-list me as an author. With regard to my *own* research it doesn't contain anything new (unless you count the second part of Eq. 7 ... which I want to lay out in much more detail when I try to put together our springtime discussions in my own way for SHPMP). And stylistically, it is your presentation and personality. Which—actually—is a very good thing for the dissemination of the program: The more angles we all hit it from, the more chance I suspect it will stick in the public's craw. Without my name on it, also, it helps give the impression of an independent construction/exposition. And thus, I hope the technique will bring in a new set of readers.

I hope you won't be offended by my withdrawal: I mean to make no negative connotation by it. It's just that time is short, and when Fuchs gets involved with something, he tends to spend too much time trying to work it into a Fuchsian style (whenever he can get away with it, that is)—and that is a bad trait, especially with respect to the present project.

Now that my head is more clear, and I'm back in a more technical environment, I dearly want to get back into doing calculations. But I also must clear up all these old projects that are still waiting (like SHPMP and Kluwer and such). So, the clearer I can keep my plate the better ... the better for us all.

28-10-04 *Mathematical Metascience* (to D. J. Foulis)

Are you out there somewhere? Would it be possible to send me an electronic copy of your article "Mathematical Metascience"? If you can't, I can get Howard Barnum to mail me a xerox copy of it; he was already on the verge of sending it, but I thought this might be faster.

28-10-04 *Reference, 2* (to F. E. Schroeck)

Below are the references to all three of my quantumness papers. I hope you can understand clearly enough the archaic code that I used. Renes, by the way, in a couple of papers on `quant-ph`, now has a full-fledged quantum cryptographic application for these SIC ensembles.

I'm curious to see what you've written about. Please send me a copy of the paper when you can—by email if possible.

No need for an absentee ballot: We're back in New Jersey now!

- C. A. Fuchs, "On the Quantmness of a Hilbert Space," in *Quantum Information, Statistics, Probability: Dedicated to Alexander S. Holevo on the Occasion of His 60th Birthday*, edited by O. Hirota (Rinton Press, Princeton, NJ, 2004), pp. 65–77. `quant-ph/0404122`.

- K. M. R. Audenaert, C. A. Fuchs, C. King, and A. Winter, "Multiplicativity of Accessible Fidelity and Quantumness for Sets of Quantum States," *Quantum Information and Computation* **4**(1), 1–11 (2004). `quant-ph/0308120`.

- C. A. Fuchs and M. Sasaki, "Squeezing Quantum Information through a Classical Channel: Measuring the 'Quantumness' of a Set of Quantum States," *Quantum Information and Computation* **3**(5), 377–404 (2003). `quant-ph/0302092`.

29-10-04 *URGENT: Exact Quote* (to G. Brassard)

You're in luck. The following paragraph can be found in the JMO paper:

> The task is not to make sense of the quantum axioms by heaping more structure, more definitions, more science-fiction imagery on top of them, but to throw them away wholesale and start afresh. We should be relentless in asking ourselves: From what deep *physical* principles might we *derive* this exquisite mathematical structure? Those principles should be crisp; they should be compelling. They should stir the soul. When I was in junior high school, I sat down with Martin Gardner's book *Relativity for the Million* and came away with an understanding of the subject that sustains me today: The concepts were strange, but they were clear enough that I could get a grasp on them knowing little more mathematics than simple arithmetic. One should expect no less for a proper foundation to quantum theory. Until we can explain quantum theory's *essence* to a junior-high-school or high-school student and have them walk away with a deep, lasting memory, we will have not understood a thing about the quantum foundations.

I've got to run to lunch in a second, so I may not be around for the next couple of hours.

29-10-04 *Intrigue!* (to W. K. Wootters)

I was on the web trying to find the title I gave for a talk at Jeff Bub's "New Directions" conference last year, and I ran across a schedule already posted for next year's meeting. Beside your name, I saw the title: "Measurement-loops as Elemental Quantum Processes." I've got to say, that really, really intrigues me! What are you gonna talk about? If you've got the time to commit a sketch of the idea to email, I'd love to read it!

01-11-04 *Abstract Abstracts* (to C. Beisbart)

OK, here they are, 50 days late:

> Title: Some of the Phenomena of Quantum Information Theory
>
> Abstract: The no-cloning theorem. Quantum entanglement. Quantum teleportation. Quantum key distribution. Positive-operator-valued measures (POVMs). Quantum nonlocality without entanglement. The monogamy of quantum entanglement. Bell inequalities. The Kochen- Specker theorem.
>
> Title: Bayesian-Like Ways to Think of Those Phenomena
>
> Abstract: A Bayesian understanding of no-cloning. A Bayesian description of quantum teleportation. The connection between Bayesian conditionalization and POVMs. ... And so on down the line. Until, finally, the Kochen-Specker theorem: This one may actually be a statement about ontology rather than a statement about degrees of belief! And without some ontology, Bayesians would have very little reason to be.

01-11-04 *Rational Hilbert Space* (to S. Aaronson)

I'm sure you're already aware of this paper, but I just ran across it this morning:

> L. Adleman, J. Demarrais, and M.-D. A. Huang, "Quantum Computability," SIAM J. Comput. **26**(5), 1524-1540 (1997).

Anyway, it caught my attention because it shows that the answer to my bar-room question to you, Toner, and Childs may not have been completely obvious. At least someone found some aspects of it worth writing a paper about.

So, despite the fact that there is no usual Kochen-Specker theorem for rational Hilbert spaces, BQP survives unscathed for them. Just an interesting little factoid for me. Don't know what to do with it, but it's an interesting factoid for me.

I need to come to Princeton sometime soon to get a new library card (probably within the next two or three weeks). Maybe we could meet up for lunch or something.

01-11-04 *No Reductive Physicalism!* (to H. Halvorson)

I ran across your title for the College Park meeting next year, "No Reductive Physicalism, No Measurement Problem," and have become quite intrigued! It looks very, very interesting from my perspective. What sorts of things are you thinking now?

I never heard back from you after you requested some reading suggestions from me. Was any of that useful? Or did it all just look like a load of muck?

Anyway, I'm back in New Jersey again ... and this time I'd like to do things right. In particular, not pass up the opportunity of visiting or collaborating with interesting colleagues in the area. How are things with you? I presume you're at Princeton permanently now. It'd be great if I could give you a visit soon. I've been meaning to come to campus to renew my library card in any case, and I definitely would like to do that before Butterfield departs so I get a chance to see him a little. Might you have any time in the next two or three weeks?

02-11-04 *Election Day Blog* (to C. M. Caves, R. Schack, and N. D. Mermin)

The *New York Times* this morning started one of their columns in this way, and I thought it was particularly relevant for our collaboration:

> Every four years, by journalistic if not political tradition, the presidential election must be accompanied by a "revolution." So what transformed politics this time around? The rise of the Web log, or blog. The commentary of bloggers – individuals or groups posting daily, hourly or second-by-second observations of and opinions on the campaign on their own Web sites – helped shape the 2004 race. The Op-Ed page asked bloggers from all points on the political spectrum to say what they thought was the most important event or moment of the campaign that, we hope, comes to an end today.

So, let me do my duty as an avid reader of the *New York Times* and tell you what I think was the most important event of the campaign. It was near the end of the first presidential debate, 3 October 2004, when John Kerry said, "... this issue of certainty: it's one thing to be certain, but you can be certain and be wrong."

True of politics, true of human relations, true of what can be derived from a quantum state.

Unraveled, it is quite a deep statement, as we know. One might even say, a "revolution." Quantum certainty is not a state of affairs, but a state of mind. And we knew it even before the election year!

Maybe I'll cc this note to Mermin too. Even he, I bet, would agree that one of the key issues in the campaign has to do with the meaning of "certainty."

05-11-04 *I Had To Ask!* (to W. K. Wootters)

Well, I had to ask, didn't I? ...

I got both your notes, and I've read them several times over. But I have to confess that I'm confused about what you're up to.

Is a measurement loop this (at least in the quantum mechanical setting)? Ingredients: 1) a bipartite system comprised of identical components (and hence isomorphic Hilbert spaces), 2) a *fixed* initial state for that bipartite system, 3) a (unknown?) unitary operator on one of the systems (expressing their relative evolution), and 4) the set of all imaginable complete orthogonal measurements on the bipartite system?

Is part of your point—again, in the quantum setting ... I know you ultimately want to abstract away from that—that these ingredients are sufficient for doing tomography on the unitary? Just a question so I can get better oriented.

On a maybe related matter, do you know this phrase I like? That, "a quantum operation is just a quantum state in disguise." What I mean by this is: If from the Bayesian view, a quantum state is the analogue of a (unconditioned) probability distribution, one might ought to think of a quantum operation as the analogue of a conditional probability distribution. And just as the conceptual difference between an unconditioned and a conditioned probability distribution is not so very important, so one might imagine for the conceptual difference between quantum states and operations—namely that there isn't really one.

Anyway, this train of thought led me to try to get the structure of quantum time evolutions out of something like a Gleason theorem for measurements upon a "single system" posed at two points in time. I never could quite make that work the way I wanted it to (though I never completely gave up hope either).

Just thinking out loud now, and wondering whether there might be any connections between the two problems ... since they are both about tomography of time evolutions in way. But before I do more thinking, I should understand whether I've gotten your scenario right. I suspect I didn't.

07-11-04 *Mermin on Dirac Notation* (to A. Wilce, H. Barnum & J. M. Renes)

Taken from Chap. 1 of his lecture notes for his course on quantum computation:

> This is a good example of the primary point of Dirac notation: it has many built in ambiguities, but it is designed so that any way you chose to resolve those ambiguities is correct. In this way elementary little theorems become consequences of the notation. Mathematicians tend to loathe Dirac notation, because it prevents them from making distinctions they consider important. Physicists love Dirac notation, because they are always forgetting that such distinctions exist and the notation liberates them from having to remember.

10-11-04 *Being Bayesian in a Quantum World — Invitation* (to all BBQWers)

Dear Colleague,

We hope you will accept our invitation to the meeting detailed below. We expect to obtain some amount of funding to help cover your travel costs and expenses. Please let us know as soon as possible whether you think you are interested in the meeting and will be able to come. (I, of course, have already fielded the idea of the meeting with many of you: So, I expect we shall have a great turnout!) Once we hear back from you, we will provide more details as the organization proceeds.

On behalf of all the organizers,

Best regards,
Chris Fuchs

BEING BAYESIAN IN A QUANTUM WORLD
1-6 August 2005, Konstanz, Germany

Organizers:	Carlton M. Caves	(University of New Mexico)
	Christopher A. Fuchs	(Bell Labs, Lucent Technologies)
	Stephan Hartmann	(London School of Economics and University of Konstanz)
	Rüdiger Schack	(Royal Holloway, University of London)

To be a Bayesian about probability theory is to accept that probabilities, whenever used, represent subjective degrees of belief and nothing else. This is in distinction to the idea that probabilities represent long-term frequencies or intrinsic, chancy propensities "out there" in nature itself. But how well does a subjective account of probabilities mesh with the existence of quantum mechanics? To accept quantum mechanics is to accept the calculational apparatus of quantum states and the Born rule for determining probabilities in a quantum measurement. If there were ever a place for probabilities to be objective, one would think it ought to be here! This raises the question of whether Bayesianism and quantum mechanics are compatible at all. For the Bayesian, it suggests that perhaps we should rethink what quantum mechanics is actually about!

There is no doubt that we live in a quantum world. From transistors to lasers to nuclear warheads, the evidence is all around us. One could take from this that the individual elements in the quantum formalism give a mirror image of nature: That is, that the wave function is so successful as a calculational tool precisely because it represents an element of reality. A more Bayesian (or, at least, Bayesian-like) perspective is that if a wave function generates probabilities, then they too must be Bayesian degrees of belief, with all that such a radical idea entails. In particular, quantum probabilities have no firmer hold on reality than the word "belief" in "degrees of belief" already indicates. From this perspective, the only sense in which the quantum formalism mirrors nature is through the normative constraints it places on gambling agents trying to navigate through the world. To the extent that an agent should use quantum mechanics for his uncertainty accounting rather than some foil theory tells us something about the world itself—i.e., the world independent of the agent and his particular beliefs at any moment. The task of the quantum Bayesian is to make this argument explicit and rigorous and to reap any benefit such a clarification can give to philosophy and physical practice.

Hogwash or deep idea? The time seems ripe for a discussion, pro and con. At this meeting, in the pleasant surroundings of Lake Konstanz, we envision a roughly fifty-fifty mix of philosophers (who have thought long and hard about probability and quantum foundations) and quantum-information physicists (who have developed an impressive box of mathematical tools for prying apart the probabilistic structure of quantum mechanics) to set the tone. The goal is to make real progress on these issues through a complementarity of talents and some good-hearted debate. Might we better understand the power of quantum computation through Bayesian techniques? Does a Bayesian conception of the quantum state really make "the measurement problem" go away? How secure is quantum cryptography really if a quantum state is "just" a state of belief? Less secure? Or maybe more (honestly) secure? Does a Bayesian conception of the quantum state lead us closer to or further away from the Copenhagen interpretation? What about many-worlds? ... And so the list of topics goes on. We hope the discussions will go long into the night and fill the lakeside walks.

The proposed set of participants is as follows:

Marcus Appleby	(physicist, London, USA)
Guido Bacciagaluppi	(philosopher, Paris, France)
Howard Barnum	(physicist, Los Alamos, USA)
Hans Briegel	(physicist, Innsbruck, Austria)
Todd Brun	(physicist, U. Southern California, USA)
Jeffrey Bub	(philosopher, Maryland, USA)
Paul Busch	(physicist, Hull, UK)
Jeremy Butterfield	(philosopher, Oxford, UK)
Ignacio Cirac	(physicist, Max Planck Inst., Germany)
John Earman	(philosopher, Pittsburgh, USA)
Arthur Fine	(philosopher, Washington, USA)
Jerry Finkelstein	(physicist, San Jose, USA)
Branden Fitelson	(philosopher, Berkeley, USA)
Henry Folse	(historian, Loyola, USA)
Bas van Fraassen	(philosopher, Princeton, USA)
Nicolas Gisin	(physicist, Geneva, Switzerland)
Hans Halvorson	(philosopher, Princeton, USA)
Lucien Hardy	(physicist, Perimeter Inst., Canada)
Jim Hartle	(physicist, UC Santa Barbara, USA)
Jenann Ismael	(philosopher, Arizona, USA)
Norbert Lütkenhaus	(physicist, Erlangen, Germany)
David Mermin	(physicist, Cornell, USA)
Gerard Milburn	(physicist, Queensland, Australia)
Wayne Myrvold	(philosopher, Western Ontario, Canada)
Michael Nielsen	(physicist, Queensland, Australia)
Itamar Pitowsky	(philosopher, Hebrew U., Israel)
David Poulin	(physicist, Queensland, Australia)
Huw Price	(philosopher, Sidney, Australia)
Benjamin Schumacher	(physicist, Kenyon College, USA)
Abner Shimony	(jack of all trades, Boston, USA)
John Smolin	(physicist, IBM Research, USA)
Rob Spekkens	(physicist, Perimeter Inst., Canada)
Christopher Timpson	(philosopher, Leeds, UK)
Jos Uffink	(philosopher, Utrecht, Netherlands)
Bill Unruh	(physicist, British Columbia, Canada)

David Wallace	(philosopher, Oxford, UK)
Reinhard Werner	(physicist, Braunschweig, Germany)
Howard Wiseman	(physicist, Griffith U., Australia)
Anton Zeilinger	(physicist, Vienna, Austria)

We look forward to seeing you in Konstanz!

Best wishes,

Carl Caves, Chris Fuchs, Stephan Hartmann, and Rüdiger Schack

10-11-04 *Being NON-Bayesian in a Quantum World* (to R. Werner)

By now you'll have seen the invitation I sent you for our meeting "Being Bayesian in a Quantum World." I know that you're negative on Bayesian probability as a whole, but for precisely that reason I hope you'll still come to the meeting. Rüdiger Schack and I agree that you have given us some of the best runs for the money we've ever had! And we think you could help keep the meeting quite lively in that regard. Your arguments are sharp and to the point. Whatever the outcome (i.e., pro- or anti-Bayesian), I want the meeting to be a productive one, and you would be great in that regard.

So, I'm definitely hoping to hear back from you!

10-11-04 *$\psi^*\psi$, Subjective Probability?* (to J. Earman)

By now you'll have seen the invitation to our BBQW meeting that I sent you. I definitely hope you'll come! I remember at the end of the Minnesota meeting, you said: "Psi-star psi generating subjective probabilities? Could not be!" So, I know you already have an opinion! But it'd be great to see you engaged on the subject, arguing your point. You'd be a great addition to the meeting. And particularly, I have so many things to discuss with you that I first learned from your book, it'd be a great honor if you were there.

10-11-04 *Do Correlations Need To Be Explained?* (to A. Fine)

By now you'll have seen the invitation to the BBQW meeting I sent you. I so hope you'll come. That old paper of yours was quite influential on me several years ago. So I was thinking of that one of your many hats, when I argued for your inclusion in our list. It would be great to get your feedback, pro or con, on this whole movement as a foundational approach to quantum mechanics. Plus I think you'd just have a lot of fun!

10-11-04 *Even Better Than Your Talk Title* (to H. Halvorson)

Halvorsonism 2: *This project was motivated by your overall program (which, if I have interpreted it correctly, rejects the idea that there is a "measurement problem"). But I've added a bit of gloss that connects this idea with recent debates in philosophy of mind. (Debates about how to formulate "physicalism", etc..)*

In short, all philosophers of physics I know – with the possible exception of Bub – seem to think that the "measurement problem" is a problem that nobody can avoid, no matter what their metaphysical persuasion. But the more I re-read the standard derivations of the problem, the more

I suspect that some bogus metaphysics gets invoked at the last step – viz., reduction of mental events to physical events.

Now, I'm not committed to anti-reductionism, or to some sort of dualism. If pressed, I might say the whole physicalism versus dualism debate is ill-founded. (I think that was James' position; and it is certainly van Fraassen's position.) But I think now that only strong reductionists (namely, those who don't think that the problem is ill-founded, and who think that, in fact, mental events are identical to physical events) have a measurement problem. This is good news for those of us who have a sane view, because we can stop worrying about the supposed problem and get on to more interesting topics!

That sounds great! Now you have my mouth watering to hear more about it all. (I guess I shouldn't say my ears are watering ... that sounds disgusting.) Certainly you know I have read a lot of James by now; he's turned into one of my heroes. Anyway, it sounds like you've got some good meaty thought. Looking forward to your explanations.

Halvorsonism 3: *By the way, John Conway is giving a talk "Free Will, Elementary Particles, & the Kochen-Specker Paradox" on November 19th at 4pm. The talk is based on a recent theorem by Conway and Kochen. They tell me that they have decisively proven, once and for all, that QM is indeterministic. Hmm!*

Frankly, I think I'd almost give up all of PSA to see this one! My own feeling is that nothing in quantum mechanics gets closer to a (trial) ontological statement (or ontological relative to the theory) in quantum mechanics than the Kochen-Specker theorem. Here's the way I put it tongue-in-cheek in a couple of talk abstracts recently (for the summer school that will follow our Konstanz meeting):

> Title: Some of the Phenomena of Quantum Information Theory
>
> Abstract: The no-cloning theorem. Quantum entanglement. Quantum teleportation. Quantum key distribution. Positive-operator-valued measures (POVMs). Quantum nonlocality without entanglement. The monogamy of quantum entanglement. Bell inequalities. The Kochen- Specker theorem.

> Title: Bayesian-Like Ways to Think of Those Phenomena
>
> Abstract: A Bayesian understanding of no-cloning. A Bayesian description of quantum teleportation. The connection between Bayesian conditionalization and POVMs. ... And so on down the line. Until, finally, the Kochen-Specker theorem: This one may actually be a statement about ontology rather than a statement about degrees of belief! And without some ontology, Bayesians would have very little reason to be.

Anyway, I suspect Conway will be talking about another version of Kochen-Specker (or something similar). I'd like to see the mechanics of that.

Hope to hear a positive response from you soon on the BBQW meeting! I think this is going to be the best (most productive, most exciting, most memorable) meeting I've ever been involved in organizing!

10-11-04 *The BBQW Thing* (to N. Lütkenhaus)

By now you'll have seen the invitation I sent you to the BBQW meeting. I hope you'll seriously think about coming and will not feel out of place with so many philosophers. Particularly, I think you could make an important contribution to this meeting, by helping us understand whether our attempt for a Bayesian-like formulation of QM has any implication on information security (or vice versa). Or, even how to pose various protocols—Rüdiger, in particular, would like to get into this aspect of the discussion. Joe Renes is likely to be there too. (Also maybe you've seen the recent papers by the Maurer group on quantum de Finetti theorems and could comment, etc.) Anyway, I'm just saying, your inclusion in the list of invitees was very intentional, and we hope you can come.

11-11-04 *Free (Bayesian) Housecleaning!* (to A. Shimony)

Shimonyism 4: *The conference in Constanz is very tempting. I would learn a lot and would be forced to sharpen the presentation of my objectivist position. But I anticipate such a burden this coming summer that I cannot make a commitment to attend. If there is a change I shall inform you.*

Oh, I do hope that burden will go away, because I dearly want you at our meeting. I want to get so many of these quantum-probability issues settled in our community sooner rather later, and your input really is crucial for that. You've been thinking deeply about probability for so many years, I think it would be great if our participants could get a sense how those thoughts apply to our particular context. If it'd help you out, I could even come to Boston to clean your house this summer!

Seriously, if there's any way you can make the trip happen, I think our whole debate would be much better primed for progress with your presence. Please let me know if there's any way you can rearrange.

11-11-04 *BBQW and Unique Butterfields* (to J. N. Butterfield)

I'm glad you're intrigued by the conference! But I oh so hope you can come. Your presence would fill a unique role there, the way you strive to find common ground between seemingly opposed points of views. We need you actually. Seriously. So I do hope things will work out with your and your family's schedule.

11-11-04 *Making Every Effort* (to D. Poulin)

It's great to hear that you want to come to BBQW!

On your comment, actually I think Smolin, Gisin, and Hartle are all pretty good to being "open to discussion"—each in their own way, of course. I've had very good (and productive) discussions with all of them in the last year or two. But, in any case, rest assured that we're doing our best to round up some *productive skeptics* for the meeting. The notes below show a sampling of the effort specifically in that direction.

The point is, I think you'll have plenty of opportunity to sharpen your viewpoint, rather than either just a) preaching to the choir, or b) being buried asunder. It's gonna be a great meeting: Definitely, you gotta come!

12-11-04 *Philosopher Henry* (to H. J. Folse)

That is great news to hear that you can come! It's gonna be a good meeting, and I'm pretty excited about it.

Sorry to have called you a historian; for some reason, I thought that was your official job title. I should have checked.

Folsesm 22: *What are you looking for from participants, a 20–30 minute paper? I'll have to think up something to put on a power point.*

That's hard to say at this point. The note below is our last exchange on the subject (with which at least Stephan agreed), but I can't say yet whether it represents the final word.

Be thinking about what Bohr would have thought about de Finetti! Is there enough evidence in his work to give us any indication? It would be wonderful if you could give us a report on that. I'm thinking of say: B. de Finetti, "Probabilism," Erkenntnis **31**, 169–223 (1989). Exempting the first couple of sections (where I can't quite figure out how far deF is really going), I think this is his definitive philosophical statement.

16-11-04 *Copenhagen Hoping* (to A. Zeilinger)

I just sent you an invitation for our meeting "Being Bayesian in a Quantum World", and I'm writing again because I hope, hope, hope you can come. The main thing is that I've had enough contact with the philosophers recently to see that we're starting to chip away at their resistance to the Copenhagen interpretation. And I'm hoping with this meeting we'll finally have the strength to make a full frontal assault. If you could be there that would be a great help, and I think you would find the experience very satisfying.

I hope you will give a reply as soon as possible.

16-11-04 *Symmetry Magazine and Article Request* (to D. J. Harris)

I apologize for keeping you waiting. I thought a lot about your proposal, but ultimately, I don't think I'm going to be able to find a way to tie in what I'd like to say about Einstein and quantum foundations with his photoelectric effect paper. If your call were to write a 650-word version of what I think was the main quantum foundational theme of his life (from 1932 to the end)—i.e., a story like I wrote up on pages 9–11 of `quant-ph/0205039`—then I think I could do it. And I'd do it because that's how the man should be remembered, and the widest possible community should recognize that of him: He had a very clear understanding—maybe more than anyone else—that the quantum state must represent incomplete information. And where we have come to nowadays—particularly in quantum informational approaches to the foundations—is in trying to explain why the information cannot be completed. But I just haven't found a clever way to tie that in with the photoelectric effect. So, I better desist at this point; I understand your deadlines.

17-11-04 *Bayes, Bennett, and Bull* (to M. Pérez-Suárez)

Sorry to hear you're not quite happy there. Just keep in mind the crowd you're hanging out with and learn what you can with regard to their specialties. There'll always be time to Bayesianize at other meetings.

On your Smolin query, it might well be John. He told me that he's going back to Cambridge for a week in December. Also it sounds like Charlie Bennett is back in town now. You'll find that he's not very philosophical (in fact he tries to be anti-philosophical), nor is he very sophisticated (he tries to be anti-sophisticated), but he can be great fun. And I venture to say he's probably the greatest genius (if there can be an overall mark for such things) in the whole city.

I hope things are on course for you to spend some time in Albuquerque.

01-12-04 *BBQW Responses — Progress Report, as I near the Pacific* (to S. Hartmann, C. M. Caves & R. Schack)

Friends in Barbecue,

Below is how it stands, just as I am poised for my jump over the Pacific to Sydney. We've had a couple more replies, and at least one E has turned into a Y. I think Carl was going to write Nielsen again; and Stephan was going to write Uffink. We can probably write off Fine and Werner at this stage, since I've written them secondary notes and still gotten no response.

Also, see the note from Milburn below. It looks like he will contact Stephan with some more funding ideas. Carl, is there something you're pursuing that I should help with?

To answer Stephan's question, I think the PSA session on quantum information and foundations went very well. Or at least I think so. The biggest bright eyes in the audience were Bas van Fraassen, Harald Atmanspacher, Steve Savitt, Jossi Berkovitz, someone named Antigone (prof in Minnesota?), John Norton, and maybe Michael Dickson. Berkovitz and Antigone were particularly interested in the quantum de Finetti theorem. In addition to that, though he wasn't at the session, I met Alan Hájek at the conference. He spoke at the Richard Jeffrey memorial session (along with Brian Skyrms, Lyle Zynda, and Persi Diaconis), and I got a pretty good impression of him. Afterward, I fielded the question of whether he would be interested in BBQW, and he was actually very enthusiastic. I think now I'm inclined to say he would be my top pick for the Fitelson spot. But why don't we invite both Hájek and Howson? (Also, does anyone know Urbach? What's he like?)

Beyond that, I wonder whether we might consider Diaconis? I got one heck of a good impression from his talk. On top of that, it's clear that he's got technical skills like no other: Skyrms may talk "radical probabilism", but Diaconis calculates "radical probabilism"! And I do think we could use some representation of that. Diaconis gave the impression that he may be particularly interested in foundations at this point in his life.

Are things in good shape for Stephan to apply to the VW foundation? Or should we send out the second round of invitations first. I could do that from Sydney this week: I'm hoping to get a lot of work done from there in the wee hours of the morning. We'd just need to decide upon who's next.

That's all I can think of at the moment.

04-12-04 *From Australia* (to J. Bub)

I'm sorry I forgot to give you the recommended reading list before I got involved with my brother's visit to NJ and then had to scuttle off to Australia. (I'm visiting Huw Price.) Here's what I can give you at the moment as a "must read":

B. de Finetti, "Probabilism," Erkenntnis **31**, 169–223 (1989).

It seems way off the mark in the first two sections (seemingly portraying that de Finetti is almost a solipsist ... maybe something got really screwed up in the translation), but it soon recovers after that to become what I would say is THE most powerful article on Bayesian probability I have ever read. It was the article that finally convinced me of the nonfactivity of all probability distributions.

Now, it took me four separate readings of the article over six years, and a lot of rumination in between, to get to that point. But with the hindsight of that experience, I hope I'm in a much better position to help you guys slog through it more effectively than I did.

You might also want to read Richard Jeffrey's accompanying article

> R. Jeffrey, "Reading *Probabilismo*," Erkenntnis **31**, 225–237 (1989).

to help set the historical context.

I also want to suggest to you some pages from Bernardo and Smith's book,

> J. M. Bernardo and A. F. M. Smith, *Bayesian Theory*, (Wiley, New York, 1994).

but it'll have to wait till I get back home Wednesday before I can suggest anything specific to you.

How does that sound? Is that enough to get you started until I can get back to you Wednesday or Thursday.

08-12-04 *BBQW Topics — Just Some Ideas* (to the BBQW Boys)

Here are some other topics for your VW Foundation proposal for our meeting, and more generally, for the conference itself. I guess I'll also send this to Gerard Milburn in case he might need it for his own funding efforts.

---

1. Could the Everett Interpretation of quantum mechanics really give rise to a Bayesian derivation and interpretation of the quantum probability rule? (Wallace, Uffink, Barnum, ... and Greaves if we sneak her in as a discussant)

2. Can or cannot one contemplate doing quantum cosmology with a Bayesian interpretation of quantum states? Assuming one can, what does Bayesianism add for helping to solve existent technical problems? (Hartle, Unruh, Brun, Caves, ... and maybe Srednicki.)

3. How does a Bayesian interpretation of the quantum state impact information security in the sense of quantum cryptography? Is there a serious difference between subjective and objective interpretations of the quantum state in this regard? Does one really need an objective notion of randomness to make the idea of a quantum random number generator fly? Even if one will not buy into the idea of a Bayesian interpretation of the quantum state, will Bayesian techniques for standard statistical practice nevertheless make a difference for security analyses? (Lütkenhaus, Gisin, Schack, ... and maybe Renner and Renes.)

4. What does objective chance in the sense of David Lewis's "principal principle" or a propensity interpretation (as in Giere's early paper or as a special case of Popper's) add to the interpretational issues of quantum mechanics? Or does an objective interpretation of probability only impede quantum foundational progress? (Myrvold, Shimony, Butterfield, Gisin, Howson – pro objective chance; Appleby, Fuchs, Schack, Caves – con objective chance)

5. Quantum computing. How might quantum computational algorithms be understood as Bayesian inference engines? Do any of the known quantum computational models (unitary-gate implementations, measurement-based models, or adiabatic models) favor or disfavor a Bayesian interpretation of quantum states and operations? How to pose some known quantum computational algorithms as Bayesian updating questions? (Nielsen, Briegel, Cirac, Wiseman, Caves, Milburn, Barnum, Mermin, . . .)

6. What would Bohr think? How close is a Bayesian interpretation of quantum states *really* to anything Copenhagen like? Where is a Bayesian interpretation less radical and anthropocentric than the Copenhagen interpretations (in the Bohr, Pauli, and Heisenberg varieties)? Where is it more? (Folse, Fuchs, Mermin, and Zeilinger)

7. Bayesian interpretations of the quantum state tend to suggest novel quantum measurements to use in their representations (for instance, the symmetric informationally complete positive-operator-valued measures and complete sets of mutually unbiased measures). They also suggest interesting quantum-state and operation tomography questions (like the pure-state informationally (PSI) complete measurements and the de Finetti representation theorems). It would be nice to get some technical reports on these issues. (Appleby, Caves, Schack, . . . and Diaconis, Renner, and Wootters.)

8. To what extent does quantum mechanics come about solely through information-theoretic constraints? To what extent is it not much more than a theory of missing information? Bub-Clifton-Halvorson theorem; Spekkens toy models; Smolin objections. Is a further ontology underlying the information-theoretic constraints needed or not? Can Smolin really give an Everett interpretation to Spekkens's toy model? (Bub, Halvorson, Spekkens, Smolin, Poulin . . .)

9. Is quantum mechanics an extension of (Bayesian) probability theory? For instance, through C^*-algebras or effect algebras. Or is it rather a particular application with some special assumptions? For instance, might it be little more than a theory of priors? Or is it some combination of those two ideas? (Bacciagaluppi, Busch, Hardy, Fuchs, Barnum)

10. How well does quantum mechanics mesh with the "radical probabilism" of de Finetti, Richard Jeffrey, and Brian Skyrms? Does it require radical probabilism for its understanding? Does the natural noncommutivity that arises in more general kinds of conditioning (like Jeffrey conditionalization) have anything to do with quantum mechanical noncommutivity? (Hájek, Hartmann, Schack, Fuchs, . . . and Diaconis)

11. Quantum Bayesianism and wider philosophical issues, for instance from the philosophy of language to antirepresentationalism (i.e., the sorts of things in later Wittgenstein, Rorty, Davidson, later Putnam, etc.) How do the views of Fuchs and Schack on quantum certainty mesh with Wittgenstein's book *On Certainty*? In what ways is it useful to recognize the "non-factivity" (Timpson's term) of the subjective Bayesian's view of quantum states? (Timpson, Price, Fuchs, Appleby, Schack)

12. Quantum versions of foundational Bayesian arguments: Like Dutch book (synchronic and diachronic), Cox, de Finetti representations, decision theoretic axioms, etc. (Pitowsky, Uffink, Caves, Schack, Fuchs, Poulin, Brun, Barnum, Wallace)

13. . . . And I'm sure I forgot a ton of other interesting potential topics at this sitting. But I think this is enough for now, and 13 is an unlucky number anyway.

09-12-04 *Looking Forward* (to G. Bacciagaluppi)

Now for other, less urgent business.

Bacciagaluppism 1: *I have been thinking further about "the idea": I think it can make precise in what sense the measurement problem becomes more benign. I shall try to write down a few pages and send them to you.*

I'll look forward to seeing that.

On a somewhat related matter, I went to Hans Halvorson's talk at Princeton last night and came away very disappointed and self-reflective. The disappointment (this time) was not with myself but with Halvorson. I guess I put myself up for a let down: You see, Halvorson titled his talk "No Reductive Physicalism, No Measurement Problem"—a title that I could easily imagine myself writing to try to convey some of my most beloved ideas about quantum mechanics. To top it off, Hans had told me this in one of his emails:

Halvorsonism 4: *This project was motivated by your overall program (which, if I have interpreted it correctly, rejects the idea that there is a "measurement problem"). But I've added a bit of gloss that connects this idea with recent debates in philosophy of mind. (Debates about how to formulate "physicalism", etc.)*

So, I thought, "Great! He's going to make precise and much more convincing all this stuff I've been muttering about for the last couple of years." (For instance, I was quite pleased with the fine points of our program that Chris Timpson made clearer at the end of his thesis, where he points out that it is crucial for us that quantum states be "nonfactive." That seemed a worthwhile "gloss" that may help in several ways.) Thus, it was quite a shock to me when I saw that what Hans was talking about is diametrically opposed to almost everything I think of QM. His quantum states are still *ontic* states, and (physical!) collapse comes about from some mysterious interaction between (ontic) brain states and (epistemic? ephemeral? Platonic? in any case, not ontic!) mental states. It was almost like seeing the old von Neumann solution all over again: The measurement chain stops at consciousness. I.e., it's all about that mysterious last step. It was awful.

I motivated that? That's what disturbed me. One of the most hotshot of the hotshot young philosophers could read me no more carefully than that? Am I that absolutely unclear? It's easy for me to see how someone could disagree with me on quantum foundations if they've understood but reject the Bayesian point of view—and that's fair enough—but what I can't understand is how when I strive so hard to be clear, I can still be continually misread. Especially from someone like Hans, whose recent work with Bub might have indicated that he would have at least a nominal interest in trying to get these ideas straight.

The only thing I can think is that a large class of philosophers really don't take me seriously, or at least beyond a little lip service. Halvorson put no gloss on my program; he muddled it with some pretty bad (and certainly completely independent) ideas.

Thus I really am quite thankful for the clarity you help give me. With you, I've never had the impression that you misunderstand what I'm aiming for. On the contrary, I often feel quit dumb around you, feeling that your understanding (of my own program) far outstrips mine.

But all of this is just to repeat in a long-winded way what I said in the first line about the note you're going to send me: "I'll look forward to seeing that."

In what sense does the measurement problem become more benign? You know what I've been aiming for: A way to make convincing that quantum-state updating is no more (or if you rather, no less) philosophically interesting that the process of conditionalizing a probability. It is just technically different than usual conditionalization. The extra unitary rotations are not mysterious physical actions but simply different rules for conditionalizing. Thus the technical problem becomes trying to find a way (or modification to standard Bayesian arguments) to justify why *this* conditionalization rule rather than *that* one. But the overall point: One should *only* find quantum state change mysterious if one also finds standard Bayesian conditionalizing in need of some kind of further metaphysical explanation—i.e., if one deems it important to find a literal or mechanistic explanation for how facts change beliefs.

Also, you know that that's only half the coin for me. What I think *is* philosophically interesting is that the character of the event space for our probability functions changes in going to quantum mechanics: I.e., we shouldn't—from my view—think of the h's in a $P(h)$ as signifying unknown but pre-existent properties. Rather they are values that come about from our actions upon a physical system. All I'm trying to do is cleanly isolate what I view as two very distinct issues: Change of the conditionalizing rule? Ultimately not so interesting. And, to make use of your phrase, a kind of benign change from our old view. Change of the character of the event space from pre-existent properties to the results of an agent's actions? That—my intuition tells me—is where the really good stuff is!

But I blabber, blabber. At least it's made me feel better to write all this down.

10-12-04 *The Further Reading* (to J. Bub)

I had promised to send a further list of things to read upon my return from Australia. Here they are, I hope it's not too late.

From Jose M. Bernardo and Adrian F. M. Smith's book *Bayesian Theory* (Wiley, 1994):

1) Sections 1.1, 1.2, and 1.3.

2) The subsection titled "Subjectivity of Probability" on pages 99–102.

3) Section 4.8 to page 237.

Also I think Marcus Appleby's paper "Probabilities Are Single-Case, or Nothing" (`quant-ph/0408058`) could be quite helpful. Particularly, I like the argument of Section 3.

My plan for your seminar is mostly to have a free roaming discussion about the contents of these readings. Is that OK with you? Or did you have something else in mind?

13-12-04 *The Beast* (to S. Aaronson)

Aaronsonism 8: *Hope everything's well with you. Yep, my own big 400+ page "samizdat" is lumbering toward completion over the next couple days ...*

[Reference Scott's Thesis]

Would you mind reading it through by tomorrow night and sending me detailed comments? Ha ha, just kidding. But you're mentioned in the acknowledgments, and the prologue ("Aren't You Worried That Quantum Computing Won't Pan Out?") is intended to amuse. I'd love to hear your thoughts.

I loved it! And you have helped me immensely with your Chapter 1: Soon after the new year, I've got to construct a talk to give to Jeff Jaffe (the president of Bell Labs research) and Dave Bishop (the new VP over physical-science research) on why Bell Labs should imagine spending even a cent on quantum foundations research. Among other things, I have wanted to argue that it has been the foundational mysteries all along that have motivated so much of technical quantum computing and quantum information. And that these guys who want to suck off the governmental tit spurred by this field shouldn't forget its very roots! I.e., I'm going to partly lash out at the guys who call what I'm interested in "Sunday physics" but nevertheless (have to) cite my papers in their (self-proclaimed) "hard core" physics papers.

Anyway, I was going to quote liberally from Feynman, Deutsch, early Bennett and Brassard, Wootters, and the like. But now I can also see that I'll be quoting liberally from Aaronson! Even if you never prove another great theorem again, you're turning into a great writer.

BTW, I hope you will post your thesis on `quant-ph`. But before you do, compactify it with single-space, etc. Save the trees man!

I've still got to come visit you in Princeton. I'll try to do that soon after the new year too.

14-12-04 *Thoughts on Non-nonlocality* (to H. Price)

Finally coming back to your request for what to read within my writings on how a Bayesian conception of quantum states takes care of (or should take care of) issues to do with nonlocality in QM. Let me suggest you read Section 3, "Why Information?", and the beginning part of Section 4, "Information About What?", in my paper "QM as Quantum Information (and only a little more)", `quant-ph/0205039`. In that regard, let me also paste in below some correspondence I had with David Mermin and Jerry Finkelstein on those sections—I think they clarify things a bit further—and let me also attach an abridged version of the same paper that I never posted on the archive. In that version, I changed the "Why Information?" section somewhat to better reflect what I told Mermin below.

The key issue is, what do I mean when I say that nothing physically changes on Bob's side when Alice performs a measurement on her half of an entangled pair? In that regard, I think you might also get something out of my discussions on pages 175–176 and 184–189 of my samizdat *Quantum States: What the Hell Are They?*. These discussions were motivated by some standard dictionary (can't remember which) wanting to include a definition of quantum teleportation in its latest revision, and Bennett supporting a definition that said something like, "The transference of one particle's properties onto another particle via the assistance of . . . " The thing I objected to strenuously was the idea that any properties at all were transferred. Also, let me point you to some discussion on the same point in *Notes on a Paulian Idea*. See pages 465–466, starting at the words "Quote from Draft," and see pages 467–471 in the note titled, "Detailed Commentary." Getting a description of quantum teleportation that Asher and I could both agree on for the paper we were writing was a point of serious contention for us. And I went at great lengths to try to get my point across to him. It's exactly the same point that's relevant to our own discussion (i.e., Fuchs and Price).

I guess you could say the overarching idea is "no surprises, no reality." That is an idea I flesh out in pretty good detail in my paper "The Anti-Växjö Interpretation of Quantum Mechanics." See sections 4 and 5. (They are completely independent of the rest of the paper; so don't read any of the rest of the paper.) I think (I hope) actually, that you'll find the discussion there interesting independently of any issues to do with our discussion of nonlocality. In particular, if you read those sections, I don't think you could fail to give me the credentials of a "subject naturalist." Am I right?

Let's see, anything more? One last thing: Let me also suggest Chapter 8 of Chris Timpson's PhD thesis *Quantum Information Theory and the Foundations of Quantum Mechanics*, `quant-ph/0412063`, and also the "Envoi" at the very end. He does quite a nice job of explaining how the "nonfactivity" of our quantum states buys us the ability to stop talking about nonlocality.

There, that's one thing marked off my to-do list for you. (Certainly there's no rush to respond; I know you're traveling. Just archive this note until you have the time ... even if that's six months from now.)

14-12-04 *Backward Causation* (to C. H. Bennett and B. W. Schumacher)

Did you guys (or either of you guys) ever write anything up on the stuff that got you so excited in Japan a couple of years ago?: I.e., the stuff on time travel via quantum teleportation? If you haven't written anything up, do you have some PowerPoint presentations (or such) that you wouldn't mind sharing with me? (I know that some exist because I've seen you talk on this before.) I've been discussing this stuff with Huw Price, an Australian philosopher who is quite interested in exploring ideas about backward causation in the context of QM, and I've told him about your stuff. Price is quite a good guy, and I want to make sure I've got the story straight with all this stuff. Would you mind if I also share your slides with Huw in the course of our discussion? I don't see how it could hurt (since I promise he's a nice guy), but I understand you might have some objection if you haven't published this yet.

Anyway, the way I pick on all three of you (i.e., you two and Huw) is that I think you do something dangerous with a simple "chain of inference" by mystifying it with all this forward and backward time-travel talk. But now to compliment you: I think your Japan examples are great for illustrating that!

14-12-04 *Directions, Etc.* (to J. Bub)

Bubism 3: *Unfortunately, the only copy of Bernardo and Smith is out of the library, so probably no one will have read that. A free roaming discussion is fine, I think, but you should probably be prepared to talk a bit in general first (or perhaps second) about what specific foundational issues in quantum mechanics push one towards Bayesianism, and perhaps also about information in physics, since this is the topic of the seminar. Does that sound OK?*

I'll try.

But most importantly, you gotta realize that, concerning

> "what specific foundational issues in quantum mechanics push one towards Bayesianism,"

it's the other way around. It's clear thinking about probability and the use of it that leads to Bayesianism—nothing to do with quantum mechanics. *Then*, recognizing that a quantum state is (mathematically and conceptually) *nothing more than* a compendium of probabilities, one gets to the Bayesian conception of quantum states. In other words, it is Bayesianism that carries a hope of clarifying quantum foundations—not that something in quantum mechanics specifically pushes toward Bayesianism.

I'll try to see if I can get Bernardo and Smith scanned into my computer and turned into a text file. There's some chance that that might happen tonight.

15-12-04 *Favorite Bernardo and Smith Quotes* (to J. Bub)

Well, try as I might, I couldn't get my scanner connected up last night. It always takes much more time to install these things than one expects! Very frustrating. It just confirms what I've been thinking: I never want to go through another move again. *I never ever want to move again!* Moves just disrupt everything in life, and never for the better.

In light of last night's failure, let me do this as a stopgap. Here are two of my favorite Bernardo and Smith quotes that I already have in my computer. Chew upon them, because I think they especially express the flavor of the reconception of quantum mechanics I'm shooting for: That quantum mechanics is a *normative* theory of personal behavior (or uncertainty accounting) IN LIGHT OF the peculiar, particular world in which we are immersed. Different world, different normative theory for agents immersed within it. Moreover, because of the last point, though quantum theory is a theory about agents (rather than of objective reality per se), one can still hope to glean some hypotheses about objective reality itself from it. One just has to do so obliquely. But that's our task, and that's what we're setting ourselves up to do.

I'll try to emphasize these things in a preamble to our discussion tomorrow night. But if you don't mind, distribute this note to your students first so that it'll have had at least a little time to percolate in their minds.

15-12-04 *And Just a Little More To Read* (to J. Bub)

I know you guys have already read this stuff, but maybe it'd be worthwhile going over it again before my arrival: Namely Chapter 8 of Timpson's thesis (paying attention to the issues surrounding Footnote 4) and his "Envoi" at the very end. I think he does good justice to what (and why) we Bayesians are up to. It's all about breaking the "factivity" of quantum states.

15-12-04 *And Just a Little More To Read, 2* (to J. Bub)

Bubism 4: *Re Timpson, I'd be interested in your comments on his footnote on p. 181: 'Although he does not himself put it in these terms, Fuchs' awareness of the factivity of the terms "knowledge" and "information" and his related criticism of Mermin, mark the change from the objective Bayesianism of Fuchs (2001) to the more consistent subjectively Bayesian position of Fuchs (2002a).'*

Plan to. But also, it might be useful for you to look over the pages he cites from my "Quantum States: W.H.A.T.?" (namely, 19–25 and 42–51). I think I might read 'em too.

16-12-04 *Troubles of the Slusher Kind* (to R. E. Slusher)

I'm taking off to Maryland now to give a seminar to Jeff Bub's quantum foundations group at UMD. But I've been troubled all night about how I can get us past our point of disagreement from yesterday: I.e., to try to find a way to convince you that we Bayesians are not anthropomorphizing quantum mechanics in an unnecessary way. And to try to find a way to convince you that quantum mechanics is not like Newtonian mechanics, even in the broadest of all senses. I.e., to convince you that Newtonian mechanics is a theory of systems (as they are by themselves), and quantum mechanics is rightly a theory of observers (and only observers), not a theory of systems.

I intend to convince you of that—so you're good exercise for me. That'll be my new year's present. In the meantime, have you read Section 4 of my `quant-ph/0204146`, "The Anti-Växjö Interpretation of Quantum Mechanics"? It addresses the issue at least in a way that turned Preskill's head.

16-12-04 *The Doctrine of Preemption* (to C. H. Bennett)

Bennettism 22: *Reading the end of your letter I find the usual backhanded compliment: Presumably the last word "that" refers to the dangerousness of forward and backward time travel talk. I seem to have spooked you so much with my loose talk that now you are even afraid of forward time travel, which you never used to be.*

OK, you got me … in fact, preempted me. I loved the lines near the end of your presentation:

Q. Is it time travel?

A. It depends on what your definition of "is" is.

It was as if you had already heard my snide remark of 2004 in 2002. Had you?

I'm glad to hear the Newton meeting is almost over. I'm looking forward to having you back in the neighborhood. If you've got the time, I'd love to start dropping in from time to time sometime in January. In particular, at least at the outset, if I could interest you guys in the SIC-POVM problem (i.e., do they always exist?, and if they do, how are they constructed?, what can you do with them?, etc.) it'd be great. I need someone(s) to bounce ideas off of, and I'm awfully lonely here. I keep figuring there must be some simple solution, and that one really doesn't need to go hog-wild with abstract mathematics to get at it. It probably just needs some experimental mathematics like the Smolin minimizer could give, a little Bennettian playfulness with ideas, and a Fuchsian smile. (You've long known that I'm attracted to quantum mechanics because deep inside I think I can charm things into existence … and QM is the one scientific thing that gives me hope that there's no pre-existent.)

And thanks for the pictures!

20-12-04 *The Doctrine of Preemption, 2* (to C. H. Bennett)

Bennettism 23: *What's a SIC-POVM? Is it an actual POVM or a misspelled unwell POVM?*

It stands for "symmetric informationally-complete", and yes, the pun is intended. They're annoying critters. Take the space of operators over a Hilbert space of dimension d; it is a vector space of dimension d^2. Now ask, can one find a complete *orthogonal* basis A_i on that space consisting solely of positive, rank-one operators? The answer is no. So, ask the next best thing. If one cannot satisfy $(A_i, A_j) = 0$ for $i \neq j$, can one at least satisfy $(A_i, A_j) =$ constant for $i \neq j$? The answer *appears* to be yes, and sets of such operators that sum to the identity are dubbed SIC-POVMs. So, it's a really very elementary question … but it seems to require something clever for an actual proof.

Bennettism 24: *My "It depends on what your definition of 'is' is," was meant to be a quote from Bill Clinton, not a time-traveled reaction to you.*

I understood that. But in a world with backward causation, are you so sure you can draw such distinctions?

Have a safe trip home.

21-12-04 *Know Any Young German Bayesians?* (to P. Busch and H. J. Briegel)

I should apologize for my provocative title! But I wanted to get your attention!

First off, let me give you both an update on how our meeting in Konstanz is going. I'll do that by pasting two notes below. One lists the responses we've gotten so far, and one describes various suggested topics for the meeting. I know I don't need to clench your interest since you've both already said that you would come, but I figure it can't hurt to try to stoke the enthusiasm.

Now for the real purpose of my note. Soon I'll be sending out a second round of invitations, and I would like to ask your advice. In total, we're hoping for about 36 participants (excluding the students we'll probably slip in). Thus we've got room for maybe 10 more invitees. Here's the question: Can either of you suggest any good young Germans who might be a good fit for the subject matter of the conference? You can also suggest some older Germans too!

The issue is that it seems the VW Foundation has some interest in funding a substantial part (if not all) of the meeting, but they want an increased emphasis on 1) younger researchers (i.e., ones who have not yet obtained a permanent position) and 2) Germans. So, since there's some room anyway in our ranks, I don't mind trying to accommodate their wishes if I can . . . especially if I can do it while still having the meeting of my dreams.

Thus if you have some suggestions, they would be most useful. Who am I overlooking from the German quantum information, quantum foundations, or philosophy communities who could really add something to our meeting? There's no promise that we'll add their names to the roster, but we'll definitely take anything you say seriously.

Hope to hear back from you.

31-12-04 *Dylan and the New Year* (to J. B. Lentz & S. J. Lentz)

Well, I got a little time this morning to myself while the girls were out shopping, and I finally got a chance to finish reading Bob Dylan's *Chronicles*. I had wanted to do that before the new year started up. Thank you two so much for sending it. Ever since reading these lines in the Washington Post,

> The hype seems enough to turn the most faithful acolytes into unbelievers. How can it possibly be true, as the magazine claims, that this week's celebrity memoirist is "the most influential cultural figure now alive"?
>
> Oh, you thought he was once, back in the '60s. The image of that faraway decade has now been so magnified by myth and distorted by culture-war invective that you have to strain to recall what it felt like to be alive then, but you do remember this: Half the people you knew believed that if only they could figure out what Bob Dylan was saying, the secrets of the universe would be revealed.

I had wanted to sink my teeth into the book. That last line, especially, was something that caught me. I've been through that so many times myself: from listening to John Lennon to reading John Wheeler to listening to Paul Simon to reading William James to listening to John Coltrane . . . . And even now, to reading Bob Dylan: I knew that's how I'd tackle the book if I got my hands on it. The secrets of the universe are in the end, at the high level, not the low level: Quarks and electrons are ways that we can focus our attention so that we can distill simple truths here and there, but they're not what we're "made of". Sometimes I think we're made of poetry, if anything. Or, at least, that's closer to the right idea.

Anyway, it was a great book. I enjoyed whole swaths of it and took a lot of notes.

BTW, there's a little good news on my side with respect to these same musings (on poetry and such) that I don't think I've told you about before: I learned a few weeks back that the *American Heritage Dictionary of American Quotations* is going through a revision (it'll soon be the *Oxford Dictionary of American Quotations*), and they want to include a couple of lines from some of my writing. It's very flattering to think that my little poetry could be in the same book with William James's and Bob Dylan's very big poetry, but mostly it's a statement about raw luck—the good kind for me and the bad kind for them. Still, with everything one writes, whether it is preserved by luck or not, as long as it is preserved, it's a way of living a little a longer. And the idea of that always feels good.

Good luck to yourselves in this new year, and many happy returns to both of you.

31-12-04 *New Year's Eve* (to A. Peres)

Dear Asher,

As I write you these words, it is indeed New Year's Eve, but the title of the note is meant to be read more metaphorically. It has been a very long time since I have written you. I hope your recovery from your stroke is coming along as well or even much better than you had indicated in one of your notes. Maybe even everything is back to normal by now? Or at least I'd like to dream that.

I don't know where I left off in my conversation with you. I guess you know that I did not end up getting an offer for a faculty position, either in Copenhagen or Vancouver. Nor did the Mabuchi/Preskill ploy of trying to create an interdepartmental position (physics and philosophy) for me at Caltech work out either. Thus, with no place to go, I had to come back to Bell Labs. Of course, far worse things could have happened—I look at what happened to you, and I know how selfish I am—but I fell into a fairly deep, dark depression for over four months. An amazingly illogical depression. I've done enough to survive my wife (like buying us a house and getting the family moved into it), and I've done enough to survive Bell Labs (speaking when I needed to speak and doing the administrative things required of me), but I've done little beyond that. The depression has been much worse than even after our fire: At least after the fire I kept writing and doing science. But even my writing had come to a standstill this time.

For instance, after those very nasty problems with our email server—you probably don't remember, but I told you how reams of my email had been randomly eaten up for some undetermined time on the order of two months—I just used the opportunity to effectively slip out of the email ether, and very few have heard from me in these months.

Anyway, I'm writing you now because something has been jarred loose, and my self-esteem seems to have started to come back. Or maybe my body just got weary of being depressed. I'm not sure of the source of the optimism, but I'm now finding myself looking forward to an intense new year—intense with work and intense with thought. And it's New Year's Eve!

... All of that just so I could say "Happy New Year!" to you in clear conscience. I wish you and Aviva and the whole family all the best.

On another note—perhaps some welcome news for you—I had never written you about the completion of your festschrift in my period of silence ... but at least the festschrift itself went on. All the papers have been with *Foundations of Physics* for some months now. They're a fine lot of 26 papers (including your autobiography). I'll put the full list below. vdM has most recently told me that they're next in queue after the Cushing festschrift (which itself got delayed for some reason or other), and they should start appearing early this new year.

Expect more letters from me this year! I'll be back soon.

All the best,

Chris

Papers in the Peres Festschrift:

1. H. Bechmann-Pasquinucci, "From Quantum State Targeting to Bell Inequalities"
2. Jacob D. Bekenstein, "How does the entropy/information bound work?"
3. Paul Benioff, "Towards a Coherent Theory of Physics and Mathematics: The Theory – Experiment Connection"
4. Robin Blume-Kohout and Wojciech H. Zurek, "Redundancy of Information Storage in Multiqubit Universes"
5. Gilles Brassard, Anne Broadbent, and Alain Tapp, "Quantum Pseudo-Telepathy"
6. Časlav Brukner, Markus Aspelmeyer, and Anton Zeilinger, "Complementarity and Information in 'Delayed-choice for entanglement swapping' "
7. Dagmar Bruss and Chiara Macchiavello, "How the First Partial Transpose Was Written"
8. Adán Cabello, "Bell's theorem without inequalities and without unspeakable information"
9. S. Deser, "A Note on Stress-Tensors, Conservation and Equations of Motion"
10. Bernard d'Espagnat, "Consciousness and the Wigner's Friend Problem"
11. David P. DiVincenzo and Barbara M. Terhal, "Fermionic Linear Optics Revisited"
12. Steven T. Flammia, Andrew Silberfarb, and Carlton M. Caves, "Minimal Informationally Complete Measurements for Pure States"
13. Friedrich W. Hehl and Yuri N. Obukhov, "To consider the electromagnetic field as fundamental, and the metric only as a subsidiary field"
14. Karol Horodecki, Michał Horodecki, Pawel Horodecki, and Jonathan Oppenheim, "Information theories with adversaries, intrinsic information, and entanglement"
15. Michał Horodecki, Ryszard Horodecki, Aditi Sen(De), and Ujjwal Sen, "Common origin of no-cloning and no-deleting principles – Conservation of information"
16. Elena R. Loubenets, " 'Local Realism', Bell's Theorem and Quantum 'Locally Realistic' Inequalities"
17. N. David Mermin, "What's wrong with this criticism"
18. Asher Peres, "I am the cat who walks by himself"
19. Murray Peshkin, "Spin-Zero Particles Must Be Bosons: A New Proof within Nonrelativistic Quantum Mechanics"
20. Arkady Plotnitsky, "On the Precise Definition of Quantum Variables and the Relationships between Mathematics and Physics in Quantum Theory"

21. Abner Shimony, "An Analysis of Stapp's 'A Bell-type theorem without hidden variables'"
22. Henry P. Stapp, "Comments on Shimony's Analysis"
23. Anthony Sudbery and Jason Szulc, "Compatibility of subsystem states"
24. Daniel R. Terno, "Inconsistency of a quantum-classical dynamics, and what it implies"
25. William K. Wootters, "Quantum Measurements and Finite Geometry"
26. Mario Ziman, Martin Plesch, and Vladimir Buzek, "Reconstruction of superoperators from incomplete measurements"

Asher Peres died 1 January 2005.

01-01-05 *Our Dear Asher* (to D. R. Terno)

That is very sad news indeed. I feel knocked over. Asher was a great man—among the greatest I have ever known and ever read. I owe him my whole career in fact—from the things I learned from him to the way he supported me to the ways he lifted my life by taking me seriously like few others. He was one of the few people who actually read my samizdat, for instance, and I cherished his opinion. I feel that I betrayed him greatly with my comparatively petty problems of the last few months—they kept me silent when maybe he needed me most. Below is the letter I wrote him just yesterday, explaining what was up—finally breaking my long silence. I am sure he never saw it. I am very sad.

I think that you should send an announcement to the quantum information community, much like the one I sent when Jaynes, Landauer, and Lewis each passed away. If it would be useful to you, I could send you my email address book with maybe 300 or 400 quantum-information/foundations names in it.

I will call Aviva tomorrow when the time is more proper in Haifa. She is a gem, and I hope that she will keep shining.

Asher was a great man, a great friend, a great scientist.

Announcement I Sent Out Broadly 3 January 2005 on Behalf of the Authors

Quantum information science lost one of its founding fathers.

Asher Peres died on Sunday, January 1, 2005. He was 70 years old.

A distinguished professor at the Department of Physics, Technion – Israel Institute of Technology, Asher described himself as "the cat who walks by himself". His well-known independence in thought and research is the best demonstration of this attitude. Asher will be missed by all of us not only as a great scientist but especially as a wonderful person. He was a surprisingly warm and unpretentious man of stubborn integrity, with old-world grace and a pungent sense of humor. He was a loving husband to his wife Aviva, a father to his two daughters Lydia and Naomi, and a proud grandfather of six. Asher was a demanding but inspiring teacher. Many physicists considered him not only a valued colleague but also a dear friend and a mentor.

Asher's scientific work is too vast to review, while its highlights are well-known. One of the six fathers of quantum teleportation, he made fundamental contributions to the definition and characterization of quantum entanglement, helping to promote it from the realm of philosophy to the world of physics. The importance of his contributions to other research areas cannot be overestimated. Starting his career as a graduate student of Nathan Rosen, he established the physicality of gravitational waves and provided a textbook example of a strong gravitational wave with his PP-wave. Asher was also able to point out some of the signatures of quantum chaos, paving the way to many more developments. All of these contributions are marked by a surprising simplicity and unbeatable originality.

Of all his publications, Asher was most proud of his book *Quantum Theory: Concepts and Methods*. The book is an example of Asher's scientific style: an uncompromising and deep understanding of the fundamental issues expressed in a form which is as simple and accessible as possible. It took Asher six years to carefully weave the threads of his book together. The great quality of the work is acknowledged by anyone acquainted with the final result.

In a favorite anecdote, Asher told about a reporter who had interviewed him on quantum teleportation. "Can you teleport only the body, or also the spirit?" the reporter had asked. "Only the spirit," was Asher's reply. Our community has been privileged to know him and have been touched by his spirit.

"I am the cat who walks by himself" is the title of a charming twelve-page autobiography covering his life from his birth in the village Beaulieu-sur-Dordogne in France until his meeting with Aviva on a train to Haifa [`physics/0404085`]. The rest of his story is in his formal CV.

Netanel Lindner, Petra Scudo, Danny Terno

01-01-05 *A Backup for Us Both* (to J. W. Nicholson)

A Time to Mourn
(From *New York Times*, 1 January 2005)
by David Brooks

I have this week's front pages arrayed on the desk around me. There's a picture of dead children lined up on a floor while a mother wails. There's a picture of a man on the beach holding his dead son's hand to his forehead. There are others, each as wrenching as the last.

Human beings have always told stories to explain deluges such as this. Most cultures have deep at their core a flood myth in which the great bulk of humanity is destroyed and a few are left to repopulate and repurify the human race. In most of these stories, God is meting out retribution, punishing those who have strayed from his path. The flood starts a new history, which will be on a higher plane than the old.

Nowadays we find these kinds of explanations repugnant. It is repugnant to imply that the people who suffer from natural disasters somehow deserve their fate. And yet for all the callousness of those tales, they did at least put human beings at the center of history.

In those old flood myths, things happened because human beings behaved in certain ways; their morality was tied to their destiny. Stories of a wrathful God implied that at least there was an active God, who had some plan for the human race. At the end of the tribulations there would be salvation.

If you listen to the discussion of the tsunami this past week, you receive the clear impression that the meaning of this event is that there is no meaning. Humans are not the universe's main concern. We're just gnats on the crust of the earth. The earth shrugs and 140,000 gnats die, victims of forces far larger and more permanent than themselves.

Most of the stories that were told and repeated this week were melodramas. One person freakishly survives while another perishes, and there is really no cause for one's good fortune or the other's bad. A baby survives by sitting on a mattress. Others are washed out to sea and then wash back bloated and dead. There is no human agency in these stories, just nature's awful lottery.

The nature we saw this week is different from the nature we tell ourselves about in the natural history museum, at the organic grocery store and on a weekend outing to the national park. This week nature seems amoral and viciously cruel. This week we're reminded that the word "wilderness" derives from the word for willful and uncontrollable.

This catastrophic, genocidal nature is a long way from the benign and rhythmic circle of life in *The Lion King*. It's a long way from the naturalist theology of Thoreau's *Walden* or the writings of John Muir.

The naturalists hold up nature as the spiritual tonic to our vulgar modern world. They urge us to break down the barriers that alienate us from nature. Live simply and imbibe nature's wisdom. "Probably if our lives were more conformed to nature, we should not need to defend ourselves against her heats and colds, but find her our constant nurse and friend, as do plants and quadrupeds," Thoreau wrote.

Nature doesn't seem much like a nurse or friend this week, and when Thoreau goes on to celebrate the savage wildness of nature, he sounds, this week, like a boy who has seen a war movie and thinks he has experienced the glory of combat.

In short, this week images of something dark and unmerciful were thrust onto a culture that is by temperament upbeat and romantic.

In the newspaper essays and television commentaries reflecting upon it all, there would often be some awkward passage as the author tried to conclude with some easy uplift - a little bromide about how wonderfully we all rallied together, and how we are all connected by our common humanity in times of crisis.

The world's generosity has indeed been amazing, but sometimes we use our compassion as a self-enveloping fog to obscure our view of the abyss. Somehow it's wrong to turn this event into a good-news story so we can all feel warm this holiday season. It's wrong to turn it into a story about us, who gave, rather than about them, whose lives were ruined. It's certainly wrong to turn this into yet another petty political spat, as many tried, disgustingly, to do.

This is a moment to feel deeply bad, for the dead and for those of us who have no explanation.

02-01-05 *I Hope You Are OK* (to U. Mohrhoff)

I was reading the news tonight and learned that Pondicherry had significant damage from the tsunami. My knowledge of geography is very bad, and I did not know before that Pondicherry is near the sea. I so hope you are safe. I keep my fingers crossed.

Ulrich's Reply

> I am really touched by your inquiry. We (that is my wife and I) felt the earthquake as we sat down for breakfast (at this distance only a gentle swaying of the ground). We then monitored the news to know the location of the epicenter, and when we learned of the magnitude of the quake, we waited for the tsunami. Pondy town is sufficiently above sea level to have remained undamaged, but fishing communities nearby and some Auroville beach settlements were hard hit. One office near the beach had 20 computers flushed out.
>
> P.S. I still feel that our views on QM have so much in common that we should form a common front against the quantum state realists ... If you can spare 30 minutes, he a look at my PowerPoint presentation "Beyond causality...", which you can be downloaded from my website. (You are even quoted there. Favorably!)

02-01-04 *Omphaloskepsis* (to J. W. Nicholson)

I think you and Sumitra might get a kick out of how this dictionary described my behavior tonight.

> OMPHALOSKEPSIS: Contemplating one's navel as an aid to meditation.
>
> This word seems to be relatively new, at least the Merriam-Webster "Word of the Day" column claims it to have been invented only in the 1920s. It turns up in only a few dictionaries and seems to be a word that survives more for the chance to show off one's erudition than as a real aid to communication. If so, this article is a further perpetuation of its unreal status. It is formed from two Greek words, omphalos, "navel, boss, hub", and skepsis, "the act of looking; enquiry". The former turns up in words such as omphalotomy, "cutting of the umbilical cord", in the related omphalopsychic for one of a group of mystics who practised gazing at the navel as a means of inducing hypnotic reverie, and omphalomancy, an ancient form of divination in which the number of children a woman would bear was determined from counting the knots in her umbilical cord at birth.

03-01-05 *Safety* (to U. Mohrhoff)

I am so relieved to hear that you are safe. I became very worried. Some time good luck happens too (but I've gotten where I don't expect it much anymore).

Now that I know you are safe, let me tell you some sad news that I could have told you yesterday. Asher Peres passed away New Year's Day. It was either a stroke or a heart-attack; it happened very quickly. He was buried yesterday. I will distribute an obituary written by his last three students in a few hours; you are in the distribution list. I'm going to miss him very much.

With regard to your "P.S.", thanks for sending me your webpage link. Indeed for some reason I feel re-energized to try to sort our similarities and differences in point-of-view about QM (and metaphysics). I hope that I can come to a better understanding. I tried downloading the PowerPoint presentation you told me about, but had no luck. Could perhaps you just send it to me as an email attachment? Likely, I will be able to open that. I will also enjoy trying to read some of your papers again.

Ulrich's Reply

I really appreciate your concern. Thanks again.

Although I did not have the good fortune to meet Asher Peres, I am saddened by the news of his passing. I treasure his one (unsolicited) email in which he expressed appreciation for my AJP paper "What quantum mechanics is trying to tell us" (responding to Mermin's "What is quantum mechanics trying to tell us?"). My copy of his *Concepts and Methods* has disintegrated from overuse, and I loved him for his insistence that "there is no interpolating wave function giving the 'state of the system' between measurements". (It's echoing through all my papers.) If I have recently taken to criticizing the paper you coauthored with Asher Peres, it is because the closer one's views are, the larger loom the remaining differences ....

> [Quoting CAF:] ... for some reason I feel re-energized to try to sort our similarities and differences in point-of-view about QM (and metaphysics). I hope that I can come to a better understanding .... I will also enjoy trying to read some of your papers again.

I very much look forward to that. (Let's bear in mind the warning my grandmother gave to my father long before email made matters worse: "Letters don't smile.") My recent relatively short `quant-ph/0412182` (to appear in the Indian journal of physics *PRAMANA*) may be a good starting point. I also would like you to have a look at my class notes, once they are online. The trouble is that they keep changing all the time ... I can see why it took Asher Peres six years to write his book.

03-01-05 *The Alchemical New Year* (to M. Pérez-Suárez)

I apologize for taking so long to write you back; I had wanted to send you a timely New Year's greeting myself. But when I sat down at my computer New Year's Day, I found the news that my mentor, colleague, and friend Asher Peres had died. That led to a lot of sadness and also a lot of email in its own right. You'll be receiving an obituary by Asher's students that I'm helping distribute in a few hours.

Let me come back to our happy alchemical musings though. Your note intrigued me. I'm looking forward to whatever you're going to write up.

In the meantime, let me send you some of my own mumbo-jumbo. This comes from something I had written to a *Scientific American* reporter earlier in the Fall. Tell me if you can see the alchemical strain running through it—I think there's one there. Didn't the alchemists too see the big bang as all around us?

Best wishes for the new year! This year I'm planning to make it quite a productive one (to counterbalance last year).

05-01-05 *Fingers Crossed* (to T. Mor)

Morism 1 : *I was there in the funeral. Did you know he is now buried right next to Nathan Rosen? He bought that area, and even planned carefully that the height of the stone on his grave is a little <u>below</u> Rosen's stone. [This I learnt yesterday, when visiting Aviva and Asher's daughter Lydia.]*

That's a great story; I didn't know that.

07-01-05 *Krugman on Reality (again)* (to me)

From Paul Krugman, "Worse Than Fiction," *New York Times*, 7 January 2005:

> I've been thinking of writing a political novel. It will be a bad novel because there won't be any nuance: the villains won't just espouse an ideology I disagree with – they'll be hypocrites, cranks and scoundrels.
>
> In my bad novel, a famous moralist who demanded national outrage over an affair and writes best-selling books about virtue will turn out to be hiding an expensive gambling habit. A talk radio host who advocates harsh penalties for drug violators will turn out to be hiding his own drug addiction.
>
> In my bad novel, crusaders for moral values will be driven by strange obsessions. One senator's diatribe against gay marriage will link it to "man on dog" sex. Another will rant about the dangers of lesbians in high school bathrooms. [...]
>
> In my bad novel the administration will use the slogan "support the troops" to suppress criticism of its war policy. But it will ignore repeated complaints that the troops lack armor.
>
> The secretary of defense – another "good man," according to the president – won't even bother signing letters to the families of soldiers killed in action.
>
> Last but not least, in my bad novel the president, who portrays himself as the defender of good against evil, will preside over the widespread use of torture.
>
> How did we find ourselves living in a bad novel? It was not ever thus. Hypocrites, cranks and scoundrels have always been with us, on both sides of the aisle. But 9/11 created an environment some liberals summarize with the acronym Iokiyar: it's O.K. if you're a Republican.
>
> The public became unwilling to believe bad things about those who claim to be defending the nation against terrorism. And the hypocrites, cranks and scoundrels of the right, empowered by the public's credulity, have come out in unprecedented force. [...]
>
> Either way, when the Senate confirms Mr. Gonzales, it will mean that Iokiyar remains in effect, that the basic rules of ethics don't apply to people aligned with the ruling party. And reality will continue to be worse than any fiction I could write.

11-01-05 *Our Bayesian QM Meeting — Why You* (to P. Diaconis)

By now I hope you have seen the invitation I sent you last night for our meeting "Being Bayesian in a Quantum World" to be held in Konstanz later this year. In case you are wondering why I sent it to you, I should say that I heard your talk at the PSA meeting this year, and I liked what I saw. In particular, it struck me that you could be a very helpful participant in our meeting with regard to the technical side of things: I.e., helping us distill various philosophical issues into some well-posed mathematical questions ... and to help us see them solved!

So, I very much hope that you can come and will want to come. I think we've made great progress recently in inserting the Bayesian conception of probability into quantum mechanics and quantum information theory. But our effort is still in its infancy, and we need all the help we can get.

To help convince you that there is some serious work to be done, please allow me to point you to a few papers of mine along with colleagues that I hope will give you a flavor of the sorts of technical issues that you might help address or learn about etc., etc., through your participation at our meeting. These things are along the lines of quantum versions of various de Finetti representation theorems, new kinds of diachronic coherence, etc.:

- C. A. Fuchs and R. Schack, "Unknown Quantum States and Operations, a Bayesian View," `http://www.arxiv.org/abs/quant-ph/0404156`
- C. M. Caves, C. A. Fuchs, and R. Schack, "Conditions for Compatibility of Quantum State Assignments," `http://www.arxiv.org/abs/quant-ph/0206110`
- C. A. Fuchs, "Quantum Mechanics as Quantum Information (and only a little more)," `http://www.arxiv.org/abs/quant-ph/0205039`
- R. Koenig and R. Renner, "A de Finetti Representation for Finite Symmetric Quantum States," `http://www.arxiv.org/abs/quant-ph/0410229`

I hope that's enough to pique your interest, and enough to indicate that your presence at the meeting would be very valued!

11-01-05 *Wheeler, Bayes, Schleich* (to W. P. Schleich)

Thank you for sharing your memories about Asher. I have collected many words of remembrance in reply to our announcement, and I will pass them on to Asher's family after the collection looks complete.

I hope you will also note the conference invitation I sent you last night. I very much hope you will attend. Caves, Schack and I—and I especially—regard these efforts to get a Bayesian view of quantum mechanics as a detailed carrying-out of the program John Wheeler first set us onto: "law without law" and "it from bit". John Wheeler was a great influence on me, as he was on you. Your participation in this whole program would be a great addition to it, and our conference, I think, will really get you in the mood. So, please do say *yes* (so that we can hold you a spot), even if your schedule is only tentative at the moment!

As it turns out, I looked at your webpage yesterday (to make sure that I had the correct email address for you), and I was reminded of your early work on phase-space representations of quantum mechanics. Let me draw your attention to a couple of my own papers where I show how one can get something like a coordinate-space representation of the quantum state (on finite-dimensional Hilbert spaces) in terms of a *single* probability distribution. And by "probability distribution" I really mean that: It's not something that goes negative like the Wigner function. Instead, rather than through negativity, the unique quantum features of a system are expressed by other properties of the distribution. Anyway, here are the papers, and I'd enjoy any feedback you can give me:

- "Quantum Mechanics as Quantum Information (and only a little more)," `http://www.arxiv.org/abs/quant-ph/0205039`. (See particularly Sections 4.2 and 6.1 for the representations I'm talking about.)
- "On the Quantumness of a Hilbert Space," `http://www.arxiv.org/abs/quant-ph/0404122`. (See equations 28–32 for a particularly clean representation of the variety introduced in the other paper.)

I think we're at the beginning of something very big in physics; we're carrying the torch that John first lit. I hope you'll write to say, "Yes, I'll see you in Konstanz!"

Wolfgang's Preply, "Asher Peres"

Many thanks for your message concerning Asher Peres. I am deeply saddened and shocked by the news. The last time I have met Asher was in Rome during the celebration of De Martini's 70th birthday. At that time he did not look very good and he also looked rather confused. I was worried about him and had a longer talk with him. He told me that he will not travel again without his wife.

I have known Asher since 1984 when he came to Austin to give a talk on the influence of initial state to problems in quantum chaos. It is interesting that recently we have returned to just his approach again in some common work with Mark Raizen and Thomas Seligman. Asher was a great scientist and a wonderful human being who taught us all a lot in science and humanity. He will be certainly missed by the whole community.

13-01-05 *Another Chance . . .* (to G. Brassard)

Brassardisme 17: *Here's another chance for us to write the paper that we had planned for Asher's 70th birthday . . .*

This is a good point. I will try, but I can't make a promise at the moment: Almost all desire to write (even my usual nonsense) has left me for a while. I have to struggle with each and every word lately—and I've been dreaming of the day that I wouldn't have extant and unfulfilled writing projects hanging over me. But Asher deserves much, and I will try to find some way to accommodate. Still I don't venture a promise at the moment.

17-01-05 *Need Answer Quickly* (to R. W. Spekkens)

Could we get you to come out and give us a visit this Spring? Ideally I'd like to have you around for a week or more and give us a seminar on your noncontextuality work (pointing out connections between it and issues in quantum computing). I ask because Lov has some money to spend and we haven't been able to get rid of it in big chunks. So we're resorting to a more vigorous short-term visitor program for the short term (and are trying to lure some people here for sabbatical in the longer term). I'd very much like to have you out, and I've gotten Lov's approval.

The reason I'm asking for a quick answer is that DARPA will be out here on the 20th to review Lov, and he'd like to have as complete a list as possible of visitors to advertise. So, could you give me a quick reply letting me know if it's possible.

Spekkensism 28: *I would like to hear your thoughts on a result I just came up with the night before last (hot off the presses). I like to call it the "reverse Gleason theorem". The theorem states that if a functional f on the space of density operators satisfies*

$$0 \le f(\rho) \le 1,$$

and

$$f\left(\sum_k p_k \rho_k\right) = \sum_k p_k f(\rho_k)$$

for some probability distribution then it can be written as $f(\rho) = Tr(\rho E)$ for some effect E.

Yeah, I knew that one. One can prove it with essentially the same techniques that we proved the POVM Gleason theorem with, though you may have come across another way. In fact it really is the same theorem—certainly technically (except for little issues about scaling), but also conceptually (if one has already accepted that POVMs are refinements of knowledge full stop).

With hindsight, I also know that Holevo knew it sometime in the 70s. He told me about it as we were flying to Pasadena in 1997; he said I could read about it in his 1980s book. He kept emphasizing how difficult it was to prove the theorem in the infinite dimensional case, which I didn't care about, and, particularly, which obscured the content of what he was saying to me: I didn't realize any connection between this and POVM-Gleason until long after our/Busch's papers when I was writing a review on Holevo's second book. It brought the conversation back to me.

Anyway, Holevo's starting point for the theorem is the operational approach to quantum mechanics (of Davies and Lewis and himself, etc.), and I never liked that motivation. I.e., he starts by considering the probability of a preparation (identifying a preparation with a density operator), but for a Bayesian about quantum states, that's like talking about a probability of a probability. At the time I'd have none of that. It's nice as an expedient in speech, but for a Bayesian it shouldn't be a low-level way of talking. So more analysis is needed to get at the nub of the formulation. And that's where I left it at the time.

But who knows, maybe you'll have some spin on it that'll intrigue me afresh. Come out for a visit, and we can talk about all these things.

18-01-05 *Two More For You* (to L. K. Grover)

OK, I've got two more visitors for you to mark down for your presentation.

1) Rob Spekkens said he could come April 25th through May 4th, and he would talk on how the source of quantum computational speedup may be the Kochen-Specker theorem (or contextuality as he likes to call it) rather than entanglement per se, etc. So this is something you can properly call quantum *computation* research to the funding agents rather than quantum communication (as you had indicated to me earlier).

2) Walter "Jay" Lawrence, a professor at Dartmouth College, who works with Zeilinger from time to time, can come for two or three days in mid-March. So he'll be a cheap visitor—that doesn't help you spend a lot of money, but I'm trying my best. Anyway, he'll give us a talk on the mutually unbiased basis problem. And, at least in the case of he and I, we'll be collaborating on the same problem that Wootters and I will be collaborating on when he comes for sabbatical: representing quantum mechanics by way of these structures. By the way, for your own edification, you might have a look at Paz and collaborators' stuff on such representations of quantum *computing*:

- `http://www.arxiv.org/abs/quant-ph/0204149`
- `http://www.arxiv.org/abs/quant-ph/0204150`
- `http://www.arxiv.org/abs/quant-ph/0410117`

I plan to do something similar with my SIC-POVM representation of QM.

Also, Wootters reiterated in a note last night that he'll be coming for a couple of weeks in the Fall and a couple of weeks in the Spring.

I hope that helps you out.

24-01-05 *Proposal Criteria* (to G. J. Milburn)

Milburnism 1: *The other aspect that worries me a little are two rules regarding what they support:*

> participation in international activities, such as meetings and workshops, that are likely to move the research agenda of the field(s) forward, and shape collaborative and complementary research programs to address significant problems or capture new opportunities

but do not support:

> conference organisation or attendance where the purpose is the reporting of research findings.

It is my belief that our BBQW is a workshop of the kind that they do support. Is that also your view? I will need to make this clear in the application.

I *definitely* view the conference as a specimen of their first criterion: That's effectively the whole point of the meeting. However, I would have never thought that to be mutually exclusive to their second criterion (which seems to be what they are implying). It is true that I'm hoping we will get some presentations like:

> Spekkens
> `http://www.arxiv.org/abs/quant-ph/0406166`
> `http://www.arxiv.org/abs/quant-ph/0401052`
>
> Appleby
> `http://www.arxiv.org/abs/quant-ph/0412001`
>
> Renner
> `http://www.arxiv.org/abs/quant-ph/0410229`
>
> Wallace
> `http://www.arxiv.org/abs/quant-ph/0312157`
>
> Srednicki
> `http://www.arxiv.org/abs/quant-ph/0501009`
>
> Wootters
> `http://www.arxiv.org/abs/quant-ph/0401155`

etc., etc. To the extent that these are all relatively new works, this conference will be partially devoted to "the reporting of research findings." But the ulterior purpose of that is "to move the research agenda of the field forward, and shape collaborative and complementary research programs to address significant problems [and] capture new opportunities." That is, I want to see our various diverse efforts turned into a single agenda—the BBQW agenda—but for that to happen we will necessarily have to share our recent results with each other.

Does that help any for how to spin your proposal?

25-01-05 *MaxEnt 2005 Invitation* (to K. H. Knuth)

Thanks for the call yesterday. Your invitation to MaxEnt is very flattering. When I was a grad student, I used to pore over the old proceedings trying to get ideas—so a potential appearance at a MaxEnt would be a great honor. Also, as you seem to know, I think there is plenty of room to a

Bayesian about probabilities at the same time as rejecting the idea of a hidden-variable explanation underneath quantum mechanics. I like to spread the word of that view anytime I can … and I would particularly like to spread the word the attendees of MaxEnt, who would likely make the most progress with it.

But the trouble is, I've already committed myself to lecturing at the Konstanz summer school on "Philosophy, Probability, and Physics" and the dates of that are also August 7 to 13. [An aside: Also, in fact, the week before that, Aug 1–6, I will be in Konstanz running my own conference "Being Bayesian in a Quantum World" (with Carl Caves, Rüdiger Schack, and Stephan Hartmann) with about 20 philosophers and 20 quantum information theorists in attendance.] After that I was to rejoin my family for a week in Munich, where I they will deposited with my in-laws while I'm in Konstanz.

So, I'm torn. On the one hand I don't want to turn you down. But on the other, I did already commit to lecture at the summer school. Let me ask you a couple of questions. 1) Will your budget permit you to fly me to and from Germany, along with my local expenses? And, 2) would it be acceptable for me to attend only part of MaxEnt? If there's a yes answer to both of these questions, I could try to see if the Konstanz guys will schedule my lectures for one end or other of the time period, whichever is the more convenient for your meeting. Just an idea; I don't know if I've got enough nerve to really pull it off (i.e., all the quick flights), but if you're game, I would think about it harder.[79]

30-01-05 *My Last Email to Asher* (to Lydia Peres-Hari & Aviva Peres)

Below is the very last email I sent Asher. I don't know whether he saw it before passing away. I will share it with you, though it contains some fairly private information. Sadly, I did not write Asher much in the last three months; the note below explains why. I regret that very much now.

Asher was a great man, and in many ways, far beyond a friend to me—a father actually. I don't know whether he knew that, but I hope he did. In physics he had a great deal to do with my learning to stand on my own two feet. Without his support in 1994, I very likely would have stayed crawling. He gave me confidence in myself like no one else.

I looked back in my email records after talking to Aviva this morning. Since May 9, 1997, I saw that I had 1129 emails from Asher! And I myself had sent him 789 in that same period. We also had several hundred emails beyond that, written between November 7, 1994 and May 1997; unfortunately I used a different filing system back then, so it is not easy to figure out how many we actually exchanged. Still, by any measure, that's a lot of writing! (At least I have all our notes recorded, so they can be retrieved with a sufficient effort.)

I loved him, and love him.

31-01-05 *Quote of the Day* (to N. D. Mermin)

I just ran across the following quote of Nietzsche in Jauch's book on quantum foundations, and it reminded me of you:

[79]Indeed, my records show that I arrived in San Jose, California at 5:42 PM August 9, and departed 9:37 AM August 12 to head back to Munich, Germany and finish up the other trip! My travel schedules in those days were like Ezekiel's "wheels within wheels".

> That things have a quality in themselves quite apart from interpretation and subjectivity, is an idle hypothesis: It would presuppose that to interpret and to be a subject are not essential, that a thing detached from all relations is still a thing.
>
> — from *The Will to Power*

I don't know that you'll like the first part; but I'll bet that the second part makes the phrase "correlation without correlata" pop into your head (for whatever reason).

31-01-05 *Made My Reservations, Incompleteness, and (Irrelevance of) Decoherence* (to J. Bub)

OK, I made my reservations at the Jury's Normandy. For my own records, this is the confirmation number: 94740.

I've been meaning to write you ever since my visit to UMD to try to frame some of the issues you helped me think through with your questions. But my recent anathema to email has really gotten in the way of any writing bug I may have had. So, as a stopgap, and perhaps a starting point for further discussion when we get together again, let me attach a file with two old notes in it. The first concerns the sense in which I think it is fair to say that quantum mechanics is incomplete (even though I think hidden variable completions are the wrong way to go). The second comes out of my "Notes on a Paulian Idea" and concerns what I think is the more proper direction for study of "classicality" than notions to do with "decoherence." The point of the latter is that the classical or macroscopic world is not a state of nature in need of an explanation, but rather an artifact of our common states of knowledge. And so, as with much of quantum mechanics, take out the observer, and you take out whether some phenomenon can be classified as classical or not. Anyway, that's my point of view presently. Though admittedly it's only the hint of a program.

Luckily, I've been thinking very little about these things the last few weeks. Instead, I've been calculating, calculating, calculating. One finds a kind of calm in that that's found nowhere else.

09-02-05 *Measures of Our Field* (to R. Laflamme)

I am putting together a high-level presentation for the Bell Labs executives for next week to give some evidence of how "big" the field of quantum information and computing is, and I'm trying to do it by various measures. I wonder if I can ask you can to help me a little with some numbers? Is it possible to put an easy figure on how much money Canada is spending on quantum information and computing research each year lately? Do you know how that breaks down between theory and experiment? Also do you have an estimate on how many students and postdocs there are there working in the field? And if you can't answer these questions, do you know where I might try to find the answers?

I apologize for bothering you with this, but it'd help my presentation look spiffier if I had some numbers like this, and I'm guessing you may be able to help (and Gilles Brassard suggested the same). Thanks for any help you can give!

Ray's Reply

The only reasonable thing I can offer is a rough guess for the last 4 years:

- around \$40M from private sector (\$33M at IQC, \$7M at D Wave)

- infrastructure + personnel, about \$17M (\$12M at IQC, the rest at Montréal/Calgary/ Toronto and CIAR)
- \$1.5M/year for personal grants in the area (NSERC/MITACS/CIPI)

Total \$63M in the last 4 years

Hope that helps and good luck with your talk.

10-02-05 *Being Bayesian in a Quantum World – for Qubit News* (to Qubit News)

A previous post said, "It looks like they, in fact, are amidst quantum computing scientists." Indeed! And we're hosting our first international conference on the subject. The meeting is titled "Being Bayesian in a Quantum World," and will be held in Konstanz, Germany, August 1–6, 2005. It is now closed to further participants—because of space limitations and a desire to keep the discussion intimate—but I'll attach the meeting's announcement and the confirmed-participant list to give some flavor of the subject and to indicate whose writings to turn to if you want to learn more. [See 10-11-04 note "Being Bayesian in a Quantum World — Invitation" to the invitees.] Not all participants are by any means Bayesian (and also, there are many flavors of Bayesianism), but it shows that there are several quantum information scientists who consider the subject serious enough to entertain its potential.

18-02-05 *Lost Opportunity* (to R. E. Slusher)

I just read this quote in Feynman's 1982 paper on quantum computing, and boy how I wish I had used it to end my talks to Jaffe and Bishop. It might have also benefited Bernie when Bishop was being stubborn about quantum limits too. Here it is:

> ... full attention and acceptance of the quantum mechanical problem—the challenge of explaining quantum mechanical phenomena—has to be put into the argument, and therefore these phenomena have to be understood very well in analyzing the situation. And I'm not happy with all the analyses that go with just the classical theory, because nature isn't classical, dammit, and if you want to make a simulation of nature, you'd better make it quantum mechanical, and by golly it's a wonderful problem, because it doesn't look so easy. Thank you.

Let's make that road trip to Peirce's house sometime.

02-03-05 *Will You Find It Interesting?* (to M. Pérez-Suárez)

Thanks for bringing that book to my attention! It looks exciting.

I'm glad to hear that you got the approval for a very long stay in Albuquerque. I think you'll find the time productive (much more productive than your time with me).

I'm on my way to Poland at the moment to talk on quantum foundations. Why I'm going there, I'm not quite sure, ... I guess it's because I'm easily flattered. But you're right: aside from this anomaly, I've been spending most of my time trying to calculate something. (Unfortunately to little success.)

Marcos's Preply

I apologize for my silence. But I have found a moment to tell you that you should take a look at this book, which I have been browsing in the last days:

`http://www.springer.com/physics/quantum+physics/book/978-3-540-20856-3`.

William James, the "ideal of the detached observer", subjectivism ... a lot of subjects of your interest (even though you have readjusted yourself —or was it the world that made the readjustment on you?— a "true physicist" once again) are considered in the book (surprisingly enough, Harald's work is not mentioned).

I'll return to you in a few days (at least I hope so) in order to make my point on the "alchemical connection" and other issues.

Good news (at least, they are for me): The application for my stay with Carl has been accepted for the whole period of six months. I'll tell Carl about this, and I'll try to begin arranging things concerning it as soon as possible.

02-03-05 *And Yesterday* (to R. E. Slusher)

Slusherism 1: *I finished "The Sentiment of Rationality" and some other James stuff. Now I need more counseling from you! I am determined to understand the dynamics of measurement by an apparatus. I still don't see the human observer being involved (except to come by and readout the apparatus hard drive) — especially since I've been reading a lot about how complex the "SELF" is.*

You can't blithely say the parenthetical remark. The very most important thing we have learned from quantum mechanics is that there is no such thing as readout. Supplement your William James (particularly the essay *Pragmatism*) with:

N. D. Mermin, "Hidden variables and the two theorems of John Bell," Rev. Mod. Phys. **65**, 803 (1993).

That's one of the best articles on the Kochen-Specker theorem you can read.

But you're right, human is not the essential concept ... unless to bear probabilities and make decisions in the face of uncertainty is to be human. (But I don't think it is.)

I'll gladly talk about this when I get back.

07-03-05 *I Won't Be There Tuesday* (to J. B. Lentz)

What am I doing in Wrocław? It's the usual evangelical mission. They invited me to give some lectures on my point of view of quantum mechanics. When confronted with an offer like that, it's hard to turn down the invitation ... no matter where it is. It's the usual story we encounter in most aspects of life: One tries one's best to increase his children's chances of survival. Mostly I did it out of a sense of duty. The trip however, has turned out to be a pleasant surprise. They have treated me royally. The vice-president of the city even attended my first (more public) lecture, and presented me with a nice coffee-table book about the city. The food, the cognac, the jazz restaurants, have all been very nice too.

07-03-05 *No Laws at All* (to C. G. Timpson)

Indeed, I love that quote! Thanks for sending it. I have been told by someone (can't remember who at the moment) that I should read Cartwright's book, but until now I've put it off. However you have an awfully good track-record with your recommendations to me of books, and this quote definitely seals it. Better than reading it: I'll buy it and then read it!

I'm in Wrocław in Poland at the moment, finally enjoying a beer after all the hard work of this week. When I wasn't lecturing, I couldn't seem to stop my obsession with a certain calculation: It kept me up day and night, and thus the jetlag was much worse than usual. But at least I learned a lot by my random walk in Platoland.

Chris's Preply

> I am re-reading Cartwright's *How the Laws of Physics Lie* and am being struck how the position in that book seems in many ways sympathetic to the kind of view of science, and qm in particular, you'd like to adopt.
>
> Here in particular is a little passage I thought would please you:
>
>> Covering-law theorists tend to think that nature is well-regulated; in the extreme, that there is a law to cover every case. I do not. I imagine that natural objects are much like people in societies. Their behaviour is constrained by some specific laws and by a handful of general principles, but it is not determined in detail, even statistically. What happens on most occasions is dictated by no law at all. (OUP 1983, p.49)

08-03-05 *Spelled Wrocław, Pronounced Vrotswav, but Germans Still Say Breslau* (to D. B. L. Baker)

"It's been a long time since I've written you from a far-away place. I guess that's because far-away places have become little more than a pain for me. Trip after trip seems to drone on, and I've lost so much purpose. But tonight I feel like writing something. I'm captured by the charm of what I see around me. The snow coming down, the muffled sounds and the romance in this city square; a kiss I spied in a dark corner of the cathedral."

I wrote those lines in my head last night, thinking that I would go back to my hotel room, have a beer or two, and write you a long note. It didn't happen. I had the beer, you see, but I got wrapped up in music and the newspaper. Hans Bethe died yesterday at the age of 98, and I got sucked into stories about him. He was a great physicist and a great man. The last time I saw him, about 6 years ago, he was still reporting his research! In slow motion, but he was still reporting topical research! Amazing. Get on Google News if you can, and read about him. He was an important part of America and of all time; he brought the cores of stars into the hands of man. You read about someone like that, and I challenge you to think that man is an insignificant force in nature.

It's early morning, and I just arrived at Wrocław airport. I have a tortured route today: First to Munich, then to Paris, then to Chicago, and finally to Newark. Humbug, bah humbug. But at least I found last night romantic in the extreme. There were such big flakes of snow coming down, while a few people in the city square waited patiently for the Zamboni to smooth the ice in the skating rink; the couple I saw at the corner of the cathedral; the music trickling out of the basement clubs. It was those things combined with all that I had seen and heard this week; it came to a sort of fester. It's a strange world here. One that is still getting over World War II (everyone still talks about it, even the twenty-somethings), and one that reminisces the "funny" days of communism. It is a world a few years behind ours, at least emotionally.

I had the nicest experience and was treated royally by my hosts. What's the phrase? "Famous in Peoria," or something like that? The vice-president of the city even attended my first lecture and presented me with a big coffee-table book (of city things of course). There was a set of people that took a four hour train-ride to hear my lecture. And, I can't believe this one: There was a student who wanted my autograph! That's a first ... but then again it was Peoria ... I mean Wrocław. Ah, what's the difference. Still, it was touching. I wish I could live up to that young guy's dreams, but I don't have it in me anymore. Most of the time I feel like such a has-been.

But last night, everything felt right just briefly. In the city square I felt so small, but in just the right way. You know what I mean? I felt like ...

Well, once again, I didn't manage to finish my note to you before having to get on the plane. Now after all the delays and the nearly missed flights, the mood is broken. Munich has passed, Paris has passed, and I'm somewhere over the Atlantic. I strongly suspect however that my luggage isn't. Over the Atlantic, that is. Sad how some bad flights can shatter a day ... which I guess gets me back to where I started: "It's been a long time since I've written you from a far-away place. I guess that's because far-away places have become little more than a pain for me."

Maybe I'll have better luck the next time I try to write you.

11-03-05 *A Quiet Fuchs ... for once* (to H. Price)

I'm back from Poland, and I'm trying to get caught up on my email and other things. (Among them, emails from long before Poland!)

Question: Have you sent off your "Truth as Convenient Friction" to the memorial volume? Sorry I never sent you that list of typos. Trouble was, I wanted to reread it, and reread the relevant Rorty, and make some idiosyncratic comments at the same time ... maybe to show you that I really do have a philosophical streak. It was laid out beautifully in my mind: I would title the note "Value Added." But then a bad thing happened—I got obsessed with a certain calculation, and I haven't been able to let it go for over two months now!

Still, if you haven't sent your paper to the publishers, I might use that as an excuse to reread it this weekend (skipping Rorty, and making no promises to even attempt value-addedness, but at least refreshing myself of your arguments as a kind of payment for the editorial work).

11-03-05 *Chance* (to J. Ismael)

I'm just coming back to email after a long hiatus. (Even for a guy whose professional career is based on his knack for correspondence, sometimes a hiatus is overdue.) Anyway, thanks for the paper. I just printed it out and will *certainly* read it. Too bad you're not coming to Konstanz to read it to us!

There's a good (subjective) chance I'll be in Sydney at your meeting, but I don't want to give it a certainty yet.

Ismaelism 1: *But be patient; after hearing your talk in October, and rereading some of your work, I realized we share something perhaps more important than the surface disagreement: viz., the conviction that probability is information.*

Without doubt, I'll be patient. But it's hard at this point to imagine that our disagreement will only be a surface one: I have so much invested in taking a subjective interpretation of probability down into quantum theory's core—as a research program—that a reversal at this point might amount to schizophrenia. In fact, I think my ideas on quantum foundations hang together *only* because of a de-Finetti style interpretation of probability. But still, I know I'll learn a lot by studying your paper. And we shall see.

I'm curious to know which of my things you've read, so that I can know which version of me you've seen. I'm fairly fluid in some aspects. But, in particular, if I think I might further our discussion on chance by pointing you to some particular passage, it would be useful to know which part of my writings you've digested.

15-03-05 *Down with Properties!* (to S. J. van Enk)

- The wavefunction is not a property of the quantum system.
- Nor is a measurement outcome the signifier of some property (either one pre-existent or one created from the measurement process itself).
- States and POVMs play essentially the same roles: Subjective judgments.
- Measurement outcomes (I would guess) do have a kind of reality—they do come into existence via the measurement process—but they don't signify properties. Rather they are rawer than that: Kind of like the nodes in your graphs. Anyway, see "Preamble" at the end of the samizdat. New outcome, new graph? Just playing with ideas.

Steven's Preply

> When I read your email to Spekkens I saw why you're interested in the book about how Asians think.
>
> I liked Rorty's description of the world and his example of numbers. That somehow made me think of dictionaries, where words are defined only in relation to other words. Whereas I used to think a dictionary, therefore, doesn't define anything, thanks to Rorty I now think the opposite: it determines everything! In fact, I think if you give me a Swahili dictionary I could in principle translate almost every Swahili word into English by just looking at how all Swahili words relate to one another.
>
> That in turn made me think of graphs and the graph-isomorphism problem: a graph is defined completely by relations between all nodes, where the nodes only have completely meaningless labels. The graph-isomorphism problem is like finding the translation of a dictionary.
>
> And that, I suppose, is also the essence of Mermin's correlations without correlata.

16-03-05 *Stein* (to A. Radosz)

I've been meaning to write to you since my return, but I've only now gotten your email address.

I did find the Gertrude Stein quote you mentioned in one of my papers! It was in a review I wrote of Alexander Holevo's new book:

> The clear-cut purpose of the monograph is not to go through the mechanics of each theorem, but to paint a picture in modern art. Throughout, there is an emphasis on

> how each and every quantum result differs from its analog in the classical probabilistic model. One does, however, fear that a central illuminating thread is somehow missing from the exposition, though the author cannot be blamed: It is a thread no one has yet seen. A radical departure from classical probability theory, yes. But why? What is the all-important, undeniable physical fact that forces this revised calculus upon us? Can we state it in a way that does not consist of a dozen disparate theorems? One day we will get there. In the mean time, though, an exposition like this is part of the necessary journey. It is likely to be as Gertrude Stein said of the more classical kind of modern art, "It looks strange and it looks strange and it looks very strange; and then suddenly it doesn't look strange at all and you can't understand what made it look strange in the first place."

I'm sorry I forgot that. I was first alerted to that particular quote of Stein's by John Wheeler. To see another Gertrude Stein quote in action, see an old paper of mine with Carl Caves: `quant-ph/9601025`, "Quantum information: How much information in a state vector?". See page 26 and footnote 43.

It was great meeting you and dining with you, and thanks again for the lovely introduction you gave to my talk!

16-03-05 *Reply from the Lusitania* (to K. H. Knuth)

Knuthism 1: *I have been extremely interested in the logic of questions, and have recently found that they follow the free distributive algebra and possess a measure that is a natural generalization of information theory. I can now perform computations that determine the degree to which one question answers another, and I have been applying some of this work here at NASA to design intelligent instruments that decide which measurements to take next given the data that they already possess. You may be interested in the three papers I am attaching for your perusal .... I will be giving a tutorial on this work at MaxEnt 2005 on Sunday.*

I have been mightily impressed by a skim of some of your papers. I hope I get a chance to actually understand them over the course of this Spring and Summer. In particular, the two that most rise to my attention at the moment are "What is a Question?" and "Lattice Duality." For about three years now I've been emphasizing the direct analogy between the formal structure of quantum measurements (aka questions) and quantum states (aka Bayesian degrees of belief in the quantum context). If a quantum state is akin to a probability (and therefore subjective), a quantum measurement is akin to a conditional probability (and therefore subjective)—that's the kind of idea. You can find some of these thoughts tabulated in `quant-ph/0205039`, particularly in Section 6, but I go into much greater depth in *Quantum States: What the Hell Are They?* posted at my website. (Unfortunately, the latter has not been distilled into a proper paper yet, but maybe it's entertaining nonetheless.) As I understand it, these papers of yours (and the Cox work that started them off, which I did not know about) seem to indicate that this is a much larger phenomenon than I had contemplated. I'll definitely have to understand this stuff that you're uncovering.

17-03-05 *It's All About Gram Matrices* (to K. R. Duffy)

Dear Old Friend,

By the time you read this note, I know you'll have a horrible headache (assuming you read email at all the day after St. Patty's Day), but I thought I'd say hi anyway while the day is still here. Ireland has been on the whole family's mind all week—in lots of ways we all miss it, and we've been talking about it a lot and reminiscing. I even endured watching Bobby Flay (who I don't like) on the Food Channel last night so that we could see "A Taste of Ireland." The scenery made it worth it (at least whenever Flay wasn't in the same picture). Hey, we even put an Irish flag on the pole at the front of our house this week, finally retiring the University of Texas flag we put up when we first moved in.

How are things go with you? For myself, I've been scrambling the last two months to get a good result to present at the JTL meeting—not a lie. At the other meetings I've been going to recently, I've been presenting slight variations on the same-old-same-old, knowing that I could always get away with it. But at John's meeting, I want to present some mathematics that would have maybe put a smile on his face. I keep thinking I'm this close "", then it all vanishes. Still, there's a running chance! And I'm little if not determined.

Say hi to Jo and Dave and anyone else I'd remember if you see them. And take some Nurofen!

21-03-05 *Changing the World* (to C. H. Bennett)

Here's a little story I've got to tell you and Theo. Ever since you wrote me these lines soon after Katie's birth,

Bennettism 25: *Theo enjoyed your birth announcement for Katie. When I read her that Katie was beautiful in every way and would shape the world by her presence and will, she said she wasn't surprised. That is just what she would expect from another baby that came from the same parents as Emma. Theo told me that her grandfather, when told of the birth of a baby from someone he admired, would typically say "That baby will change the world." (After the world changes it a few hundred times, I couldn't help thinking.) Congratulations to all four of you from the two of us.*

I have from time to time told her that one day she will change the world—that that's her destiny. Last night I told her that as I was tucking her into bed and asked, "Do you know it?" How did she reply? "Yeah. Today I changed the batteries in my toy."

I loved it and had to record it.

25-03-05 *[SPAM?] At It Again: Delirium Quantum* (to H. M. Wiseman)

Wisemanism 34: *I'm writing a foundational paper (partly to prepare myself for your workshop, but its been on the go for years) and want to quote parts of the following:*

> Any single application of quantum theory is about ME, only me. It is about MY interventions, MY expectations for their consequences ... and MY reevaluations of MY old expectations in the light of those consequences. It is noncommittal beyond that. This is not solipsism; it is simply a statement of the subject matter. ... What quantum theory does is provide a framework for structuring MY expectations for the consequences of MY interventions upon the external world. At least that is what the formal structure is about. There is no "we," there is no "our."

from your "Delirium Quantum" collection. Is this going to be made public any time soon so I can give it a proper reference?

Hmm, what do you think? You think I should post that? How much more foolish than usual would I look with this one? [See "Delirium Quantum" `arXiv:0906.1968v1`.]

Another question. Guido Bacciagaluppi once told me that "Delirium Quantum" was an abomination of a title: It should be "Delirium Quanticum" so that both words are Latin (after I explained to him that I was thinking of "delirium tremens" when making the title). In a way he's right, but on the other hand I've got a certain redneck kind-of persona to preserve: I'm not sure I want to get too fancy with my titles. The present one seems just incorrect enough to fit me.

30-03-05 *Civil Disobedience* (to G. L. Comer)

Thanks for your notes bringing me up-to-date on your tripartite career: poetry, music, and physics. And I applaud your efforts to find linearity in each of them! (I.e., the place of the observer/actor/agent in each of them.) [...]

I look forward to reading your discussion of linearity in GR. Definitely, send it by me as it comes along.

For myself, I've been obsessed by a basic linear algebra for two months now, and I've thrown myself into it like I was a graduate student again. That is one of the great things about quantum information: One starts to realize how many very basic questions in finite-dimensional linear algebra have simply never been explored. And sometimes, they're really tough questions despite the finite dimensions. Take the linear vector space of $d \times d$ complex matrices. That's a d^2 dimensional vector space, and you can equip it with an inner product, say the Frobenius one $\mathrm{tr}(A^\dagger B)$ where $\dagger$ denotes Hermitian conjugation. Question: Can one always construct a complete orthonormal basis for this vector space consisting solely of unitary matrices? It's not obvious, but the answer is yes—it took Schwinger to note it. New question: Can one always construct a complete orthonormal basis consisting of Hermitian matrices? Much easier, and the answer is yes. New question: Can one always construct a complete orthonormal basis consisting of positive semidefinite Hermitian matrices? Much harder! But the answer is no. In fact, it looks like the closest one can come is to get a normalized basis with pairwise inner products of value $1/(d + 1)$. But proving it, that has turned out to be really hard. Even constructing a set of (positive semidefinite Hermitian) matrices with those inner products has turned out to be elusive. Constructions exist for $d = 2, ..., 8$ and 19, but there's only numerical evidence for the other dimensions up to 45 (and after 45 there's not even numerical evidence, the problem becomes too big for easily accessible computers). But dammit, it's an important question. For these are precisely the things we should have been using all along to express quantum mechanics, rather than expansions in terms of orthonormal bases.

But such is the life! Interpreting and reinterpreting the scripture.

06-04-05 *Internal Realism?* (to J. E. Sipe)

Finally, let me point you to `quant-ph/0204146`. The relevant sections for our Putnam discussion last night are 4 and 5. I'm curious to know whether that sounds like Putnam's internal realism to you (as I think Rob thought it did), or whether it sounds like a different beast? Of course, I should read Putnam myself ... but your opinion might tide me over until I get a chance to.

06-04-05 *Being Bayesian in a Quantum World* (to G. Musser)

I am sorry I've been out of contact for so long, but of course nothing has worked out on the schedule I had wanted to keep to this year. In particular, I hope you and *Scientific American* might still be interested in an article from me. I have decided that if I were to write one, I would like to title it "Being Bayesian in a Quantum World" and with it convey some of the excitement a rather large community of us are starting to feel for this aspect of the "Quantum Foundations in the Light of Quantum Information" program I described to you previously.

Now, what I think I'd like to do is start putting some words together right after our big meeting on the subject in Konstanz in early August of this year. That way I think I'd be better able to take into account all the things I see and hear around me there, which would probably quite benefit the article. The particular subject of the article would pretty much be along the lines of a little abstract I just wrote up for the MaxEnt and Bayesian Methods meeting, which will be held in San Jose just after BBQW: I'll place the abstract below so that you might get a feel for the subject matter.

Would *Scientific American* be interested in an article from me along these lines?

The abstract below is actually a variation on some paragraphs I wrote to announce our Konstanz meeting. Thus, in a separate email, I think I will send you the full (original) announcement. More particularly, if you're interested you can take a look at our website to see the final list of participants, the program, the research questions, etc. Here's the web address:

`http://web.archive.org/web/20090511060206/http://`
`www.uni-konstanz.de/ppm/events/bbqw2005/`.

At least given your seeming excitement in our discussions last year, you might just be interested—I hope so! Anyway, one idea that comes to mind is that if you think you might like to cover the meeting for a little description or blurb or whatever in *Scientific American*, you are certainly welcome to come. There will be plenty of good people to talk to there, and I doubt you'd be bored. You'd just have to let me know fairly quickly so that we can make sure there is still a room available at the conference hotel.

07-04-05 *Recovery of Philosophy* (to J. E. Sipe)

Sipesm 1: *Here's the quote by Dewey that I mentioned:*

> Intellectual advance occurs in two ways. At times increase of knowledge is organized about old conceptions, while these are expanded, elaborated and refined, but not seriously revised, much less abandoned. At other times, the increase of knowledge demands qualitative rather than quantitative change; alteration, not addition. Men's minds grow cold to their former intellectual concerns; ideas that were burning fade; interests that were urgent seem remote. Men face in another direction; their older perplexities are unreal; considerations passed over as negligible loom up. Former problems may not have been solved, but they no longer press for solution.

I find this really very amazing, especially since it was written in 1917. I don't think Thomas Kuhn ever knew about it (– while I certainly haven't read everything Kuhn wrote, I'm not aware of him acknowledging any debt to Dewey anywhere –) especially since the quote occurs in an essay ("The Need for a Recovery of Philosophy") that Dewey wrote about contemporary philosophy in America. But the approach is pure Kuhn (or rather Kuhn-before-Kuhn), with a clear articulation of what would later be called "normal science" and "paradigm shifts."

Hey, I've read that article—relatively thoroughly in fact. But I didn't catch the similarities to Kuhn in it! Below are the quotes I took from the article for my upcoming "The Activating

Observer: Resource Material for a Pauli'an-Wheeler'ish Conception of Nature" ... which pretty much reveals the parts of the article I was paying attention to at the time.

The quotes come from (and the page numbers refer to), J. Dewey, *John Dewey: The Essential Writings*, edited with introduction by D. Sidorsky, (Harper & Row, New York, 1977).

malleable world, pp. 70–71:

> [I] set out with a brief statement of some of the chief contrasts between the orthodox description of experience and that congenial to present conditions.
>
> (i) In the orthodox view, experience is regarded primarily as a knowledge-affair. But to eyes not looking through ancient spectacles, it assuredly appears as an affair of the intercourse of a living being with its physical and social environment. (ii) According to tradition experience is (at least primarily) a psychical thing, infected throughout by "subjectivity." What experience suggests about itself is a genuinely objective world which enters into the actions and sufferings of men and undergoes modifications through their responses. (iii) So far as anything beyond a bare present is recognized by the established doctrine, the past exclusively counts. Registration of what has taken place, reference to precedent, is believed to be the essence of experience. Empiricism is conceived of as tied up to what has been, or is, "given." But experience in its vital form is experimental, an effort to change the given; it is characterized by projection, by reaching forward into the unknown; connection with a future is its salient trait. (iv) The empirical tradition is committed to particularism. Connections and continuities are supposed to be foreign to experience, to be by-products of dubious validity. An experience that is an undergoing of an environment and a striving for its control in new directions is pregnant with connections. (v) In the traditional notion experience and thought are antithetical terms. Inference, so far as it is other than a revival of what has been given in the past, goes beyond experience; hence it is either invalid, or else a measure of desperation by which, using experience as a springboard, we jump out to a world of stable things and other selves. But experience, taken free of the restrictions imposed by the older concept, is full of inference. There is, apparently, no conscious experience without inference; reflection is native and constant.
>
> These contrasts, with a consideration of the effect of substituting the account of experience relevant to modern life for the inherited account, afford the subject matter of the following discussion.

time, pp. 73–74:

> The preoccupation of experience with things which are coming (are now coming, not just to come) is obvious to any one whose interest in experience is empirical. Since we live forward; since we live in a world where changes are going on whose issue means our weal or woe; since every act of ours modifies these changes and hence is fraught with promise, or charged with hostile energies—what should experience be but a future implicated in a present! Adjustment is no timeless state; it is a continuing process. To say that a change takes time may be to say something about the event which is external and uninstructive. But adjustment of organism to environment takes time in the pregnant sense; every step in the process is conditioned by reference to further changes which it effects. What is going on in the environment is the concern of the organism; not what is already "there" in accomplished and finished form. In so far as the issue of what is going on may be affected by intervention of the organism, the moving event is a challenge which stretches the agent-patient to meet what is coming.

Experiencing exhibits things in their unterminated aspect moving toward determinate conclusions. The finished and done with is of import as affecting the future, not on its own account: in short, because it is not, really, done with.

Anticipation is therefore more primary than recollection; projection than summoning of the past; the prospective than the retrospective. Given a world like that in which we live, a world in which environing changes are partly favorable and partly callously indifferent, and experience is bound to be prospective in import; for any control attainable by the living creature depends upon what is done to alter the state of things. Success and failure are the primary "categories" of life; achieving of good and averting of ill are its supreme interests; hope and anxiety (which are not self-enclosed states of feeling, but active attitudes of welcome and wariness) are dominant qualities of experience. Imaginative forecast of the future is this forerunning quality of behavior rendered available for guidance in the present. [...] Imaginative recovery of the bygone is indispensable to successful invasion of the future, but its status is that of an instrument. To ignore its import is the sign of an undisciplined agent; but to isolate the past, dwelling upon it for its own sake and giving it the eulogistic name of knowledge, is to substitute the reminiscence of old age for effective intelligence.

time and control, p. 78:

Experience, to return to our positive conception, is primarily what is undergone in connection with activities whose import lies in their objective consequences—their bearing upon future experiences. Organic functions deal with things as things in course, in operation, in a state of affairs- not yet given or completed. What is done with, what is just "there," is of concern only in the potentialities which it may indicate. As ended, as wholly given, it is of no account. But as a sign of what may come, it becomes an indispensable factor in behavior dealing with changes, the outcome of which is not yet determined.

The only power the organism possesses to control its own future depends upon the way its present responses modify changes which are taking place in its medium. A living being may be comparatively impotent, or comparatively free. It is all a matter of the way in which its present reactions to things influence the future reactions of things upon it. Without regard to its wish or intent every act it performs makes some difference in the environment. The change may be trivial as respects its own career and fortune. But it may also be of incalculable importance; it may import harm, destruction, or it may procure well-being.

control, p. 79:

As we have already noted, the environment is rarely all of a kind in its bearing upon organic welfare; its most wholehearted support of life activities is precarious and temporary. Some environmental changes are auspicious; others are menacing. The secret of success that is, of the greatest attainable success—is for the organic response to cast in its lot with present auspicious changes to strengthen them and thus to avert the consequences flowing from occurrences of ill-omen. Any reaction is a venture; it involves risk. We always build better or worse than we can foretell. But the organism's fateful intervention in the course of events is blind, its choice is random, except as it can employ what happens to it as a basis of inferring what is likely to happen later. In the degree in which it can read future results in present on-goings, its responsive choice, its partiality to this condition or that, become intelligent. Its bias grows reasonable. It can deliberately, intentionally, participate in the direction of the course of affairs. Its foresight of different futures which result according as this or that present factor predominates in the shaping of affairs permits it to partake intelligently instead of blindly and fatally in the consequences its reactions give rise to. Participate it must, and to its own weal or woe. Inference, the use of what happens, to anticipate what will—or at least may—happen, makes the difference between directed and undirected participation. And this capacity for inferring is precisely the same as that use of natural occurrences for the discovery and determination of consequences—the formation of new dynamic connections—which constitutes knowledge.

existence of reality, p. 81:

One of the curiosities of orthodox empiricism is that its outstanding speculative problem is the existence of an "external world." For in accordance with the notion that experience is attached to a private subject as its exclusive possession, a world like the one in which we appear to live must be "external" to experience instead of being its subject matter. I call it a curiosity, for if anything seems adequately grounded empirically it is the existence of a world which resists the characteristic functions of the subject of experience; which goes its way, in some respects, independently of these functions, and which frustrates our hopes and intentions. Ignorance, which is fatal, disappointment, the need of adjusting means and ends to the course of nature would seem to be facts sufficiently characterizing empirical situations as to render the existence of an external world indubitable.

Bergson, pp. 86–87:

What are the bearings of our discussion upon the conception of the present scope and office of philosophy? What do our conclusions indicate and demand with reference to philosophy itself? [...]

It is easier to state the negative results of the changed idea of philosophy than the positive ones. The point that occurs to mind most readily is that philosophy will have to surrender all pretension to be peculiarly concerned with ultimate reality, or with reality as a complete (i.e., completed) whole: with *the* real object. The surrender is not easy of achievement. The philosophic tradition that comes to us from classic Greek thought and that was reinforced by Christian philosophy in the Middle Ages discriminates philosophical knowing from other modes of knowing by means of an alleged peculiarly intimate concern with supreme, ultimate, true reality. To deny this trait to philosophy seems to many to be the suicide of philosophy; to be a systematic adoption of skepticism or agnostic positivism.

The pervasiveness of the tradition is shown in the fact that so vitally a contemporary thinker as Bergson, who finds a philosophic revolution involved in abandonment of the traditional identification of the truly real with the fixed (an identification inherited from Greek thought), does not find it in his heart to abandon the counterpart identification of philosophy with search for the truly Real; and hence he finds it necessary to substitute an ultimate and absolute flux for an ultimate and absolute permanence. Thus his great empirical services in calling attention to the fundamental importance of considerations of time for problems of life and mind get compromised with a mystic, nonempirical "Intuition"; and we find him preoccupied with solving, by means of his new idea of ultimate reality, the traditional problems of realities-in-themselves and phenomena, matter and mind, free will and determinism, God and the world. Is not that another evidence of the influence of the classic idea about philosophy?

reality, pp. 88–89:

It is often said that pragmatism, unless it is content to be a contribution to mere methodology, must develop a theory of Reality. But the chief characteristic trait of the pragmatic notion of reality is precisely that no theory of Reality in general, *überhaupt*, is possible or needed. It occupies the position of an emancipated empiricism or a thoroughgoing naive realism. It finds that "reality" is a denotative term, a word used to designate indifferently everything that happens. Lies, dreams, insanities, deceptions, myths, theories are all of them just the events which they specifically are. Pragmatism is content to take its stand with science; for science finds all such events to be subject matter of description and inquiry—just like stars and fossils, mosquitoes and malaria, circulation and vision. It also takes its stand with daily life, which finds that such things really have to be reckoned with as they occur interwoven in the texture of events.

The only way in which the term reality can ever become more than a blanket denotative term is through recourse to specific events in all their diversity and thatness. Speaking summarily, I find that the retention by philosophy of the notion of a Reality feudally superior to the events of everyday occurrence is the chief source of the increasing isolation of philosophy from common sense and science. For the latter do not operate in any such region. As with them of old, philosophy in dealing with real difficulties finds itself still hampered by reference to realities more real, more ultimate, than those which directly happen.

I have said that identifying the cause of philosophy with the notion of superior reality is the cause of an increasing isolation from science and practical life. The phrase reminds us that there was a time when the enterprise of science and the moral interests of men both moved in a universe invidiously distinguished from that of ordinary occurrence. While all that happens is equally real—since it really happens—happenings are not of equal worth. Their respective consequences, their import, varies tremendously. Counterfeit money, although real (or rather *because* real) is really different from a valid circulatory medium, just as disease is really different from health; different in specific structure and so different in consequences. In occidental thought, the Greeks were the first to draw the distinction between the genuine and the spurious in a generalized fashion and to formulate and enforce its tremendous significance for the conduct of life. But since they had at command no technique of experimental analysis and no adequate technique of mathematical analysis, they were compelled to treat the difference of the true and the false, the dependable and the deceptive, as signifying two kinds of existence, the truly real and the apparently real.

malleable world, p. 91:

The epistemological universe of discourse is so highly technical that only those who have been trained in the history of thought think in terms of it. It did not occur accordingly, to nontechnical readers to interpret the doctrine that the meaning and validity of thought are fixed by differences made in consequences and in satisfactoriness, to mean consequences in personal feelings. Those who were professionally trained, however, took the statement to mean that consciousness or mind in the mere act of looking at things modifies them. It understood the doctrine of test of validity by consequences to mean that apprehensions and conceptions are true if the modifications affected by them were of an emotionally desirable tone.

Prior discussion should have made it reasonably clear that the source of this misunderstanding lies in the neglect of temporal considerations. The change made in things by the self in knowing is not immediate and, so to say, cross-sectional. It is longitudinal—in the redirection given to changes already going on. Its analogue is found in the changes which take place in the development of, say, iron ore into a watch spring, not in those of the miracle of transubstantiation. For the static, cross-sectional, nontemporal relation of subject and object, the pragmatic hypothesis substitutes apprehension of a thing in terms of the results in other things which it is tending to effect. For the unique epistemological relation, it substitutes a practical relation of a familiar type—responsive behavior which changes in time the subject matter to which it applies. The unique thing about the responsible behavior which constitutes knowing is the specific difference which marks it off from other modes of response, namely, the part played in it by anticipation and prediction. Knowing is the act, stimulated by this foresight, of securing and averting consequences. The success of the achievement measures the standing of the foresight by which response is directed. The popular impression that pragmatic philosophy means that philosophy shall develop ideas relevant to the actual cries of life, ideas influential in dealing with them and tested by the assistance they afford, is correct.

11-04-05 *Another Query* (to A. Kent)

Kentism 7: *Another query on* `9512023`*. I'm puzzled by the comment on p. 12 which says that A_{rs00} implies $|Phi_{00}\rangle = 0$ and similarly for 11. That doesn't immediately seem to fit with eq (12), which suggests that you'd need $A_{00rs} = 0$ to imply $|Phi_{00}\rangle = 0$. Also, I'm struggling to see how the optimal Eve strategy in the paper defines a unitary evolution if $|Phi_{00}\rangle = |Phi_{11}\rangle = 0$.*

Am I confused or going mad? Or is it possible there's a glitch in the conventions somewhere? (Is the `arXiv` *version isomorphic to the published version, btw? I'm working from the* `arXiv` *one.) You probably won't remember after 10 years, I realize. But if you happen to be able to shed any light, I would be grateful.*

Wow, that was a long time ago! I'd have to relearn the paper—like you seem to be doing at the moment. All my notes (and there were substantially more calculations than made it into the paper) burned up in the Cerro Grande fire. As a first pass, does my paper `9611010` help any? I remember trying to tie up some loose ends there (though for some different measures). Also, concerning the conjecture—I presume you mean the conjecture that a two-state probe is good enough—I don't know that anyone ever proved it. I gave up trying after `9611010`, though I did make a little progress in the direction there (see the discussion in the right column of page 10). I think maybe Bob Griffiths tried his hand at it too, but didn't make headway—though I'm not sure.

Anyway, let me know if any of that helps, and if it doesn't I'll try to think about it next week (after I get the seminars I've got to give this week off my back).

12-04-05 *Chris Fuchs, Apr. 14, MH* (to H. J. Landau)

Here's something of an abstract. Sorry to be getting back to you so late.

Abstract: Sets of quantum states good for quantum key distribution. Discrete positive-operator-valued measures on finite-dimensional vector spaces. Representing quantum states as probability distributions. Gram matrices. Schur product theorem. Hadamard exponential. Schwarz inequality. If any of these words or phrases interest you, come to the seminar.

21-04-05 *Another Idea* (to R. W. Spekkens)

Another thing that might make your visit fun. Maybe we could drive to Princeton one day and have a visit with John Conway and get him to give us a presentation of this new KS construction he's rumored to have with Kochen. (I did a quick google search and found this, for instance, but haven't read it yet: `http://www.cs.auckland.ac.nz/~jas/one/freewill-theorem.html`.)

Do you know if there's anything new in this?

25-04-05 *Your Talk (or your talks)* (to R. W. Spekkens)

Spekkensism 29: *I'm thinking that it might be useful for us to discuss what sorts of information-theoretic axioms might get us to the tensor product structure of Hilbert space. Another interesting project would be to try to reduce Lucien's axioms about subspaces and subsystems to a single axiom. [...] Then again, we could try to work out the number of "mutually unbiased bases" in the toy theory. This might be easier to solve than the equivalent problem in quantum mechanics. Or ... something entirely different.*

I wouldn't mind talking about a range of things, as I've grown flaccid in my old age. Maybe something new from you could perk me up.

Though probably this is what I'll be most interested in: I'm presently in the process of working out what the qutrit state space looks like, solely in terms of a constraint on the probability distributions over nine possible events. Think "toy model." Similarly, I *think* that with enough coffee, I could explicitly work out the constraints for the two-qubit case. Say that I can actually get that done. I'd like to understand a) in what way or not those constraints look like your toy model's constraints, and b) if getting the quantum constraints exactly right (i.e., what I'm doing) adds any qualitative phenomena over the long list your toy model already recovers. Surely, it'll give entanglement, whereas your model cannot, but what does that amount to?

26-04-05 *Thanks!* (to W. E. Lawrence)

Lawrencesm 2: *Thanks for the great visit and kind hospitality. It was invigorating and informative.*

No, thank you. I got every bit as much out of it, if not more. You reminded me of how important it is to just role up your sleeves and get to work. For instance, to stop toiling with the abstract when you're stuck and see what comes out in the three-dimensional case—it's super-important to make that move every now and then, and I sometimes forget.

26-04-05 *Eagle Eyes* (to C. G. Timpson)

Wow, with a friend like you, who needs ... any other friends at all! Just one good one would do. Thanks for the defense! I read it and enjoyed it. You always have the power to lift my spirits simply by understanding the (essentially trivial) things I've been saying — you're a rare bird in the philosophical community. Even Jeff Bub and Hans Halvorson surprise me in these matters. Every time I see Jeff try to re-ontologize "information" I cringe—I sometimes wonder why he even bothered to go through the motions of the Clifton-Bub-Halvorson exercise, when information to him is just another ontic entity. With that misreading of the very idea of information, it seems to me at best one makes no progress at all; at worst one just mystifies the problem further and erodes any confidence in the community that this is an interesting research direction.

I haven't seen the Palge/Konrad paper. I wonder why they didn't send it to me too? Interesting. Probably, it was because I was a bad boy about replying to an email of questions Veiko had when he first started the critical project. He hit me at a time when I could hardly stand to lift a finger for email. It takes a toll trying to say and resay old things in better and better ways just to fend off another critical paper. Somehow I need to get re-energized to try to write a "definitive" paper on the view, and then let come what may in the aftermath.

BTW, yes Eq. (97) was a typo, just as you sensed. Try as I might—and I tried all weekend—I can't remember who first pointed it out to me. I was able to trace some correspondence about it back to Tony Sudbery, 18 December 2003, which went:

> **Tony:** I'm sure I'm not alone in seeing your dissolving of the "violent" state change (on p. 34) as a cheat. Calling it a "mental readjustment" doesn't make it any less violent. Incidentally, there's something wrong with eq. (97); these U_i are not unitary.
>
> **Chris:** Fair enough. It is violent—every bit as violent, discontinuous, and irreversible as a usual application of Bayes' rule. But the point is that it is on the inside of the agent's head, and no one cares what is going on in the agent's head. What physicists should be worried about is the physics of the external world (and not the agent's head). And who knows what really happens there ... especially if physics itself is only really about the interface.
>
> About the U_i's you are correct. I'm sorry, I've prepared an updated version with a lot of the typos, etc., fixed, but I haven't reposted it yet. Here's what the new edition says:
>
> That is to say, there is a sense in which the measurement is solely disturbance. In particular, when the POVM is an orthogonal set of projectors $\{\Pi_i = |i\rangle\langle i|\}$ and the state-change mechanism is the von Neumann collapse postulate, this simply corresponds to a readjustment according to unitary operators U_i whose action on the subspace spanned by $|\psi\rangle$ is
>
> $$|i\rangle\langle\psi|\ .$$

For the life of me, I can't remember who first brought up the point, and my high-tech desktop-search tools haven't been of help this time. I do distinctly remember it was someone before Tony. Anyway, little things like this bug me at times ... when I can't put my finger on them. If the person is not already in the acknowledgement list, he should be.

Seeing that someone made a big deal of that one line of bad exposition in a paper, though, tells me that I really should get the thing re-posted. Most of the other typos were even more minor—for instance, I originally placed Strasbourg in Germany rather than in France—but there is another one that's on the level of the one above—i.e., one with the potential to cause real confusion. If you look carefully at Eq. (61), you'll see that there's a slip-up of the same order there. I wrote the swap-operator on the wrong space. To do it right, I need to add two or three more sentences and change the notation. I should do that, and then re-post the thing.

All that said, I actually do look forward to the day that you'll write a critical analysis of the Bayesian program. I feel in my heart that that analysis will be worthwhile, and the flaws you dig up will force us to a new level of consistency. (Of course, your analysis could simply break us, but I'm betting—I can't do otherwise!—that the outcome will much more positive than that.)

28-04-05 *Infinite Limits* (to G. Valente)

Thanks for sending me your paper. I've printed it out and will bring it to Maryland with me today. I'll look forward to a personal explanation of its content when I see you.

I have to tell you right now though that I am skeptical of its conclusion. This comes predominantly from a long-standing belief that was made forcefully upon me when I was a student of Carlton Caves (who himself was influenced on this issue by Ed Jaynes)—namely, that the infinite cases *never* carry the *essence* of a problem. In the present context what this means is: If something works in all finite dimensional cases, but *apparently* not in the infinite dimensional case, my faith in the former won't be eroded at all. It just means something has gone awry with one's analysis of the infinite dimensional case. And this conviction comes about because, in my mind, the infinite is just a convenient approximation, of use in this or that calculation, but without any autonomy.

I dug up a great quote from Chapter 2 of Jaynes' book on probability that frames the issue, and I'll place it below.

You'll also have to tell me about how miserable College Park is. I suspected it would be so. But when I saw that your being there would be a grand opportunity for a fellow alchemist[80] to make some influence on Jeff, I closed my eyes to it. Perhaps I shouldn't have. Still, I am very happy that you are there to influence Jeff.

Jaynes quote below.

> It is very important to note that our consistency theorems have been established only for probabilities assigned on finite sets of propositions. In principle, every problem must start with such finite set probabilities; extension to infinite sets is permitted only when this is the result of a well-defined and well-behaved limiting process from a finite set. More generally, in any mathematical operations involving infinite sets the safe procedure is the finite sets policy:
>
> > Apply the ordinary processes of arithmetic and analysis only to expressions with a finite number of terms. Then after the calculation is done, observe how the resulting finite expressions behave as the number of terms increases indefinitely.
>
> In laying down this rule of conduct, we are only following the policy that mathematicians from Archimedes to Gauss have considered clearly necessary for nonsense avoidance in all of mathematics. But more recently, the popularity of infinite set theory and measure theory have led some to disregard it and seek short-cuts which purport to use measure theory directly. Note, however, that this rule of conduct is consistent with the original Lebesgue definition of measure, and when a well-behaved limit exists it leads us automatically to correct "measure theoretic" results. Indeed, this is how Lebesgue found his first results.
>
> The danger is that the present measure theory notation presupposes the infinite limit already accomplished, but contains no symbol indicating which limiting process was

[80] I remember fondly what you wrote in your very first letter to me: "I wake up thinking about our alchimistic touch to the nature yesterday morning. As soon as I started studying, I read the same idea (alchemy) in your first statement about Pauli. I closed my books and I run away to phone my mum in Vicenza. . . "

used. Yet as noted in our Preface, different limiting processes—equally well-behaved—lead in general to different results. When there is no well-behaved limit, any attempt to go directly to the limit can result in nonsense, the cause of which cannot be seen as long as one looks only at the limit, and not at the limiting process.

09-05-05 *Being Bayesian in a Quantum World — Conference Invitation* (to J. B. Hartle)

I'm sorry to hear you can't come after all. Particularly, with what would have been your talk plan, your participation seems even more urgent than ever. Too bad! Well, we will think of you—among other things, I will present my standard slide of the "The Jim Hartle 1964, Sect. 4, Interpretation of Quantum Mechanics (suitably modified)" in my introductory talk—and please pass on my best wishes to your daughter.

09-05-05 *Becoming in the World (much more important than being)* (to H. J. Briegel)

I am sorry to take so long to respond to you. There are a million things I need to get going on with the conference organization . . . and there'll soon be a flurry of activity in that direction.

The format of the meeting is that we hope to have less than about half of the attendees speaking: Two talks in the morning, two talks in the afternoon. Then after each set of two, the idea is to have open floor discussion somewhat related to their topics. It's based on the model of the Seven Pines meetings, where I've seen it work well. At some point soon, we'll start soliciting "volunteers".

Would you be interested in giving a talk on one-way quantum computing, and how it might shake up the "standard" ideas about what powers quantum computing. And—if possible—say something about how well that meshes (or does not mesh) with a Bayesian take on probability theory? I might put you back-to-back with Nielsen for a session.

Is that enough detail to help you in your planning? We actually have a conference web site that's very close to being posted. But we've been keeping it secret (and you should too) until some issues with a funding agency get resolved.

09-05-05 *Justifying Conditionalization* (to H. Greaves)

I'm always desperate; it's part of my character: And so . . . thanks a million for the paper! Indeed I'm quite curious about this "kick" you mention.

Are you sure we can't convince you to come to Konstanz if we can secure funds for you? In another act of desperation, I'll show you our secret website in case it might help tip the scales for you:

`http://web.archive.org/web/20090511060206/http://www.uni-konstanz.de/ppm/events/bbqw2005/`.

Please peruse it, and if you reconsider let me know. (BTW, when I say it's a secret website, I'm relatively serious: we can't go public with it until some issues with one of our funding agencies are resolved. So please do keep the address to yourself until we go public with it ourselves.)

Hilary's Preply

Good to see you again this weekend. I mentioned a paper by myself and David Wallace, justifying conditionalization (QM aside) via an expected-epistemic-utility proof. In case you're interested, it's at

`http://philsci-archive.pitt.edu/archive/00002212/`

Incidentally, the one type of updating rule that is allowed in principle, as a consequence of our framework (it dropped out of the proof and refused to go away — we didn't want it), consists of rules of the form conditionalization-followed-by-a-kick ...

... I would be astounded if this stuff had any relevance whatsoever for your project, but if you're desperate and/or curious, you might like to take a look.

10-05-05 *BBQW Things* (to S. Hartmann)

I hope that bug has now left your body; sorry for the late reply to your note. Indeed, I've been meaning to write you for quite a while now, so I'm running far later than you probably even perceive.

From looking at the conference website, it looks like you got the note from Hartle saying that he cannot attend after all. It is kind of a shame because his subject did look quite good. But in the light of this, let me cause some new trouble: Looking back at our attendee list, 47 starts to look like such an unsymmetric number! I fear to ask this, but might you consider upping it to 50? My reasons for inquiring are both scientific and political.

First the science. Two weeks ago, I discovered an *outstanding* new candidate. His name is Matthew Leifer, and he is a postdoc at the Perimeter Institute. If you look at his webpage, via this link ... or ... you'll see that among his interests are "the Bayesian approach to quantum probabilities" but that far understates his knowledge and ambition in the area. Indeed, I've come to the opinion that he would be one of our most interesting participants (when we can get him to open his mouth — he's a very quiet person in a crowd, though he definitely opens up in one-to-one talk and that too would be a good role for him). He has some extremely interesting ideas about how quantum states better connect up with de Finetti's more general notion of "previsions" than with probabilities per se, and he has started to explore some very concrete proposals in this direction. A very, very interesting guy; he spent a week here recently, and I was ashamed that I had not pushed for him at our meeting before. (Well, I couldn't really be ashamed — I didn't know him — but I'd be ashamed now if we didn't get him; we really could get a good bang for the buck from him.) And Matt would really like to be there.

Now, making the transition from science to politics, though still on the scientific end: [...]

Now, all the way on the political end. [...]

Thus my question is, would these new additions (or some portion thereof) be OK with you? Can the budget still afford it?

As you suggest, it is about time to start soliciting talks and scheduling. I think it would be most useful for the website to be accessible before I start making those requests large scale.

Concerning number of speakers, I think I would suggest that we have about 20 total, and indeed follow the Seven Pines model. Thus we could have four talks and two discussions per day, with two talks and one discussion on the day of the excursion. That would only leave us with two other talks to squeeze in somewhere else. Maybe we could have one evening session.

If it is honorable to suggest it, I think I would like to give the opening talk. What I would do is give some very general words about the Bayesian program for QM as a whole, and suggest discussion points and open questions. I'd also give a quick overview about how the various talks in the schedule fit together. In other words, I'd like my talk to serve the purpose of giving a direction to the meeting; it would not be particular to my own latest research efforts. As you hoped for me when I came to the LSE, I will try to be provocative.

Concerning your website questions, I hope to have some detailed comments for you in the near future. One thing I already know that I'd like to do is start a section that has various papers for download. For instance, I intend to scan in de Finetti's "Probabilism" and a Richard Jeffrey article on radical probabilism and issue these as suggested readings. Once the speakers have been decided upon, we can also ask them to post their own picks of relevant readings.

11-05-05 *LOL* (to C. P. Hains)

After all these years, I finally hear from you, and what do you send me??! National Orgasm Day? I like it. But you probably knew I'd be particularly receptive to the idea. It's appropriate. Since we haven't talked in so long, you probably don't know that I finally lighted on a name for the view of QM I've been trying to develop over the years. I now call it "the sexual interpretation of quantum mechanics"—Copenhagen and many-worlds interpretations are so dull in comparison. Anyway, it makes for a lot of good bawdy bar-room talk at conferences. Do a Google search on the term if you want to learn a little about it.

I hope things are going well for you—I imagine they are. The big excitement here is that Kiki decided to paint the house orange. ... I guess I should have seen it coming 11 years ago!

12-05-05 *Smelling Correlation without Correlata* (to N. D. Mermin)

I was listening to a talk of Robert Raussendorf yesterday, who is visiting us here at Bell Labs, on cluster-state computation, and I'm almost ashamed to admit it, but I just about blurted out "Correlation without Correlata!" right in the middle of the talk! There was something in all he said that made the idea come to the surface in a way it hadn't (for me) in years. Particularly, I was moved by his point (actually, the particular way he presented it because I had already known it) that in a direct simulation of a quantum circuit in this model, one could perform the measurement that represents the readout in the first step, in the last step, or anywhere in between. It's only the correlation, not the correlata (not the particular measurement outcomes themselves), that matter in this model of quantum computation.

Anyway, I found myself wondering if this model of quantum computation might not be a better home for your "Copenhagen Computation" ideas than the usual unitary model. Have you thought about that?

17-05-05 *Spontaneous Syntax Breaking* (to G. L. Comer)

I feel your pain ...

On a related subject (to which your note brings me back, as did a couple of sentences in this talk by Healey that I heard a couple weeks ago: `http://carnap.umd.edu/philphysics/healey.htm`), back in my early years at UNC I went through an obsession for a while of looking up formal developments of the idea of a differentiable manifold. The thing that I was troubled by at the time was that in all the developments I could find, the idea of a set *plus* a set of coordinate charts (along with a requirement that it be possible to paste them together) was *primary*. I could find no definition of differentiable manifold that didn't rely on a more primitive definition of coordinate chart. The reason that troubled me—these are all vague memories now, so please don't press me to try to defend any of the ideas anymore or even try to make them precise—was that when it came time to describe what general relativity was about *but in words*—and all books of course strived to do that—the differential manifold was taken as a *primary* construct with coordinate charts being something of a secondary nature. See the circularity in that? You can't get the idea of a differentiable manifold off the ground without the idea of a coordinate chart, but then you're told that the differentiable manifold is the primary idea and coordinate systems are only gratuitous additions.

Do you remember in discussions of ours along these lines (circa 1991/1992)? And if so, can you dig up any of the old mails/emails?

Friday I leave for beautiful Vienna. But my romanticism for the place is marred by the sad fact that I have no idea yet what I'll say in my talk! There'll be a lot of sleeplessness between now and then.

17-05-05 *Numbers and Deeper Things* (to S. H. Simon)

Going back to our conversation yesterday, it dawned on me that it might be useful for you to have the numbers I compiled for my presentation to Jaffe too.

Now to more fun things also related to our conversation yesterday: You might enjoy reading through the Andrew Steane paper I mentioned. Here's a link: `http://www.arxiv.org/abs/quant-ph/0003084`. I read it again over breakfast this morning, and it's as good as I remembered it. (The last version I had read of it was in 2002 when I edited it for a special issue of SHPMP.) It's easy reading, but it's deep reading. In particular, I think it contains the roots of a much better way to start thinking about quantum computation, and thus a better way to present the phenomena to anyone interested (like our executives and VPs). Steven's way of presenting things yesterday might be viewed as a stopgap in that direction, but clearly there's a lot of room for honing.

In any case, if we get the ideas right, results can't help but flow faster—and that's what we're about. I think this paper deserves to be better known.

17-05-05 *Steane Paper* (to R. E. Slusher & S. J. van Enk)

I read the Steane paper that I mentioned yesterday over breakfast this morning, and it's every bit as good as I remembered it! You two should have a look at it too: `http://www.arxiv.org/abs/quant-ph/0003084`. It's easy reading, but it's deep reading. And it touches on a lot of points that Dick was worried about yesterday.

Quoting Steane, and inserting my own snide remark,

> The answer to the question 'where does a quantum computer manage to perform its amazing computations?' [this is Deutsch's standard rhetorical question showing that he has little imagination beyond his cooked-up many-worlds imagery] is, we conclude, 'in the region of spacetime occupied by the quantum computer'.

The paper's great! And looking back, it clearly needs to be better known! Citebase shows that it has only accrued 9 citations in the last 5 years.

18-05-05 *Being Bayesian, Pro or Con* (to T. Rudolph)

Now that I've decided I wholeheartedly like you again (never again steal my badge young man!), I've also decided that I'd like to invite you to our meeting "Being Bayesian in a Quantum World," August 1–5, in Konstanz. If I haven't too offended you by this delayed invitation, I hope you'll consider and let me know as soon as possible. On the off chance that you'll say yes, we've gone ahead and reserved a hotel room for you. We can definitely pay your local expenses, and will most likely be able to pay your travel expenses too.

In a day or two I'm going to start soliciting volunteers for talks. Though we plan to max out with a participation of exactly 50 people, I'm hoping for no more than 20–22 actual speakers—the rest will be "discussants" during the long discussion sessions after each pair of talks. Thus, having to have a talk to actually give is by no means mandatory.

18-05-05 *Coordinate Charts* (to G. L. Comer)

The point I didn't emphasize in my last note—where at least it looks like I was successful in emphasizing that, in all the formal developments I've seen, "coordinate chart" is a more basic notion than "differentiable manifold" (otherwise the definition of manifold would not make use of coordinate charts in any way)—is that this may mesh very well with what you wrote me:

Comerism 8: *General covariance is the process through which results in one coordinate system can be translated into results for another coordinate system.*

From that point of view, coordinate chart should indeed be primary, with differentiable manifold only secondary: "Differentiable manifold" is only the formal object that falls out of the *physical* statement that all coordinate systems should be smoothly translatable into one another (locally).

A little bit of these thoughts were on my mind when I wrote that old draft/notes "an information theoretic hole in general covariance" (or with such title), circa '91. You probably don't remember it because you probably thought I was a quack then (maybe you still do). Anyway, the wacky idea on my mind at the time was that *I hoped* that if one restricted oneself to *only* the coordinate charts that were computably (in the Turing sense) generatable from one another, one might not be able to distill a full-fledged manifold from the process but a different, more loosely connected structure for spacetime. In this way, I hoped to make sense of EPR phenomena by explaining that the two particles in it are not so far from each other after all.

With the years and the thoughts that have intervened, I know that those ideas were indeed very misplaced: They were indeed quackery. But it laid the groundwork for me to better appreciate your point: Coordinate systems are a more basic mathematical structure than manifolds for a rather deep reason. They are proxies for potential observers (agents, in my favored language), and the key issue is translatability.

20-05-05 *Room for One Very Last One* (to A. M. Steane)

Carl Caves, Stephan Hartmann, Rüdiger Schack and I are organizing a rather large (but invitation only) conference in Konstanz this summer, August 1-5, titled "Being Bayesian in a Quantum World." The reason I'm writing you is because we have one last spot and, as it turns out—literally by coincidence—I happened to read your paper "Quantum Computing Only Needs One Universe" again the other day. I was struck once again by how much I think you're on the right track in that paper, and I was re-energized to think we might have a good discussion along those lines if you were to be in Konstanz. I had already planned a discussion of measurement-based quantum computing, as Hans Briegel and Mike Nielsen will be there. But your participation would round out things even better.

Below, I'll paste in the original announcement. Also, let me refer you to the "secret" webpage for the meeting (we haven't gone public with it, and can't until a certain funding agency makes a decision): There you can read more about the topics that will be explored at the meeting, and also see the almost-final participant list. It's really—I think—going to be a fabulous meeting. There will be no more than 20-22 talks—i.e., not every participant will be speaking—so you won't be overloaded with talks. Plenty of discussion and thinking time.

If you're interested in coming, we can fund you completely. Just let me as soon as possible what your decision is.

23-05-05 *Whitehead and the Quantum* (to R. E. Slusher)

Too bad you're not here: I think you would have enjoyed the talks and exchanges between Abner Shimony and Shimon Malin about Whitehead's philosophy and what it might have to do with quantum mechanics.

I didn't remember that Bill Wootters had once written me about Malin's book until I ran across his old note with Google Desktop by accident a while ago. I'll paste it below as you might get something out of it too.

My talk went well today; an audience of 250 or so. Not too many fainted when I said, "Roughly speaking, a Bayesian is someone who believes there cannot be probabilities without gamblers."

04-06-05 *Quantum Bayesians & Anti-Bayesians* (to all BBQWers)

Thank you all once again for planning to participate in our upcoming meeting Being Bayesian in a Quantum World, Konstanz, 1–5 August 2005. It's going to be a great time, and I think we're going to get a lot done.

With that in mind, it's time to start planning the talks. There is now a conference webpage set up at

`http://web.archive.org/web/20090511060206/http://`
`www.uni-konstanz.de/ppm/events/bbqw2005/`

and there, along with various pieces of practical information, you can catch a glimpse of your fellow participants and some suggested research topics and questions. (However, please do keep the webpage private at the moment, making no links to it, etc., as certain issues with our funding agencies must be settled before we can go public. Nevertheless, the webpage is already there for your use.)

The final number of participants at the meeting is 47, and we think we have struck a good balance of Bayesian pro and con, physicist and philosopher, introvert and extrovert, and so on. From this group, ideally we'd like to have about 20–22 speakers—enough to give some focus to the meeting, but not so many as to make all our heads swim. In fact, the plan is to follow the method of the Seven Pines meetings that some of you have participated in before: Each day there will be four talks, two in the morning and two in the afternoon. The talks will be 45 minutes each, and following each pair, there will be a coffee break and then an extended roundtable discussion (45 minutes to 1 hour) to further explore the topic at hand. There may be one evening session to help compensate for an afternoon off. The organizers will try to pair up the talks so that they complement one another and make for an even discussion afterward.

With that in mind, we'd like to start asking for volunteer speakers. If you would like to speak, please send me a tentative title and enough of an abstract that the organizers can get a feel for the content of your proposed talk. If there are too few volunteers, you can count on us to do some arm-twisting and guilt-tripping until we get what we want. If there are too many—the much preferred option—we will have to make some tough decisions, excising overlap, etc. In any case, it is expected that all participants will have a significant impact on each other, either through their lively exchanges at the roundtables or via their good-hearted debate over a beer or three.

Please let us know your thoughts as soon as possible. It'll be great to hear from each of you.

04-06-05 *Being Bayesian in a Quantum World* (to A. Cho)

I don't know if I ever told you how much I enjoyed the article you wrote for Science covering the discussions at the Seven Pines meeting last year. I mailed it to all my relatives saying, "Quail and pheasant? I thought it was chicken." But, particularly, I loved the napkin you pictured that showed a figure from my lecture in it!

Anyway, I'm writing you to see if you might be interested in repeating the experience in Konstanz, Germany this summer? I and a few others have organized what I think is a very nice meeting on information theoretic views of the quantum state—i.e., views centering around the view of the quantum state you depicted in that napkin. If you were interested in attending to cover the meeting, you would certainly be welcome!

To try to whet your appetite, I'll place the original conference announcement below. Also, you can have a look at our "secret" website (we haven't gone public yet) to see the final list of speakers, the conference program, the talk topics, etc. I think you'll note that we have some of the best of the best in quantum information and computing there—you'll have to take my word for it if you don't know the field—but in any case you'll probably at least know some of the more famous names (like Milburn, Unruh, Mermin, Nielsen).

Anyway, if you're interested, please do come. I think it is fair to say you would not be bored! Just let me know as soon as possible if you would like to come, so that we can make sure that there is still room at the conference hotel if you're interested.

04-06-05 *BBQW Sauce* (to H. M. Wiseman)

No, I'm just going to have to drop out of the Sydney workshop: I'm way overbooked, I've realized. I intend to write Huw about this in the next few hours. (I'm in Miami, making my way to Stockholm; plenty of email time.)

Anyway, to answer your question: See the mass mailing I just sent out.

Concerning Delirium Quantum, I'll post it soon … especially if you send me one more note nudging me in that direction. I wish you were going to be at this meeting in Sweden: I'm going to unveil the story of two islands (and its impact on the quantum Bayesian view): The Island of Nurturing Wives and the Island of Bad Girlfriends. (There is an alternative universe where the two islands are the Island of Supportive Husbands and the Island of Annoying Boyfriends. I'll be sure to mention both universes.) Anyway, I think you would find it efficacious, and I would value your feedback. Too bad.

In a hurry …

05-06-05 *MaxEnt 2005 Invitation, 2* (to K. H. Knuth)

I am so sorry I am running almost a month behind on replying to your email!

Please title my talk "Being Bayesian in a Quantum World" and maybe use the two paragraphs below as my abstract. I hope it is not too long, but now that I've spent a while working on it, I rather like it.

I hope to be able to drop this email off in London, on my way to Sweden. At the moment, I'm somewhere over the Atlantic.

> Abstract:
>
> To be Bayesian about probability theory is to accept that probabilities represent subjective degrees of belief and nothing more. This is in distinction to the idea that probabilities represent long-term frequencies or objective propensities. But, how can a subjective account of probabilities coexist with the existence of quantum mechanics? To accept quantum mechanics is to accept the calculational apparatus of quantum states and the Born rule for determining probabilities in a quantum measurement. If there were ever a place for probabilities to be objective, one might think it precisely here! (And many do.) This raises the question of whether Bayesianism and quantum mechanics are compatible at all. For the Bayesian, it only suggests that we should rethink what quantum mechanics is actually about. Is it "law of nature" or really more "law of thought," though "law of thought" conditioned by the particularities of our world?
>
> From transistors to lasers, the evidence abounds that we live in a quantum world. However, one should not confuse the quantum WORLD with quantum THEORY. In particular, one should not jump to the conclusion that wave functions are as successful as calculational tools as they are because they mirror some kind of elements of reality. A more Bayesian-like perspective is that if wave functions generate probabilities, then they too must be Bayesian degrees of belief, with all that such a radical idea entails. In particular, quantum probabilities have no firmer hold on reality than the word "belief" in the phrase "degrees of belief" already indicates. From this perspective, the only sense in which the quantum formalism mirrors nature is through the normative constraints it places on gambling agents who wish to better navigate through this (quantum) world in which they are immersed. It might be thought that this is rather thin information about nature itself—and thus that the whole view collapses into a kind operationalism or positivism—but the information is not insubstantial! To the extent that an agent should use quantum mechanics for his uncertainty accounting rather than some other theory tells us something about the world itself—i.e., the world independent of the agent and his particular beliefs at any moment. In this talk, I will try to shore up these ideas by showing what quantum mechanics looks like when represented using probability simplexes rather than Hilbert spaces. It can be done, and when done, one starts to get a feeling for how little quantum theory deviates from Bayesianism after all.

08-06-05 *Classical No-Cloning* (to J.-Å Larsson)

The '96 paper with the basic point was actually written first, but posted later.

09-06-05 *The Bell Quote* (to M. O. Scully)

What was that God, Buddha, Bell quote you challenged me to find? If you give it to me again, I'll bet decent odds I find it.

Marlan's Reply

> Bell said something like:
>
> > "What if all this led us to the existence of God or Buddha; wouldn't that be very, very interesting?"
>
> If you can find anything like that I would be grateful (and surprised).
>
> Concerning your book and Pauli—does the connection with Pauli have to do with his ideas on the objective and mystical as complementary (Bohr) opposites?

10-06-05 *Film (!) from 1927 Solvay Conference, on Web* (to H. Barnum)

Barnumism 11: *A good friend of mine, Alex Wilce (Univ. of Susquehana, Mathematics) shared the following link with me; the site has short home-movie film clips from the 1927 Solvay Conference:*

`https://www.youtube.com/watch?v=8GZdZUouzBY`

Here's the description from the website:

> *Following is a "home movie" shot by Irving Langmuir, (the 1932 Nobel Prize winner in chemistry). It captures 2 minutes of an intermission in the proceedings. Twenty-one of the 29 attendees are on the film. The film opens with quick shots of Erwin Schrödinger and Niels Bohr. Auguste Piccard of the University of Brussels follows and then the camera re-focuses on Schrödinger and Bohr.*

That is really great! It cheered me up in this annoyingly delayed-flight time while I twiddle my thumbs in the American Airlines club.

13-06-05 *Wonderful Meeting* (to A. Y. Khrennikov & C. Eriksson)

Now that I'm home (... though I am just about to turn around to go to Europe again, for the J. T. Lewis Memorial Meeting), I wanted thank you both for a very fine meeting. I got lots of ideas at this one, and think it's rejuvenated my research—I have not felt this good in a long time. You guys are performing a valuable, valuable service to the physics community.

19-06-05 *Philosopher's Stone* (to G. L. Comer)

[...] The week turned out to be quite productive, and ideas started flowing.

The main thing on my mind has been viewing the quantum measurement process as a kind of modern version of alchemy. I guess I've been talking about this on and off for several years now, having been exposed to the analogy through Pauli's letters to Jung and Fierz, but the transformation in Sweden was that the stuff really got into my way of thinking, and I could start to see how to formalize it. I'm toying with the idea of writing a paper titled, "The Consequences of Our Interventions," to try to redo my paper with Asher "Quantum Theory Needs No Interpretation" from this new perspective. In that paper, we had written,

> The thread common to all the nonstandard "interpretations" is the desire to create a new theory with features that correspond to some reality independent of our potential experiments. But, trying to fulfill a classical worldview by encumbering quantum mechanics with hidden variables, multiple worlds, consistency rules, or spontaneous collapse, without any improvement in its predictive power, only gives the illusion of a better understanding. Contrary to those desires, quantum theory does *not* describe physical reality. What it does is provide an algorithm for computing *probabilities* for the macroscopic events ("detector clicks") that are the consequences of our experimental interventions. This strict definition of the scope of quantum theory is the only interpretation ever needed, whether by experimenters or theorists.

First off, I wish I had never said, "quantum theory does not describe physical reality"—I really only meant "the wave function does not describe reality" and should have stuck with that formulation. But more importantly, what precisely are these "consequences of our interventions"? From the wording we used, one surely gets the impression that, whatever they are—we said "detector clicks," but what a glib phrase!—they somehow live outside of the agent performing the experiment. And I guess that's what I thought at the time.

Now I'm quite internal about it all; those "consequences" really live in the agent himself, not in the quantum system or even in some "detached" measurement device. And I think I now have a clear enough formulation of the idea that I ought to go public with it.

Quantum THEORY (I emphasize theory to draw a distinction between quantum theory and the quantum world, i.e., that stuff outside of us which is independent of the agent) is predominantly about the changes we bring about within ourselves by interacting with the external world. Very little of quantum theory is about the external world itself. Particularly, the clicks are not "out there," but rather "in here."

I've been scouring the Pauli quotes I have in my computer to see exactly where I got these ideas from, and so far I haven't read nearly as forceful of a version of it as I seem to remember—so I'm pretty sure I still haven't quite found the right passage. The only thing that comes close, so far, is this passage from Pauli's article on Kepler:

> Now, there is a basic difference between the observers, or instruments of observation, which must be taken into consideration by modern microphysics, and the detached observer of classical physics. By the latter I mean one who is not necessarily without effect on the system observed but whose influence can always be eliminated by determinable corrections. In microphysics, however, the natural laws are of such a kind that every bit of knowledge gained from a measurement must be paid for by the loss of other, complementary items of knowledge. Every observation, therefore, interferes on an indeterminable scale both with the instruments of observation and with the system observed

and interrupts the causal connection of the phenomena preceding it with those following it. This uncontrollable interaction between observer and system observed, taking place in every process of measurement, invalidates the deterministic conception of the phenomena assumed in classical physics: the series of events taking place according to pre-determined rules is interrupted, after a free choice has been made by the beholder between mutually exclusive experimental arrangements, by the selective observation which, as an essentially non-automatic occurrence (Geschehen), may be compared to a creation in the microcosm or even to a transmutation (Wandlung) the results of which are, however, unpredictable and beyond human control.

> In this way the role of the observer in modern physics is satisfactorily accounted for. The reaction of the knowledge gained on the gainer of that knowledge (Erkennenden) gives rise, however, to a situation transcending natural science, since it is necessary for the sake of the completeness of the experience connected therewith that it should have an obligatory force for the researcher (für den Erkennenden verbindlich). We have seen how not only alchemy but the heliocentric idea furnishes an instructive example of the problem as to how the process of knowing is connected with the religious experience of transmutation undergone by him who acquires knowledge (Wandlungserlebnis des Erkennenden). This connection can only be comprehended through symbols which both imaginatively express the emotional aspect of the experience and stand in vital relationship to the sum total of contemporary knowledge and the actual process of cognition. Just because in our times the possibility of such symbolism has become an alien idea, it may be considered especially interesting to examine another age to which the concepts of what is now called classical scientific mechanics were foreign but which permits us to prove the existence of a symbol that had, simultaneously, a religious and a scientific function.

Or maybe I picked it up from this passage in Heisenberg's article, "Wolfgang Pauli's Philosophical Outlook,"

> The elaboration of Plato's thought had led, in neo-Platonism and Christianity, to a position where matter was characterized as void of Ideas. Hence, since the intelligible was identical with the good, matter was identified as evil. But in the new science the world-soul was finally replaced by the abstract mathematical law of nature. Against this one-sidedly spiritualizing tendency the alchemistical philosophy, championed here by Fludd, represents a certain counterpoise. In the alchemistic view "there dwells in matter a spirit awaiting release. The alchemist in his laboratory is constantly involved in nature's course, in such wise that the real or supposed chemical reactions in the retort are mystically identified with the psychic processes in himself, and are called by the same names. The release of the substance by the man who transmutes it, which culminates in the production of the philosopher's stone, is seen by the alchemist, in light of the mystical correspondence of macrocosmos and microcosmos, as identical with the saving transformation of the man by the work, which succeeds only 'Deo concedente.'" The governing symbol for this magical view of nature is the quaternary number, the so-called "tetractys" of the Pythagoreans, which is put together out of two polarities. The division is correlated with the dark side of the world (matter, the Devil), and the magical view of nature also embraces this dark region.

Or finally, maybe from this letter from Pauli to Fierz:

> All of this then led me onto further, somewhat more phantastic [*sic*] paths of thought. It might very well be that we do not treat matter, for example viewed in the sense of *life*, "properly" if we observe it as we do in quantum mechanics, *specifically when doing so in complete ignorance of the inner state of the "observer."*
>
> It appears to me to be the case that the "after-effects" of observation which were ignored would *still* enter into the picture (as atomic bombs, general anxiety, "the Oppenheimer case" e.g. etc.), but in an *unwanted form*. The well-known "incompleteness" of quantum mechanics (Einstein) is certainly an existent fact somehow-somewhere, but certainly cannot be removed by reverting to classical field physics (that is only a "neurotic misunderstanding" of Einstein), it has much more to do with *integral relationships between "inside" and "outside" which the natural science of today does not contain* (but which alchemy had suspected and which can also be detected in the symbolics of my dreams, about which I believe them specifically to be characteristic for a contemporary physicist).
>
> With these vague courses of thought I have reached the border of that which is recognizable today, and I have even approached "magic." (From this standpoint observation in quantum mechanics might even appear to someone as a "black mass" after which the "ill-treated" matter manipulates its counter-effect against the "observer," thereby "taking its revenge," as a "shot being released from behind"). On this point I realize well that this amounts to the threatening danger of a regression into the most primitive superstition, that this would be much worse than Einstein's regressive remaining tied to classical field physics and that everything is a matter of holding onto the positive results and values of the *ratio*.

Still I have the nagging feeling that there is something much better if I could just dig it up.

Anyway, the way I view quantum measurement now is this. When one performs a "measurement" on a system, all one is really doing is taking an ACTION on that system. From this view, time evolutions or unitary operations etc., are not actions that one can take on a system; only "measurements" are. Thus the word measurement is really a misnomer—it is only an action. In contradistinction to the old idea that a measurement is a query of nature, or a way of gathering information or knowledge about nature, from this view it is just an action on something external—it is a kick of sorts. The "measurement device" should be thought of as being like a prosthetic hand for the agent—it is merely an extension of him; in this context, it should not be thought of as an independent entity beyond the agent. What quantum theory tells us is that the formal structure of all our possible actions (perhaps via the help of these prosthetic hands) is captured by the idea of a Positive-Operator-Valued Measure (or POVM, or so-called "generalized measurement"). We take our actions upon a system, and in return, the system gives rise to a reaction—in older terms, that is the "measurement outcome"—but the reaction is in the agent himself. The role of the quantum system is thus more like that of the philosopher's stone; it is the catalyst that brings about a transformation (or transmutation) of the agent.

Reciprocally, there should be a transmutation of the system external to the agent. But the great trouble in quantum interpretation—I now think—is that we have been too inclined to jump the gun all these years: We have been misidentifying where the transmutation indicated by quantum mechanics (i.e., the one which quantum theory actually talks about, the "measurement outcome") takes place. It should be the case that there are also transmutations in the external world (transmutations in the system) in each quantum "measurement", BUT that is not what quantum theory is about. It is only a hint of that more interesting transmutation. And, as you know, somehow out of all this I think of the agent and the observer as being, together, involved in a little act of creation that ultimately has an autonomy of its own—that's the sexual interpretation of quantum mechanics. (However the ideas in that last sentence are a little murkier than what I'm trying to get at now.)

Does "measurement" in this new sense explicitly require consciousness (whatever that is)? I don't think so. But it does require some kind of nonreductive element—some kind of higher-level description that cannot be reduced to a lower-level one. Here's the way I've been putting it in my last three lectures, when talking more particularly about quantum mechanics from the Bayesian perspective. I point out that a Bayesian is, roughly speaking, someone who believes that without gamblers, there cannot be probabilities. Probabilities are not external to gamblers. Then someone always asks, must you have consciousness to have probabilities? And I say, "No." Take as an example my laptop computer loaded with a Bayesian spam filter. It is a perfectly good gambler in the Bayesian sense, but I think most people would be hard-pressed to call it conscious. Similarly, I think we're going to ultimately learn an analogous lesson about all this transformation/transmutation/creation/measurement business.

On the other hand, I do find myself being tickled toward a more Whiteheadian-like view that, whatever this higher-level description is, every piece of nature has more or less of it, from people all the way to stones and atoms. It's just that you have to be on the inside of the philosopher's stone to see it.

30-06-05 *Wittgensteinian Arm Twisting* (to H. Price)

One of the people I was really hoping would volunteer to talk at Konstanz was you! Since, however, I haven't heard anything from you, maybe it's time to do a little arm-twisting. Particularly, I wonder if I could entice you to give a talk that shuffles around in some way or other, or gives an introduction to, Wittgenstein's book *On Certainty*? As I recall, you'll be going to the Wittgenstein symposium the very next week, so he'll certainly already be on your mind. This aspect of his thought may not be on your mind for *that* meeting, but without doubt you'll be the closest we have to an expert on the subject at *this* meeting!

Still more particularly, I would love some sort of discussion to build up about the ties (or contradictions) between Wittgenstein's notion of certainty and the radical Bayesian notion of certainty (à la de Finetti and Richard Jeffrey)—i.e., that even "certainty" is a state of mind, just like a 50/50 assignment (or any other one, for that matter). (Compare how Wittgenstein says certainty is a "tone of voice".)

If you'd take the task, I'd be forever grateful. And I can supply you with relevant passages in Jeffrey's writings and even some of our debate with Mermin to give you something of a foil to work against, if you'd like.

It'd be really great to have a discussion of this subject, and there's no doubt you'd be the right man to lead it.

Huw's Reply

> I'm afraid there's no way I could talk about *On Certainty*. I'm not much of a Wittgenstein scholar in any case, and what little I do know (certainly) doesn't include anything about *On Certainty* (I've been invited to the Kichberg meeting as an expert on the arrow of time, not Wittgenstein!) Sorry!

30-06-05 *Flattered* (to A. Duwell)

I'm flattered by your abstract! A couple of typos though that maybe you can fix:

> **Sorting the objective from the subjective: remarks on Fuchs**
>
> Chris Fuchs seeks to identify the features of quantum theory that reflect the structure of the world and are not artifacts of the quantum formalism. To this end, Fuchs advocates attempting to interpret as many elements of quantum mechanics as reflective of subjective beliefs about quantum systems [as possible??]. The elements of the theory that resist this subjective interpretation are thereby candidates for reflecting elements of reality. The obvious problem with this methodology is that just because one can interpret an element of a theory subjectively, doesn't mean one ought to interpret it subjectively. In this paper I advocate the use of eliminative or demonstrative induction as a partial solution to the problem of sorting subjective from objective elements of theories. I discuss the application of this method to quantum theory and the limitations of the [what comes here??]

30-06-05 *Konstanz Talk?* (to J. B. M. Uffink)

You were one of the guys I was really hoping to hear from regarding a talk at the BBQW meeting in Konstanz, but I haven't heard anything from you! If you'd take the task we'd certainly be delighted! Particularly, even something like the talk you gave at LSE last year could be very useful. Might we entice you to give your thoughts on anything around the subject matter—it could be pro or con, it doesn't matter—I just want to get a lively discussion going. Or if you wanted to use this as an opportunity to formalize your thoughts on Everettian attempts to derive the quantum probability rule that could be very useful too. Whatever. The main thing is, it'd be great to see your clarity of thought in action with respect to this cluster of ideas.

Please let me know as soon as possible whether you think you could give us a talk, or whether you're definitely going to decline (despite my heartfelt plea!).

30-06-05 *A BBQW Talk?* (to A. Hagar)

Since I haven't heard back from you following my call for "volunteers", I wonder if we might entice you to submit a talk proposal for the BBQW meeting? Particularly, if you still think the BBQW way is "doing quantum mechanics in the dark" it'd be great if you'd organize your ideas on the subject afresh and give us a presentation. It could be a lively discussion point. If you have a tentative title and abstract, it'd be great to throw it in the pot of possibilities. We'll probably be making our talk decisions by the end of next week.

30-06-05 *New Delirium* (to H. M. Wiseman)

I'm sorry: I've been very slow to reply to your proposal for a talk at BBQW. I think it sounds great, and almost surely we'll pick it from the pool of potential talks. We'll let everyone know the final verdict next week (but as I say, you might as well start planning your talk now).

I like the phrase in your abstract, "... accepting that quantum mechanics is incomplete" because if you nuance it enough, and take out the idea of hidden variables, I'd even agree with it. Thus, thinking about that, I decided to extend Delirium Quantum a little with two more excerpts before posting it for you. Particularly, the new Sections 6 and 7 might give you a way of thinking "quantum mechanics is incomplete" in a way that you haven't thought before. I'll attach the new version. [See "Delirium Quantum" `arXiv:0906.1968v1`.]

Looking much forward to this meeting and sparring with you there.

01-07-05 *Bell, Buddha, Pauli* (to M. O. Scully)

Thanks for the Bell phrase to be on the lookout for. I'll keep my eyes peeled, and if I find something I'll let you know.

Scullyism 1 : *Concerning your book and Pauli—does the connection with Pauli have to do with his ideas on the objective and mystical as complementary (Bohr) opposites?*

My original interest in Pauli had more to do with a point he made over and over about how A) the quantum mechanical observer takes *part* in a little act of creation with each quantum measurement (very John Wheelerian also), yet B) there remains a kind of objective reality within the quantum description in that the observer cannot control the outcome of that creation. The observer is participatory, but not overpowering. Here it is, in one version, in Pauli's own words:

> In the new pattern of thought we do not assume any longer the detached observer, occurring in the idealizations of this classical type of theory, but an observer who by his indeterminable effects creates a new situation, theoretically described as a new state of the observed system. In this way every observation is a singling out of a particular factual result, here and now, from the theoretical possibilities, thereby making obvious the discontinuous aspect of the physical phenomena.
>
> Nevertheless, there remains still in the new kind of theory an objective reality, inasmuch as these theories deny any possibility for the observer to influence the results of a measurement, once the experimental arrangement is chosen.
>
> Like an ultimate fact without any cause, the individual outcome of a measurement is, however, in general not comprehended by laws. This must necessarily be the case . . .

It's the conjunction of all that that I call "the Paulian idea" (and thus the title of my book, which is really an elaboration of those ideas). The part after the "Nevertheless" is particularly important.

However, I am aware of the complementarity you mention, though with Pauli it was more precisely a complementarity between "physical" and "psychic" or "psychological". He devoted a lot of discussion with his assistant Markus Fierz and with the psychologist Carl Jung to try to flesh out a "neutral language" that would somehow be able to drop the distinction between "physical" and "psychic". I'll give you an example of the sort of stuff he was up to, by pasting in a letter that Pauli had written to Jung below. I've got a lot of material like that in my upcoming posting to `quant-ph`, "The Activating Observer: Resource Material for a Paulian-Wheelerish Conception of Nature."

Anyway, that sort of idea is starting to intrigue me more now than it used to. Another interesting fellow to read along those lines is William James, the great American pragmatist.

I'll look for the Bell quote.

Letter from Pauli to Jung, 31 March 1953:

The labeling of ideas as either of spiritual origin or physical (or physiological) origin and your corresponding definition of physics as a science of ideas of the second kind has revived memories of my youth.

Among my books, there is a somewhat dusty case containing a Jugendstil silver goblet, and in this goblet there is a card. A gentle, benevolent, and cheerful spirit from days of yore seems to be issuing forth from this goblet. I can see him shaking your hand in a friendly way, welcoming your definition of physics as a pleasing, albeit somewhat belated, indication of your insight and understanding; he goes on to add how suitable the labels are for his laboratory, and expresses his satisfaction at the fact that metaphysical judgments in general (as he was wont to say) "have been relegated into the realm of the shadows of a primitive form of animism." This goblet is a baptism goblet, and on the card it says in an old-fashioned ornate script: "Dr. E. Mach, Professor at the University of Vienna." It so happened that my father was very friendly with his family, and at the time totally under his influence mentally, and he (Mach) kindly agreed to take on the role of my godfather. He must have had a much stronger personality than the Catholic priest, with the apparent result that I was thus baptized in an antimetaphysical manner rather than in a Catholic one. Be that as it may, the card remains in the goblet, and despite all the great mental changes I went through later on, it remains a label that I myself bear—namely: "of antimetaphysical origin." And in fact, to put it in a somewhat simplistic way, Mach regarded metaphysics as the root of all evilin this world—in other words, in psychological terms, as the Devil himself—and that goblet with the card remained as a symbol of the *aqua permanens* that keeps evil metaphysical spirits at bay.

I do not need to describe Ernst Mach more closely, for if you look at your own description of the extroverted sensation type, then you will see E. Mach. He was a master at experimentation, and his apartment was crammed full of prisms, spectroscopes, stroboscopes, electrostatic machines, and the like. Whenever I visited him, he always showed me some neat experiment, already completed, partly so as to eliminate unreliable thinking, with the ensuing illusions and errors, and partly to support it and correct it. Working on the assumption that his psychology was a universal one, he recommended everyone to use that inferior auxiliary function as "economically" as possible (thought economy). His own thought processes closely followed the impressions of his senses, tools, and apparatus.

This letter is not meant to be a history of physics, nor the classical case of type opposites: E. Mach and L. Boltzmann, the thinking type.[81] I last saw Mach just before the First World War, and he died in 1916 in a country house near Munich.

What is interesting in connection with your letter is Mach's attempt to fall back on psychic facts and circumstances (sensory data, ideas) within the realm of physics as well and especially to eliminate as far as possible the concept of "matter." He regarded this "auxiliary concept" as grossly overrated by philosophers and physicists and viewed it as a source of "pseudo problems." His definition of physics basically coincided with

[81] I should like to recount an anecdote here because I am sure you will really enjoy it. Mach, who was by no means prudish and was most interested in all the intellectual trends of the day, once pronounced judgment on the psychoanalysis of Freud and his school. He said: "These people try to use the vagina as if it were a telescope so that they can see the world through it. But that is not its natural function—it is too narrow for that." For a while this became a popular quotation at the University of Vienna. It is very typical of Mach's *instrumental* way of thinking. For him, psychoanalysis immediately conjures up the vividly concrete image of the wrongly applied instrument: namely, the female organ where it does not belong.

the one proposed by you, and he never failed to stress that physics, physiology, and psychology were "only different in the lines of investigation they took, not in the actual object," the object in all cases being the constant psychic "elements" (he exaggerated their simplicity somewhat, for in reality they are always very complex). I was surprised that despite your sweeping criticism of what later came to be called *"Positivism"* (Mach used this term a great deal), there are nevertheless also fundamental similarities between you and this line of thought: In both cases there is the *deliberate elimination of thought processes.* And of course there is nothing at all wrong with these labels for ideas and the corresponding definition of physics, especially as it accords perfectly with the idealistic philosophy of Schopenhauer, who consciously uses "Idea" and "Object" synonymously. But it all depends on *how one proceeds.* What Mach wanted, although it could not be carried out, was the total elimination of everything from the interpretation of nature that is "*not* ascertainable *hic et nunc.*" But then one soon sees that one does not understand anything—neither the fact that one has to assign a psyche to others (only one's own being ascertainable) nor the fact that different people are all talking about the same (physical) object (the "windowless monads" in Leibniz). Thus, in order to meet the requirements of both instinct and reason, one has to introduce some *structural elements of cosmic order*, which "in themselves are not ascertainable." It seems to me that with you this role is mainly taken over by the archetypes.

It is right that what one does or does not call "metaphysics" is, to a certain extent, a matter of taste. And yet I agree with you totally that in practical terms, great value is to be attached to the demand that metaphysical judgments be avoided. What is meant by that is that the "not in themselves ascertainable" factors (concepts) that have been introduced do not completely escape the controlling, checking mechanism of experience, and that *no more of them may be introduced than is absolutely necessary*: They serve the purpose of *making statements about the possibility of ascertainments hic et nunc.* This was the sense in which the concept of "possibility" was meant, and it was in this sense that I called such concepts *"symbolic things in themselves"* and the *"rational aspect of reality."* As you rightly point out, *there is absolutely no need to make statements of Being in the metaphysical sense about these "things in themselves."* In the natural sciences, one makes the *pragmatic statement of usefulness* about them (in order to understand the ordering system of the ascertainable); in mathematics there is just the *formal logical statement of consistency.* In psychology, those "not in themselves ascertainable" concepts include, the unconscious and the archetypes, and in atomic physics, they include the totality of the characteristics of an atomic system that are *not all simultaneously* "ascertainable *hic et nunc.*"

In my last letter, I referred to that which is actually "ascertained *hic et nunc*" as "concrete phenomenon" and the "irrational aspect of reality." It is always present in the psyche of an observer, whatever the "label of origin" might be. At this point, however, the question arises of whether the description "psychic" or the term "psyche" can go *further* than the "ascertainable *hic et nunc.*" I am inclined to reply to this question in the negative and to take the "not in themselves ascertainable" structures, which are introduced as conceptual indications of possibilities of the ascertainable, and give them the definition *"neutral"* and *not the definition "psychic."*

To me, this view also seems to be supported by Plato's expressions *meson* (middle) and *tritoneidos* (third form), which both meet my requirements for "neutrality" (=middle position), nay, actually seem to *emphasize* it. Plato certainly had the word "psyche" at his disposal, and if he opts to use a different word instead, then it must be one with a deeper meaning, one that calls for careful consideration. For me, this deeper meaning lies in the need to make a clear distinction between the experience of the individual, which exists in his psyche as something ascertainable *hic et nunc*, and the general concepts, which, "nonbeing ascertainable in themselves," are suitable for taking up a middle position. Your *identification of psyche = tritoneidos* thus seems to me a *retrograde step*, a loss in terms of conceptual differentiation.

With my call for "neutral" general concepts, I find myself in agreement with your article "The Spirit of Psychology," which struck me as fundamental, especially when you say: "The archetypes have ... a nature which one cannot definitely describe as psychic. Although by the application of purely psychological considerations I, have come to question the solely psychic nature of the archetypes, etc." I feel that you should certainly *take these doubts seriously and not once again* make too much of the *psychic factor*. When you say that "the psyche is partly of a material nature,"[82] then for me as a physicist this takes on the form of a metaphysical statement. I prefer to say that psyche and matter are governed by common, neutral, "not in themselves ascertainable" ordering principles. (Unlike the psychologist, the physicist has no problem, for example, with saying "the U field" instead of "the unconscious," which would thus establish the "neutrality" of the concept.)

But I wish to make it quite clear that my hope that you might agree with this general point of view is based on the impression that some of the *pressure needs to be removed* from your analytical psychology. The impression I have is of a vehicle whose engine is running with overloaded valves (expansion tendency of the concept "psyche"); that is why I should like to relieve some of the pressure and let off steam. (I shall come back to this later on p. 10 below).

I would also hope that a clarification of the scope of the concept of the psyche might include your *de iure* recognition of the fact that the heart is not just a psychological symbol but also a conception labeled "of physical origin." Economy with the inferior function on the lines of E. Mach often serves to fulfill a function, even if it is not actually that of thinking!

07-07-05 *Hook or Crook* (to K. H. Knuth)

OK, I booked some flights now. But I had to get tricky to trim the price down. The way I did it was to book TWO separate tickets: One roundtrip between Munich and Brussels, and one roundtrip between Brussels in San Jose. [...]

Here's the schedule: [...]

Another request: I know there are going to be a lot of pressures on you by being the organizer of this meeting, but might you be able to find some time August 10 to give me a private rendition of the tutorial "Probability and Entropy: Statements and Questions," you're giving the first day. Or at least a gentle introduction to your work on the logic of questions? I'd like very much to use this opportunity to get those ideas pumped into my head.

I think that's it for now. I'll try my best to give you guys a rousing talk. At these travel prices, I certainly won't be giving you your money's worth, but I'll try my best to inspire the young ones that there is a wide-open research field out there for being Bayesian in a quantum world.

[82] Your letter, p. 6. This statement seems to me alarmingly close to the definitely *meaningless* statement that "everything is psychic"! For "psychic" to acquire any meaning, there must also be something nonpsychic involved, and this is where the "not in itself ascertainable" seems to me suitably *neutral*.

Just because you're Bayesian, it doesn't mean you have to believe in hidden variables underneath quantum mechanics: The world is way more interesting than that.

08-07-05 `Your Touch, My Touch` (to M. S. Leifer)

Concerning:

Leiferism 1 : *The main point is that it is not necessary to include "mental readjustment" unitaries in a world that only includes a single agent. They are only required if a measurement is made by a second agent who has incompatible information. To summarize, I would consider replacing your motto "quantum mechanics describes a world that is sensitive to our touch" by "QM describes a world in which my information is sensitive to your touch, your information is sensitive to my touch, but my information isn't necessarily sensitive to my touch and yours isn't necessarily sensitive to your touch." (less catchy I know).*

But as you say, more accurate.

Anyway, this sounds strongly akin to something I once wrote in the introduction to `quant-ph/0009101` (a paper with Kurt Jacobs). Read that intro—as you get a chance!—and tell me whether that meshes with your motto. Particularly, note the stuff that starts up at the passage:

> Note the two ingredients that appear in this formulation. First, the information gathering or measurement is grounded with respect to one observer (in this case, the eavesdropper), while the disturbance is grounded with respect to another (here, the sender). In particular, the disturbance is a disturbance to the sender's previous information-this is measured by his diminished ability to predict the outcomes of certain measurements the legitimate receiver might perform. No hint of any variable intrinsic to the system is made use of in this formulation.

Don't forget the footnotes.

Speaking of mottos, since I still haven't written that note about the Växjö insight, let me try to put it in a single sentence. The extra unitary captures the agent's *judgment* of how he should conditionalize believing what he does about how he interacts with the "measured" system. The unitary is literally about the extent he judges he should reject Goldstein conditionalization. We know from Richard Jeffrey's remarks that even the method of updating is a judgment (that's why he mentions in one of those papers even wilder things than Goldstein). That's the idea anyway—that diachronic coherence relies itself on a prior judgment—and I'd like to see if that can be made precise (and applicable to the quantum case).

08-07-05 *The Bell Quote, at your request* (to M. O. Scully)

It took some devious ways, but I found it. Here's the part you were most interested in:

> Suppose for example that quantum mechanics were found to resist precise formulation. Suppose that when formulation beyond FAPP is attempted, we find an unmovable finger obstinately pointing outside the subject, to the mind of the observer, to the Hindu scriptures, to God, or even only Gravitation? Would not that be very, very interesting?

It's probably best, however, to look at the extended quote below to get a more complete sense of what he was getting at. I'll place the extended quote at the end of this note.

The source is Bell's article: J. S. Bell, "Against 'Measurement'," Physics World 3, pp. 33–40 (1990).

I believe the advertised reward for finding this stuff was \$100? Maybe I have the exact number wrong. In any case, I'd be happier to take a faculty appointment at Princeton instead.

Extended Bell Quote:

SURELY, after 62 years, we should have an exact formulation of some serious part of quantum mechanics? By 'exact' I do not of course mean 'exactly true'. I mean only that the theory should be fully formulated in mathematical terms, with nothing left to the discretion of the theoretical physicist ... until workable approximations are needed in applications. By 'serious' I mean that some substantial fragment of physics should be covered. Nonrelativistic 'particle' quantum mechanics, perhaps with the inclusion of the electromagnetic field and a cut-off interaction, is serious enough. For it covers 'a large part of physics and the whole of chemistry' (P A M Dirac 1929 Proc. R. Soc. A **123** 714). I mean too, by 'serious', that 'apparatus' should not be separated off from the rest of the world into black boxes, as if it were not made of atoms and not ruled by quantum mechanics. ...

[Dirac] divided the difficulties of quantum mechanics into two classes, those of the first class and those of the second. The first-class difficulties concerned the role of the 'observer', 'measurement', and so on. Dirac thought that these problems were not ripe for solution, and should be left for later. He expected developments in the theory which would make these problems look quite different. It would be a waste of effort to worry overmuch about them now, especially since we get along very well in practice without solving them.

Dirac gives at least this much comfort to those who are troubled by these questions: he sees that they exist and are difficult. Many other distinguished physicists do not. ...

I agree with ["the most sure-footed of quantum physicists"] about [this]: ORDINARY QUANTUM MECHANICS (as far as I know) IS JUST FINE FOR ALL PRACTICAL PURPOSES.

Even when I begin by insisting on this myself, and in capital letters, it is likely to be insisted on repeatedly in the course of the discussion. So it is convenient to have an abbreviation for the last phrase: FOR ALL PRACTICAL PURPOSES = FAPP.

I can imagine a practical geometer, say an architect, being impatient with Euclid's fifth postulate, or Playfair's axiom: of course in a plane, through a given point, you can draw only one straight line parallel to a given straight line, at least FAPP. The reasoning of such a natural geometer might not aim at pedantic precision, and new assertions, known in the bones to be right, even if neither among the originally stated assumptions nor derived from them as theorems, might come in at any stage. Perhaps these particular lines in the argument should, in a systematic presentation, be distinguished by this label — FAPP — and the conclusions likewise: QED FAPP.

I expect that mathematicians have classified such fuzzy logics. Certainly they have been much used by physicists. But is there not something to be said for the approach of Euclid? Even now that we know that Euclidean geometry is (in some sense) not quite true? Is it not good to know what follows from what, even if it is not really necessary FAPP? Suppose for example that quantum mechanics were found to resist precise formulation. Suppose that when formulation beyond FAPP is attempted, we find an unmovable finger obstinately pointing outside the subject, to the mind of the observer, to the Hindu scriptures, to God, or even only Gravitation? Would not that be very, very interesting?

Marlan's Reply

Very impressive—well done!

A 200$ check "in the mail". How about coming down to Princeton next week for lunch?

14-07-05 `hput diracqphsub.tex` (to H. Barnum)

Barnumism 12: *Make sure you mention to your boss that the paper primarily concerns states that as far as we know, aren't physical!*

I think he's already well aware that almost everything I do is unphysical . . . by his standards of the word "physical" that is. But he's good to me nonetheless. (We're even planning a pilgrimage to the home of C. S. Peirce together.)

15-07-05 *Krugman on Reality, Again* (to me)

From Paul Krugman, "Karl Rove's America," *New York Times*, 15 July 2005:

> John Gibson of Fox News says that Karl Rove should be given a medal. I agree: Mr. Rove should receive a medal from the American Political Science Association for his pioneering discoveries about modern American politics. The medal can, if necessary, be delivered to his prison cell.
>
> What Mr. Rove understood, long before the rest of us, is that we're not living in the America of the past, where even partisans sometimes changed their views when faced with the facts. Instead, we're living in a country in which there is no longer such a thing as nonpolitical truth. In particular, there are now few, if any, limits to what conservative politicians can get away with: the faithful will follow the twists and turns of the party line with a loyalty that would have pleased the Comintern.
>
> I first realized that we were living in Karl Rove's America during the 2000 presidential campaign, when George W. Bush began saying things about Social Security privatization and tax cuts that were simply false. At first, I thought the Bush campaign was making a big mistake – that these blatant falsehoods would be condemned by prominent Republican politicians and Republican economists, especially those who had spent years building reputations as advocates of fiscal responsibility. In fact, with hardly any exceptions they lined up to praise Mr. Bush's proposals.
>
> But the real demonstration that Mr. Rove understands American politics better than any pundit came after 9/11.
>
> Every time I read a lament for the post-9/11 era of national unity, I wonder what people are talking about. On the issues I was watching, the Republicans' exploitation of the atrocity began while ground zero was still smoldering.
>
> Mr. Rove has been much criticized for saying that liberals responded to the attack by wanting to offer the terrorists therapy – but what he said about conservatives, that

they "saw the savagery of 9/11 and the attacks and prepared for war," is equally false. What many of them actually saw was a domestic political opportunity – and none more so than Mr. Rove.

A less insightful political strategist might have hesitated right after 9/11 before using it to cast the Democrats as weak on national security. After all, there were no facts to support that accusation.

But Mr. Rove understood that the facts were irrelevant. [...]

[W]hat we're getting, instead, is yet another impressive demonstration that these days, truth is political.

15-07-05 *Arm Twisting* (to N. Lütkenhaus)

We never heard back from you when we made a call for speakers at BBQW in Konstanz. Thus maybe it's time to do a little arm twisting now—particularly as we have been studying the mix of volunteered talks and it would be nice to have one or two more on "applications." Could we get you to give a talk on something to do with quantum crypto (predominantly) and any thoughts you have (even tangential or wildly speculative) on how the Bayesian view of quantum states might make a difference (or not) in the planning, design, or implementation of quantum cryptosystems? It would just make our program a little more solid and less philosophical to see some of these ideas in action.

If you can work up the nerve to take the task, it would be great! Remember this is a very informal meeting—only about science, and not about egos—so really you have nothing to lose, and you might spur some great discussions or applications with your talk.

Whatever your decision, please let me know asap.

17-07-05 *Take the Task!* (to D. M. Appleby)

I apologize for taking so long to get back to you. As it turns out, we finally made all the final talk decisions today (since Caves, Hartmann, Schack and I all happen to be in Waterloo). Anyway, the decision is Yes, please do give us a talk. And particularly, yes please do give us your passioned defense of the subjectivist account of probability. So, you've got a task ahead of you: But remember you basically asked for the challenge.

Your slot is on the first day, the third talk down the line. Speakers are in order:

Morning:

- Spekkens (toy model, and arguing that quantum states should be viewed epistemically)
- Schack (not only epistemically, but subjectively—because that's the only sensible account of probability and "objective chance" plays no role anyway—and the consequences of that view for quantum operations)

Afternoon:

- Appleby (you give your talk just as you had outlined; subjectivist ideas are so foreign to some it would be good to hear them twice even if there is any overlap with Schack; so basically don't worry about overlap)
- Myrvold (rebutting, tries to argue that objective chance really is needed, otherwise Bayesianism would collapse when confronted with a fundamentally probabilistic theory like QM)

- Timpson ("if the quantum state is to be associated with any cognitive state, it must be belief not knowledge," ... if you want to solve the "measurement problem")

Thus ends our arguing-for-the-subjective-view day.

Anyway, I hope that gives you a feeling for how you'll fit.

We'll post the full schedule in a couple of days; I'll send out a general announcement soon. In the meantime, could you please send us an official title and a short abstract ASAP (preferearably before Thursday).

Certainly thanks for doing this Marcus! As I've told you before, I think your papers on probabilities are gems.

18-07-05 *Your BBQW Talk* (to T. A. Brun)

Sorry to be getting back to you so late. Sadly, we've only finally made our final plans for the talks in Konstanz (Carl, Stephan, Ruediger and I are all together this week at a meeting in Waterloo).

Anyway, yes please do plan to give a talk on compatible state descriptions. You'll be talking on a more technical, less philosophical day, along with Mermin, Briegel (both on quantum computing things), Renner, and Srednicki (on de Finetti representation stuff). But don't let that deter you from making foundational statements too. Since we don't have any other representation of compatibility questions, your talk will be ideal—much needed as an intro to the question(s) and subject. More than likely, you can expect that Caves, Schack, or I will make some comments along the lines of our paper in the discussion session: so that could be a nice discussion.

Looking forward to seeing you soon!

18-07-05 *Your BBQW Talk* (to D. Wallace)

Thanks again for offering to give a talk at BBQW. I hope you don't mind my scratching my earlier approval of your "global criticism" suggestion: We've finally gotten to making decisions on the talks, and believe me, there's more than enough criticism of the Bayesian approach! (Myrvold, Mermin, Wiseman, Hagar, and probably a couple others).

Anyway, we think it'd be much more productive for you to talk about your decision theoretic derivation of the probability law in Everettian QM—actually that subject sorely needs some representation. Your talk will be the Wednesday morning. In the same session, we're hoping to also get Barnum to talk a little dually on your stuff and on Zurek's recent derivation. Also Carl Caves may talk on the frequency operator approach of Hartle and Farhi-Goldstone-Gutman.

We'll send out an announcement with the full talk schedule soon. However, in the meantime, if you could send an official title and a short abstract ASAP that'd be great!

I hope you'll find this meeting a productive one; in any case, I'm looking forward to seeing you again.

25-07-05 *Sessions and Chairs* (to V. Palge)

Below you'll find the session titles and chairs. Also, please change the title of my opening talk to "Fuchsian BBQ(w), a Sampler of Meats and Sauces". After lunch, I'll send you some extra abstracts from some of the speakers that I have accumulated. I'll be back in about an hour.

- Monday Morning
  "Epistemic Quantum States and the Paths They Lead To"
  Chair: Stephen Bartlett

- Monday Afternoon
  "Subjective vs. Objective Probabilities in QM"
  Chair: Jeffrey Bub

- Tuesday Morning
  "Implications from Quantum Computing"
  Chair: Mauro D'Ariano

- Tuesday Afternoon
  "Technical Bayesian Theorems"
  Chair: Norbert Lütkenhaus

- Wednesday Morning
  "Bayesian Probabilities in Everettian Worlds"
  Chair: Huw Price

- Thursday Morning
  "Updating Beliefs and Diachronic Coherence"
  Chair: Jos Uffink

- Thursday Afternoon
  "Updating Beliefs and a Touch of Copenhagen"
  Chair: Holger Lyre

- Friday Morning
  "Separating Subjective from Objective in QM (if possible!)"
  Chair: Paul Busch

- Friday Afternoon
  "Changing the Course of Physics, Some Ideas"
  Chair: Joseph Renes

25-07-05 *Bad Jokes* (to N. D. Mermin)

Regarding:

Merminition 152: *Please use the full title I sent you:*

> Does being Bayesian illuminate the quantum world?
> Or is the quantum world an embarrassment to the Bayesian?
>
> Abstract: The speaker will meditate on what he likes and what he dislikes about taking a Bayesian view of quantum theoretic probabilities. The talk will be very informal if only because, as we all know, there is no quantum world.

As you should know, I think there is ONLY a quantum world. Did you forget about me when you wrote your abstract?

Merminition 153: *Just an example of the kind of bad jokes I hoped I'd be able to string together. I had in mind the Bohr quote. Nothing more. But I did think it was a Law of Thought for you. Not the same as a world.*

I knew you had the Bohr quote in mind; I was trying to make my own bad joke.

Concerning, "But I did think it was a Law of Thought for you." ... you never cease to shock me .... And you never cease to cause me to strive to try to convey the very simple little idea more effectively! I wonder when I'm gonna finally hit the sweet spot? Quantum THEORY, a law of thought: Yes. Resoundingly yes. But the quantum WORLD—i.e., that situation, that world, that reality, which conditions us to choose THIS law of thought rather than THAT law of thought (in other words some alternative or imaginary law of thought)—is something else entirely. It's the stuff that's here whether there are any law-of-thoughters around or not. That's what I really want to get at; that's what I've always really wanted to get at.

26-07-05 *Am I Turning Into You?* (to S. Aaronson)

Aaronsonism 9: *Consider the terrifying evidence at*

`http://www.scottaaronson.com/papers/are.ps`

and in particular, the following sentence:

> "If exponentially-long strings were rocket fuel, and probability distributions were grape juice, then quantum states would be wine – the alcoholic 'kick' in this analogy being the minus signs."

Headed for an `arXiv` *near you (though there's still time to revise, and thereby reduce the foolishness quotient ...).*

For God's sake let's hope not! I've seen what it looks like from the inside, and I can tell you it ain't pretty.

However, I very much like this turn I'm seeing in you of dispelling *some* of the mystery of quantum computing by comparing quantum states to probability distributions. The exponentiality in the latter is something Caves and I have played up here and there over the years. Have you ever read our old paper, `quant-ph/9601025`? Caves probably has something better by himself by now, but we laid the groundwork there.

Anyway, you don't realize it, but you might just be starting to fall down the slippery slope of becoming a quantum Bayesian.

Incidentally, I'm starting to think there must be something wrong with the idea that it's the minus signs that give the kick. For the minus signs are representation dependent. Take the representation of QM that I keep playing up, where the quantum state is represented as a single probability distribution full stop. No minus signs at that level. Now it is true that the minus signs then reappear in the time evolution equations. But if one talks about the one-way computational model of Raussendorf and Briegel, even those minus signs go away. So a kind of probabilistic model for quantum computation with no minus signs ever appearing. What appears instead is an interesting relation between the marginal and joint event spaces. One that apparently can't be sustained classically. I wish I had your brain so that I'd be better equipped to explore these kinds of questions.

I'm finally going to go to Princeton today. I guess you won't be there!

27-07-05 *Wow!* (to M. Dickson)

I just saw your talk proposal for BBQW,

> Subjective and Objective in Quantum Theory
>
> Chris Fuchs has proposed to understand the quantum state in terms of the "Bayesian idea that the probability one ascribes to a phenomenon amounts to nothing other than the gambling commitments one is willing to make on it" (Fuchs 2003). Correctly predicting that jaws will drop in reaction to such an idea, Fuchs goes on to emphasize that it is part of a larger project of disentangling the subjective from the objective in quantum theory. This talk will be a reflection on that project. First, drawing on philosophical movements from the late 19th and early 20th century, specifically surrounding the philosophy of geometry and the role of analytic truths in physical theories, I will suggest that the interplay between subjective and objective in physical theory is complex and subtle, and itself depends on certain choices made by us. (Fuchs drops hints in the same direction. I will try to flesh out my own understanding of these subtleties.) Second, I will illustrate this idea, drawing on themes from Bohr (and possibly other Copenhagen-type approaches to quantum theory, but I make no claims on that point). Specifically, I will consider, as (I would argue) Bohr did, the question of how we make 'contact' between quantum state-ascriptions and actual experimental observations. The result is suggestive of a neo-Kantian (or neo-Carnapian) philosophical foundation for the 'subjectivist' approach to quantum theory, and in any case it might contribute to Fuchs's project.
>
> Reference: C. A. Fuchs, "Quantum Mechanics as Quantum Information, Mostly," J. Mod. Opt. **50**, 987 (2003).

and wow! I'm flattered that you'd take me seriously enough to talk about some of my stuff (even if only to speak to its difficulties).

I guess I've talked more about the specific subject of your abstract in several places (other than the paper you cite, that is), but maybe let me draw your attention to the most relevant one in case you haven't seen it yet—I think it's a substantial development of what you've seen (if that's all you've seen). It's a weird pseudo-paper titled "The Anti-Växjö Interpretation of Quantum Mechanics". You can find it here `http://xxx.lanl.gov/abs/quant-ph/0204146`, and the most relevant sections for you would be Sections 4 and 5.

I've had only one significant response to it from a philosopher—it was from Michel Bitbol. Since you will also talk of the neo-Kantian tradition, let me place it below. [See preply to 10-12-03 note "First Meeting" with M. Bitbol.]

I don't know if these materials will help you in any way—particularly at this late date—or only paint a more inconsistent picture of myself, but in the interest of making as much progress as we can in our limited time, I thought I should point them out to you.

I'm definitely looking forward to meeting you; I've only seen you in the distance before. And I'm looking forward to learning from you.

28-07-05 *Asynchrony!* (to A. Plotnitsky)

Plotnitskyism 14: *I assume that you got an invitation from George Welch for the Snowbird conference, since I just got one myself. I did manage to get in touch with David from Australia, who cannot come–too bad of course.*

No, I did not get anything from George Welch. Could you have him send whatever he sent again? (I don't know George Welch.) Coincidentally, I just had lunch with Marlan Scully a couple of days ago. We talked mostly about his son's book and about free will. Marlan has quite a religious side too—I had not realized the extent of that before.

At the very least, looking forward to seeing you in Snowbird … but I hope we hook up again before that.

Maybe I should give as a title for my talk, "Not the Incompleteness of Quantum Mechanics, but the Incompleteness of Bohr's Reply to EPR". Who are you going to get as a replacement for David?

28-07-05 *Calendar Marked* (to W. E. Lawrence)

OK, I've marked out my calendar for Sept 29 through Oct 1. I'll plan to drive in the Thursday morning (well before the afternoon talk), and take off Saturday morning after breakfast. Maybe there's some chance I can get my family to come with me; if I do, I'll certainly pay any extra hotel costs that incurs. I'll let you know their decision as the time draws nearer.

Have fun on your vacation. We're just taking off for Germany ourselves today. The family will be there for 3 weeks, as I shuttle about here and there for meetings. I'm very proud of the meeting I organized on Bayesian probability in quantum mechanics. You might snoop around the webpage if you get a chance:

`http://web.archive.org/web/20090511060206/http://www.uni-konstanz.de/ppm/events/bbqw2005/`.

I suspect there are several talks you would have enjoyed there. So, anyway, that part of my shuttling about will be a labor of love. The ridiculous part of my shuttling comes from my jumping back to San Jose for a two-day visit to the MaxEnt conference in the middle of all that! Now that there's no way for me to get out of it, I'm really starting to regret it! Thus much is now for sure though: From August 19, when we return to New Jersey, to September 29, when I come to Hanover, I'm not traveling anywhere else!!

So I should be fresh and happy again by the time I give your seminars.

28-07-05 *Bernardo and Smith and Savage* (to S. Hartmann & V. Palge)

Do either of you have a copy of Bernardo and Smith's book *Bayesian Theory* and Savage's book *Foundations of Statistics* or the book *Studies in Subjective Probability* (can't remember the editors)? Anyway, I'm bringing a few books, like Jeffrey's two books and de Finetti's collected papers, but I can't fit much more into my suitcase. If you guys have the above-said books (and maybe Howson and Urbach too), could you bring them to the meeting? We could put things like this out on a display table for perusing or if anyone needs something for a sleepless night. Also it'll make it easier for us to dig up a quote if need be.

Also, we should have a display table for the participants to lay out copies of recent papers, etc., if possible.

09-08-05 *Slides* (to H. M. Wiseman)

Would you mind sending me a copy of the talk you gave at BBQW? I'd like to study the slides and ultimately reply.

(You know, if I were a solipsist, I wouldn't have to ask you for the slides ... nor would I ever have to use the Born rule, as I'd know the outcomes of all measurements in advance. Solipsists have no need to make requests or gamble.)

09-08-05 *Figure Supplement* (to H. Poirier)

It dawned on me that this figure from my talks might be a useful supplement for you with respect to the paper I sent you last week. Unfortunately I don't have the latest version of it scanned into my computer, but this might still help. (The stick figure now says, "Ouch, *d*!" rather than "Aha, *d*!" Small conceptual difference, as "aha!" conveys a discovery, while "ouch!" conveys the idea of a simple physiological reaction.)

Anyway, the figure is attached. Looking forward to your article.

11-08-05 *So Slow Fuchs* (to A. Wilce)

Sorry to take so long to reply to you; I've fallen by the wayside again with this exhausting schedule of travels and particularly the Konstanz meeting. As I write to you, I'm returning to Munich from the MaxEnt meeting in San Jose.

Wilce-ism 1: *The conference has left my head buzzing with ideas, some of which I'd like to discuss with you at some point.*

Glad to hear that. And I always enjoy my discussions with you; I'm always impressed by your simultaneous mix of precision and tolerance (particularly for the imprecise likes of me).

Wilce-ism 2: *Also – I've finally unearthed an ancient, but possibly very interesting, doctoral dissertation on Bayesian methods in generalized probability theory (read, quantum logic), by Marie Gaudard, a student of C. H. Randall. Would you like to have a copy?*

Yes please. I have this dream of traveling no more until the new year come August 19. If I can follow that, there some chance I might actually a paper or two read this Fall!

12-08-05 *Per Diem?* (to K. H. Knuth)

Thanks again for inviting me. I got a lot out of interacting with you, Ariel, Carlos, John Skilling, Andy Charman, Mike West and others. We definitely should have had you all at our QM-Bayesian meeting in Konstanz; that was a big oversight, and I won't make it again.

12-08-05 *Thanks* (to R. Renner)

Rennerism 1: *I am writing you to thank you again for the invitation and also for the organization of the nice BBQW workshop. I really enjoyed it and, clearly, I learned a lot. (Unfortunately, I had to run for the train last Friday, so I missed to say you goodbye personally.)*

I'm glad you enjoyed it.

Homework Assignment: Go to Bernardo and Smith's book *Bayesian Theory*, turn to Chapter 4 on "modelling." Prove quantum versions of all the representation theorems in there.

Take care, and I hope to see you soon.

12-08-05 *Quantum Bayesians and Anti-Bayesians* (to W. C. Myrvold)

Thanks for including me on the distribution list of your long note. This is something I want to eventually come back to, but at the moment I'm going to have to plead "organizer's exhaustion". As I write to you, I'm on my way back to Munich from the MaxEnt conference in San Jose. Soon after completing this note, my plan is to simply fall into a deep, deep sleep—it may last a couple of weeks. (First I plan to vacation a little in Munich, but then it'll probably take me a week to get my life established again in New Jersey upon my family's return home.) Plus by the time I finally open my sleepy eyes, I'll have the benefit of being able to review everyone else's reply to you before composing my own thoughts.

Keep up the good work!

Hey, here's a challenge to you. I think the single most significant reading for sending me toward the radical-probabilist end of Bayesianism was de Finetti's paper, "Probabilism," in *Erkenntnis* **31**, pp. 169–223 (1989). I'm pretty sure the same is true for Rüdiger, and possibly even for Appleby. Here's my challenge: Pinpoint the places where you think de Finetti errs in that paper. If you can convince me of some significant errors in that paper, you might just turn me back toward the temple of objective chance (from whence I originally came into this game). Maybe Unruh, Duwell, and Harper could take the challenge too.

But as I say, for now I close my sleepy eyes.

Wayne's Preply

> I don't know about you guys, but I found the Konstanz conference very valuable, and I believe I have a better grasp now of the views on the 'quantum Bayesians', and my conversations with people at the conference helped me to sharpen my own thoughts. Following is meant to be an attempt to continue the discussion, and to get clearer in my own mind what I think. Response (and disagreement) welcome!
>
> We're all interested, I think, in the question: What do we accept when we accept qm? And accepting qm means, at minimum accepting the quantum rules as the ones to adjust one's credences to. And so I'm going to couch everything that follows in terms of what accepting certain credences commits one to.
>
> Start with a case that has nothing distinctively quantum about it. I'm thinking of a quantum experiment with a fixed experimental setup, but that won't be essential. Suppose there is a sequence of events over which Bayesian Peter (a character I borrow from Bas van Fraassen) has an exchangeable credence function (and here I'm departing a bit from deF's terminology, which makes "exchangeable" modify "sequence"; from deF's own point of view, this is misleading, because exchangeability has to do with a credence function and not with the events themselves). What does such a credence function commit Peter to?
>
> (Though I'm going to assume exchangeability, pretty much everything I'm going to say goes through if Peter's credences can be written as a mixture over a richer set

of distributions, including, perhaps, correlations between elements of the sequence or between elements of the sequence and other events; invoke the appropriate generalization of the de Finetti representation theorem).

Suppose that Peter has an opportunity to bet on the 101st element of the sequence, and he is given a choice between betting according to his current credences, and learning the outcomes of the first 100 elements, and then betting on the 101st. Unsurprisingly, he can't prefer the former; he must regard the more informed credences as being at least as good as the less informed, and, provided that he attaches nonzero credence to the proposition that his credence in the 101st will undergo some change as a result of conditionalizing on the first 100, he will strictly prefer the informed credences.

Of course, we could save Peter the trouble of conditionalizing and just tell him what his credences would be if he were to conditionalize on the first 100, and he would gladly swap these credences for his current ones. Moreover, we can write his current credences regarding element #101 as his current expectation value of what his credences will be after learning the first 100 elements of the sequence.

And so on; Peter will prefer credences conditional on more data to credences conditional on less, in the sense that he will pay some money to be told what they are, and will adopt them once he knows what they are. Consider the set of credence functions consisting of all the credence functions that would result from Peter's priors by conditionalizing on finite initial segments of the sequence. Peter believes — that is, he assigns credence one to it — that this set has a limiting distribution. Moreover, if he knew what this limiting distribution is — if God could hand it to him on a platter — he would prefer it to all the members of the set.

Of course, what Peter would prefer to all of these, would be for God to hand him on a platter the results of the whole infinite sequence, once and for all. Moreover, if Peter is a determinist, he believes that these results are already determined by the current state of the world, which is of course imperfectly known to him. Since Peter will, at any given time, only have a finite body of data, data about past events, all he will ever have, with regards to future events, is credences conditional on finite initial segments. The limiting distribution is the least upper bound, in Peter's preference ordering over things that God could hand him on a platter, of the set of finitely attainable credences.

Peter has certain credences about what this limiting distribution is, and his current credences about future events are his epistemic expectation values of the probability they have on the limiting distribution. (That is, though Peter doesn't know what the limiting distribution is, he has some opinions about it, and his current degree of belief in an event E is his estimate of what probability is given to E by the limiting distribution).

What status does this limiting distribution have, for Peter? It is *not* epistemic, in the sense of being anyone's degree of belief. It's also the sort of thing once can have degrees of belief about, and Peter regards his process of updating on data as becoming better and better informed about what the limiting distribution is.

Now suppose we have a situation like that envisaged by Lucien Hardy in his 5 axioms papers: we have a preparation device, a transformation device, and a measurement device, all with various knobs on it. Peter starts fiddling with the apparatus, doing various experiments with the knobs at various settings, and conditionalizing on the results. If his initial credences concerning the outcomes of the experiments are reasonable, he will, with enough experimentation, start to converge towards the quantum rules concerning correlations of outcomes with the settings of the various knobs. For any setting of the knobs on the devices, Peter's credences will be a mixture over possibilities of an ideal limiting distribution associated with those settings. This ideal limiting distribution has the same status as it did before. It is not Peter's or anyone else's actual belief state, but an imperfectly known, ideally optimal belief state for a given configuration of knob settings. ('Optimal' meaning judged by Peter to be optimal, in the sense that he prefers having it to any finitely attainable belief state.)

If Bayesian Alice starts with priors different from Peter's, no finite amount of data will bring them into exact agreement. But, provided neither regards the other as excessively dogmatic, they both believe (attach probability one to) the proposition that experimentation indefinitely continued would lead both of them to converge to the same limiting distribution. And they can both regard their current differences in credences to be differences in opinion about what that ideally optimal limiting distribution is. (And this last remark would be true even if the conditions for convergence were not satisfied. Both could regard their differences in opinion as differences in opinion about the ideally optimal distribution, but each regard the other of incapable of properly learning about it)

So — at what point in the above train of thought would the quantum Bayesians want to get off? Because we've gotten close to how I characterized objective chances. They are associated with chance set-ups (knob settings), and are optimal credences in the sense that they cannot be bettered on the basis of information that is in principle available to agents making wagers on the events in question. They are the sorts of things one can have degrees of belief about, have differences of opinion about, and regard ourselves as learning about.

Wayne's Reply

Chris suggested that I look at "Probabilismo," and it so happened that, when I got that e-mail, I had just come back from the library, where I was copying it. I've since finished reading it, and I must say that last paragraph came as a nasty shock! (I had previously known nothing of de Finetti's political convictions). It should come with a disclaimer: Warning: Political content may offend some reader!

But of course it's not de Finetti's politics that are at issue. Here are a few preliminary comments on "Probabilismo."

1. It is simply presumed throughout that "probability" is univocal; the notion that (as Poisson pointed out) "probability" is used in two distinct senses is wholly absent. Hence there is a presumption that we are looking for a single notion of probability to cover all its uses. This is a royal road to subjectivism regarding probability. If the choice had to be between holding (a) "probability" always refers to degrees of belief, and (b) "probability" always refers to objective chance, then (a) wins hands down and in fact (b) doesn't even get out of the gate.

This isn't a minor point; I think that a major source of confusion in the literature on the interpretations of probability has been the idea that we have to pick *one* interpretation as the sole legitimate notion. It's as if someone were reading my e-mails over the past few months, unaware that there are two cities named "London"; such a person could easily come to the conclusion that London is a strange and peculiar place or that at least I have bizarre or contradictory beliefs about it (E.g, I got on a plane in London for a 7-hour plane ride to Toronto, after which I took a 2-hour bus ride to London.)

Having decided that probability is always epistemic, de Finetti calls the notion of an unknown probability of heads that we are trying to estimate nonsensical and metaphysical. As indeed it would be if we were talking about an unknown credence. An unknown chance that we have credences about is less obviously nonsensical.

The closest the de Finetti comes to offering an argument against admitting chances is the assertion that the hypotheses that the chance of heads has a certain value is not directly verifiable. Which is true; we test such hypotheses by constructing a sequence of events that we are reasonably certain all have close to the same chance, and update our credences on the results of that sequence. I count this as a measurement of the value of the chance. Rejecting this as excessively indirect would be to reject far too much, as the procedure is not essentially different from the measurement of *any* physical quantity using noisy data (and *all* data is at least somewhat noisy). Any epistemological considerations that could be held against one could equally well be held against the other. In particular, it does no good to point out that one must start the procedure with certain assumptions, or that no amount of data will dictate a unique value as our estimate of the parameter or a unique set of posterior credences regarding that value of the parameter; this holds for *any* parameter estimation via statistical techniques, not just to estimation of chances.

2. De Finetti's subjectivism seems, at least in part, to be motivated by a fallacious inference from the fact that every judgment is subjective — that is, made by and belonging to a subject — to a conclusion about the content of the judgment, namely, that the subjective judgment cannot be a judgment *about* anything that is not subjective. This inference, fortunately, is not a valid one, because, if it were, we would have to conclude, not merely that all probabilities are subjective, but that everything is, and we would land in idealism or even solipsism. To his credit (?), de Finetti does indeed take this extra step. In section 30 (p. 214) he denies the existence of "external reality" (his scare-quote), and in section 2 (p. 171) he quotes Tilgher, apparently with approval: "All the objects, men, and things of which I speak are, in the last analysis, only the content of my present act of thought: the very statement that they exist outside and independently of me is an act of my thought . . . ." This is Tilgher's paraphrase of what Berkeley commentators call Berkeley's "master argument" for idealism. And it's no better here than it is in Berkeley.

3. De Finetti frequently draws an analogy between judgments of probability and matters of taste. This is not part of any argument but merely part of the rhetoric of his presentation. But in case this rhetoric is having any persuasive effect, perhaps I can curb the appeal of this analogy by pointing out that, from the point of view of Bayesian decision theory, the analogy is not a very strong one. Matters of taste come into decisions via their influence on utilities; and utilities and probabilities play essentially different roles in decisions. One important difference is that we are obliged to regard new information as potentially improving our probability judgments; given the choice of choosing according to my present credences, or first updating on information relevant to my choice and then making my choice, an expected utility calculation tells me to choose the latter. There is nothing comparable when it comes to utilities. Suppose I am reasonably certain that Alice started out with priors similar to mine, and then gained new information, so that her current credences are close to what mine would be if I were to update on the information she has. Then, judged by my own current credences, I would be better off following her choices than making the choice based on my own. If, on the other hand, I know that Alice started out with tastes similar to my own and then underwent a process that made her prefer castor oil to cognac, I will still order cognac after dinner; I do not regard the fact that Alice chooses castor oil as relevant to

my decision. One way to put this is: we can regard change of credences as pure learning experiences. A chance of tastes (utilities) is *never* a pure learning experience.

12-08-05 *Your Summary* (to W. G. Unruh)

Thanks for sending me the summary of your concerns. As you'll see from the other note that I just wrote to Wayne Myrvold (and cc'd you on) though, I'm going to drop out of discussion for a couple of weeks. So I don't have a detailed reply for you at the moment.

I did however take ten minutes to compile a couple of emails that I wrote to Mermin a couple of years ago on the very subject you bring up. The notes are somewhat inadequate as a reply to you, but they're along the lines to a beginning of a reply, so I'll go ahead and attach them to the present email. You'll see their relevance if you have a read, but I can predict in advance that I didn't say anything that will convince you.

More later, but it may be a couple or three weeks.

Bill's Preply

Hope you had a good trip to Munich, got there safely and had a good birthday celebration with your wife.

Just to summarize my concerns. You want the probabilities to be a state of belief because you want to argue that when, in the Bell problem, A measures her S_x and finds $+1/2$, then the change in the probability at B of S_x from 50-50 to "certainty" for $+1/2$ is simply a change in the state of belief of the person who who has this additional fact. That change in belief, of the person, has nothing to do with the world itself, and such a change in belief thus does not (non-locally) affect the world itself. I would say that the main problem with that line of argument is that then there is an additional fact, namely if you bet on the basis of that belief, then you keep winning. Now, the belief may be personal, but the fact that that that belief keeps you winning is more than just personal, it also tells you something about the world. There is some matter of fact of the world which puts its behavior into compliance with your state of belief. That compliance, that correlation is something that needs explanation, just as in your opinion, in the Bell case, where the probabilities are considered objective facts about the world, the change in the probabilities for B in the face of the measurements by A is something that requires explanation (and you explain by non-locality). I.e., it is not at all clear to me that making the probabilities to be beliefs and subjective buys you much (anything) except to change what it is that needs explanation. Saying that that correlation between your beliefs and outcomes at A requires no explanation seems to me to be as problematic as saying that the change in objective probabilities at B due to the measurement at A requires no explanation.

On the commutation of the informations, I guess I would take the state of two two level particles to be $\sqrt{.51}|11\rangle + \sqrt{.49}|00\rangle$. This is all that B knows and for him the state which best describes the second system is diagonal in the above $|0\rangle$,$|1\rangle$ basis, with .51 and .49 on the diagonal. However A measures the first particle in the $|+\rangle$,$|-\rangle$ basis (call it the z basis $|+\rangle = 1/\sqrt{2}(|1\rangle + |0\rangle)$, and finds its value to be $+$. For A, the optimal state of the second particle is in the state $\sqrt{.51}|1\rangle + \sqrt{.49}|0\rangle$ Whose projector does not commute with B's density matrix.

The 0 probability case is more difficult (I think I misunderstood that constraints on the problem when on the train), and I am not sure what to think in that case. Have you actually come up with a case where it is zero (i.e., where the density matrix for B times that for A is 0)?

18-08-05 *The Big Bang Happened Here* (to T. Duncan)

Not much time for a long note at the moment: My wife, children, and I are on the last day of our vacation in Munich (seeing the grandparents), and we've got a dinner date soon … followed by packing up for an early morning flight tomorrow. So I can't write much. But I've been enjoying getting to know you a little today.

First off thanks for the note—which I'll study and reply to eventually—and thanks for the links at the bottom of it that led me to the SII pages and others. I've got to say, I'm quite intrigued by your life and efforts—what a beautiful idea the SII is!

As I say, I'll try to address your note specifically in the near future; you have a point worth mulling over in more detail (about what one might mean more specifically by "incomplete information" in a world without hidden variables). In the meantime though, let me attach a little something somewhat on the subject that I have been contemplating posting on `quant-ph` (at least Howard Wiseman wants me to, so that he can reply to it officially). It's attached as a PDF file; the title is "Delirium Quantum". I titled the present email after your textbook's title because it reminded me of a line I use in Section 7 of this paper: "That (metaphorically, or maybe not so metaphorically) the big bang is, in part, right here all around us?"

Listen, I didn't give you a copy of my book *Notes on a Paulian Idea* in Sweden, did I? At least I don't have your name recorded in my list. If you'd like a copy, I'll have one sent to you: I still have loads of copies of the VUP edition to give away (before the Springer edition comes out), and you might enjoy perusing it given your interests.

Todd's Preply

> It was good to meet you in Växjö back in June — thanks for the references you pointed me to. The Spekkens paper helped clarify the vague question I was trying to articulate after your talk, about how interference effects arise in the epistemic view of quantum states. From the correspondence between spin states and epistemic states in the toy model, I see now how the incompleteness of maximum knowledge makes it possible to define a binary operation that behaves as a coherent superposition (and hence produces interference). This is appealing since it's a glimpse of a deeper principle that could underlie the coherent superposition of quantum states.
>
> I'd still like to gain a more concrete understanding of why this happens and what it means. It's difficult to get direct intuition into what's going on because much is buried in whatever "nature" (in the toy model) must be doing in order to enforce the knowledge balance principle. I guess this is essentially the point you make for the real universe, in asking (of the fact that maximal knowledge of a system is incomplete knowledge), "Why can it not be completed?" The heart of the matter lies in that question. As I think about it, I'm not even sure what it means for knowledge to be incomplete other than in relation to hidden variables in the spirit Einstein described. But as you said, that cannot be the type of incompleteness that's really going on.
>
> This leads to a point that is still muddy to me. It may be a naive question and I'm not quite sure how to phrase it, but let me try this to get started: Given that we must ask what the ontic states can be, such that they force this restriction of incomplete knowledge on the epistemic states, why not just place the entire restriction

directly on the ontic states themselves? Why not simply say there is a limit to what we can *know* about the state of the world because there is a fundamental limit to how much information can actually be "stored" about its state? As I understand it, this is something like the view expressed e.g. by Zeilinger ("A Foundational Principle for QM", *Found. Phys.* 1999). I realize this is not what you're saying. So, I'd like to better understand why you emphasize the distinction between epistemic and ontic states, when it seems possible that all of the restrictions on our knowledge could be absorbed as consequences of the restrictions on the ontic states. Anyway I'd appreciate any thoughts you have to point me in the right direction here.

On a more general note, I've read and pondered more of your writing. Your ideas are inspiring — I found myself cheering you on as I read, even (perhaps especially) the asides and footnotes. (I'm thinking particularly of your replies to Preskill and to Wootters, in "The Anti-Växjö Interpretation of QM.") I have no idea if you make these comments for the same underlying reasons that I make similar comments, but I'd very much like to learn more about your philosophical perspective behind them. So I'll highlight a few points that struck me, and if you have time/interest, I'd love to hear your additional thoughts.

First, thanks for leading me back into William James' writing. I remember reading several of his essays and finding encouragement when I was in grad school trying to articulate the deeper motives and questions guiding my work. I especially like the opening pages of "The Present Dilemma in Philosophy" because he articulates so well the practical importance of one's view of the universe: "The philosophy which is so important in each of us is not a technical matter; it is our more or less dumb sense of what life honestly and deeply means. It is only partly got from books; it is our individual way of just seeing and feeling the total push and pressure of the cosmos." (*Pragmatism*, lecture 1 – The present dilemma in philosophy)

Next, your reminder that the usefulness of theories does not mean they are part of the blueprint of the universe is well articulated — and very important, I think. Have you read Edward Harrison's book, *Masks of the Universe*? My background is in cosmology so I'm used to thinking of the issue in that language, but it's very similar. Harrison expresses it by highlighting the distinction between the real Universe (capital U) and our model universes (lowercase u) which are masks that we try to fit to the real Universe. Here's a passage from Harrison which captures the essence of the point:

> The universes are our models of the Universe. They are great schemes of intricate thought — grand belief systems — that rationalize the human experience. They harmonize and invest with meaning the rising and setting Sun, the waxing and waning Moon, the jeweled lights of the night sky, the landscape of rocks and trees, and the tumult of everyday life. Each determines what is perceived and what constitutes valid knowledge, and the members of a society believe what they perceive and perceive what they believe. A universe is a mask fitted on the face of the unknown Universe.

Of course it's one thing to acknowledge superficially that, yes, of course, our models are limited and don't really capture everything about reality, ... but then going about our day-to-day work acting as if we can capture everything. (And as Wootters mentioned, there probably is some practical value in pretending this as a matter of methodology.) But what particularly intrigues me about what you're doing is that you seem to be bringing this awareness directly into the practical methodology of doing science. I'm not sure I said that very well —I guess what I mean is that there could be situations where there is practical value in NOT pretending that theories can perfectly mirror reality. Explicitly building that point into a theory (as you seem to be doing for QM, if I understand correctly) is tremendously important I think.

This email is already getting long, so I'll stop here and save comments about other points from your writing for another day.

22-08-05 *Exercise 1.image* (to T. Duncan)

Duncanism 1: *Thanks for the "Delirium Quantum" paper, which I've started browsing. I love your idea that new facts are being created around us all the time. The* Big Bang Happened Here *title evolved from a somewhat weaker point I like to make in lectures — that when we learn about the history of the cosmos, we are not just learning about distant things detached from us. Rather, we are discovering the history even of the space we are immersed in right here. A little bit of space we can hold in our hands once glowed with the heat of the big bang. Your point is a stronger one, that the process is ongoing even now. And yes, it is spine-tingling to think about that, to feel that our actions may "count" in some truly fundamental way. (BTW the title of our textbook has changed now to* Your Cosmic Context*, so it's funny that you found an old reference to it. I've attached a draft of the first chapter since it has some comments on models of the universe that might be of interest to you.)*

OK, so you already know how I'd answer your Exercise 1.image: "I am a cosmic artist – a contributor to a universal creative process." Thanks for sending Chapter 1 of your book, *Your Cosmic Context*. I just enjoyed reading the first 13 pages of it.

I sent a note the secretary at VUP to have a copy of *Notes on a Paulian Idea* sent to you. Per my promise, I will eventually get back to your more substantial points (from your first email), I just have to have a thought or two before embarking on the mission. (And I've got to get caught up a lot, after having been absent from Bell Labs for almost a month!)

23-08-05 *The Article for Science & Vie* (to H. Poirier)

Poirierisme 1: *Hardy proved that QM can be seen as a Generalised Probability Theory, or in other words, as a tool to calculate the probability associated with each outcome of any measurement that may be performed on a system prepared by the associated preparation.*

As far as I understand your position, this redefinition of QM is not so far from yours (when you say that the quantum state is solely an expression of subjective information about the potential consequences of our experimental interventions into nature).

So my problem is: If all the characteristics of QM can be seen as generalised probability tools, how can you think that there will remain a piece of quantum theory with no information theoretic significance?

The formal structure of quantum mechanics is like a sacred text, isn't it? There are so many ways to read it, so many diverse and conflicting meanings to be found in its pages. At weaker moments, one starts to wonder how one is going to reconcile all those meanings.

You ask a good question: "If all the characteristics of QM can be seen as generalized probability tools, how can you think that there will remain a piece of quantum theory with no information theoretic significance?"

This is a place where Hardy and I presently diverge, I think. There is great stuff in his derivation, and a lot that we've all learned from it—particularly, for me, I'm thinking of the origin of the multiplicative structure of Hilbert space dimension—but by thinking of quantum mechanics as a kind of *generalized* probability theory, I think Lucien swings too far toward a purely operational interpretation of quantum mechanics. It becomes a theory *purely* of knobs and transformations and clicks, and stops saying anything particular about reality itself.

What is the origin of the divergence between us? I think it is in his move of thinking that probability theory and information theory are malleable or fluid or empirical to some extent. In my approach, on the other hand, I think of probability theory as a kind of "a priori," much like simple arithmetic is "a priori"—its structure does not depend upon the particular details of the world. In other words, probability theory is not something that can be generalized; it is what it is.

Now, from that point of view, if we find that the content of quantum mechanics is, say, 1) a restriction on the set of probability distributions used to describe one's expectations about measurement outcomes, and 2) a modification from Bayesian conditioning—these are the two ingredients I standardly advertise in my own rewrite of the sacred texts—then those two ingredients are saying something about empirical reality. They are not part of the a priori structure of probability theory.

Another way I sometimes say it in my lectures is that, in the past there has been a lot of work in trying to view quantum mechanics as a kind of larger structure than probability theory, and one recovers standard probability theory in the commutative case. (Hardy's work is along the lines of that tradition.) What I am shooting for, however, is something different. I want to view quantum mechanics as a proper subset of probability theory to the extent that I can. To the extent that I can't, then that is saying something about reality.

I think Hardy's derivation has some element of that approach in it too, but in order to disentangle it all, I think there's still some work to be done. In particular, we've still got to get a better handle on what part of his derivation is actually *generalizing* probability theory—perhaps some of what he was doing has actually been misidentified. I.e., in the end, maybe he wasn't generalizing probability at all, but applying it to a specific physical context.

Anyway, that's my take on it at the moment.

I hope that helps. Good luck with your writing.

25-08-05 *De Finetti's Fascism* (to W. C. Myrvold)

Myrvoldism 3: *I've since finished reading it, and I must say that last paragraph came as a nasty shock! (I had previously known nothing of de Finetti's political convictions). It should come with a disclaimer: Warning: Political content may offend some readers!*

Sorry I didn't mention that detail—his (early-in-life) fascism is certainly an embarrassment. In any case, in that regard, you should have a look at the disclaimer at the end of page 31 of Carl's "Resource Material for Promoting the Bayesian View of Everything" posted at

`http://info.phys.unm.edu/~caves/thoughts2.2.pdf`.

30-08-05 *From Mineralarians to Pastafarians* (to C. H. Bennett and J. A. Smolin)

I'm guessing you guys have already heard about the Pastafarians, but in case you haven't, let me forward on this link that I just got from my friend Jeff.

Nicholsonism 10: `http://www.venganza.org/`

May you be touched by His noodly appendage. RAmen.

01-09-05 *Jazz in Westfield* (to J. W. Nicholson)

Nicholsonism 11: *Now where is my Geritol?*

That reminds me of a time when I was visiting Charlie Bennett and Herb Bernstein in Amherst. Bernstein stopped the conversation to take a break when he remembered that he should take his Metamucil. Then he came back into the room with the bottle and a spoon asking if anyone else would like some.

01-09-05 *BBQW Report* (to S. Hartmann)

How's this? Hope it fulfills your needs pretty well.

Being Bayesian in a Quantum World: A Report

"We've got to change the course of physics; nothing less will do!" That was the rallying cry for our meeting, *Being Bayesian in a Quantum World*, in Konstanz, August 1-5, and the VW Foundation can be sure that we tried our best to live up to this call. With a gathering of nearly 50 of the world's best quantum information theorists and philosophers of quantum mechanics, the sparks were certain to fly and they did. There arose a palpable sense that something new and powerful is brewing in the foundations of quantum mechanics with this Bayesian turn, and the posing of clear-cut research problems became the task of the day. The city of Konstanz provided the perfect setting for the meeting, with just the right variety of restaurants, biergartens, cafés, and walks to keep everyone stimulated from beginning to end. The discussions, often heated, literally started every day in the hotel's breakfast room with the first cups of coffee and often lasted late into the night, moving with the participants from coffee break to lunch to dinner to a café here or there.

The meeting was organized around sets of two or three formal talks at a go—for instance, two talks in the morning, followed by three in the afternoon, most days—with long audience-wide discussions following each set. In total, there were 24 formal talks, with the remainder of the invitees playing the role of session chairs and official discussants. In the following pages, we attempt to give a sense of the subject matter of these talks along with some of the discussion that surrounded them.

For instance, the first three talks of the conference went as follows.

- Christopher Fuchs: This talk tried to set the tone of the meeting by demonstrating that much of the content of finite-dimensional quantum mechanics reduces to two simple modifications of Bayesian ideology—1) the setting of a theory of prior probabilities with regard to the outcomes of a single special quantum measurement, and 2) a modification of the standard Bayesian conditionalization rule for updating probabilities in the light of new information. From this perspective, the formal structure of quantum mechanics becomes *mostly* a "law of thought" (in the same sense that George Boole called probability theory a "law of thought") rather than a "law of nature." Where nature still rears its head—i.e., makes its contingently given empirical content known—is through the higher-level set of reasons for why decision-making agents in this world should use *this* law of thought (i.e., quantum mechanics) rather than *that* law of thought (i.e., some foil theory other than quantum mechanics). Much of this talk was based on `http://www.arxiv.org/abs/quant-ph/0205039`, but there were also many newer points that have not yet been published. For instance, it was shown that the theory of priors mentioned above could be written as two simple restrictions on a probability distribution $p(i)$:

$$\sum_i p(i)^2 = \text{constant} \qquad \text{and} \qquad \sum_{i \neq j \neq k} C_{ijk}\, p(i)p(j)p(k) = \text{constant}$$

for a certain set of coefficients C_{ijk}. A research problem posed to the audience was to give an information theoretic reason for such constraints, particularly for the second one.

- Robert Spekkens: This talk set itself the task of giving a very strong argument for the view that quantum states should be viewed epistemically (i.e., as having to do with states of mind) rather than ontically (i.e., as having to do with states of nature, independently of any agent or observer). The structure of the argument was based on delineating the properties of the epistemic states about a certain toy-model universe and showing that (qualitatively at least) a large number of the most significant results of quantum information theory can be recovered in this model. The reason for introducing the toy model, rather than argue for the epistemic nature of the quantum state directly, is that the toy model allows a means for making a clear-cut distinction between ontic and epistemic states at the outset—that is, it leaves no room for confusion between the two concepts by its very construction. Much of this talk was based on the paper `http://www.arxiv.org/abs/quant-ph/0401052`, but the case was made even more convincing with several new examples exploring the structure of time evolution laws for such toy models.

- Rüdiger Schack: This talk attempted to go still further than the last by arguing that not only should quantum states be viewed epistemically, but more particularly as personalistic Bayesian degrees of belief. That is, even the idea of "a quantum state as a state of knowledge," with knowledge interpreted as "justified true belief," does not go far enough for a satisfactory Bayesian interpretation of quantum states. The argument was made quite thoroughly and generally by mapping the uses of quantum states to the uses of probability itself and then arguing for a "radical probabilist" interpretation of probabilities along the lines of Bruno de Finetti and Richard Jeffrey. Following that setting of the stage, a list of more technical results was shown to the audience. For instance, it was demonstrated that a nearly identical repertoire of theorems are available to the "quantum radical probabilist" as to the "classical radical probabilist" for responding to frequentists and propensitists who feel that quantum experiments can be doing nothing other than manifesting objective chancy propensities—a good example is the quantum de Finetti representation theorem for exchangeable density operators. This talk was in part based on `http://www.arxiv.org/abs/quant-ph/0404156`, but also contained much new material.

Thus went the first evening and then the first morning of the first full day. And the participants saw that it was good! In the afternoon, they came back for more—this time, the subject turned to refining the debate set forth by Professor Schack in the morning: Namely, does or does not the Bayesian project of interpreting quantum states require the notion of "objective chance" in sense of David Lewis or perhaps in the sense of something like Karl Popper's "propensities"?

To that end:

- Marcus Appleby, in his talk, gave a detailed argument for why probabilities should be viewed in the radical probabilist way and significantly expanded a line of thought started in his paper http://www.arxiv.org/abs/quant-ph/0402015, where he compares probabilities to qualia in the old primary-secondary quality distinction.

- Wayne Myrvold, in his talk, argued strenuously that even Bayesians need objective chance to make sense of what they are doing, along with a guiding idea like Lewis's "principal principle" for connecting objective chance to subjective credence. This work is presently being prepared as a paper with William L. Harper, "Why Bayesians Should Countenance Objective Chance."

- Christopher Timpson, in his talk, still further firmed up the debate by using various definitions and techniques drawn from the philosophy of language. Part of his argument can be read at http://www.arxiv.org/abs/quant-ph/0412063 where the main conclusion is: If one is going to get any interpretive traction in solving issues like the quantum measurement problem or the issue of nonlocality in quantum mechanics, "the cognitive state with which one must associate the quantum state is the state of belief, not that of knowledge."

The second day of the meeting, the presentations turned to far more technical and less foundational material. The first two talks concerned the revolutionary subject of quantum computing.

- N. David Mermin, in his talk, considered the model universe of a quantum computer in the way that he presents it in his Cornell course on quantum computing for computer scientists. The main conclusion he draws from this is that one is very naturally led to something like Bohr's view of quantum mechanics; see http://www.arxiv.org/abs/quant-ph/0305088. In the present context, he particularly focused on how a radically probabilist Bayesian view of the quantum state could contend with what he now considers the main mystery of quantum mechanics—those situations where quantum mechanics can make predictions with certainty.

- Hans Briegel, in his talk, gave a detailed description of a model of quantum computation (different from Mermin's) where the computation is enacted solely from quantum measurements (rather than unitary time evolution) on an array of quantum systems initially prepared in a fixed entangled quantum state; see http://www.arxiv.org/abs/quant-ph/0301052 and http://www.arxiv.org/abs/quant-ph/0504097 for two reviews of this very deep idea. In the present context, it was explored how this model seems to demonstrate that it is nonclassical *correlations* that lie behind the power of quantum computation, rather than the sensationalistic imagery used by the popular press and David Deutsch—namely, that quantum computation attains its power from parallel computations in parallel universes. To the extent that the idea of correlation can be given a purely Bayesian treatment, one can start to search for deep connections between a Bayesian interpretation of quantum states and the power of quantum computation.

The afternoon talks concerned various Bayesian-like representation theorems for quantum states:

- Mark Srednicki addressed the quantum de Finetti representation theorem, exploring whether one could indeed make sense of the idea of a "probability of a probability" and, consequently, the probability of an unknown quantum state.

- Renato Renner gave a representation theorem for finitely exchangeable quantum states (along the lines of a similar classical theorem of Diaconis and Freedman) and then showed that the theorem was crucial for proving the unconditional security of certain quantum cryptosystems.

- Todd Brun displayed a criterion (and proved a uniqueness theorem) for when two separate agents with distinct quantum states for a single quantum system can pool their expectations to form a new and improved quantum state. He also explored several notions for quantifying the amount of compatibility of distinct states, and posed various technical questions to the participants along those lines. Some of those problems were solved by Michael Nielsen and will eventually lead to publication.

Thus the afternoon and the morning of the second day passed. And the participants saw that it was still good! So too went so much of the rest of the conference. The third day saw in the talks of David Wallace, Howard Barnum, and Carlton Caves an eager, and very technical, debate on whether the quantum probability rule can be derived (or even made sense of!) in the context of a many-world interpretation of quantum mechanics (which is so popular in the quantum computing community). The fourth day brought attention back to some of the ideas explored in the opening talk of Fuchs: Namely, the extent to which the quantum updating rule can be viewed as a variation on Bayesian conditionalization. The talks of Veiko Palge, Matthew Leifer, Guido Bacciagaluppi, and Thomas Konrad all dealt with various details and critiques of this idea. On a more philosophical note, the talk by Michael Dickson—editor of the prestigious journal *Philosophy of Science*—placed the discussion of a Bayesian view of quantum mechanics within a neo-Kantian or neo-Carnapian framework. On the fifth day of the meeting, Armond Duwell and Amit Hagar opened the morning session by exploring the extent to which one might really hope to make a clear-cut separation objective and subjective aspects of quantum theory. The afternoon talks by David Poulin, Howard Wiseman, and Lucien Hardy explored the extent to which Bayesian and operationalistic interpretations of quantum theory can be motivating factors in finding new physics—one particular item of concern was in aiding the formation of a quantum theory of gravity.

In general, the meeting was a significant success. As already stated, the debate was strong, but the sense of a certain momentum forward was even stronger. It is fair to say, for instance, that a significant fraction of the participants will be having their students, graduates students, and postdocs exploring subjects brought to the fore in this meeting for a significant time to come.

Finally, we mention that a further sense of the excitement felt at this meeting can be read about in the French magazine *Science et Vie*, which is devoting its October 2005 cover story to our meeting, and also in an upcoming article in the American magazine *Scientific American* by one of the organizers.

06-09-05 *A Homer Simpson Drool* (to J. W. Nicholson)

Look at this baby, `http://www.pcmag.com/article2/0,1895,1850249,00.asp`. I'm toying with the idea of getting something like this.

I picked out a book for you, I think: Michael Polanyi's *Science, Faith, and Society*. It's a small one. I might try to read it again before I hand it off to you (to see if I'm able to believe it now, like I think I did before).

07-09-05 *EPR* (to A. Plotnitsky)

Plotnitskyism 15: *I am not sure, however, that I am quite ready to make any serious statements concerning entanglement in qft theory, and for the moment I mostly doing some reading. There is not that much actually.*

Let me try remedy your last sentence, a little at least, by giving you a few more references. First and foremost let me recommend a tutorial paper by my colleague here at Bell Labs, Steven van Enk. You can find it at: `http://www.arxiv.org/abs/quant-ph/0403119`. His discussion there is quite in line with the sorts of things I was telling you the last time we met (was it in Sweden?).

Steven also recommended the following two papers by Werner (and a student maybe)—S. J. Summers and R. Werner, J. Math. Phys. **28**, 2440 (1987); ibidem **28**, 2448 (1987)—though he warned that they are quite technical.

Finally, for the heck of it, I used the ISI index to see what papers have cited the Summers-Werner paper, and I paste in my findings below. Articles 1, 3, and 4 may be particularly useful to you. And within that you might get the most from the Peres-Terno paper. That paper can also be found on `quant-ph` at: `http://arxiv.org/abs/quant-ph/0212023`. Have a look at the section titled "Entanglement in quantum field theory" starting on page 21; that may give you some useful pointers.

Good luck in your thinking.

07-09-05 *Quantum Theology* (to M. O. Scully)

Now that Labor Day has passed, it's time for me to get back to work in a serious way. I apologize for taking so long to comment on your son's draft—and I'm still not going to do so in any detail today—but after my schedule of constant meetings this summer, I found myself so mentally drained that I seem to have lost the ability to speak for a while. But my tongue is getting loose again.

I read Chap. 11—the one on quantum theology—of Rob's draft on a plane somewhere between Brussels and San Jose a while ago. First off, I caught a lot of typos [. . .]

Second, before I comment in any detail, I want to read it again. So, if there have been any major revisions, maybe it'd be a good idea to email me the new version before I plunge ahead.

Concerning one thing you seemed to ask about particularly at our lunch meeting—i.e., about the spaceship example, where the uncertainty principle is amplified up to a level where it may affect practical human decisions—I think I like it. *But* I wouldn't call it a "proof" of free will as you seemed to want to do at lunch that day. Instead I think its import is that it forces us to contemplate as ubiquitous (rather than rare) the kind of situation William James talks about in two quotes that I'll attach as a PDF file. Particularly, look at the second quote. Its message is that free-willed agents can "shape" reality (in a way) when they have to, and what Rob's example shows is that it is a consequence of quantum mechanics that we have to do such a thing all the time.

But as I say, I'll try to comment in detail later. In the meantime, you and Rob might want to read (and start thinking about) these great James quotes. [See 21-11-01 note to Schack, "Pragmatism versus Positivism".]

07-09-05 *Heisenberg Quote* (to M. O. Scully)

Right, I had also promised to send you a quote of von Weizsäcker's about meeting Heisenberg. One such quote is below, but it is not quite as I remembered it. I thought I remembered von Weizsäcker as saying that Heisenberg told him that he had "proven free will" that day—a much more dramatic statement than what he says below. So, either I was thinking of a different version of the same story—and I'll have to work harder to dig up that quote—or maybe my memory is simply failing me finally. I'll let you know if I come to a conclusion.

From C. F. von Weizsäcker, "Physics and Philosophy," in *The Physicist's Conception of Nature*, edited by J. Mehra (D. Reidel, Dordrecht, 1973), pp. 736–746:

> I remember very well how I met Heisenberg for the first time when I was a boy of fourteen. We happened to be in Copenhagen at the same time. Soon afterwards, in a taxi in Berlin in April 1927, he told me about the uncertainty principle. I was fourteen years old, and I was greatly moved by this new idea. I got the impression that if this was physics, one must study physics. This was the first moment when I saw that there was a hope of bringing together the two different parts: the objective world described by classical mechanics and the world of man. I didn't know how, but somehow it meant that there was a connection between the two. And this was the way in which Heisenberg himself was expressing it when he said that the sharp distinction between subject and object was no longer possible in quantum theory.

07-09-05 *The Activating Observer* (to M. O. Scully)

While I'm sending you multiple emails today, let me go ahead and send you another. I call it "The Activating Observer: Resource Material for a Paulian-Wheelerish Conception of Nature," and it's been the source of some of the quotes I've sent you (more accurately, it's where I've been storing them). With regard to Rob's book-writing project, he may find some useful material in there.

As you'll see, I've long had an interest in the idea that quantum mechanics may show that nature is a little more malleable to the presence of decision-making agents than had previously been conceived. Part of Rob's Chapter 11 seems to be concerned with that too, so that's why I say he may find some useful resources in the present draft. Sorry John Wheeler is not yet better represented in this draft, but the problem there is a historical one: I had read all those papers of his that I cite a long time ago, before I started collecting quotes. Now I need to go back and scan that material in with my scanner. It'll happen eventually; it just hasn't been done yet.

21-09-05 *Egregiously Ingenuous* (to G. Brassard)

Brassardisme 18 : *According to my dictionary,*

> **egregious**: adjective
> 1. outstandingly bad; shocking: egregious abuses of copyright.
> 2. archaic: remarkably good.

Here's another word I've always loved as having dual and contradictory meanings:

> **ingenuous** (în-jèn′yi-es) adjective
> 1. lacking in sophistication or worldliness; artless.
> 2. obsolete: ingenious.

And just in case you don't know:

> **ingenious** (în-jên′yes) adjective
> 1. Marked by inventive skill and imagination.
> 2. Having or arising from an inventive or cunning mind; clever.

I learned the meanings of ingenuous (it wasn't a word I had known before) when Göran Lindblad wrote in his paper "A General No-cloning Theorem"

> A number of different versions of no-cloning theorems have been published. In particular, the recent no-broadcasting theorem of Barnum et al. is a very general result. The proof is ingenuous, and the method used is far from obvious. Their result inspired me to try to find another approach which uses standard results on operator algebras and systematically exploits the structure of completely positive maps.

I was always very proud of Lindblad's saying that, but who knows!

Compost is finished now, and the new grass is already coming up. Rüdiger Schack is visiting and we're working on our latest Bayesian screed. (You tell me which meaning.) And in particular, I'm heartened again to get at the question, when it comes to quantum states, if they are nothing more than information, then "Information about what?"

By the way, we're also dropping in on Hans Halvorson and Bas van Fraassen's course today at Princeton. Have a look at: `http://www.princeton.edu/~hhalvors/teaching/phi538_f2005/`.

23-09-05 *Bayesians at FPP?* (to A. Y. Khrennikov)

Khrennikovism 8: *I would like to try to stimulate you to submit a paper to our conference proceedings which will be published by American Institute of Physics.*

I'm sorry, I would like to, but I just can't get a paper out at this time. I will definitely make a promise to give you a paper for your next proceedings.

Speaking of that, as I understand, you want me to be one of the organizers of your next meeting on Foundations of Probability and Physics. Do you know when that will be held yet? Anyway, I have an idea: What would you think of having a session devoted to the Bayesian or "radical probabilist" approach to quantum probabilities? I can think of several very good people I could invite (including Persi Diaconis). You'll note I organized a rather large international meeting on this subject just this year with a lot of relatively famous people there (look at

`http://web.archive.org/web/20090511060206/http://www.uni-konstanz.de/ppm/events/bbqw2005/`.

So, I hope to impress on you that this is a growing and important subject, and it would be nice if you had some representation of it beyond me at your FPP meeting. As you can guess—as I did before for you—I'll try to bring the American entrepreneurial attitude to my organizing of this session to maximize its success.

Also, there is a very large Bayesian meeting in Valencia, Spain from June 1–6, 2006. See `http://www.uv.es/valenciameeting`. There will be over 600 attendees there, they say, and maybe that will help us draw in some of the bigger names as they will be flying to Europe during a time very similar to the time of your meeting anyway.

28-09-05 *Visitor Exhaust* (to J. W. Nicholson)

Did you have any luck with the Polanyi book? Believe it or not there were couple of times this and last week when I wanted to be able to quote one of the passages in it to Rüdiger. (Probably just a function of it being fresh on my mind.)

05-10-05 *Nobel* (to J. W. Nicholson)

BTW, you must be pleased with this year's picks for the Nobel physics prize . . .

05-10-05 *Too Long Draft* (to A. P. Ramirez)

I'll be in tomorrow at 9:00, and I'll drop by your office. Attached is my "first draft" of a Form 1. Somehow I got confused and thought the rules had changed this year and that we were supposed to write 2 pages front and back. Dick set me straight today, so I'm going to condense significantly ... but not tonight. Anyway, maybe the present draft will give us something to talk about tomorrow, and I'll attach it forthwith. Also forgive me for the too flowery style—I'll be fixing that too—or at least tolerate me for a while.

> EMPLOYEE REPORT ON ACTIVITIES AND ACCOMPLISHMENTS
>
> This year, unfortunately, I talked far more than I wrote . . . but at least I calculated more than I talked, if that's any consolation! Allow me to report my progress in that order: 1) talks and organizational efforts, 2) completed and near-completed scientific papers, and finally 3) the yet unpublished calculations that consumed much of my attention.
>
> 1) Much of this year represented a whirlwind of travel for me. I made 10 (invited) international conference appearances and gave 6 external physics colloquia and seminars. I had to turn down at least 6 colloquia and conference invitations for lack of time or scheduling difficulties—one invitation even a Caltech colloquium. (In dollar terms, I tabulated that my hosts spent over \$19,000 on my behalf; in contrast, I spent only \$1,500 of my allotted \$3,000 of Lucent travel funds.)
>
> My overwhelming reason for taking on all this travel was to establish and entrench a certain point of view about quantum states within the quantum information community. This point of view—sometimes called the Bayesian approach to quantum probabilities—is my strongest intellectual child and has finally started to command serious attention around the world. For myself, I truly believe it is an engine that will take quantum information theory and computing to new heights. The key idea is that *almost* all of the formal structure of quantum theory (complex Hilbert spaces, state vectors, unitary time evolution, etc.) represents not so much a *direct* description of the quantum world itself, but rather a modification of probability theory induced upon the gambling agents (a.k.a. experimentalists) immersed within that peculiar world. Thus the research task becomes to find the residue of quantum theory that *is not* merely a modification of probability theory—the suspicion is only therein lies the real source of power in quantum information and computing. In fact, only once that part of quantum theory is uniquely identified will we have a firm grasp on the most interesting things that can be done with quantum information.
>
> In Andrew Steane's seminal paper "A Quantum Computer Only Needs One Universe" [*Studies in History and Philosophy of Modern Physics* **34B**, 469–478 (2003)], he fairly well demolishes the idea that the power of quantum computers comes from massively parallel computation (in parallel universes). In its place, he puts the following conjecture:
>
>> A quantum computer can be more efficient than a classical one at generating some specific computational results because quantum entanglement offers a

> way to generate and manipulate a physical representation of the correlations between logical entities without the need to completely represent the logical entities themselves.

Or, as he goes on, "[T]he basic fact which quantum computers take advantage of is that multi-partite entanglement offers a way to produce some computational results without the need to calculate a lot of 'spectator' results. For example, we can find the period of a function without calculating all the evaluations of the function." This idea rings true within the Bayesian approach to quantum information, with its emphasis on 'correlation' as just another species of the peculiar probability calculus the world forces upon us. Fleshing out ideas like this are indeed a prime area for exploration in the Bayesian approach.

Particularly to get the community thinking in these directions, I, along with Carlton Caves, Stephan Hartmann, and Rüdiger Schack, organized one of the more significant quantum information meetings this year to explore just such issues. The meeting title was *Being Bayesian in a Quantum World* and it was held in Konstanz, Germany, August 1–5, by way of generous funding of the Volkswagon Foundation (67,000 euro). We had 54 participants drawn from some of the best of the best of quantum information theory—the names Michael Nielsen, David Mermin, Gerard Milburn, John Smolin, William Wootters, Carlton Caves, Lucien Hardy, Norbert Lütkenhaus, William Unruh, and Hans Briegel will hopefully ring a bell or two. For five days the talks and discussions centered on the issues raised above, and the verdict is that this point of view is definitely on the map. For instance, the French magazine *Science et Vie* made a report of the meeting as their cover story for this month's issue, and *Scientific American* has invited me to write a full article on the subject in the coming couple of months.

In total, I am quite pleased about the extent to which my talks and organizational efforts have gotten the quantum information community thinking along these directions.

2) With regard to publications, let me mention the two most significant pieces of *new* work—one recently posted on the archive and submitted to *Physical Review A*, and one in draft form, soon to be posted.

The first—titled "Influence-Free States on Compound Quantum Systems" and coauthored with H. Barnum, J. M. Renes, and A. Wilce—explores the connection between a previously published derivation of mine of the tensor-product rule for combining quantum systems and the idea that measurements on one side of an entangled quantum state cannot be used to communicate instantaneously to the other. In particular it is shown that a kind of Bayesian updating of the remote system's quantum state after a localized measurement goes hand in hand with the idea of no-signalling. Beyond that, we further elucidate a trouble that came up in the previous derivation of the tensor product rule: Even though a no-signalling assumption specifies a kind of Bayes rule, and indeed even specifies the tensor-product rule for combining quantum systems, it is not strong enough to uniquely pin down that the joint probabilities for the outcomes of localized measurements must be derived from a standard quantum state (i.e., a bipartite positive-semidefinite operator of unit trace). It only specifies the weaker requirement that the probabilities be derived from bipartite operators that are "positive on pure tensors." Thus an extra assumption is clearly needed to get all the way back to quantum mechanics. What that extra assumption is, unfortunately, we do not yet know. However, we were able to show in this paper that this more general class of operators are pathological in the sense that they are not well behaved when they are incorporated into a quantum teleportation scheme. In general, this work is part of a larger effort to get a the root of the idea of quantum entanglement.

The second paper — tentatively titled "Accurate Quantum State Estimation via 'Keeping the Experimentalist Honest'" and co-authored with R. Blume-Kohout and P. Hayden — takes another look at the process of quantum-state tomography, but via Bayesian ideas and methods. It is based on first defining an "honesty" function that derives from the old (Bayesian) mathematical puzzle of "keeping the expert honest." In this puzzle, an expert is hired to give his opinion of whether one or another event i will occur, and he expresses that opinion in terms of a probability assignment p_i, where $p_i \geq 0$ for all i and $\sum_i p_i = 1$. But *opinions* are not objectively testable—certainly not by simply looking at the actual event that occurred. So how would one ever know whether the expert is lying about his opinions? For instance, the expert might actually believe p_i, but because he does not particularly like his customer and ultimately wants to see him fail, he might offer the distribution q_i instead. The trick is to choose a payment scheme that gives an incentive for the expert to keep honest. For instance, if the client agrees only to pay the expert after the actual event i happens, and only then an amount $f(q_i)$ for some function f acting on the expert's offered opinion q_i, then one can see that a good incentive scheme should have the property that

$$\sum_i p_i f(q_i) \leq \sum_i p_i f(p_i) \ ,$$

with equality if and only if $q_i = p_i$. In other words, if the expert's real opinion is p_i, then he should expect to lose money any time he offers an opinion different from his true one. Remarkably, it can be shown that this inequality alone uniquely specifies the function f up to a constant and it is $f(x) = -\log x$. (I believe this was first shown by Aczél in the mid 1970s.) A consequence of this result is that when an expert is honest, he can expect to be paid (up to a constant) an amount that is equal to the Shannon entropy $H(p) = -\sum_i p_i \log p_i$ of his true opinion.

In any case, on these ideas, we build the concept of an honesty function and generalize it to the quantum case, where an expert offers as an opinion a density operator ρ rather than a probability distribution. In particular, we show that Bayesian updating in the usual sense (for an exchangeable density operator assignment) is the most honest strategy a quantum-state tomographer can use before passing his opinion on.

3) Now let me come to my most passionate work for this year—it is work that is still not complete and certainly not published. What I have been seeking is a well-behaved and *insightful* representation for quantum states (in finite dimensional Hilbert spaces) that is purely in terms of a single probability distribution for each state. It is easy enough to see the starting point for such an endeavor: One merely chooses a generalized measurement or positive-operator-valued measure $\{E_h\}$, $h = 1, \ldots, d^2$, for a Hilbert space of dimension d, where all the operators are linearly independent to be a kind of fiducial measurement. Then the probability distribution $p(h) = \mathrm{tr}\, \rho E_h$ for the outcomes h of such a measurement will uniquely specify the density operator ρ. This can done easily enough, as there are many constructions $\{E_h\}$ that will do the trick. But which of these constructions will lead to the most insight with regard to the source and ultimate power of quantum information processing? The hope here is to find a transparent way to see the extent to which the structure of Hilbert space arises from a kind of information theoretic constraint on the expectations any experimentalist should adopt for the outcomes of his quantum experiments.

One promising candidate for an insightful fiducial measurement comes from my work in defining a measure of "quantumness" for sets of quantum states that I reported in last year's Form 1 (and was published in the journal *Quantum Information and Computation* this year). There, it was shown that if any set of d^2 one-dimensional projectors $\Pi_i = |\psi_i\rangle\langle\psi_i|$ exist with the property that $\operatorname{tr}\Pi_i\Pi_j$ is constant for all $i \neq j$, then such a set would fulfill a criterion for being the most quantum a set of states can be. Concerning the present issues, a nice corollary of the old work is that if such a set exists, then the operators $E_h = \frac{1}{d}\Pi_h$ would be linearly independent and thus the set $\{E_h\}$ would be adequate for giving rise to a fiducial measurement.

Ostensibly another promising measurement comes about by simply trying to choose a set of E_h to be as orthogonal to each other as possible—i.e., one would like to get as close as possible to an orthonormal basis of operators while still preserving that the set of operators describes a potential measurement. One of the things I proved this year is that this other class of candidate measurements actually turns to be identical to the previous one!

Thus the more reason to try to work out quantum mechanics in the language of this particular class of fiducial measurements. But do they exist? Computational work from several groups seems to confirm that they do (for dimensions up to $d = 45$ at least). But despite a handful of papers on the subject now posted on the `quant-ph` archive by various groups and a couple hundred pages of my own calculations, an actual proof—and more interestingly an analytic construction—is still up for grabs. I have, however, made plenty of progress ... and in directions that no one else seems to have taken. For instance, to record my strongest result yet, I have reduced the problem to simply showing the existence of a $d^2 \times d^2$ Hermitian matrix G with constant diagonal entries and off-diagonal entries all of the form $e^{i\theta_{hk}}$ such that

$$\operatorname{tr} G^3 = \operatorname{tr} G^4 = d\ .$$

If one can prove the existence of any solution whatsoever to those two equations, then the existence of such a measurement will be ensured.

On top of that I have been able work out what the full set of quantum states looks like in this language if these very nice measurements always exist—that is, I am getting very close to my real goal. For instance, in this language a pure quantum state is any probability distribution $p(h)$ over d^2 outcomes satisfying the following two equations:

$$\sum_h p(h)^2 = \frac{2}{d(d+1)}\ ,$$

$$\sum_{jkl} p(j)p(k)p(l)\operatorname{tr}(\Pi_j\Pi_k\Pi_l) = \frac{d+7}{(d+1)^3}\ .$$

The first of these equations is very clearly an information theoretic constraint, in terms of a Rényi entropy. But what of the second? This strikes of the sort of "residue" mentioned of the first section of this report. The numbers $\operatorname{tr}(\Pi_j\Pi_k\Pi_l)$ represent universal constants whose values are deeply intertwined with what quantum mechanics is actually about. At the moment, I think there is no more exciting question than pinning down what exactly this means.

SUMMARY: I hope the three sections above give some flavor of my research activities this year. As it turns out, yesterday I was heartened to hear that Roy Glauber won part of this year's Nobel prize in physics . . . not because I think I could ever aspire to those heights, but because Glauber's work reminds us of the power that can be had by finding just the right representation for certain physical phenomena—in his case recognizing the importance of coherent states for representing quantum states of the electromagnetic field.

Quantum information is still in search of the right representation for its most fundamental phenomena, and I hope the work described above is a significant contribution in that direction.

13-10-05 *Nature Physics Article* (to G. Brassard)

Brassardisme 19: *Ever heard of Frieden, Soffer or Brown?*

Frieden's stuff is pretty soft—i.e., not to be taken seriously. The basic thing he gets is the time-independent Schrödinger equation to come out of a kind of stochastic (hidden-variable) model. But that's a far cry from quantum mechanics . . . and not even nearly as complete as Bohm's hidden-variable theory (of which I wouldn't consider a real derivation of QM either). The only minor similarity between Frieden's work and our program is that we both use the word "information"—there the resemblance stops.

17-10-05 *Stomach Bug* (to S. L. Braunstein)

I remember ending our conversation last Friday by saying, "I'll almost surely be in next Monday." Teaches you something about the concept of certainty (and its fallibility). I've been up much of the night with a stomach bug and there's every indication this morning that it still hasn't abated. So, I think in good conscience, I probably shouldn't come in today . . . for myself and everyone around me. Hope that doesn't screw up your day's plans too badly, and I hope you get this note before you get on the road.

18-10-05 *Hello* (to C. Hewitt)

Thanks for all that; I'm flattered. (Though, too bad you—or, your admiration at least—weren't around when I interviewed with the MIT EECS dept in '97 or '98! I might be living in Cambridge, MA rather than Cranford, NJ!) I'll have a look at those links; I had never heard about actor theory before. But then again, I know almost nothing about programming—I've got a lot to learn.

If there really is a similarity between the actor model and my thoughts on quantum mechanics, then I suspect there is an even larger similarity between it and the "radical pluralism" of William James (i.e., a particular flavor of American pragmatism). If you haven't discovered James yet, you might enjoy reading him—it's a whole philosophy built on the very idea that there's no "global state."

Carl's Preply

I am an admirer of your work. In fact I made use of it in the following Wikipedia article (hopefully not distorting your views too much):

`http://en.wikipedia.org/wiki/Actor_model_history#Relationship_to_physics`

Also you might be interested in the following article:

http://en.wikipedia.org/wiki/Actor_model_theory

Your comments, questions, and suggestions are greatly appreciated.

Carl's Reply

Sorry that I missed your job talk. But since I am CS my admiration might not have been of much help!

Meanwhile, your ideas have proved too radical for some of the current physics moss backs at the Wikipedia so the ideas have migrated to[83]

http://en.wikipedia.org/wiki/Actor_model%2C_mathematical_logic%2C_and_quantum_physics

You should be able to read most of the above article in conjunction with

http://en.wikipedia.org/wiki/Actor_model_theory

even without any background in software.

I would greatly appreciate your comments, questions, and suggestions.

PS. Yes, James is wonderful.

18-10-05 *Lazy Abstract* (to H. C. von Baeyer)

With time running short today, I think I'll just send you an old abstract (with only some very minimal modifications), rather than writing you something new. Hope you don't mind.

Title:

Drawing Quantum Mechanics on a Probability Simplex

Abstract:

What is the difference between a quantum observer and a weather forecaster who uses classical probability theory? Not much. But where there is a difference, there lies quantum theory's most direct statement about properties of the world by itself (i.e., the world without observers or weathermen). In this talk, I will try to shore up this idea by writing quantum mechanics in a way that references probability simplexes rather than complex Hilbert spaces. By doing so, the connection between quantum collapse and Bayes' rule in classical probability theory becomes evident: They are actually the same thing up to a linear transformation depending upon the details of the measurement method. Looking at quantum collapse this way turns the usual debate in quantum foundations on its head: only local state changes look to be a mystery. State changes at a distance (as after a measurement on one half of an EPR pair) are completely innocent—they simply correspond to applications of Bayes' rule itself, without the extra transformation; that is, collapse-at-a-distance is nothing more than the usual method of updating one's information after gathering data. Thus the idea develops that if a quantum reality is to be found in the quantum formalism, it will be found only in the formalism's *deviations* from classical probability theory: Reality is in the difference.

[83] Apparently they are not represented there anymore either; maybe they were migrated into oblivion, or this is what was being referred to: https://en.wikipedia.org/w/index.php?title=History_of_the_Actor_model&oldid=29339394.

18-10-05 *Flight Schedule?* (to H. C. von Baeyer)

von Baeyerism 1: *The question I am most interested in concerns Zeilinger's principle:*

`http://www.univie.ac.at/qfp/publications3/pdffiles/1999-10.pdf`.

I would say the most serious technical development of an idea along those lines is Rob Spekkens' "toy model" even though, by its very construction, it can only go part of the way toward quantum theory. Download: `http://arxiv.org/abs/quant-ph/0401052`. In any case, I think it is one of the best, most convincing arguments for the epistemicity of quantum states around. It's worth the study, both for what it does and what it can't do.

Is there something to Zeilinger's principle? Maybe, but at present I think it's still more of an "idea for an idea" than a full-blown idea itself. Certainly it seems important to better understand how (and then find the reasons for why) our uncertainties scale with the amount of quantumstuff that they do—there's strong indications that this is indeed a fruitful direction for research. It'll be fun discussing these things with you.

24-10-05 *Books, Bookcases, and Information* (to J. B. Lentz & S. J. Lentz)

Thanks for the nice electronic birthday card. The kids and I both loved it. I had a nice and thoughtful day for my birthday. I went in to New York City and acquired 10 more books for the "pragmatism collection." If we could just find the right bookcases, the front room—i.e., the library—would look great. Who would have thought the books (given the subject) would be easier to get than the bookcases?

Thursday I fly to Newport News to give the physics colloquium at William and Mary in Williamsburg. In preparation for that, I've been reading Hans Christian von Baeyer's book, *Information: The New Language of Science*, this week. I figure it is a nice courtesy since von Baeyer is the fellow who invited me (never met him before). The book has turned out to be quite a pleasure though—accurate and entertaining, both; so I'm glad I took on the project. Brad, I think this is one you might enjoy if you're looking for some leisure reading—the kind of thing, at least, that I might imagine as leisure reading for a Chief INFORMATION Officer. Von Baeyer is exceptional in that his research field as listed by his department is literally "public understanding of science." Anyway, he does a very good job on everything from Bayesian probability to quantum computing in this book—you might find it an enjoyable introduction.

25-10-05 *GOBs, Bobs, Steering & Teleportation* (to H. Halvorson & B. C. van Fraassen)

... and if you're patient there's even a little bit about perspectivalism at the end.

Thanks again for letting me attend your seminar last Wednesday. I had a good time, and I hope I will push myself to continue coming. (If it only weren't for that darned long drive: 45–65 minutes, depending on traffic.) The main thing I get out of the deal, of course, is not so much the quantum-information material, but that the lectures and discussion points give me a window into how philosophers are starting to think about this subject. That's valuable for me.

Anyway, spurred by what I heard at the last seminar, I put together a few notes, and they're pasted below. Feel free to not read any further than this sentence if you're getting tired of my emails: These exercises of sentence construction are always useful for me, even if for no one else; so certainly I won't be hurt if you send this email to the recycle bin and don't reply. However, since you were the discussion leaders, I figure I might as well share the notes with you, even if only out of courtesy—I only hope they won't cause you to give me a failing grade for the semester!

Maudlin

First off, let me tackle something Maudlin said near the end of the seminar. As I recall, he basically asserted that the phenomenon of "steering" is a very real effect (I'm tempted to put the word "ontic" into his mouth here), that Bell had taught us such, and that the phenomenon has very useful consequences—for instance he tried to make the last point dramatic by putting a gun to Bob's head. As I recall, the point that started all this drama was Hans' statement that he was reluctant to accept the idea that a localized measurement could change the global *quantum* state for a bipartite system.

The main point I want to make here is that Maudlin's drama really carries no force as far as saying something *unique* about the quantum world. Let me give a contrived example that is a) not quantum mechanical, but b) serves the role Tim sought to fulfill via quantum entanglement (and quantum entanglement only).

Suppose Bob has in front of him four buckets, labeled 1, 2, 3, 4, and that there is a ball in precisely one of them—the rest of them are empty—but Bob has no clue which one. Furthermore unfortunately for him, these buckets along with the one ball are all themselves hermetically sealed in a GREAT OBFUSCATING BOX, or GOB. The definition of a great obfuscating box is that one can query it to ask a yes-no question of the ball's position within the collection of buckets, but it will never let the questioner know the position more precisely than two buckets' worth. For instance, one might ask "1v2?", meaning "is the ball in bucket 1 or 2?", to which the GOB will answer yes or no. If it answers "yes", then one is assured that the ball is indeed in bucket 1 or bucket 2; if it answers "no", then the ball must be in either bucket 3 or 4. Similarly one could ask the GOB "2v3?" A "yes" answer narrows the ball's position down to 2 or 3, and a "no" answer narrows it to 1 or 4. And similarly still, one could ask the GOB "1v3?" to get an appropriate answer for that question. The nasty trick is that only one of these three questions can be asked and never another one.

So, with a GOB in place of a qubit, let's now go back to the rest of Maudlin's scenario. Charlie holds a gun to Bob's head and says, "I'm going to ask the GOB this question "XvY?", and if you correctly predict the outcome before I get the result from the GOB itself, then I'll let you go free; but if you get it wrong, then BAM!, a bullet in the head! By the specification of the scenario, without any further help, there's very little Bob can do but make a guess and say his prayers.

But suppose Bob's friend Alice happens to overhear what's going on and can surreptitiously talk to him. If it turns out that she knows she has an identically manufactured GOB—assured by the factory to have a ball in precisely the same bucket as Bob's—then everything changes. She can help her friend by asking her GOB the question Charlie is about to ask his GOB and then slipping the answer back to Bob. Bob's GOB, we know, will give the same answer if she asks the same question. Alice, of course, still won't know precisely what bucket her ball is in (and consequently which bucket Bob's is in), but the information she gained is enough to keep Bob from getting shot.

So there: All the drama of Maudlin's example, all the same conclusions operationally, but where's the quantum mechanics? Where's the nonlocality? There is none. The example is powered solely by Bob's having a friend who is capable of relieving him of some of his uncertainty. Alice passes off her own incomplete information to Bob, and that saves the day. In the context of quantum mechanics, Schrödinger called that first action of Alice's (before passing off the information) "steering," but that seems like such a weird term for an example like this: Alice isn't steering anything at all; she's just trimming her uncertainty one way or another by making the choice to ask one question or another.

Having a hidden variable—i.e., the actual position of the ball in the buckets—serves only as a dramatic device in this example: For it makes it absolutely clear that Alice's action of learning at her site changes nothing about the reality at Bob's site. The reason the situation *seems* to look different in quantum mechanics is because we have all become convinced (through Bell-like arguments) that there can be no local hidden-variable theories underlying quantum mechanics. But from my own perspective, that's an over-hasty conclusion. In fact, it's a *non sequitur*. One can have uncertainties about many things, from localized variables to relations between very distant systems to the consequences of one's own actions. And in all of those cases, one can invent "passing off privileged information" scenarios like the one above to make dramatic a kind of "steering phenomena." Ruling out localized hidden variables (which I definitely believe has been done in quantum mechanics) in no way pushes the further consequence that "steering" is an ontic phenomenon rather an epistemic one.

In fact, I have always hated the word "steering" as a name for this phenomenon in the quantum context because it already loads the dice toward an ontic interpretation of quantum states. Indeed, one can see that from the very beginning in Schrödinger's early 1935 papers and his correspondence with Einstein. Schrödinger *starts* with the assumption that quantum states are ontic states (rather than epistemic states), and is therefore led to introducing some ad hoc rules for entanglement-decay so as to get out of a kind of action at a distance. On the other hand, Einstein (as exhibited in correspondence with Schrödinger reprinted in Fine's book *The Shaky Game*) starts with the rejection of action at a distance, and concludes that "steering" must be an epistemic phenomenon.

I side with Einstein, of course. Thus, to load the dice toward my own interpretation, I much prefer the words "conditioning" or "conditionalizing" (as from simple probability theory) or even "updating" over "steering." These words much more adequately convey the passive nature of what is going on in updating the quantum state of a far away system.

By the way, now that I've said all that, let me report that I'm doing nothing with my GOBs that Rob Spekkens isn't already doing with his toy model: `quant-ph/0401052`. I think that is conceptually the most important paper written concerning the interpretation of quantum information written in long while, and well worth everyone's understanding.

Teleportation

But isn't quantum teleportation the indication of something much deeper going on with quantum steering than with epistemic updating? No, it is just about the same thing fancied up into a more complicated situation.

Let me try to make that clear by writing down an example that I told Hans about in conversation at our second-to-last meeting. In usual teleportation, the cast of characters includes an Alice and a Bob who share two systems in a maximally entangled state, and implicitly, a Charlie who prepares a third system in the state of his choice and then hands it off to Alice. Alice then performs a measurement on the two systems in her possession and announces the result of the measurement to Bob. The teleportation process is completed with Bob performing an operation on his system conditioned upon his newly acquired information.

In what sense is it completed? Only in this: If Charlie has the promise that Alice and Bob went through all the actions described above, then he can safely ascribe the same quantum state to Bob's system that he had originally ascribed to the system he handed off to Alice.

Here's a corresponding classical example. In place of entanglement, let us equip Alice and Bob each with a coin (oriented heads or tails) encased in a magical opaque box. These magical opaque boxes have the following properties: 1) though one cannot see how a coin is oriented within it, one can nevertheless reach inside a box and turn the coin over if one wishes, and 2) if one touches two of these boxes together, they will glow green if the coins within them have the same orientations, and they will glow red if they have opposite orientations—the glowing reveals nothing about the actual orientation of either coin, only about their relationship. Finally let us stipulate the following for Alice and Bob: That their opaque boxes contain identically oriented coins, but Alice and Bob (or anyone else for that matter) know nothing more about the coins beyond that. In other words, Alice and Bob possess HH or TT, but they do not know which.

Now, as in quantum teleportation let us introduce a third character, Charlie. Charlie has an opaque box of his own. But let us give him some partial certainty about the orientation of his coin. Particularly, let us suppose he ascribes a probability p for his coin to be heads. This is a real number between 0 and 1, and in principle it might take an infinite number of bits to specify.

Here's the protocol. Charlie hands off his coin (encased in a magical opaque box) to Alice. Alice touches her newly acquired box to her old box. The two glow red or green, and she communicates the result to Bob. If the result was green, Bob leaves his coin alone. If the result was red, he reaches into his opaque box and turns the coin over. At that point the "teleportation" process is completed.

In what sense is it completed? Only in this: If Charlie has the promise that Alice and Bob went through all the actions described above, then he can safely ascribe the same probability p to the coin in Bob's box (i.e., p that it will be heads) that he had originally ascribed to the coin in his own box. In other words, Charlie has everything it takes to update his epistemic state about the orientation of the coin in Bob's box to what he had originally thought of the coin in his own box.

Is this wildly exciting? The stuff that would make headlines in papers all around the world and be called "teleportation"? At the material cost of transferring a single bit from Alice and Bob, an infinite number of bits (in the form of the real number p) has been transferred between the two sites instantaneously? Not at all! The only thing that was materially transported from one site to the other was a single bit (that the boxes glowed red or green). The rest was just "conditionalizing" or "updating". And there is no mystery whatsoever in that. Dumb and dull, it would never make a headline.

And so too, I would say with quantum teleportation, even though it has built my career. (Our Caltech experiment of it has over 600 citations now.)

At the end of this note, I'll place some of the correspondence I had with Asher Peres as we were writing our ill-fated paper "Quantum Theory Needs No 'Interpretation'." (Of course the whole paper is about a particular interpretation, but most critics never read beyond the title.) In it, we had a paragraph on quantum teleportation and how it helps to illustrate the epistemic nature of quantum states. And boy did we fight about how to write that paragraph, and even—at that time—about the meaning of teleportation. Seeing some of our own wrangling may be of use to you, if you care to explore this idea further. The main points of the part attached below are 1) how there is no THE quantum state for a system (there as many as there are potential observers) and how teleportation makes use of that idea, and 2) when Alice performs her actions, nothing physical changes on Bob's side.

Finally, let me comment on:

Hans's Seemingly Black-and-White-ism or All-or-Nothing-ism

Two or three times now, I have heard Hans equate the idea of interpreting quantum states epistemically (i.e., as knowledge or like a Bayesian degree of belief or whatever) with giving up on the project of thinking that *physics* has something to say about the real world (i.e., presumably the world as it is without any knowers or even Bayesians). That is altogether too glib of a position, and I want to do whatever I can to ease him out of thinking it.

The stuff that Caves and Schack and Spekkens and Appleby and Timpson (and sometimes Mermin and Unruh and Milburn and whoever else) have been talking about is much more subtle than that, and it should be recognized as such—this field of thought is at a respectable enough level now that it shouldn't be caricatured. I for one, for instance, pretty much characterize myself as a realist in the time honored sense: That there is a real world out there beyond our whim and fancy, and it is the task of science to hypothesize about its attributes and properties. I am not a philosophical idealist and certainly not a solipsist. And I don't think I am a positivist or an empiricist. Predominantly, I think I lean toward a kind of materialism (though tempered by a lot of pragmatic subtleties).

The main way I think Hans errs is that when he hears a phrase like "quantum states are states of knowledge," he thinks that that throws *everything* away to knowledge (or Bayesian degree of belief)—that nothing is actually hypothesized about the world. But quantum theory contains so much more than simply quantum states: There are Hilbert spaces; there are Hilbert-space dimensions; there are Hamiltonians; there are eigenvalues; there are notions of *separate systems* whose joint description is worked up through a tensor product. The quantum state is only one lonely piece of quantum theory.

When it comes to quantum states, our point is simply scientific open-eyedness and conceptual clarity: 1) Open-eyedness. We see so very many analogies between quantum states and incomplete knowledge—just look at Spekkens's paper for more than 20 such—that it would be scientifically foolish to not take those analogies absolutely seriously and explore them for all they're worth. But 2) Clarity. We think we get even more in return, via easy solutions to some of quantum foundations' main supposed conundrums. From the epistemic view, there is no measurement problem, there is no nonlocality.

Loads of questions still remain, but one shouldn't be frightened of the methodology … which is, as Spekkens put it,

> The diversity and quality of these analogies provides compelling evidence for the view that quantum states are states of knowledge rather than states of reality, and that maximal knowledge is incomplete knowledge. A consideration of the phenomena that the toy theory fails to reproduce, notably, violations of Bell inequalities and the existence of a Kochen-Specker theorem, provides clues for how to proceed with a research program wherein the quantum state being a state of knowledge is the idea upon which one never compromises.

For instance, if you would ask Carl Caves, he would classify quantum states as epistemic, but he thinks that Hamiltonians represent a decent chance of remaining ontic terms within the theory (i.e., as representing an agent-independent reality). If you ask Spekkens, his own gut feeling is that quantum states represent incomplete knowledge of *relations without relata* (whatever that would mean), but particularly those relations are to be viewed ontically. As for myself, I tend to think that the ontology lies somewhere in a quantum system's receptivity or sensitivity to external interventions (whatever that would mean), and that receptivity is to be viewed ontically.

So, there is a range of ways of staying hard-headed about the idea that *quantum states are states of mind* without becoming a postmodern or a deconstructionist—without taking a walk with Derrida. And that is what our research program is about. Here's the way I put it in my `quant-ph/0205039`:

> This, I see as the line of attack we should pursue with relentless consistency: The quantum system represents something real and independent of us; the quantum state represents a collection of subjective degrees of belief about *something* to do with that system (even if only in connection with our experimental kicks to it). The structure called quantum mechanics is about the interplay of these two things—the subjective and the objective. The task before us is to separate the wheat from the chaff. If the quantum state represents subjective information, then how much of its mathematical support structure might be of that same character? Some of it, maybe most of it, but surely not all of it.
>
> Our foremost task should be to go to each and every axiom of quantum theory and give it an information theoretic justification if we can. Only when we are finished picking off all the terms (or combinations of terms) that can be interpreted as subjective information will we be in a position to make real progress in quantum foundations. The raw distillate left behind—minuscule though it may be with respect to the full-blown theory—will be our first glimpse of what quantum mechanics is trying to tell us about nature itself.

Now, look in that, and tell me where is this view of yours that we drop the idea that "physics should be about reality"? I'll just pose that as a challenge to you.

Hopefully I'll see you both again tomorrow.

27-10-05 *It Wasn't You* (to H. C. von Baeyer)

I just looked it up again. At the web site,

http://web.archive.org/web/20060104094204/http://
www.physics.byu.edu/research/theory/papers/

someone posted this comment:

> Our own Dr. Evenson recently had dinner with Anton Zeilinger, and asked him what he thinks about the radical ideas of Christopher Fuchs. Professor Zeilinger replied that "he is not radical enough."

I don't know who Evenson is, but he's not von Baeyer.

30-10-05 *Correlation without Correlata in the Strangest Places* (to N. D. Mermin)

I read these lines in Charles Krauthammer's column in the Washington Post this morning,

> This coldbloodedness is a trademark of this nation's most doctrinaire foreign policy "realist." Realism is the billiard ball theory of foreign policy: The only thing that counts is how countries interact, not what's happening inside. You care not a whit about who is running a country. Whether it is Mother Teresa or the Assad family gangsters in Syria, you care only about their external actions, not how they treat their own people.

and thought, "Is that really the billiard ball theory or rather correlation without correlata?"

31-10-05 *One World* (to C. H. Bennett and J. A. Smolin)

On another subject, I'd be curious to know your opinion(s) on Andy Steane's article `quant-ph/0003084`, "A Quantum Computer Only Needs One Universe." I found a fair number of his points in there insightful ... but I'd be willing to listen if your opinion is that I'm not being critical enough. I talked to Sam Braunstein last week about it, and he thought it was "utter tosh," but he didn't say much that put a dent in my opinion. Just the opposite, in fact: It strikes me that there are some ideas in that paper worth really trying hard to develop, if I could just get a handle on what the next step ought to be.

Charlie's Reply

> I rather like Steane's paper, which I hadn't read before. How delightfully put when he says the amount of computation is not properly measured by the number of steps that would have been required to do a computation some other way. I quite agree with him that it generates great confusion to imagine that quantum computers are doing many computations at once. I say they are doing one computation, and can get from input to output faster because of the extra maneuvering room Hilbert space provides during the intermediate stages. Toward the end of his piece, Steane speaks of entanglement as "representing correlations between logical entities without representing the entities themselves". I think this is a less felicitous way of speaking, rather like Mermin's "correlations without correlata". The trouble with both of these, in my view, is that they treat entanglement as a kind of correlation. Rather entanglement should be viewed as the primary thing, and correlation as one of its manifestations. Speaking in the liturgical language of the Church of the Larger Hilbert Space, correlation is a sacrament, the outward and visible sign of entanglement. Alas, your seduction at a tender age by the atheistic doctrine of Jaynes probably prevents you from thinking in this satisfying and clear-headed manner. To retreat from sectarian proselytizing, let me recommend my attached talk on publicity and privacy, which you might enjoy.

31-10-05 *QMech Interpretation & a Web-Thing Against the War* (to H. J. Bernstein)

Thanks for including me as a recipient on this note, though I'm not quite sure what it's all about. Did it have something to do with your last lines? To wit,

Bernsteinism 2: *What is YOUR best argument for those who take comfort (despite the clear-cut differences between statistical ensemble "lack – of – complete knowledge" kind of probabilities and "complex square roots that superpose" kinds of probability present even in the purest of PURE quantum states)?*

Anyway, just to record one of my latest strivings for clarity: I've gotten out of the habit of regarding probability as expressing "lack of complete knowledge." For that phrase effectively already implies that there's something out there that the user of the probability just doesn't have hold of. Instead now, along with de Finetti's usage, I just think of probability as quantifying "uncertainty" full stop. Uncertainty for whatever reason.

31-10-05 *Cover to Cover* (to N. D. Mermin)

By the way, do you know this quote of Bohr's? I've been meaning to send it to you for a while (but kept forgetting), in case it complements the one I usually hear you quote (i.e., the one about "track[ing] down ... relations between the manifold aspects of our experience").

> The extension of physical experience in our own days has ... necessitated a radical revision of the foundation for the unambiguous use of elementary concepts, and has changed our attitude to the aim of physical science. Indeed, from our present standpoint, physics is to be regarded not so much as the study of something a priori given, but rather as the development of methods for ordering and surveying human experience.

01-11-05 *Martha White's All-Purpose Correlation* (to C. H. Bennett)

I'm glad you give me some evidence that I'm not crazy for liking Steane's paper.

Bennettism 26: *Toward the end of his piece, Steane speaks of entanglement as "representing correlations between logical entities without representing the entities themselves". I think this is a less felicitous way of speaking, rather like Mermin's "correlations without correlata". The trouble with both of these, in my view, is that they treat entanglement as a kind of correlation. Rather entanglement should be viewed as the primary thing, and correlation as one of its manifestations. Speaking in the liturgical language of the Church of the Larger Hilbert Space, correlation is a sacrament, the outward and visible sign of entanglement.*

I'm not in disagreement with that ... particularly as the Grand Orgy of the Sexual Interpretation (of QM) would say the same thing. (Ask John.) Entanglement is a property of a quantum state with respect to a given tensor-product structure on the quantum state's Hilbert space. Correlation, on the other hand, is something that arises only through consideration of probabilities for the outcomes of (two-indexed) quantum measurements. Entangled states, consideration of measurements with only one index, NO notion of correlation; simple as that. So correlation can't be viewed as the primary concept.

Here's something I wrote along those lines in a now long forgotten document (of 1998):

> The quantum world brings with it a new resource that senders and receivers can share: quantum entanglement, the stuff Einstein-Podolsky-Rosen pairs and Bell-inequality violations are made of. This new resource, of all the things mentioned so far, is the most truly "quantum" of quantum information. It has no classical analog, nor might it have been imagined in a classical world.
>
> What is quantum entanglement? It is *not* probabilistic correlation between two parts of a whole. Rather it is the *potential* for such a correlation.
>
> In a quick portrayal:
>
> *classical correlation*— Alice and Bob entered a lottery for which they were the only players. They have not opened their "winnings" envelopes yet, but the messages in them say that one is the winner and one is the loser. Which is which, they do not know—they only know the correlation—but the answer is there, objectively existent, without their looking.
>
> *quantum entanglement*— Alice and Bob will eventually perform measurements on the EPR pair their envelopes contain and the outcomes *will* be correlated. However, before the measurements are performed, there are no objectively existent variables already there. Different measurements can and will lead to different correlations.

> In a certain sense, entanglement is a kind of *all-purpose correlation* just waiting to be baked into something real—a quantum "Martha White's Flour" `\cite{Flatt}`. The uses for this all-purpose correlation are manifold within Quantum Information Theory.

[The citation `\cite{Flatt}` goes to Lester Flatt and Earl Scruggs for their *Martha White Theme* song. What the heck, let me include the words to that too; it's at the end of the note.]

What I'm really interested in is whether we might dream up some technical problems to try to work out based on Steane's paper. Any ideas?

By the way, let me know if you get this note; I'm a little worried that your spam filter might pick it in retribution for my indiscretions above.

> **Martha White Theme Song**
>
> Now you bake right,
> (band response:) ah ha,
> With Martha White,
> (band response:) yes ma'am,
> Goodness gracious, good and light,
> With Martha White.
>
> Now you bake better biscuits, cakes, and pies,
> With Martha White Self-Risin' Flour,
> (band response:) that one all-purpose flour,
> With Martha White Self-Risin' Flour
> You've done all right!

01-11-05 *Thanks, Shelves, and Expenses* (to H. C. von Baeyer)

Now that Halloween is over, I have a little time to reply to some emails finally. Thanks so much again for the invitation to W&M. I had a great time, and it was lovely to see so many eyes sparkle from the ideas Friday. (Though I wish I had had more of a chance to talk to Gene Tracy—his eyes particularly sparkled.) And, I'm pleased that my "job interview" seemed to go well at the crabcake place ...

Finally, a further thanks for the detailed description of your bookshelves. My wife and I spent Sunday morning intermittently staring at the walls in our (to be) library, trying to figure out just what we're going to do. With my "pragmatism" collection now just shy of 400 volumes (and growing at an even pace), we've really got to get going on a solution. I want that room to be the intellectual center of the house, and what better theme for it than that "reality is on the make" (one of James' and FCS Schiller's themes, particularly).

01-11-05 *01 + 10* (to T. Duncan)

Thanks for the latest note, and thanks for keeping your eyes peeled.

(The simple existence of) Your note reminded me that I still had not replied to your original query:

Duncanism 2: *This leads to a point that is still muddy to me. It may be a naive question and I'm not quite sure how to phrase it, but let me try this to get started: Given that we must ask what the ontic states can be, such that they force this restriction of incomplete knowledge on the* *epistemic states, why not just place the entire restriction directly on the ontic states themselves? Why not simply say there is a limit to what we can know about the state of the world because there is a fundamental limit to how much information can actually be "stored" about its state? As I understand it, this is something like the view expressed e.g. by Zeilinger ("A Foundational Principle for QM",* Found. Phys. *1999). I realize this is not what you're saying. So, I'd like to better understand why you emphasize the distinction between epistemic and ontic states, when it seems possible that all of the restrictions on our knowledge could be absorbed as consequences of the restrictions on the ontic states. Anyway I'd appreciate any thoughts you have to point me in the right direction here.*

Somehow I never got inspired to give you the answer you deserve—I guess it would require something of an essay on why this distinction should be made at all, and I never mustered the energy. But let me do this by way of a partial answer: I'm just returning from having given the physics colloquium at William and Mary, and because Hans von Baeyer is there, I have also just finished his book, *Information: The New Language of Science*. It's really very, very good, I think. Particularly, Chapter 2, "The Spell of Democritus," I think goes a little toward answering your question. Let me recommend then that you give that a shot first. If it helps, let me know. And if it doesn't, maybe try re-posing your question, and I'll try my best (with a layer of guilt for pushing it off this long) to give you some feedback.

Thanks also for bringing Louise B. Young's book to my attention. Believe it or not, I've had that book on my shelf for five years and never opened it once. (I remember picking it up at a hospital fundraiser.) I'll certainly open it now.

Todd's Preply

> [CAF wrote:] OK, so you already know how I'd answer your Exercise 1.image:
> "I am a cosmic artist – a contributor to a universal creative process."

You can probably guess that I would answer similarly. ☺ I remember reading a book in high school by Louise B. Young, *The Unfinished Universe*. Some of the technical details in the book are questionable, but the spirit of it resonated deeply with me. That spirit is pretty well expressed by the final paragraph: "The universe is unfinished, not just in the limited sense of an incompletely realized plan but in the much deeper sense of a creation that is a living reality of the present. A masterpiece of artistic unity and integrated Form, infused with meaning, is taking shape as time goes by. But its ultimate nature cannot be visualized, its total significance grasped, until the final lines are written."

02-11-05 *von Baeyer* (to A. Y. Khrennikov)

I had the good fortune to meet Hans C. von Baeyer the other day and to read his new book, *Information: The New Language of Science*. It's a very good book, and I recommend it if you haven't read it yet. Anyway, he told me that you had invited him to your next meeting in Växjö. I'm very glad you did, and it is excellent to have another Bayesian among us there!! Have you been able to give any thought to my idea of a special session of "Bayesians" attending the meeting?

02-11-05 *Zeilinger, Me, and von Baeyer Makes Three?* **(to H. C. von Baeyer)**

I'm back, though "lunch" turned out to be effectively a two-day affair! To business now:

von Baeyerism 2 : *I have been dipping into your marvellous book all weekend, and have a question (or seventeen). . . .*

In January I will give an invited talk at the 75th anniversary of the American Association of Physics Teachers, in Anchorage, Alaska. The occasion is my receiving the Gemant Award of the AIP. My title is: "How I learned to stop worrying about Schrödinger's cat." I intend to chronicle my gradual adoption of your point of view about QM. Now the question:

It seems to me that the search is on for the irreducible kernel of QM, you call it the Zing, Maxwell, as a boy, would have called it "The GO of it." You and Zeilinger approach it from opposite ends: You by stripping away all "merely" information theoretic baggage, and he by guessing the answer. You have not yet succeeded in getting down to the bottom, and he has a long way to go before he builds up to the full theory. Analysis v. synthesis, top-down v. bottom-up.

Is this a fair way to characterize your approach?

Thanks by this; I'm certainly flattered. And I hope you'll ask me all seventeen eventually. The way to do good physics is to write good physics, and in my case, I need good questions before I can even hope for the latter.

And, by the way, speaking of good books, I really did enjoy reading yours last week. I think, whether it was intended to be or not, it is a great service to the quantum Bayesian community—sort of a mortar to soften up the popular beach—and I'm grateful for that. For the heck of it, below, I've decided to type in the little notes I made on my bookmark as I read it—they record my agreements and disagreements and a little of my study of the English language. Particularly, you'll note a remark I made about something on page 38. It refers mostly to your sentence,

> If the wave function is nothing but a storehouse of information needed to make correct predictions, then the stuff of the world is really, at bottom, information.

I hope my talk at W&M emphasized that I would be in disagreement with that.

And in fact, to start to answer your question, I think that disagreement probably captures the greatest gulf between the views Anton and I are each striving to develop. It's not a difference of technique (analysis vs. synthesis) per se, but of our *guesses* of an ontology—I think they are opposed to each other.

If you can give me a few days, I plan to come back to you with a much more complete answer. But first I want to re-read all of Zeilinger and Brukner's stuff. This will be a good opportunity for me to flesh out the similarities and differences of what we're hoping to get at. In any case, I'll get back to you long, long before your January talk.

By the way, congratulations on the teaching award. But I hope Anchorage isn't too cold in January!

Notes on H. C. von Baeyer, *Information: The New Language of Science*

vB asks "why information not like energy" – 9, 10, 33
special relativity as inserting the observer into physics – 12
Wheeler, subjectivity – 13
split between objective and subjective – 13, 14
Wheeler quote – 15

relations without relata – 23, 24, 52-53
(Schrödinger) information as surprise – 25
Gell-Mann sobriety – 33
bad inference – 38
non-Bayesian view of probability? – 57, 58, 72
questionable interpretation of Bohr – 64, 65
probability as informed guess – 75
not "avoid" but "masks" – 95
quantum random numbers – 107
hearing loss – 125, 126
Wheeler grafitto from Pecan St. – 127, 128
as it were – 132, 134, 155, 166, 201, 231
Nobel prize meat – 140, 141
probability does not exist – 172
bad language for superposition – 180, 181
interventions – 183
measurement as creation – 184
qubit as state rather than system – 187, 188
the godfather of soul – 191
fey neurasthaenic – 193
analogy, maybe more accurate than you think – 195, 196
quantum crypto distinct idea from quantum computing – 197
physics as comparison – 203
Boltzmann titles – 223
correct phrase on teleportation! – 225
Zeilinger or Rovelli first? – 226
information about what? whose information? – 227
entanglement not necessarily the key to quantum crypto – 230

02-11-05 *Don't Forget Fierz!* (to H. C. von Baeyer)

In fact, I'm back again already. Just as I was sending off the last note, I realized that I hadn't mentioned the Fierz project again—surely I don't want to forget about that. I wrote my friend Greg Comer today that my mouth is already watering to see your results.

Did by chance you read the Fierz article reprinted in my 29 August 1999 letter to Rüdiger Schack in *Notes on a Paulian Idea*? If so, what did you think of it?

After sending off this note to you, I'll write Harald Atmanspacher with a brief note of introduction about you and the story of our meeting and similar interests, and then I'll put you two in contact with each other.

02-11-05 *And Holladay* (to H. C. von Baeyer)

I just can't get my email right today; I keep remembering things that I forgot to reply to.

von Baeyerism 3: *Full disclosure: Wendell Holladay was my thesis adviser, but he died last year. De mortuis nihil nisi bene. (Of the dead, say nothing but good things.)*

I am sorry to hear about that. Were you close? Probably. In reviewing what I wrote about him in *Notes on a Paulian Idea*, at least I notice that a reply to his letter seemed to be the hardest part of the paper for me to construct—i.e., apparently he gave me a run for the money. He was probably a great guy. Again, I'm sorry.

02-11-05 *Carry Cameras, not Guns* (to C. H. Bennett)

I really enjoyed thumbing through your talk. Particularly, I enjoyed this quote

> Could it be that every major past phenomenon, say Sappho's other poems, or Jimmy Hoffa's murder, can be recovered from physical evidence in principle, if not in practice?
>
> To believe otherwise is venturing dangerously close to the deconstructionist view, abhorred by most scientists, that history is not what "actually" happened, only what we think happened.

as food for thought. It put the importance of the black-hole information question in a new light for me.

But also it reminded me of some stuff I once read about the interesting things that can happen when one tries to mesh the idea of "physical indeterminism" together with the ideas of "history" and "archeology" as autonomous sciences. As it happens, I have an old PDF file which includes a description of George Herbert Mead's thoughts on the subject. I'll attach it for your fun. (Ignore the stuff I wrote at the beginning of it, and just go straight to the copied description of Mead himself on page 2.) By the way, Mead—one of the founders of American pragmatism—was born in South Hadley, MA in 1863. So I suspect his ghost is practically a neighbor to you guys in Wendell on the weekends.

07-11-05 *The Nauseating Terminus* (to G. L. Comer)

I thought your note was on the mark. What it shows is that even in our state of relative ignorance about the goings on of the universe, we should still expect life to arise somewhere/somehow simply due to the vast size of this universe.

But also keep in mind that, from the Bayesian view, probabilities (and the surprise or lack of surprise they entail when one sees the outcome of a trial) represent nothing other than one's degrees of beliefs. Probabilities are not part of the furniture of the universe. In particular, I suspect if we understood chemistry a lot better, then—conditioned on that knowledge—life wouldn't look so surprising at all: That is, *with respect to* a better state of knowledge, one wouldn't have to shore up one's argument for the inevitability of life by statements of the vastness of the universe. It'd be a simple consequence of chemistry as such (and not rare initial conditions).

So that in the end, as scientists we would say: Because our fundamental fields have these Hamiltonians, life is effectively inevitable. The religious-minded at that point should say, "So who ordered those Hamiltonians? You yourself contemplate that they could have been otherwise. Hence, at just that point, there's the concrete expression of an intelligent design. From it, as you have just proved to me dear scientist, everything inevitably flows." And how do you combat that? We each have our terminus of inquiry: ours is an equation, and theirs is an old man behind the equation. By why should either of us terminate? We should both have a horrible sense of dissatisfaction.

07-11-05 *The Second Terminus* (to G. L. Comer)

Comerism 9: *I'm also not sure that I've assumed that probabilities are real. I readily admit that I introduced them via the question asked.*

I didn't mean to imply that you weren't being a good Bayesian. I was just changing the subject a bit ... so that I could make the point that the religious can always find a place for their old man in the sky. For they can always pick up wherever we (the scientists) say THIS is the fundamental equation or THAT is the necessary class of initial conditions. On the other hand, they think they're getting somewhere deeper by positing their old man in the sky than we are with our fundamental equation or initial condition (or both). To that I ask, why have they gotten any deeper: It looks to me to be of effectively the same level. For I can ask of their god, who ordered that? In fact, one can turn their own argument upon themselves. If they ever say that the beauty or the complexity of the world around us cannot be explained without a creator, then I say that the beauty or complexity of that creator could not be explained without an even more powerful and harmonious creator. And so on ad infinitum. The only leg I've ever see them stand on is to reply that, "But God needs no explanation" ... end of argument. And then I retort, "But then why do you demand it of my equations." And of course it just goes round and round.

Anyway, sorry, I wasn't disagreeing with you ... just changing the topic a little. But also, I wasn't even sticking to one topic really. The point about my personal *belief* that life is largely independent of initial conditions (just like planet formation seems to be, for instance), was really a side point.

Or to say it another way, mostly in my last note I was just ranting because the religious right have pissed me off too.

07-11-05 *Zeilinger, Orange House, and Halvorson* (to C. G. Timpson)

You've been on my mind recently, as I was forced to rethink "Zeilinger's Foundational Principle" for a visit with Hans C. von Baeyer at the College of William and Mary last week. It still doesn't fare better in my mind (even though I know it helped inspire Rob Spekkens' "toy model," for which I have great respect). Thus I recommended your paper on the subject to von Baeyer.

Von Baeyer is an interesting guy—his profession now is in the *accurate* popularization of science—and I enjoyed his book *Information: The New Language of Science* quite a bit as a really good attempt in that direction.

Anyway, I'm writing this note because I understand you'll be in New Jersey in mid-December. Where will you be flying into and out of? Newark, presumably? If you have any extra time, it'd be great to have you in the Murray Hill / Cranford area for a day or two (or more). We could put you up in our house and fatten you up with some of Kiki's home cookin' while you and I try to come up with something new in quantum mechanics. (Perhaps I should also mention my single-malt collection? Or would that defeat the purpose?) Finally, I wouldn't mind showing off the best book stores in NY City if you happen to bring an empty case. Just let me know your plans and if you have any time. I can get you from Princeton to Cranford, and then from Cranford to the Newark airport when the time comes.

The reason I know you'll be in NJ is because I've been attending van Fraassen and Halvorson's seminar on quantum information for a few of the sessions. Connected with that, in the next note I'll forward you something I wrote to vF and H after listening to Halvorson's lecture on teleportation. [See 25-10-05 note titled, "GOBs, Bobs, Steering & Teleportation" to H. Halvorson and B. C. van Fraassen.] It's a bit long, but maybe you'll find some parts of it entertaining. To two of the questions in your Budapest slides, "How is so much information transmitted?" and "Just how does the information get from Alice to Bob?," my own answer would be: *No* information is transmitted in the process of teleportation (excepting the two bits that tell Bob which action to be performed). The only nontrivial thing transferred in the process of teleportation is *reference*. Charlie's information (in the sense of Bayesian degrees of belief) stops being *about* the qubit he just handed off to Alice and starts being *about* Bob's. I don't know what you say in your paper "The Grammar of Teleportation," but I just printed it out and hope to have it read in the next couple of days. If we disagree substantially, you can guess I'll be writing you again!

07-11-05 *Charlie Bennett Stories* (to C. H. Bennett)

My friend Greg Comer asked me to remind him of a story I had once told about coin tossing. I dug up the note below and sent it off to him to fulfill his request. Remarkable thing dawned on me though: I've been telling stories about you for at least five years. I should replenish my supply.

From a 28 July 1998 note to G. L. Comer titled "Macaroni"

> I've just been enjoying a Barcelona morning, taking care of some e-mail odds and ends. Today is my last day in Spain; tonight I spend the night in London, finally to be on my way home tomorrow. Thank you very much for your stories, especially the ones about your dad.
>
> The last time I was in Europe (last month), I met up with Charlie Bennett as usual. I don't know how it happened, but we got into a conversation about coin tossing (real coin tossing, not the philosophical issue). Charlie said, "You know, there's a really easy method for predicting someone else's tosses; I'll show you." I said, "Oh bull." Then he pulled a quarter from his pocket and gave it to me. I flipped; he called heads. It was heads. So I did it again. He called heads. It was heads. I said, "Oh you just got lucky again." "Well, do it again," he says. So I flip. He calls heads. It was heads!! In astonishment, I say, "OK what's the trick you have up your sleeve? Did you give me a fixed coin?!?" He bursts out laughing, "No, not at all. One time in eight you get lucky, and when you do, it's a really good joke!"
>
> But still, synchronicity happens. The evidence is our two stories. I'll never forget mine; maybe you'll never forget yours.

Charlie's Reply

> Your version is partly apocryphal. I was demonstrating Martin Gardner's 3-cup trick, which he calls mathematical 3-card monte, to Merrick Furst at CMU. He didn't see how the trick worked, and thought it amazing that I had "guessed" the correct cup–the one holding the little piece of crumpled paper–3 times running. When he asked me how the trick worked, I noticed that, by chance, the correct cup had always been the leftmost one, so I said, "I just always choose the one on the left." This amazed him even more.

08-11-05 *Closet Haecceity* (to H. Barnum)

By the way, I was amused with your comment

Barnumism 13: *"Well, his theory's got haecceity, and that's been déclassé since the late middle ages. You just can't have a theory like that."*

Truth is, I guess I'm a closet haecceitist. I've probably told you that before. Indeed I love this quote by William James,

> Let me give the name of 'vicious abstractionism' to a way of using concepts which may be thus described: We conceive a concrete situation by singling out some salient or important feature in it, and classing it under that; then, instead of adding to its previous characters all the positive consequences which the new way of conceiving it may bring, we proceed to use our concept privatively; reducing the originally rich phenomenon to the naked suggestions of that name abstractly taken, treating it as a case of 'nothing but' that concept, and acting as if all the other characters from out of which the concept is abstracted were expunged. Abstraction, functioning in this way, becomes a means of arrest far more than a means of advance in thought. It mutilates things; it creates difficulties and finds impossibilities; and more than half the trouble that metaphysicians and logicians give themselves over the paradoxes and dialectic puzzles of the universe may, I am convinced, be traced to this relatively simple source. *The viciously privative employment of abstract characters and class names* is, I am persuaded, one of the great original sins of the rationalistic mind.

And you yourself also have some of the blame: When I retrace the footsteps that led me to this fetish, the point of departure seems to have been a conversation with you—when you first convinced Rüdiger and me (through de Finetti's argument) that even "exchangeability" is a subjective judgment. The root of the issue is all right there.

I know you've seen an earlier version of this "Delirium Quantum" thing of mine [`http://arxiv.org/abs/0906.1968`], but I'll send it again: Section 3 on "snowflakes" expands a little on this point in the quantum context. Is it so bad being a closet haecceitist?

08-11-05 *Quibbles, Actions, and Reading* (to H. C. von Baeyer)

von Baeyerism 4: *Re Bayesian: I have a couple of the volumes of the Pauli letters here on my desk. If you look up Bayes in the index, you come to a letter from P. to F. dated 12 July 1952. It is distinctive in including the dream-drawing of quantum mechanics and deeper reality that you are going to paste into your* `PauliProject.pdf`*. Where did you see it? It also appears in a letter to Jung a year later. Is Pauli's letter available in English?*

Fierz wrote at least two detailed drafts of a reply. One bit that you would love is this: Pauli brings up people who believe – or disbelieve – a theory so much that they remain unconvinced by statistical evidence. They stubbornly continue to wait for a measurement that disagrees significantly with the theory. Pauli suggests that the state, or society, could then declare that these people belong in an insane asylum. But he himself doesn't dare to make such rules.

Fierz replies:

> I am totally against the putative opponents, in the name of the state or of society, to hold their views. Rather, one should challenge them to a *bet*. If they accept it, they

> will *lose their money*, which proves that they have not lost their reason, but everything else, in particular, money.
>
> On the other hand, if they reject the bet, it is demonstrated that their conviction is without practical consequences, in other words, that they they don't really believe what they claim.
>
> I agree with your claim, and have always shared it, that purely logically nothing follows from the laws of Bayes and Bernoulli about a concrete single event. This is the answer to your question 2.
>
> However, the maxims of our practical actions can never be justified logically. If that were the case, empirical observations could be reduced to logic. Every action requires a decision, and that is an act of will.

Betting good money, that's where it's at!!!

I like it! What a great quote. Find me a thousand more like that, and I'll be forever in your debt.

Concerning your earlier Zeilinger question, I did take the time to read the Zeilinger and Brukner-Zeilinger papers. Also I reread Hall's and Timpson's commentary on them. (I suspect Mana's commentary is also good, but I didn't discover that one until this morning; so I can't say that I read it, though I know him and think he is a very promising student.) Timpson's comment in particular, I think is very relevant for what you were wanting to know. So I would suggest you have a look at it, if you haven't already. Here are the coordinates: `quant-ph/0112178`. The paper is written in too much of an argumentative style for my tastes, but I do agree with the substantive points.

Particularly, I agree that there's nothing to Zeilinger's principle *as presently sketched* without already invoking quantum mechanics itself. See Timpson's Appendix A. This is not to say that we may not gain some insight from these ruminations. As I said before, I think Spekkens' toy model is a great example in that regard. So Zeilinger's ideas are certainly important ideas, even if ultimately flawed. Indeed, I think what Spekkens' paper really shows is that the heart of quantum mechanics is something beyond the Zeilinger principle. For one might say that Spekkens' toy model already effectively embodies the Z principle—formally through its "knowledge balance principle"—and yet the model is *not* quantum mechanics. Rather it is a local hidden variable theory. As Rob says in his abstract, "A consideration of the phenomena that the toy theory fails to reproduce, notably, violations of Bell inequalities and the existence of a Kochen-Specker theorem, provides clues for how to proceed with this research program."

For my own money, I now think the real heart of the theory is in the Kochen-Specker theorems; and the Z principle just doesn't capture that. In particular, I think the KS theorems are likely the most direct statements we yet have that the "observer cannot be detached" in an ultimate account of reality. Particularly, that's where I think our research needs to focus most: Finding a way to justify a Kochen-Specker-like theorem directly from the idea of engaged/activating observers, and bypassing the details of quantum mechanics. But I just don't see how to go that route yet.

Finally, let me go back to what I view as the more fundamental disagreement in outlooks for Zeilinger and me at the moment. (The disagreement may not be a permanent thing, but it is definitely here for the moment.) The point is made by Timpson pretty clearly:

> Before stating the Foundational Principle, it is helpful to identify two philosophical assumptions that Zeilinger's position incorporates. The first is a form of phenomenalism: physical objects are taken not to exist in and of themselves, but to be mere constructs relating sense impressions [Footnote: Here I take phenomenalism to be the doctrine that the subject matter of all conceivable propositions are one's own actual or possible

experiences, or the actual and possible experiences of another.]; the second assumption is an explicit instrumentalism about the quantum state:

> The initial state ... represents all our information as obtained by earlier observation ... [the time evolved] state is just a short-hand way of representing the outcomes of all possible future observations.

Zeilinger and I are certainly in agreement on the second assumption, but it is the first that drives a wedge between us presently. In fact, just last week, I wrote Bas van Fraassen and Hans Halvorson these words:

> I for one, for instance, pretty much characterize myself as a realist in the time honored sense: That there is a real world out there beyond our whim and fancy, and it is the task of science to hypothesize about its attributes and properties. I am not a philosophical idealist and certainly not a solipsist. And I don't think I am a positivist or an empiricist. Predominantly, I think I lean toward a kind of materialism (though tempered by a lot of pragmatic subtleties).

That's the key point: As far as I can tell, I think I almost lean toward a kind of materialism. Metaphorically: Outside of the alchemist is the philosopher's stone. Without it, there is nothing to enact the transmutation of the baser metals or of the alchemist himself.

If you decide after reading a good portion of the stuff I've already sent you that I'm not completely crazy, and you're interested, then I'll go on a limb and tell you more about what I meant in the last two lines above. And I'll tell you why I'm really so interested in this Pauli-Fierz correspondence (and Fierz's own writings). But if you're already thinking I'm a little crazy, I don't want to fuel the fire.

08-11-05 *A Few More Things* (to H. C. von Baeyer)

At your house, you asked why I called my compendium "The Activating Observer" rather than "The Participating Observer" or some such. Looking in the LaTeX file, I see that I marked out at least this many other tentative titles:

> The Undetached Observer:
> The Catalyzing Observer:
> The Malleable Reality:
> A Malleable Reality:
> The Malleable Substrate:

von Baeyerism 5 : *While I am happy that you are reading my book carefully, I won't spend much effort on defending it. I have learned a lot since I wrote it, and am much more of a Bayesian now.*

If you want to go to the real extreme—the place where Caves, Schack, and I now sit in the spectrum of Bayesianisms—then let me recommend you read these things:

1. Bruno de Finetti, "Probabilism: A Critical Essay on the Theory of Probability and on the Value of Science," Erkenntnis **31**, 169–223 (1989).

2. Bruno de Finetti, *Theory of Probability* (Wiley, New York, 1990), volume 1.

3. Richard Jeffrey, *Subjective Probability (The Real Thing)* (Cambridge University Press, Cambridge, UK, 2004).

4. Richard Jeffrey, *Probability and the Art of Judgment* (Cambridge University Press, Cambridge, UK, 1992).

The two de Finetti pieces are phenomenal, and they were life-changing for me (particularly the first reference, *after I read it the fourth time*!). (It's this life change that is recorded in my samizdat, *Quantum States: What the Hell Are They?*) My only warnings are: 1) to take his hint of solipsism in Section 2 of the first reference above with a grain of salt—he backs off on it by the time he gets to his book—, and 2) and to disregard his support for Mussolini and fascism in the last section of the same paper. Those things are independent of the rest of the development, and one should not get distracted by them—the rest of the paper really is phenomenal.

von Baeyerism 6: *If you look up Bayes in the index, you come to a letter from P. to F. dated 12 July 1952. It is distinctive in including the dream-drawing of quantum mechanics and deeper reality that you are going to paste into your* `PauliProject.pdf`*. Where did you see it? It also appears in a letter to Jung a year later. Is Pauli's letter available in English?*

Those figures that I'm going to paste in refer to two letters from Pauli to Jung: One from 27 May 1953 and one from 31 March 1953. The Pauli-Jung correspondence has been translated into English; that's where I got those long quotes from. They start up on pages 146 and 144 of `PauliProject.pdf`, respectively.

There. Now I think I've answered everything you've ever asked me.

10-11-05 *Kaine, Corzine, Kochen, Krazy Kats and All That* (to H. C. von Baeyer)

von Baeyerism 7: *By the way, the reason I am no longer worried about Schrödinger's cat is not that I think that q.m. is now understood, but that I feel, for the first time in my career, that the problem is in good hands with young folks like you and your friends. I think that where I can make a contribution is in explaining to other physicists and to the public that y'all are NOT crazy, that progress HAS been made, that new ideas ARE being brought to bear, and that there actually IS a hope of realizing Wheeler's sibylline predictions.*

I am very happy to hear that. I didn't get a chance to write you this morning, but you made my day.

10-11-05 *Delirium Quantum* (to B. C. van Fraassen)

I've got to say, I really, really enjoyed today's discussion. Now, I'm getting my money's worth! I thought you did a great job of giving a kind of (perhaps momentary) suspension of disbelief about Rovelli's ideas—i.e., making an honest attempt to get your head around them—and I thought Maudlin did a great job as skeptical counterpoint. I was very pleased with the food for thought it all gave me, and it made the drive back to Cranford go like a flash.

Particularly I'm struck that there really is more of a similarity between Rovelli's outlook and our quantum-Bayesian outlook than I had thought. Of course, there are plenty of differences too (and likely big ones). But I think it is much worthwhile for me to rethink all the various issues surrounding his view.

Anyway, let me attach a file that I hope will amuse you; it's titled `DeliriumQuantum.pdf`. The parts I'm interested in your reading connect mostly to your remarks today about Rovelli's view of the *domain* of quantum theory. In particular, I shoot for some explication of how I can at once say "quantum mechanics is incomplete"—I do that a lot now—and still emphatically deny that it would be worthwhile to try to complete it with a hidden-variable theory. Particularly, I like the analogy to do with a map vs. a globe that you'll see at the end of this file. In total, the only parts that I really care for you to see are Section 4 "Me, Me, Me," Section 6 "Preamble," and Section 7 "B." Of course, you can look at all the rest if you got nothin' better to do, but I don't think the other parts are connected to your discussion today.

I apologize in advance that the pieces I'm recommending were written in a more overtly William Jamesian style than usual (even by my own standards). Sadly, I find more clarity for myself when I do that, but I suspect not all my readers do! I remember I once gave some lectures at Case Western Reserve U., and one of the professors wrote to John Preskill, "During Fuchs's lectures everyone became convinced that quantum information theory was the most important thing ever. But when he left, no one could remember why!" You may have a not-unconnected reaction to these writings.

I'm taking the family on a little "road trip" vacation to New Hampshire for the next four days—starting in about six hours if I ever get to sleep—but I suspect I'll be dropping in on you electronically over the next few days. I'm quite excited about this, and I will probably spout things from time to time as they come to mind. I hope you don't mind: As always, feel free to ignore these notes and chalk them up to being my diary entries if you wish.

10-11-05 *"Action" instead of "Measurement"* (to B. C. van Fraassen)

Let me also elaborate a little on the spiel I gave today condoning the word "action" more than the words "measurement" or "question" in the context of "quantum measurement."

The following explanation comes from an email to another friend last Spring. I do think the very word "measurement" is fraught with trouble, particularly for what Rovelli and us quantum-Bayesians are trying to get after.

> Anyway, the way I view quantum measurement now is this. When one performs a "measurement" on a system, all one is really doing is taking an ACTION on that system. From this view, time evolutions or unitary operations etc., are not actions that one can take on a system; only "measurements" are. Thus the word measurement is really a misnomer—it is only an action. In contradistinction to the old idea that a measurement is a query of nature, or a way of gathering information or knowledge about nature, from this view it is just an action on something external—it is a kick of sorts. The "measurement device" should be thought of as being like a prosthetic hand for the agent—it is merely an extension of him; in this context, it should not be thought of as an independent entity beyond the agent. What quantum theory tells us is that the formal structure of all our possible actions (perhaps via the help of these prosthetic hands) is captured by the idea of a Positive-Operator-Valued Measure (or POVM, or so-called "generalized measurement"). We take our actions upon a system, and in return, the system gives rise to a reaction—in older terms, that is the "measurement outcome"—but the reaction is in the agent himself. The role of the quantum system is thus more like that of the philosopher's stone; it is the catalyst that brings about a transformation (or transmutation) of the agent.
>
> Reciprocally, there should be a transmutation of the system external to the agent. But the great trouble in quantum interpretation—I now think—is that we have been too inclined to jump the gun all these years: We have been misidentifying where the transmutation indicated by quantum mechanics (i.e., the one which quantum theory

actually talks about, the "measurement outcome") takes place. It should be the case that there are also transmutations in the external world (transmutations in the system) in each quantum "measurement", BUT that is not what quantum theory is about. It is only a hint of that more interesting transmutation. And, as you know, somehow out of all this I think of the agent and the observer as being, together, involved in a little act of creation that ultimately has an autonomy of its own—that's the sexual interpretation of quantum mechanics. (However the ideas in that last sentence are a little murkier than what I'm trying to get at now.)

Does "measurement" in this new sense explicitly require consciousness (whatever that is)? I don't think so. But it does require some kind of nonreductive element—some kind of higher-level description that cannot be reduced to a lower-level one. Here's the way I've been putting it in my last three lectures, when talking more particularly about quantum mechanics from the Bayesian perspective. I point out that a Bayesian is, roughly speaking, someone who believes that without gamblers, there cannot be probabilities. Probabilities are not external to gamblers. Then someone always asks, must you have consciousness to have probabilities? And I say, "No." Take as an example my laptop computer loaded with a Bayesian spam filter. It is a perfectly good gambler in the Bayesian sense, but I think most people would be hard-pressed to call it conscious. Similarly, I think we're going to ultimately learn an analogous lesson about all this transformation/transmutation/ creation/measurement business.

On the other hand, I do find myself being tickled toward a more Whiteheadian-like view that, whatever this higher-level description is, every piece of nature has more or less of it, from people all the way to stones and atoms. It's just that you have to be on the inside of the philosopher's stone to see it.

10-11-05 *Wheeler's 20 Questions and Nordheim* (to B. C. van Fraassen)

Below is Wheeler's account of the original incident. It comes from

> J. A. Wheeler, "Bohr, Einstein, and the Strange Lesson of the Quantum," in *Mind in Nature: Nobel Conference XVII, Gustavus Adolphus College, St. Peter, Minnesota*, edited by R. Q. Elvee (Harper & Row, San Francisco, CA, 1982), pp. 1–23, discussion pp. 23–30, 88–89, 112–113, and 148–149.

I'll work on digging up that Nordheim / von Neumann reference I told you about. I don't think it is the Hilbert / Nordheim / von Neumann paper that one easily finds on the web, but something later. But maybe I'm wrong (and in more than one way).

> What is the difference between a "participatory" reality and a reality that exists "out there" independent of the community of perceivers? An example may illustrate a little of the difference. Edward Teller and I, and a dozen other guests, were sitting in the living room of Lothar Nordheim in Durham after dinner. From general conversation we moved on to the game of twenty questions. One, chosen as victim, was sent out of the room. The rest of us agreed on some implausible word like "brontosaurus." Then the victim was let back into the room. To win, he had to discover the word with no more than twenty yes/no questions. Otherwise, he lost. After we had played several rounds, my turn came and I was sent out. . . .

10-11-05 *Nordheim?* (to A. Wilce)

Could you give me the reference to the Nordheim / von Neumann paper you mentioned in your talk (at Perimeter? and maybe Växjö?)? Also can you refresh me on what you actually said about it? I ask because I was telling Bas van Fraassen today about Nordheim's involvement in Wheeler's famous story about playing the game of twenty questions in reverse. And I remarked to vF about how it was interesting that someone involved in quantum logic would have been the instigator of that.

Below is the beginning of Wheeler's account of what happened. [See 10-11-05 note "Wheeler's 20 Questions and Nordheim" to B. C. van Fraassen.]

10-11-05 *Our Own Rovellian Analysis* (to B. C. van Fraassen)

I particularly got a lot out of your "puzzle" analysis at the end. There were some points there, particularly Puzzle 1, that I don't think I've thought much about (or maybe any) before.

About the issue of consistency in Wigner's friend scenario, here's how Asher and I put it in our *Physics Today* piece:

> Does quantum mechanics apply to the observer? Why would it not? To be quantum mechanical is simply to be amenable to a quantum description. Nothing in principle prevents us from quantizing a colleague, say. Let us examine a concrete example: The observer is Cathy (an experimental physicist) who enters her laboratory and sends a photon through a beam splitter. If one of her detectors is activated, it opens a box containing a piece of cake; the other detector opens a box with a piece of fruit. Cathy's friend Erwin (a theorist) stays outside the laboratory and computes Cathy's wavefunction. According to him, she is in a 50/50 superposition of states with some cake or some fruit in her stomach. There is nothing wrong with that; this only represents his knowledge of Cathy. She knows better. As soon as one detector was activated, her wavefunction collapsed. Of course, nothing dramatic happened to her. She just acquired the knowledge of the kind of food she could eat. Some time later, Erwin peeks into the laboratory: Thereby he acquires new knowledge, and the wavefunction he uses to describe Cathy changes. From this example, it is clear that a wavefunction is only a mathematical expression for evaluating probabilities and depends on the knowledge of whoever is doing the computing.
>
> Cathy's story inevitably raises the issue of reversibility; after all, quantum dynamics is time-symmetric. Can Erwin undo the process if he has *not yet* observed Cathy? In principle he can, because the only information Erwin possesses is about the consequences of his potential experiments, not about what is "really there." If Erwin has performed no observation, then there is no reason he cannot reverse Cathy's digestion and memories. Of course, for that he would need complete control of all the microscopic degrees of freedom of Cathy and her laboratory, but that is a practical problem, not a fundamental one.

Of course that's not very satisfactory, but it was a *Physics Today* piece. This is extended and done much better on pages 322, 324(bottom)–325, and 19–23 of my *Notes on a Paulian Idea*. I like those discussions much better.

Still the whole thing can/should be done much, much better and more formally, and your discussion today inspired me to try do it from my perspective with all i's dotted and t's crossed.

Then it'd be nice to compare whatever comes out to your analysis of Rovelli's. Certainly the developments are going to be similar, but there may be differences here or there.

14-11-05 *American Private Equity* (to H. Mabuchi)

> My firm recently spoke with Hideo Mabuchi in the quantum theory group at Cal Tech and David Deutsch at Oxford University among other leading minds, and I thought I would drop you a quick note. My firm is currently looking to fund companies within the quantum technology sector. I spend a portion of my day speaking to experimentalists and theorists in the quantum theory looking for applications.

Is this is a whole new style of crackpot coming at me ... Or by wild chance—not a chance!—is there something to this? Is it time to fund our quantum information retreat in the woods of New England? (Don't forget, you pledged $100K!!)

14-11-05 *Desperately Seeking Postdoc (Funds)* (to G. Brassard)

I'm sure you can guess the pressure Bell Labs is putting on all the researchers here to obtain outside funds for this and that. Well, they've stepped it up a notch again ... and this is partially why I'm writing.

I had an idea (they don't come that often). Can you think of any way we might be able to fund a kind of "joint postdoc" between the two of us to work on our qm-foundational program? If we could do that—in such a way that Lucent could pick up some overhead from the project—something nice might come out of this pressure they're putting on me. Indeed, I'd love to have a postdoc focused on this sort of stuff, rather than the more mundane issues in quantum information, and could make a promise to you to steer the guy right. But funding is not my forte! (As you already know.)

Any ideas?

14-11-05 *Questions, Actions, Answers, & Consequences* (to B. C. van Fraassen)

> But physicists are, at bottom, a naive breed, forever trying to come to terms with the 'world out there' by methods which, however imaginative and refined, involve in essence the same element of contact as a well-placed kick.
>
> — Bryce DeWitt and Neill Graham, 1971

> I think that the sickliest notion of physics, even if a student gets it, is that it is 'the science of masses, molecules, and the ether.' And I think that the healthiest notion, even if a student does not wholly get it, is that physics is the science of the ways of taking hold of bodies and pushing them!
>
> — W. S. Franklin, 1903

Thanks for the note. In my own case, I didn't get nearly as much reading and thinking done over the weekend as I had hoped to—indeed, the time turned out to be a great vacation for the kids, but not so much for dad.

van Fraassenism 3: *I thought I would after all not follow you in replacing the term "measurement", despite all the bad effects old connotations have had in various discussions.*

Fine. That's your business. I just offered my two cents because Maudlin made one of his impassioned spiels precisely on the point of what "measurement" could mean in the Rovelli context—it seemed that some clarification was in order, and particularly worthwhile reiterating the point that if better language were used, quantum "measurement" might stop looking so unfamiliar.

van Fraassenism 4: *We need to bracket the old connotations such as that a measurement result reveals a pre-existing value for the measured observable. But I think we can do that because:*

Not trying to sway you anymore, but let me comment on a couple of these.

van Fraassenism 5: *there is a certain kind of retrodictive inference possible also on the basis of qm measurements. For a long time the paradigm was a source preparing a stream of particles in a certain state – measurements on samples taken from the stream give a good basis for conclusions about just what state the source was preparing, and these conclusions can then be used to predict the outcomes of further measurements made on later samples of the stream*

This is what we in quantum information call quantum-state tomography. One can indeed think of a quantum measurement outcome as *giving information* in the old standard sense in that case and not simply being the "unpredictable consequence of one's action." But then "giving information" is quantified by Shannon's "mutual information," $I(X,Y)$ and not simply by his entropy function $H(Y)$. That is, one has two random variables in the game—one treated classically, namely the "unknown preparation" X, and the other one purely quantum mechanical, the result Y of the measurement interaction. Those two variables have quite different roles, and one indeed would not want to think of X as the "consequence of one's interaction." On the other hand, without making explicit mention of X one has no means for thinking of the elicitation of Y as giving information about anything at all. Before seeing the value of Y, one can expect to be *surprised* to the extent quantified by $H(Y)$, but that's where the story stops.

[For a more detailed Bayesian-like development of this point, you might have a look at our paper "Unknown Quantum States and Operations, a Bayesian View," `quant-ph/0404156` and some of the references therein. Particularly the Introduction and Concluding section might be of some interest to you with regard to the present discussion.]

The only point I want to make to you with regard to your remark above is that, for these reasons, I would say it has no bearing on the issue at debate: I.e., whether it is better to think of a "quantum measurement" as simply an action with an unforeseeable consequence, or rather as a kind of "question-asking" or "information-gathering." It is tangential.

On a completely different subject,

van Fraassenism 6 : *Writers on the subject have emphasized that the main form of measurement in quantum mechanics has as result the value of the observable at the end of the measurement – and that this observable may not even have had a definite value, let alone the same one, before.*

your phrase "MAY NOT even have a definite value" floated to my attention. I guess this floated to my attention because I had recently read the following in one of the Brukner/Zeilinger papers,

> Only in the exceptional case of the qubit in an eigenstate of the measurement apparatus the bit value observed reveals a property already carried by the qubit. Yet in general the value obtained by the measurement has an element of irreducible randomness and therefore cannot be assumed to reveal the bit value or even a hidden property of the system existing before the measurement is performed.

I wondered if your "may not" referred to effectively the same thing as their disclaimer at the beginning of this quote. Maybe it doesn't. Anyway, the Brukner/Zeilinger disclaimer is a point that Caves, Schack, and I now definitely reject: From our view all measurements are generative of a NON-preexisting property regardless of the quantum state. I.e., measurements never reveal "a property already carried by the qubit." For this, of course, we have to adopt a Richard Jeffrey-like analysis of the notion of "certainty"—i.e., that it too, like any probability assignment, is a state of mind—or one along (my reading of) Wittgenstein's—i.e., that "certainty is a tone of voice"—to make it all make sense, but so be it.

I'm curious to understand whether Rovelli's writings already specify an opinion on the issue.

14-11-05 *Nordheim?, 2* (to A. Wilce)

Thanks for the reference, and also for bringing Kalmbach's book to my attention. Nicely enough, we have the latter here in our library, and I just had a cursory look at it. From it, I could tell that von Neumann had at least one paper where he mentioned a logical approach to quantum mechanics (a 1936 paper) before the Birkhoff-vN paper, but do you know if that is the earliest mention? Also I found similar information in this paper by Redei, "Why John von Neumann did not Like the Hilbert Space Formalism ..." which can be found on the web. Redei, in fact, quotes a November 1935 letter from vN to Birkhoff which seems to even indicate that vN had some understanding of a Gleason-like result even at that time. Do you know anything about this?

14-11-05 *Nordheim Again* (to B. C. van Fraassen)

Following up. The paper Alex Wilce talked about was apparently,

> Hilbert, D., von Neumann, J., and Nordheim, L., "Uber die Grundlagen der Quantenmechanik," Math. Annalen **98** (1927) 1–30.

It looks now, however, like I was wrong about these guys talking about the possibility of a quantum logical approach. Instead what this paper seems to be famous for is simply giving some guidelines for what it would mean to axiomatize quantum theory. Von Neumann, as best I can tell, only first talked about lattices (in the quantum context) in a 1935 letter to Birkhoff and first in print in a 1936 paper (by himself, not the one with Birkhoff).

Sorry for feeding you some misinformation.

14-11-05 *Fierz Translator* (to H. Atmanspacher)

I hope you are OK, and that your back is better. We definitely missed you in Konstanz.

Recently I've met a very interesting man, and I want to tell you about him. He is Prof. Hans C. von Baeyer at the College of William and Mary here in the United States. The last several years his interest has been in writing popularizations of science, and he recently won a couple of prestigious awards in that regard; have a look at `http://www.aip.org/aip/awards/gemawd.html` and `http://www.wm.edu/as/physics/news/von-baeyer-receives-american-institute-of-physics-andrew-gemant-award.php`. I myself have read his latest book *Information: The New Language of Science* and was quite pleased with its presentation.

Anyway, the main reason I write you is that it turns out that his godfather was Markus Fierz's brother, and I have gotten him interested in translating the Pauli-Fierz foundational/philosophical correspondence into English. I think he would be great for the task—as he has personal reasons because of his relationship, he is fluent in English, German, and French, he knows quite a bit about our "informational turn" in quantum foundations, and he is looking for an "easy" project to fill the cracks of his larger writing projects (as he goes into retirement this coming year).

The main questions on his mind are 1) whether there is anyone else taking on a project of this nature, 2) who might be a good publisher for this kind of material, and 3) what are the best, most complete sources of this correspondence. I told him you that would be the one most likely to have answers, and I told him something of your institute. I'd like to know the answers too.

If you are interested, I could put you two in contact. Or I could pass on any information you tell me to.

15-11-05 *Canned Answers* (to B. C. van Fraassen)

> One does not infer how things are from one's own certainty.
>
> Certainty is as it were a tone of voice in which one declares how things are, but one does not infer from the tone of voice that one is justified.
>
> — L. Wittgenstein, *On Certainty*, par. 30

> But de Finetti's philosophical view does see determinism as a state of mind masquerading as a state of nature, and sees causality as a fancied magical projection into nature of our own patterns of expectation. Beneath the mask of determinism is a state of mind—certainty—that is intelligible enough ...
>
> Certainties are not the only states of mind that are made to masquerade as states of nature. Probabilistic previsions are also magically projected into nature, to produce "real" probabilities, i.e. "objective chances" or probabilistic "propensities", which de Finetti rejects as firmly as he does deterministic causality.
>
> — R. Jeffrey, "De Finetti's Radical Probabilism"

Addressing your questions:

van Fraassenism 7: *Suppose that an observer assigns eigenstate $|a\rangle$ of A to a system on the basis of a measurement, then predicts with certainty that an immediate further measurement of A will yield value a, and then makes that second measurement and finds a. Don't you even want to say that the second measurement just showed to this observer, as was expected, the value that A already had? He does not need to change his subjective probabilities at all in response to the 2nd measurement outcome, does he?*

It is not going to be easy, because this in fact is what Schack and I are actually writing a whole paper about at the moment—this point has been the most controversial thing (with the Mermin, Unruh, Wootters, Spekkens, etc., crowd) that we've said in a while, and it seems that it's going to require a whole paper to do the point justice. But I'll still try to give you the skinny of it:

- Q) He does not need to change his subjective probabilities at all in response to the 2nd measurement outcome, does he?
- A) No he doesn't.
- Q) Don't you even want to say that the second measurement just showed to this observer, as was expected, the value that A already had?
- A) No I don't.

The problem is one of the very consistency of the subjective point of view of quantum states. The task we set before ourselves is to completely sever any supposed connections between quantum states and the actual, existent physical properties of the quantum system. It is only from this—if it can be done, and of course we try to argue it can be done—that we get any "interpretive traction" (as Chris Timpson likes to say) for the various problems that plague QM. (In that regard, you might look at Timpson's explanation of the point in the Envoi at the end of his thesis, starting page 223, in connection with his discussion of the problem of the "factivity of knowledge" on pages 176-182, particularly footnote 4.)

This may boil down to a difference between the Rovellian and the Bayesian/Paulian approach; I'm not clear on that yet. I'm looking at the first box on page 3 of your last week's handout at the moment. Rovelli relativizes the states to the observer, even the pure states, and with that—through the eigenstate-eigenvalue link—, YOU SAY, the values of the observables. I'm not completely sure what that means in Rovelli-world yet, however.

I, on the other hand, do know that I would say that a measurement intervention is always generative of a new fact in the world, whatever the measurer's quantum state for the system. If the measurer's state for the system HAPPENS to be an eigenstate of the Hermitian operator describing the measurement intervention, then the measurer will be confident, CERTAIN even, of the consequence of the measurement intervention he is about to perform. But that CERTAINTY is in the sense of Jeffrey and Wittgenstein above—it is a "tone of voice" of utter confidence. The world could still, as a point of principle, smite the measurer down by giving him a consequence that he predicted to be impossible. In a traditional development—with ties to a correspondence theory of truth—we would then say, "Well, that proves the measurer was wrong with his quantum state assignment. He was wrong before he ever went through the motions of the measurement." But as you've gathered, I'm not about traditional developments. Instead I would say, "Even from my view there is a sense in which the measurer's quantum state is WRONG. But it is MADE WRONG by the ACTUAL consequence of the intervention—it is made wrong on the fly; its wrongness was not determined beforehand." And that seems to be the main point of contention.

I think I say some of this better, and give better argumentation for it, in the attached document, but I'll let you be the judge of that. Particularly, I hope the long de Finetti quote helps here. The file is `Certainty.pdf`.

I think I have more to say in a positive vein on Rovelli, but I'll come back to that after lunch.

15-11-05 *February* (to A. Wilce)

Actually, if the slot is available, why don't we see if we can do it sometime between Feb 8 and 15 (inclusive) if you have a speaking date available then.

I would talk about symmetric informationally complete POVMs—what's known about them and what's not.

For our own personal pleasure, I have some new ideas about how working with them may help us out on our tensor-product derivation problem. Hopefully I'll have something worked on the qubit and qutrit cases by then, so that we might be able to think about what to do in the general-dimensional case.

For my talk, I'll try to follow Hans C. von Baeyer's "sawtooth model": plotting difficulty vs time, it should look like a saw blade, lots of peaks, lots of troughs. The idea is to give everyone a little something, whatever their level of sophistication, and in periodic doses. (By the way, I just met von Baeyer at William and Mary, when I gave the physics colloquium there.) I'll certainly keep in mind the undergraduate side of the audience, and I'll ask you more about what that really means as the time draws near!

16-11-05 *Your Phrase* (to B. C. van Fraassen)

What was that thing you said about torture in your last lecture? It was in the context of measurement and Rovelli. I want to get it right. If I'm recalling it right, it might serve a purpose even in my own account of Wigner's friend.

Bas's Reply

> I said that we also should not expect that, if we put someone to the question under torture, we would get an answer that he already had beforehand.

16-11-05 *Phone Message and Relationalism* (to H. Barnum)

On Wednesdays, I go to Princeton to a) partly to get away, but b) partly to attend Halvorson and van Fraassen's seminar. The last couple of sessions have really turned me on to van Fraassen. He's been discussing Rovelli and potential relational interpretations of QM. The part that I'm finding useful is that he is somewhat convincing me that, if one puts the interpretation of probability on the side for a moment, then there may not be that large of a gulf between our views (at least in any nonmetaphysical way). This has taken me a little by surprise, and presently I'm trying to digest it all.

16-11-05 *Red* (to R. W. Spekkens)

Spekkensism 30: *Is "red" ontic or epistemic? On the one hand, it refers to a certain sensation which is certainly subjective and on the other it refers to a particular wavelength of light, which is certainly objective. What good does it do us to argue about this? It's much better to try and articulate the precise sense in which colour vision involves an interplay between the objective and the subjective. Similarly for quantum theory.*

Well put.

17-11-05 *Dutch Meeting* (to A. Y. Khrennikov)

By the way, concerning,

Khrennikovism 9: *This is also related to the conference "Beyond QM" that we organize with G. 't Hooft and other people in Netherlands, 29 May – 2 June, so we plan that a group of people will move from Netherlands to Sweden.*

can you tell me more about the meeting? I might be interested in coming there too if possible. Where will it be? Who else will be there? Is there a website? ... And most importantly, is there any chance I could get invited? (Even the Bayesian program I promote hopes to one day go "beyond QM"!! In fact, that's the whole aim.)

17-11-05 *Rovelli Again* (to R. W. Spekkens)

Spekkensism 31: *I understood that the comparison was between you and Rovelli. In fact, I may even have mentioned this to you myself at some point. I have a standard overhead listing a variety of papers that defend the "epistemic view of quantum states", and Rovelli's paper is on it. Of course, it's not clear to me that he would agree with this characterization of his work, but the techniques are certainly similar. He even has something akin to the knowledge-balance principle. Others have tried to leverage what he's done into an axiomatic derivation of the formalism of quantum theory, but they have yet to be free of a few highly mathematical axioms. This work tends to be in the operational or quantum logic tradition.*

Can you give me references to some of those? My frank opinion is that Rovelli really didn't even get off the ground for that part of the project. (Much of the rest of the paper I like though.) I am starting to think there is a deeper connection between Rovelli's "even measurement outcomes are personal, i.e., relational" and my "any time two things get together, something new happens—quantum measurement and quantum theory just happens to concern only the cases when one of those things is me" (i.e., F-theory), as van Fraassen has been trying to convince me. But we'll see.

17-11-05 *Cash Value* (to H. Halvorson)

I probably laid too many cards on the table yesterday when you attempted to elicit my opinion on Bohmian mechanics. For, one of the arguments I gave was essentially one I had made in a referee report some time ago. Still it's always hard to keep these kinds of things secret—they generally so infect one's way of life that surely everyone can already guess the perpetrator.

Anyway, in principle, I am not a priori against the introduction of extra, unobservable entities into a theory (over and above, say, its rawest statement). But to make me care at all about them, they have to have a "cash value." This is why I gave the example of electromagnetic potentials. In classical electromagnetism, they too are unobservable; only the fields themselves are observable. But often it is quite useful to explicitly introduce the potentials and work in terms of them when solving a problem (if one wishes, one can even believe they're as real as real can be)—their facilitating my problem solving is their cash value and my reason for taking them seriously.

My argument is in the same vein when it comes to Bohmian mechanics.

Who knows, the Bohmians might one day indeed win out with me by giving me a good dollop of cash value. But I'm not banking on it. And life is too short to pursue every wacky theory *simply* because it is consistent. One has to follow one's instincts, and my instinct is that our biggest confusions with quantum theory come about because the only way we know how to word it presently is through the use of *too many* structures, not too few. That is, the number of distinct concepts in the axioms needs trimming, not fattening.

But I don't say anything that I haven't already said a thousand times. And in your case, I'm preaching to the choir anyway!

> The Bohmians are nothing if not an honest and faithful bunch. They are faithful to a theory that, though it has more structure than standard quantum mechanics (i.e., some extra elements over and above it), nevertheless—at least they strive to show rigorously—is empirically equivalent to quantum theory in every way. I am reminded of the secularist who complained to the priest that this is a godless world. The priest replied that the world couldn't possibly make sense without a god suffused through all its parts: The world only *looks* godless, but it only makes *sense* with a god. The priest recommended that the secularist supplement his daily study of the newspaper with a daily reading of the Bible. The difference between the Bohmians and the priest is that they have an equation to supplement standard quantum mechanics, whereas the priest only has unverifiable, humanly constructed words to supplement the daily events. As far as this reviewer can tell, that's the only difference.
>
> Is that difference enough to make Bohmian mechanics a science? It is a structure within mathematics, by construction, and maybe one more or less worthy of study. What will decide its support there are the whims and tastes of mathematicians, whose culture it is to explore various logical structures for reasons more detached than those of the physicist. But is Bohmian mechanics mathematical physics? Or is it more akin

to an equationified religion? This reviewer cannot help but feel that the answer is "no" to the former and "yes" to the latter.

There are so many tough and important problems in basic quantum mechanics waiting to be solved. For instance, for two independent quantum channels (i.e., the tensor product of two trace-preserving completely-positive linear maps, say on finite dimensional Hilbert spaces), is the quantum entropy of the output minimized by an entangled or unentangled input quantum state in general? No one knows the answer, but people have been working on the problem for almost 10 years now. The standing conjecture is that it is an unentangled input that minimizes the entropy, but no one has proved it yet, nor has anyone found a counterexample. Work like that, I would say, is an example of mathematical physics with respect to basic quantum mechanics. If a problem like this can be posed without the burden of the extra structure of Bohmian mechanics, one has to wonder whether adding the extra structure could possibly help in its solution. Maybe it can. But my attitude is, "Show me." If the Bohmians can be the first to the finish line for one or more problems like the one above—i.e., one posed independently of Bohmian considerations, but badly in need of its guidance—I will certainly rethink my stance. It would be a lesson for me, and I can already foresee that I would come to think of myself as misguided as Mach was when he refused to take atoms seriously because of their unobservability. But, show me. And I will be a very different reviewer the next time I am asked to judge a Bohmian research proposal.

19-11-05 *The Pleasures of Checking Consistency* (to H. Halvorson & B. C. van Fraassen)

I'm having my Saturday coffee, reviewing last week's seminar in my head, and every now and then looking up to this week's episode of *Ask This Old House*. Good combination!

Anyway, thinking about the point I tried to make to Hans about the utility of checking for consistency of epistemic or instrumentalist views of the quantum state, here's the way I put it in `arXiv:quant-ph/0104088v1`:

> What is a quantum state? Since the earliest days of quantum theory, the predominant answer has been that the quantum state is a representation of the observer's knowledge of a system. In and of itself, the quantum state has no objective reality. The authors hold this information-based view quite firmly. Despite its association with the founders of quantum theory, however, holding this view does not require a concomitant belief that there is nothing left to learn in quantum foundations. It is quite the opposite in fact: Only by pursuing a promising, but incomplete program can one hope to learn something of lasting value. Challenges to the information-based view arise regularly, and dealing with these challenges builds an understanding and a problem-solving agility that reading and rereading the founders can never engender. With each challenge successfully resolved, one walks away with a deeper sense of the physical content of quantum theory and a growing confidence for tackling questions of its interpretation and applicability. Questions as fundamental and distinct as "Will a nonlinear extension of quantum mechanics be needed to quantize gravity?" and "Which physical resources actually make quantum computation efficient?" start to feel tractable (and even connected) from this perspective.
>
> In this paper, we tackle an understanding-building exercise very much in the spirit

> of these remarks. It is motivated by an apparent conundrum arising from quantum information theory. The issue is that of the *unknown* quantum state.

Indeed I'm getting quite a bit out of this exercise of going over Rovelli.

21-11-05 *Dutch Meeting, 2* (to A. Y. Khrennikov)

Khrennikovism 10: *This is very preliminary information about coming conference "Beyond QM", it will be one of "Lorentz workshops." In fact, I do not know yet where in the Netherlands this series of workshops will take place. The main strategy for selection is that one should really go BEYOND QM. So people who just work on foundations of QM, but think that QM is the final theory are not welcome. I already tried to discuss a few names from "Växjö-conferences team", but they were rejected on the basis that there is nothing "beyond." So this is the situation. Among organisers there are G. 't Hooft, Theo (he was in Växjö), I, two people from SED community (they also were in Växjö, Ana and Lois) and some people from France (Balian and one two more names).*

If "going beyond quantum mechanics" in their sense means the unimaginitive move of *going back* to a hidden variable theory, then you're right, the meeting is not for me. If there were instead some room for exploring other ideas—say, the idea that quantum mechanics is *only our first hint* of a fantastic new kind of reality (one even whose laws of physics can evolve like Darwinian species)—then I might get excited. But looking at the list of the other organizers outside of yourself, it looks to me to be a more closed-minded, less-creative lot. I'd probably stick out like a sore thumb.

Attached is a pseudo-paper of mine, that I might polish into a contribution for this year's Växjö proceedings if you would like. Section 7 expands on what I was saying in the last paragraph.

21-11-05 *Pull!* (to R. Schack)

I remember when I was a kid in Texas, when one went skeet shooting, the command for sending the clay pigeon into the air was "Pull!"

Pull!

It'll be a busy month at Orange House Hotel (first Valente next week, then you the following one, and Timpson the week following that), but so much the better for quantum mechanics.

I think I now see the Wigner-friend issue with complete clarity. It is not so much the subjectivity of unitaries or the definition of a man, but **a)** things-happen-ism, + **b)** extreme personalism (i.e., not only personal probabilities, but personal outcomes for quantum measurements), + **c)** the analogy between quantum measurements and torture. Ingredients **a)** and **c)** are somewhat related to your ideas, so this is not completely independent work, but I think I finally see it all in a total package.

I know you're sick of reading "Me, Me, Me," "Preamble," and "B" in *Delirium Quantum*, but with hindsight, it really was already there. I think that was what was trying to come out of me the day we were watering the lawn. So, I'm going to send you that document again. Also, along with it, I'm going to send several notes I sent Bas van Fraassen last week to help bolster where I'm coming from. They give something of the flow.

Later in the week, I hope to write up a non-poetic version of the whole thing (particular to Wigner) for you.

21-11-05 *Notes to van Fraassen* (to R. Schack)

[[This refers to my 10-11-05 notes "'Action' instead of 'Measurement'" and "Our Own Rovellian Analysis" to Bas van Fraassen.]]

One final point, not in these notes but crucial: I had an epiphany of sorts last week. Von Neumann's description of quantum measurement (and consequently the root of the Wigner conundrum) is nothing more than the "correspondence theory of truth" (that William James always assaults) suitably formalized to the quantum situation. What I learned from Rovelli's paper (or vF's discussion of it, I don't know which) was how to break the instinct to formalize things that way.

21-11-05 *Seeing the Light* (to R. Schack)

Schackcosm 84: *It's the subjectivity of the sample space, stupid!*

I am not sure this is what you are getting at, but your brief lines on Wigner's friend suddenly made me see what could be the light. The friend's sample space is {pointer to the left, pointer to the right}*. Wigner's sample space is different. By contemplating the superposition* $|\text{friend sees left}\rangle + |\text{friend sees right}\rangle$*, Wigner does not treat "pointer to the left" and "pointer to the right" as measurement outcomes. In order to give a proper analysis of the so-called paradox, we must first know Wigner's sample space. My mistake was to identify the "left" in Wigner's superposition with the "left" in the friend's set of outcomes. They are not the same thing. The latter is what the friend sees. The former is a label in an abstract Hilbert space. Wigner and his friend are not talking about the same quantum measurement. There is no paradox.*

Yep, that's essentially it. The only thing further is that with all this "Me, Me, Me" business, one gives a gloss for why the sample spaces are different: The sample spaces are tied to the agents by definition.

It's really nothing that Asher and I didn't already say in our *Physics Today* thing that I quoted for Bas (and sent to you in the compilation). It's just that now I feel much more comfortable with what I would do if confronted aggressively with a question like, "Do you or do you not think a human intervention is necessary for a quantum measurement to come about? And related, do you or do you not think things happen independently of human intervention?"

Reversing the friend's wavefunction may change the story Wigner will coerce out of him (thus the bit about torture), but it will not change what has happened in the world. They are two different things. Quantum mechanics is not about what happens in the world; it is only about what might come about from a ME's interventions into it—and that is just a very small part of reality.

21-11-05 *Update on Schack and Wigner* (to C. G. Timpson)

Let me give you an update on what Schack is up to. He is, after all, coming to New Jersey, but the dates he finally settled on are December 3-8. Thus, if during your trip, you come by the Orange House Hotel, I'll have you all to myself.

By the way, I'm now also completely prepared for your visit too. That is: I'm not completely sure which troubles you had with a quantum-Bayesian account of the Wigner's friend issue (though Rüdiger gave me something of a sketch), but I am now quite confident that I can handle anything you throw at me. (See my note to Rüdiger below.) [See 21-11-05 note "Pull!" to R. Schack.]

Sometimes you have to rework these things in your head a thousand times, but in the end it's definitely all worth it. Thanks for sewing a seed of doubt in me: It caused me to strive as I thought I would, and I'm fairly pleased with the result.

We have a lot to talk about when you come.

21-11-05 *AJP Resource Letter* (to R. H. Stuewer)

The Anchorage meeting you mention must be the same one that Hans Christian von Baeyer wrote me about recently, at which he'll be receiving the Gemant Award (I think it was called). He wrote me this very nice note saying that he would title his talk, "How I Learned To Stop Worrying About Schroedinger's Cat," and said,

von Baeyerism 8: *I intend to chronicle my gradual adoption of your point of view about QM. … By the way, the reason I am no longer worried about Schrödinger's cat is not that I think that q.m. is now understood, but that I feel, for the first time in my career, that the problem is in good hands with young folks like you and your friends. I think that where I can make a contribution is in explaining to other physicists and to the public that y'all are NOT crazy, that progress HAS been made, that new ideas ARE being brought to bear, and that there actually IS a hope of realizing Wheeler's sibylline predictions.*

I'm so very happy he's giving exposure like that to our quantum foundational program (essentially the stuff I talked about at Seven Pines when you invited me) to such a good audience. With exposure, we might just get a workforce … and then who knows how things would really fly!

22-11-05 *MGM Curiosity* (to C. M. Caves)

What is his trouble with quantum information?

This kind of reminds me of the time I heard Willis Lamb talking about quantum information in the same breath as Bohmian mechanics, GRW theories, and the like. I recall he ended the diatribe by saying "quantum teleportation is beneath contempt."

22-11-05 *Difference Between Classical & Quantum* (to C. M. Caves & R. Schack)

I enjoyed finding these words in Joel Achenbach's piece in the *Washington Post* today:

> Reality gets fuzzier under closer scrutiny. It must be some kind of law of physics. (Actually, I think it's called quantum mechanics.) You would think that abundant evidence, steadily compiled, would make everything clearer, but the opposite is true. Partial knowledge gives us a simple picture of the world and its phenomena – an extension of the ignorance-is-bliss rule. Look deeper and you wind up scratching your head.

That's about the only truth I've ever seen in decoherence.

22-11-05 *From the Poetaster* (to R. Schack)

Schackcosm 85: *If a Bayesian spam filter can be an agent, then a quantum computer can act as an agent performing a quantum measurement.*

I see two possibilities now: You don't agree with this in some essential way, or your poetry is in trouble (I am hoping for the latter).

Poetry can always be made to work; that's the beauty of it. If ostensibly it can't, then it must not have been poetry to begin with, but poetastry.

I haven't gotten my head around what you're writing yet. I'll keep trying (as time permits today).

But come on, do you really believe that a man (and consequently a Bayesian agent) CANNOT be built in a laboratory by the hand of another man? That is what is at issue. I believe there is no difference in principle between a natural human body and one that can be put together in the laboratory. And if there is no difference, then we need a de-anthropocentrized way of putting what an agent is.

Yes, we are all already potential quantum computers. As the only difference between being a classical or quantum system—as treated in physical theory—is someone's state of mind about it (i.e., one's degrees of belief as captured by their quantum states for it). I can't accept that that there's any intrinsic difference: that would be the myth of Zurek's decoherence program.

But I have to go to an annoying meeting at the moment.

Rüdiger's Preply

Note on Wigner's friend, for Chris from RS.

If a Bayesian spam filter can be an agent, then a quantum computer can act as an agent performing a quantum measurement. Consider a joint system of two qubits, and let $s_{\rm prior}$ be a bit string that uses some code to describe the prior quantum state of the joint system. Now perform a projective measurement on the first qubit and let $s_{\rm post}(j)$ ($j = 0, 1$) be bit strings that encode the post-measurement state of the second qubit, conditioned on the measurement outcome, j. Consider a composite Hilbert space,

$$\mathcal{H} = \mathcal{H}_{\rm qubit1} \otimes \mathcal{H}_{\rm qubit2} \otimes \mathcal{H}_{\rm prior} \otimes \mathcal{H}_{\rm post} \otimes \mathcal{H}_{\rm agent} \ , \tag{43}$$

where $\mathcal{H}_{\rm qubit1} \otimes \mathcal{H}_{\rm qubit2}$ is the Hilbert space of the two qubit-system above, $\mathcal{H}_{\rm prior}$ is a quantum register large enough to hold the string $s_{\rm prior}$ in the form of a computational basis state, similarly $\mathcal{H}_{\rm post}$ for the strings $s_{\rm post}(j)$, and $\mathcal{H}_{\rm agent}$ houses the working space/internal state of the quantum computer/agent.

Let $|\phi\rangle, |\phi_0\rangle, |\phi_1\rangle \in \mathcal{H}_{\rm agent}$ and U be such that

$$U\Big(|\psi\rangle \otimes |j\rangle \otimes |s_{\rm prior}\rangle \otimes |0\rangle \otimes |\phi\rangle\Big) = |\psi\rangle \otimes |j\rangle \otimes |s_{\rm prior}\rangle \otimes |s_{\rm post}(j)\rangle \otimes |\phi_j\rangle \tag{44}$$

for any one-qubit state $|\psi\rangle$ and $j = 0, 1$.

To repeat, if a spam filter is an agent, then this quantum computer is an agent. It starts from a prior judgement and a sample space, interacts with the system, brings about a measurement outcome and records the post-measurement state in a register.

Is this any different from Wigner's friend? No. Wigner sets up this device in the initial state

$$|\Psi_{\rm ini}\rangle = \frac{1}{\sqrt{2}}(|00\rangle + |11\rangle) \otimes |s_{\rm prior}\rangle \otimes |0\rangle \otimes |\phi\rangle \ . \tag{45}$$

He applies U and writes down a superposition state. Does this mean that the friend is in a funny state? Not at all. Ask him (by looking, e.g., at the register encoding the posterior) and he will give you a simple answer. Reverse him, then ask him, and he will show you a register in the erased state $|0\rangle$, ready for the measurement.

I see two possibilities now: You don't agree with this in some essential way, or your poetry is in trouble (I am hoping for the latter). Does your poetry (hands in the form of meters extending into the world, the sexual interpretation of quantum mechanics, etc) work for a Bayesian spam filter?

22-11-05 *The Point: Inanimate Object, Wigner, his Friend, or Agent — It Doesn't Matter* (to R. Schack)

> I think the greatest lesson quantum theory holds for us is that when two pieces of the world come together, they give birth. [Bring two fists together and then open them to imply an explosion.] They give birth to FACTS in a way not so unlike the romantic notion of parenthood: that a child is more than the sum total of her parents, an entity unto herself with untold potential for reshaping the world. Add a new piece to a puzzle—not to its beginning or end or edges, but somewhere deep in its middle—and all the extant pieces must be rejiggled or recut to make a new, but different, whole. That is the great lesson.
>
> But quantum mechanics is only a glimpse into this profound feature of nature; it is only a part of the story. For its focus is exclusively upon a very special case of this phenomenon: The case where one piece of the world is a highly-developed decision-making agent—an experimentalist—and the other piece is some fraction of the world that captures his attention or interest.

It's things-happen-ism, man. But the point is, that shouldn't be confused with what quantum mechanics is about. QM is only about that other point of view, what-I-happen-to-cause-ism.

22-11-05 *Spoke Too Soon?* (to R. Schack)

OK, maybe I spoke too soon when I said we were in essential agreement yesterday after you said, "It's the subjectivity of the sample space, stupid!"

I looked at your LaTeXed note over and over today, but couldn't figure out what you were trying to get at. Do you want to try again?

Was your note from today intended to be in disagreement with what I had written you in reply yesterday?

22-11-05 *Story of Bohr's Office* (to G. Brassard)

Below is a story I wrote about my own visit to Bohr's office. [See 03-02-04 note titled "The Land of Bohr" to G. L. Comer.] There is a certain spirit there, isn't there?

22-11-05 *An Amusement* (to T. Maudlin)

Maudlinism 1: *I wrote this little piece earlier in the semester, after there had been some discussion in Bas and Hans's class about using the classical notion of information in quantum contexts. I thought you might find it amusing. I somehow think you will object to something in it, but I don't know quite what…*

Thanks for sending me your piece. I gave it a once-over this afternoon, and as my six-year-old likes to say, "I didn't like it … (pause) … I loved it!" I thought it was great; quite creative. And I was particularly pleased to learn that, "Dr. Psi, like all evil geniuses, is a perfect Bayesian."

But you were right, I don't agree with everything in the document. *However*, at least at my level of thoroughness for this once-over, I do think I agree with everything in the first 7.5 pages. That's gotta count for something! Particularly, I agree with the very first paragraph of the paper, and then the way you laid everything out and unrolled it thereafter in the rest of those 7.5 pages:

> Quantum teleportation is a very interesting physical phenomenon, predicted by quantum theory and confirmed in the lab. There has been some question about what the proper information theoretic analysis of this phenomenon is. In particular, there have been doubts about whether "classical information theory" (i.e. Shannon's theory) can be applied to such a quantum situation. These worries are misplaced. Shannon's theory is "classical" only in the sense that it is a well-established, canonical theory, not in the sense that it applies only to "classical" physics (whatever that is). I hope the following little playlet will be instructive.

Where we start to part company is where you, indirectly, invoke a comparison between pure quantum states and classical phase space points in your discussion of the no-cloning theorem. I say that's a comparison that shouldn't be made; it's like comparing apples to oranges, Frank Sinatra to Mötley Crüe, beliefs to facts. And then we diverge still further with the discussion of nonlocality.

But I really did like everything else! I remember in high school once writing a paper on Thoreau. When my teacher returned it with an A+, I was really humbled when she furthermore said, "Chris, you seem to have a feeling for Thoreau!" Well, from the devious insight and style of conversation you put into this document, I almost want to say, "Tim, you seem to have a feeling for Dr. Psi, the evil genius!" But maybe that goes too far …

See you tomorrow in class.

22-11-05 *On the Fly* (to G. Musser)

By the way, I should also tell you about how I have consciously adopted some of your phraseology in my own explanations. It comes from this thing you once wrote me:

Musserism 27: *Let me see whether I understand your vision of a world in continuous creation. Ernst has bequeathed me his cat; it arrives in a box. I open it to find the cat is … alive. Before I do, the cat is neither alive nor dead; it is not even in a purgatorial superposition. In fact, the categories of cat alive and cat dead don't even exist yet. When I open the box, I create the fact of a live cat. That fact had to come into existence* <u>*sometime*</u>*. In the classical deterministic universe, it came into existence when the universe did. All the arbitrariness was in the ICs. The quantum universe makes up facts as it goes along. The arbitrariness is spread out over time. It's the distinction between my wife, who makes plans and carries them out, and me, who decides step by step on the fly.*

The main point is the one in the last sentence, that the quantum universe makes up facts on the fly. I can't tell you how many times I've used that phrase since, but the last example I can think of came last week in a letter to Bas van Fraassen (a philosophy professor at Princeton).

I'll paste it below for your amusement. [See 15-11-05 note "Canned Answers" to B. C. van Fraassen.]

23-11-05 *Cathy, the Friend, and the Device-Agent* (to R. Schack)

OK, I start to appreciate what you're trying to get at.

Among other things, you call into question how I think I can make the inference from quantum mechanics (which is about what-I-happen-to-cause-ism) to "the greatest lesson quantum theory holds for us" (which is about things-happen-ism). Is that correct?

That indeed is a good question. It is something I should unroll a little more and be a little less declarative about.

But I also think your question (or maybe it is simply an independent question) has to do with the consistency of our Wittgensteinian notion of certainty (i.e., that one can have certainty and still not have it fulfilled).

Let me read and reread your two notes a little more, now that the kids are out of the house!

23-11-05 *The Skinny Answer* (to R. Schack)

Schackcosm 86 : *There is no big problem with the following bit of poetry:*

> The role of the quantum system is thus more like that of the philosopher's stone; it is the catalyst that brings about a transformation (or transmutation) of the agent.

The qubit is a catalyst which brings about a transformation of the device-agent.

But how about the part where the world external to the agent makes one of the outcomes happen? How does Wigner's description of the device- agent tie in with the poetic tale that nothing prevents the external world from smiting the device-agent if it bets its life (let's say, its power supply) on the outcome? Doesn't Wigner have to conclude that the device-agent is wrong in thinking that the external world has made one of the outcomes come about?

Answering the last question in particular: No.

You see, if I answered "yes" it would be equivalent to saying that it is the external view that is always the right one. And that leads one down the path of many-world-ism, or at least Everettism. Instead, the move here is to say, *all* internal views are equally valid—the device-agent's (who sees an actual outcome following his interaction), Wigner's (who sees an actual outcome following his interaction), Wigner's friend's (who sees . . .), etc. When all is said and done, the "Me, Me, Me" facts actually are disembodied facts—that's the things-happen-ism part. But there is no contradiction with quantum mechanics because Wigner's degrees of belief are not degrees of belief about the device-agent's internal view. His degrees of belief are about what he might coerce out of the device-agent or even the system (or both) if he were to interact with them.

That probably obfuscated things even worse for you. But give me a reaction, and that will be a useful datum.

23-11-05 *Wigner's Impotence* (to R. Schack)

Schackcosm 87 : *To ask it in a yet different way, can Wigner undo the outcome that the world has made come about?*

No, he cannot. That is the disconnect between reality and Wigner's degrees of belief (including his certainty). Wigner can only undo *state-vector* time evolutions for systems external to himself.

23-11-05 *After-Shower Thought* (to R. Schack)

I'm going to have to pack up and get on the Princeton trek soon, but let me just record one phrase that came to mind while I was in the shower.

Schackcosm 88: *I don't feel, though, that*

> When all is said and done, the "Me, Me, Me" facts actually are disembodied facts—that's the things-happen-ism part.

gives a satisfactory connection to the things-happen-ism part. What and who determines the moment at which "all is said and done"? You certainly don't want to say it's when Wigner has queried the device-agent. To repeat, what connects the "actual outcomes" or facts that the players see to the things that happen?

Quantum theory has no more power within it to say when (quantum) events happen than classical probability theory has the power within *it* to say when its own events happen. Maybe this is why some developments of classical probability theory are careful to say that the h's in a probability assignment $P(h)$ are propositions. Propositions don't "happen", they are simply either true or false. And thus, by fiat, one never has to address the question of when h "happens". But we know that we shouldn't try to make that further move (i.e., viewing the h's as propositions with timeless truth values) in the quantum setting. Quantum events do "happen." But that doesn't mean that quantum theory should have the burden on it of explaining or determining "the moment at which 'all is said and done'."

This is ultimately, I suspect, why our view will be greeted with the same revulsion that William James's theory of truth was by Russell and Moore and the like: Because for James, too, truth is something that is made to happen; it is not something that is just there in a timeless way.

> The truth of an idea is not a stagnant property inherent in it. Truth *happens* to an idea. It *becomes* true, is *made* true by events. Its verity *is* in fact an event, a process: the process namely of its verifying itself, its veri-*fication*. Its validity is the process of its valid-*ation*.

Have we made any progress?

23-11-05 *Basil* (to A. Y. Khrennikov)

Khrennikovism 11: *I shall read your paper. I hope you are not against if I also give it Basil Hiley. He is visiting me this week.*

I meant I might polish into a real paper for you upcoming proceedings, by adding an introduction, etc. Of course it is fine to share it with Basil.

Khrennikovism 12: *More or less you are right. It is more or less about HV, or more generally about realism as the basis of QM. I think it is the continuation of the debate between Mach and Boltzmann. You are definitely Machian, he would like your new idea about the evolution of laws of nature. But do not forget that Mach rejected Boltzmann's ideas on atoms. There was no experimental evidence of the existence of atoms. Mach considered them as unuseful elements of knowledge. See! But finally Boltzmann was right!*

It's not true that I'm Machian. In fact, I just wrote some stuff to Hans Halvorson and Bas van Fraassen the other day saying the opposite. I'll paste it in below; it clarifies the point (and note the reference to Mach). [See 17-11-05 note "Cash Value" to H. Halvorson.] However, it is true that I think that toying with hidden-variable extensions of quantum mechanics is a waste of time. Trying to make an analogy between Boltzmann's introduction of atoms and Bohm's introduction of trajectories is not a good one. I think you were much closer to the mark when you were still talking about "contextual probabilities." The story of quantum mechanics, I think, is much more like that.

Read the stuff below. And don't forget to read Section 7 in the pseudo-paper I sent you; I think—but maybe I'm wrong—it's a position that both you and Basil could respect. (For it says, in the end, quantum mechanics is incomplete.)

24-11-05 *Howard's Scream!* (to H. Barnum)

Quoting you:

Barnumism 14: *I tend to think that Many-Worlds (despite my having spent a lot of effort in my life playing devil's advocate for it) gets things backwards: stuff happens, we do scientific (i.e. some variety of roughly Bayesian in a very general, not necessarily conscious, sense) inference about the stuff that happens, the definite results we experience for measurements, we come up with a theory that systematizes the resulting beliefs (as evidenced by our willingness to bet, in a very generalized sense, on the outcomes of experiments and such). This systematization of our betting behavior faced with experiments can be represented in terms of probabilities given by the Born rule. Rederiving the Born probabilities from a part of the formalism that was cooked up, and especially, further developed and held onto, in part to give a good representation of just these probabilities, seems somewhat backwards. Without the probabilities, and the terrific guidance they give to our actions, who would have bothered with quantum mechanics anyway? I guess one can say that the rederivation is a sophisticated attempt to keep the probabilities and solve other problems that came along with quantum mechanics. But it still raises, for me, a serious problem of: what then of the formal and informal scientific reasoning, based on measurements having definite results, that brought us to the QM formalism and Born rule in the first place? Must we reconstruct it all in terms of Everettian branchings, with never a definite result?*

Hear, hear! I like that line of argument. And I wonder if you can put some real flesh on it. It'd be nice to derive an honest-to-god contradiction.

But here's maybe something to think about. It's a report from Heisenberg of something Einstein said to him:

> It is quite wrong to try founding a theory on observable magnitudes alone. In reality the very opposite happens. It is the theory which decides what we can observe. You must appreciate that observation is a very complicated process. The phenomenon under observation produces certain events in our measuring apparatus. As a result, further processes take place in the apparatus, which eventually and by complicated paths produce sense impressions and help us to fix the effects in our consciousness. Along this whole path—from the phenomenon to its fixation in our consciousness—we must be able to tell how nature functions, must know the natural laws at least in practical terms, before we can claim to have observed anything at all. Only theory, that is, knowledge of natural laws, enables us to deduce the underlying phenomena from our sense impressions. When we claim that we can observe something new, we ought really

> to be saying that, although we are about to formulate new natural laws that do not agree with the old ones, we nevertheless assume that the existing laws—covering the whole path from the phenomenon to our consciousness—function in such a way that we can rely upon them and hence speak of "observation."

Particularly, I'm thinking about the part, "When we claim that we can observe something new, we ought really to be saying that, although we are about to formulate new natural laws that do not agree with the old ones, we nevertheless assume that the existing laws—covering the whole path from the phenomenon to our consciousness—function in such a way that we can rely upon them and hence speak of observation."

Could it be that this sort of thing helps save the move from "definite outcome empirical world" to "nothing happens at all Everett world" that the Everettians would like to make? I.e., that the idea of definite outcomes is just some old-theory scaffolding that eventually falls away after the shining tower of Everett is open for public service?

Happy Thanksgiving, by the way.

28-11-05 *Your Visit* (to G. Valente)

Thanks again for pushing me about Ramsey. I've been reading on and off about him over the holiday weekend, and I've learned much in the process—it's given me a lot of food for thought.

Next project, your paper!

29-11-05 *Abstract for APS March Meeting – Trial 1* (to me)

> Title:
> Quantum Mechanics in Terms of Symmetric Measurements
>
> Abstract:
> In the neo-Bayesian view of quantum mechanics that Appleby, Caves, Pitowsky, Schack, the author, and others are developing, quantum states are taken to be compendia of partial beliefs about potential measurement outcomes, rather than objective properties of quantum systems. Different observers may validly have different quantum states for a single system, and the ultimate origin of each individual state assignment is taken to be unanalyzable within physical theory—its origin, instead, ultimately comes from probability assignments made at stages of physical investigation or laboratory practice previous to quantum theory. The objective content of quantum mechanics (i.e., the part making no reference to observers) thus resides somewhere else than in the quantum state, and various ideas for where that "somewhere else" is are presently under debate—there are adherents to the idea that it is purely in the "measurement clicks," there are adherents to the idea that it is in intrinsic, observer-independent Hamiltonians, there are adherents to the idea that it is in the normative rules quantum theory supplies for updating quantum states, and so on. This part of the program is an active area of investigation; what is overwhelmingly agreed upon is only the opening statement. Still, quantum states are not simply Bayesian probability assignments themselves, and different representations of the theory (in terms of state vectors or Wigner functions or C^*-algebras and the like) can take one further from or closer to a Bayesian point of view. It is thus worthwhile spending some time thinking about which representation might be the most propitious for the point of view and might, in turn, carry us the most

quickly toward solutions of some of the open problems. In this talk, I will present several results regarding a representation of quantum mechanics in terms of symmetric bases of positive-semidefinite operators. I will also argue why this is probably the most natural representation for developing a Bayesian-style interpretation of quantum mechanics.

30-11-05 *TGQI Nomination Votes ...* (to H. Mabuchi)

Sorry I dropped out of sight almost as soon as you last heard from me: Mr. Giovanni Valente arrived for his visit and has kept me fascinated with all kinds of "noncommutative probability" ever since. But I'll forward on my picks in a couple of minutes, while he takes a breather from our debate.

01-12-05 *Focus Session Quantum Foundations* (to R. W. Spekkens)

OK, I did it. Thanks for keeping me abreast of this.

Below is the abstract I originally wrote up before the submissions page made me trim it. (I include it here so that I have a record of it.)

Title: Quantum Mechanics in Terms of Symmetric Measurements

Abstract: [See report of it in 01-12-05 note "The Swedish Bayesian Team," and add these words to its end:] In this talk, I will present several results regarding a representation of quantum mechanics in terms of symmetric bases of positive-semidefinite operators. I will also argue why this is probably the most natural representation for developing a Bayesian-style interpretation of quantum mechanics.

01-12-05 *The Swedish Bayesian Team?* (to D. M. Appleby & Others)

I'm writing this note to see if you might be available to come to a meeting in Växjö, Sweden, June 4-9, 2006? The general meeting is *Foundations of Probability and Physics – 4* organized predominantly by Andrei Khrennikov along the lines of his previous meetings, but he has given me a small budget to contribute toward trying to attract a group of quantum-Bayesians. If this meeting goes like the ones I've been associated with before, it will turn out to be a pleasant and productive time for the group I hope to attract there. (It is a nice village with a couple of bars and a nice lake to walk around and discuss things.)

Ideally, I'd like to have you, Itamar Pitowsky, Richard Gill, Matt Leifer, Ariel Caticha, and Rüdiger Schack there to contribute toward a discussion. [...]

The sort of idea I have in mind for a focused discussion can be read in some of the words I used in a recent abstract I wrote for my talk at the APS March meeting. I'll place those words below to give you a kind of feeling.

> Opening from Fuchs's APS abstract:
>
> In the neo-Bayesian view of quantum mechanics that Appleby, Caves, Pitowsky, Schack, the author, and others are developing, quantum states are taken to be compendia of partial beliefs about potential measurement outcomes, rather than objective properties of quantum systems. Different observers may validly have different quantum states for a single system, and the ultimate origin of each individual state assignment is

taken to be unanalyzable within physical theory—its origin, instead, ultimately comes from probability assignments made at stages of physical investigation or laboratory practice previous to quantum theory. The objective content of quantum mechanics (i.e., the part making no reference to observers) thus resides somewhere else than in the quantum state, and various ideas for where that "somewhere else" is are presently under debate—there are adherents to the idea that it is purely in the "measurement clicks," there are adherents to the idea that it is in intrinsic, observer-independent Hamiltonians, there are adherents to the idea that it is in the normative rules quantum theory supplies for updating quantum states, and so on. This part of the program is an active area of investigation; what is overwhelmingly agreed upon is only the opening statement. Still, quantum states are not simply Bayesian probability assignments themselves, and different representations of the theory (in terms of state vectors or Wigner functions or C^*-algebras and the like) can take one further from or closer to a Bayesian point of view. It is thus worthwhile spending some time thinking about which representation might be the most propitious for the point of view and might, in turn, carry us the most quickly toward solutions of some of the open problems.

01-12-05 *State Spaces* (to H. Halvorson)

Luckily, our library had the right volume of Alfsen and Shultz, and I checked it out. This new kind of characterization of complete positivity has me quite intrigued: Now if I can only translate the stuff I find in this book to finite dimensional language so I can see what it means!

What were the additional references you were going to give me on the relation between convex (state-space) structures and algebraic properties?

By the way, in times past, I've had the hope of deriving the idea of complete positivity from a Gleason-like theorem for the joint probabilities over measurement outcomes for measurements on a single system at two separate times. I've had some concrete ideas about how to articulate that (and a good load of calculations), but I never could quite get a theorem to work. If you'd like to throw in on a project like this, maybe we could discuss this too in the coming weeks.

01-12-05 *Finite Sets (then limits) Policy* (to H. Halvorson)

Also, here's the quote from Ed Jaynes that I almost read aloud in your seminar yesterday. I suspect nothing deeper than this is going on with Redei's criticism of *whatever he is imagining is* the Bayesian approach. (I.e., there are many different approaches that one might think of as more or less Bayesian, and whichever one Redei is attacking, I doubt his problems are of any origin other than what Jaynes expresses below.)

> It is very important to note that [the theorems we have just proven] have been established only for probabilities assigned on finite sets of propositions. In principle, every problem must start with such finite sets of probabilities; extension to infinite sets is permitted only when this is the result of a well-defined and well-behaved limiting process from a finite set. More generally, in any mathematical operations involving infinite sets the safe procedure is the finite sets policy:
>
> > Apply the ordinary processes of arithmetic and analysis only to expressions with a finite number of terms. Then after the calculation is done, observe

how the resulting finite expressions behave as the number of terms increases indefinitely.

In laying down this rule of conduct, we are only following the policy that mathematicians from Archimedes to Gauss have considered clearly necessary for nonsense avoidance in all of mathematics. But more recently, the popularity of infinite set theory and measure theory have led some to disregard it and seek short-cuts which purport to use measure theory directly. Note, however, that this rule of conduct is consistent with the original Lebesgue definition of measure, and when a well-behaved limit exists it leads us automatically to correct "measure theoretic" results. Indeed, this is how Lebesgue found his first results.

The danger is that the present measure theory notation presupposes the infinite limit already accomplished, but contains no symbol indicating which limiting process was used. Yet as noted in our Preface, different limiting processes—equally well-behaved—lead in general to different results. When there is no well-behaved limit, any attempt to go directly to the limit can result in nonsense, the cause of which cannot be seen as long as one looks only at the limit, and not at the limiting process.

02-12-05 *Princeton Quantum Informatics Conf* (to M. O. Scully)

I'd be happy to help you organize a Princeton Quantum Informatics conference, particularly if it will involve in some part a tribute to John Wheeler (as you had mentioned previously). Anyway, whichever way, I have a lot of friends in that community, and I think we could make a good meeting . . . if I didn't try too many of their patiences with my quantum Bayesian conference in Konstanz last year!

As it turns out, I'll be in Princeton December 14 to attend Chris Timpson's lecture at Bas van Fraassen's seminar. (Then Timpson will come back with me to Bell Labs for a couple of day visit.) How about we get together then for a little planning session: You can tell me much more about what you're thinking and what your constraints are, etc.

02-12-05 *Gleason Frames* (to I. Bengtsson)

Bengtssonism 1: *I'm looking for a topic for a Master's Thesis, and I am wondering whether I can ask the undergraduate in question to study Gleason's theorem, more specifically to understand the "general POVM" version, to get some feeling for why the "only projective" version is hard, and then to ask what happens if one places oneself somewhere in between—say admit ONLY tomographically complete but otherwise minimal POVMs, or something like that (I might ask her to invent restrictions herself). As a way to start, first study Kochen-Specker for $N = 2$, which has been done for cubes inscribed in a dodecahedron (Aravind, I believe), and then try to do it with tetrahedra inscribed in a dodecahedron (I don't think I have seen that).*

Question (that the supervisor ought to ask himself, really): Is the answer trivial, or known, or obviously too hard?

Any advice that you care to give would be appreciated.

I think the research project you suggest for your student is a great one! (I wish I were your student, in fact, for this one.)

The question you ask is by no means trivial. Have you looked at our paper `http://www.arxiv.org/abs/quant-ph/0306179`?

See Section IV in particular. My original expectation was that the set of symmetric informationally complete POVMs would be sufficient for deriving the probability rule, but it was not! (In fact, I'm still disappointed that that's not true: It still seems that it should be.) So, one question I might ask is how much asymmetry must be introduced before a Gleason theorem becomes viable again? For instance, is it enough to consider one very asymmetric frame and all unitarily equivalent ones?

Keep me up to about your progress. I think this is an exciting question.

02-12-05 *Notes to van Fraassen and Delirium Quantum (some nested)* (to G. Valente)

Contained within the attachments are all the notes I had promised to send you. [See the 10-11-05 notes "'Action' instead of 'Measurement'" and "Our Own Rovellian Analysis" to Bas van Fraassen.] You will see why I say they touch on our view of the "stability condition" with respect to quantum measurement, and why I sometimes say that the very existence of repeatable measurements is something of a mystery from our perspective.

Thanks again for spending some time at the Orange House. I got a lot out of the visit; you gave me much food for thought.

02-12-05 *Sounds of Silence and CBH* (to G. Brassard)

OK, I'll accept your sounds of silence for a while ... until my own stress levels start to go over the top about how I might fund this magically gifted postdoc who wants to work on these things ...

Too bad you couldn't have been around here the last three weeks or so. Bas van Fraassen and Hans Halvorson have been going over the CBH theorem in their seminar. And Jeff Bub has been making the three- and four-hour drives (each way) to attend the sessions! A lively discussion has ensued, with the obstinate Tim Maudlin in the audience. Anyway, you should have been there. I've gotten a lot from the discussion.

03-12-05 *Subjective Quantum Information* (to M. Bahrami)

Bahrami-ism 1: *I have studied the articles as you told me. There is a core stone in your attitude which can be called Subjectivness of Information.*

I pretended I am on your side and accept this vision. Then I tried to exploit this vision in a real experimental setup. So I choose Interaction-Free Measurement as proposed by Elitzur-Vaidman. To be honest I feel I can say nothing about why the existence of an object in one of the ways causes such a strange result. I have checked the journals to find other physicists interpretations on this subject, but I could find just tow different attitude: 1) many-world interpretation of this experiment, mainly by Vaidman, 2) objective interpretation of information by Auletta (Foundations of Physics, May 2005) Let alone the first one, but the second is in great contrast with the common beliefs of physicists like you on subjectiveness of information.

I would be grateful if you let me know how you interpret (or explain) this experiment with a subjective attitude toward information.

To be honest, that is a thought experiment that I never gave too much attention to, because I always thought it was hype without too much substance. The concept of "interaction-free measurement" uncovers what had in earlier days been called *interference* and gives it a new, more dramatic name, but that's qualitatively as deep as it goes. (Quantitatively, there are some differences with previous techniques, and this may be thought of as a clever interferometric technique.)

But now that you push me on it, I think this would be an excellent project for you to take on. Why not let this be the subject of your Master's thesis? Give a detailed quantum information theoretic analysis of this phenomenon. And particularly, test your understanding of the Bayesian approach to quantum states with respect to it. I, for instance, might learn a lot from your thinking, and then you can call the analysis your own.

12-12-05 *The Great Pumpkin* (to J. W. Nicholson)

I think you'll love this thing Greg Comer is going to do in his physics class today. Read below.

Comerism 10: *I can't believe I'm going to give the following question on my physics exam today:*

> Charlie Brown tells Linus that he has developed a theory of gravity that is based on mass and energy causing curvature in the spacetime continuum. He also shows Linus his experimental data which confirms that the theory works within the accuracy and precision of the experiments. Linus tells Charlie Brown that, regardless of the agreement with the data, the new theory is wrong, because it is known that the Great Pumpkin is responsible for gravity, and the new theory makes no reference to the powers of the Great Pumpkin. How should Charlie Brown respond? Assume a rational and respectful discourse from both.

19-12-05 *The Detached Fuchs* (to H. C. von Baeyer)

I'm finally replying to your nice note: Several visitors and Montezuma's revenge have gotten in my way since your writing me.

von Baeyerism 9: *I came across a footnote specifically about the term "der losgelöste Beobachter: the detached observer" in Wolfgang Pauli, Wissenschaftliche Briefwechsel, Vol. IV part I, page 343, footnote 13 to the commentary on letter [1263] from Bohm to Pauli, which is of course in English.*

Yes, of course, I would like that quote translated very much; as far as I know I don't already have it. All in the greater cause!

19-12-05 *Thanks and Question* (to H. Halvorson)

This is a belated thanks for sending me the Alfsen, Schultz, and Mielnik references. I've got to get on this!!

Now a question. I noticed that you're on the PSA 2006 program committee. The reason I was snooping there is because I had a flash that maybe I'd like to organize a session or workshop at the meeting comparing and *contrasting* epistemic views of the quantum state to Bayesian views of probability. It'd be nice if I could get, for instance, Persi Diaconis or Brian Skyrms and Abner Shimony to give talks, along with, say, Rob Spekkens and/or Huw Price and/or Itamar Pitowsky and/or Bill Demopoulos, etc., etc.—I'm just starting to think about it all. The trouble is, the deadline for proposals has already passed. Do you know whether this deadline is really strict? I noticed that the proposals won't start being reviewed until mid-February. If the deadline is a little loose and I work at it, I could probably have something submitted in the break between Christmas and New Year's. Thanks for any advice you can give.

19-12-05 *A Small(?) Request* (to A. Radosz)

I have skimmed your student's paper. I'll just reply by telling you a story from my first year of study with Carlton Caves, in 1993. At the time, I had just read a paper by Braunstein and Caves on information-theoretic Bell inequalities. One of the things they note in that paper is that whereas their information-theoretic inequalities have an advantage over CHSH-type inequalities because of the ease and automated nature of their derivations, they have a *dis*advantage in that they are not violated over as large of a range of measurements as the CHSH ones. Well, in my digging up various references in information theory (as I was learning the ropes), I learned about a whole new class of information functions—the Daróczy entropies—and as I played with them, I discovered that they too could be used in a Bell inequality derivation ... just along the same lines as Braunstein and Caves had discovered for Shannon's measure of information. Excited, I ran to Caves, told him about my result—I think it was something like the Daróczy 2.73 entropy was optimal for finding a result, and with it I could find a violation over 12.7 degrees more than the Braunstein and Caves result. Then I asked him if I should publish it?!?! He replied, "Well, I wouldn't." I replied, "But that's you; you've got a hundred papers, and I have none." He replied, "I'm just saying, if it were me, I wouldn't." I got the hint, finally, and never published it. Caves always wanted his students to stay away from incremental work or isolated results. In my case, it helped; but different students have different requirements. It'll be your call.[84]

27-12-05 *Randomness and Quantum* (to D. Overbye)

While up this morning with a little insomnia (it's 4:00 AM as I write this), I skimmed over your *NY Times* article on "Quantum Trickery." I especially enjoyed some lines near the end:

> As a result of the finiteness of information, he explained, the universe is fundamentally unpredictable.
>
> "I suggest that this randomness of the individual event is the strongest indication we have of a reality 'out there' existing independently of us," Dr. Zeilinger wrote in *Nature*.
>
> He added, "Maybe Einstein would have liked this idea after all."

That's an idea I'm very attracted to and have explored in a decent set of my writings. (There's a sampling of some posted at my webpage, link below.) With regard to entertainment value along those lines, you yourself might enjoy Sections 4 and 5 of this 2002 pseudo-paper:

`http://www.arxiv.org/abs/quant-ph/0204146`.

[84] I suppose for the purposes of subtle persuasion I intentionally left off an addendum to the story that I *do usually* include with it. Not fair of me really! Some time in the mid to late 1990s, I was having a walk with Michał Horodecki, and the conversation turned to the Braunstein and Caves inequalities. Michał noted, "Sadly, they cannot be generalized to the Rényi information measures. The derivation just doesn't work." I said, "Oh, that's right; that's because the Rényi entropies are additive, but not subadditive. The same derivation does however go through if you use the Daróczy entropies instead. For, though they are not additive for independent random variables, they are subadditive generally, and that's all you need." Michał became quite excited and asked, "Where have you written this?" I said, "Oh, I never published it. I worked it out a long time ago, but it didn't seem very important." He responded, "That is wrong, you should publish it even now."

Here's a sample paragraph from that connected to the above:

> I would say all our evidence for the reality of the world comes from without us, i.e., not from within us. We do not hold evidence for an independent world by holding some kind of transcendental knowledge. Nor do we hold it from the practical and technological successes of our past and present conceptions of the world's essence. It is just the opposite. We believe in a world external to ourselves precisely because we find ourselves getting unpredictable kicks (from the world) all the time. If we could predict everything to the final T as Laplace had wanted us to, it seems to me, we might as well be living a dream.
>
> To maybe put it in an overly poetic and not completely accurate way, the reality of the world is not in what we capture with our theories, but rather in all the stuff we don't. To make this concrete, take quantum mechanics and consider setting up all the equipment necessary to prepare a system in a state $|\Psi\rangle$ and to measure some noncommuting observable H. (In a sense, all that equipment is just an extension of ourselves and not so very different in character from a prosthetic hand.) Which eigenstate of H we will end up getting as our outcome, we cannot say. We can draw up some subjective probabilities for the occurrence of the various possibilities, but that's as far as we can go. (Or at least that's what quantum mechanics tells us.) Thus, I would say, in such a quantum measurement we touch the reality of the world in the most essential of ways.

27-12-05 *A Little Christmas Randomness* (to A. Zeilinger)

Merry Christmas! I hope you and your family are doing well and are having a relaxing holiday.

Anyway, you are on my mind again this morning because I read Dennis Overbye's article in today's *New York Times* on "quantum trickery," and I was struck once again by the similarities in the essential parts of our views. Overbye wrote this about you:

> As a result of the finiteness of information, he explained, the universe is fundamentally unpredictable.
>
> "I suggest that this randomness of the individual event is the strongest indication we have of a reality 'out there' existing independently of us," Dr. Zeilinger wrote in *Nature*.
>
> He added, "Maybe Einstein would have liked this idea after all."

Compare that with some things I wrote in several places in *Notes on a Paulian Idea*, but particularly in the pseudo-paper `quant-ph/pdf/0204/0204146.pdf` where in Sections 4 and 5, I said:

> I would say all our evidence for the reality of the world comes from without us, i.e., not from within us. We do not hold evidence for an independent world by holding some kind of transcendental knowledge. Nor do we hold it from the practical and technological successes of our past and present conceptions of the world's essence. It is just the opposite. We believe in a world external to ourselves precisely because we find ourselves getting unpredictable kicks (from the world) all the time. If we could predict everything to the final T as Laplace had wanted us to, it seems to me, we might as well be living a dream.

To maybe put it in an overly poetic and not completely accurate way, the reality of the world is not in what we capture with our theories, but rather in all the stuff we don't. To make this concrete, take quantum mechanics and consider setting up all the equipment necessary to prepare a system in a state $|\psi\rangle$ and to measure some noncommuting observable H. (In a sense, all that equipment is just an extension of ourselves and not so very different in character from a prosthetic hand.) Which eigenstate of H we will end up getting as our outcome, we cannot say. We can draw up some subjective probabilities for the occurrence of the various possibilities, but that's as far as we can go. (Or at least that's what quantum mechanics tells us.) Thus, I would say, in such a quantum measurement we touch the reality of the world in the most essential of ways.

AND

So, I myself am left with a view of quantum mechanics for which the main terms in the theory—the quantum states—express nothing more than the gambling commitments I'm willing to make at any moment. When I encounter various other pieces of the world, if I am rational—that is to say, Darwinian-optimal—I should use the stimulations those pieces give me to reevaluate my commitments. This is what quantum state change is about. The REALITY of the world I am dealing with is captured by two things in the present picture:

1. I posit systems with which I find myself having encounters, and
2. I am not able to see in a deterministic fashion the stimulations (call them measurement outcomes, if you like) those systems will give me—something comes into me from the outside that takes me by surprise.

Just two examples, but I think they indicate I'm going to enjoy your paper very much! Could I ask you to send me a copy of it electronically, however? (I can't access it directly from the journal until I am back at Bell Labs, and that won't happen until the holidays are over.) It would give me some holiday cheer.

27-12-05 *Indistinguishable Particles* (to Y. Omar)

Thanks for the warm Christmas wish! I enjoyed it and laughed and laughed.

I will try to take care of the bureaucratic things I owe you within the first week after New Year's Day.

By the way, I think I have discovered a reason why nature allows for indistinguishable particles. It comes from observing my two children play with their new toys on Christmas. After listening all day to *each* say of the *other's* toys, "I wish I had that," I thought, wouldn't it be nice if there were a way for them to not know whose was whose? And, indeed, a way for them not to see any distinguishing qualities for the toys at all, other than the amount of sheer pleasure they give? Then the parents' job would be so simple: Simply give them identical quantities of pleasure to play with at their leisure, and be done with it.

27-12-05 *Regarding the Detached Observer Attached* (to H. C. von Baeyer)

von Baeyerism 10 : *Dear Chris, the detached observer is attached. I thought this footnote might interest you not so much for its text, which is less than limpid, as for its citations of the phrase.*

> In Wolfgang Pauli, *Scientific Correspondence with Bohr, Einstein, Heisenberg, a.o.* (Springer, 1996) Volume IV, Part I: 1950-1952, page 340 there is a three-page editorial comment on letter number [1263], from David Bohm to Pauli. The penultimate paragraph of this comment, in German, begins:
>
>> Pauli, on the other hand, under the influence of his psychological point of view, had progressively moved away from the classical-Cartesian assumption of the detached observer (cf. letters [1313] and [1314])[14] who assumes a *fixed or pre-arranged game* behind the stage *(abgekartetes Spiel)* [letter 1388]: (in English) 'For me, however, it is much more satisfactory if the laws of nature themselves exclude in principle the possibility even to conceive the disturbances in the observers own body and own brain connected with his own observations. . . .'
>
> {I believe the editor may be mixing up two different notions here, that of the detached observer, and that of the view of nature as a pre-arranged game, but I wanted to give the context of footnote 14. HvB}
>
>> [14]This term first appears in this context in Pauli's letter [1197] of 31 January 1951 to M.-L. von Franz and then again in the letter from M. Fierz [1288] of 10 October 1951. From now on Pauli used it more frequently in his lectures, publications, and letters. In a letter of 5 May 1953 to C. F. von Weizsäcker he mentioned this question in connection with his Kepler study: "As I hinted in my essay, it seems to me that Fludd was much closer to the symbolic formulation of the *unity of existence*, which in turn so paradoxically divides into 'observer' and 'external world' ('the cut'), than was Kepler, with his 'detached observer' of classical physics. The 'archaic' Fludd had the stronger feeling for the proposition that the 'position of the cut' is arbitrary (Heisenberg)." Similarly Pauli wrote on 15 May 1953 to M.-L. von Franz: "Holding on to these assumptions requires one to restrict oneself to *statistical* laws and to 'sacrifice' the individual case. Einstein, on the other hand, would like *both* to 'have his cake and eat it.' He yells 'incomplete', regresses to the detached observer of classical physics, and places 'world formulae' into a blue fog (which does not contain the observer).

Thanks so much for the quote! I've just incorporated it into my "activating observer" compendium (and given you credit for the translation). But now you'll start to see my insatiable appetite! For I'd dearly love to see the FULL letters 1197, 1288, 1313, 1314, 1388, as well as the 5 May 1953 letter to von Weizsäcker and 15 May 1953 letter to von Franz (for some reason there were no numbers listed next to the latter two).

In my existing collection, a search on the year 1951 only gives this quote from a Primas paper,

> Faced with the wholeness of the reality, scientists have been slow to accept the challenge of discussing the premises of Baconian science. They have even been reluctant to

> consider the simplest modification of a mechanistic world view, namely the inclusion of teleological considerations as an essential part of their discipline – a relatively simple problem for which in the framework of modern quantum mechanics all necessary tools are available presently. But Pauli was looking for an incomparably deeper approach which goes far beyond the limits of current quantum theory, and which includes *physis* and *psyche* as complementary aspects of the same reality. A reality containing both rational and irrational elements, and alchemic *conjunctio* of spirit and matter. In psychology as well as in physics, quaternity is taken to be an expression of all concepts of unbroken totality. In a letter Pauli wrote: "Ich bin ja auf Kepler als Trinitarier und Fludd als Quaternarier gestossen – und fühlte bei mir selbst, mit deren Polemik, einen inneren Konflikt mitschwingen. Ich habe gewisse Züge von beiden, sollte aber jetzt in der zweiten Lebenshälfte zur quarternären Einstellung übergehen. Das Problem ist, dass dabei die positiven Werte der trinitarischen Einstellung nicht geopfert werden dürfen." (Pauli to Fierz on October 3, 1951, quoted in Enz, p. 509). Pauli could not solve his dilemma of three and four which plays a great role in alchemy as "the axiom of Maria Prophetissa" ("Out of the Third comes the One as the Fourth"), and this shows that we are at the bare beginning to understand reality. But we again reached a turning point, a way of thinking is developing which is very different from that which has been dominant in the past decades, and which recognizes the repression of the irrational as incongruous.

(of which I don't know what the German part is saying) and this point of interest from a Lindorff paper

> This statement, taken together with the way Pauli associated the radioactive atom with the lapis, moved Jung to question whether 'the archetype and its effects and the effect of the active atom on its environment is not more than a metaphor.'
>
> With these thoughts in mind Jung said he would amplify his essay, 'Synchronicity: an acausal connecting principle'. He presented the material to the Psychological Club in two parts on 20 January and 2 March 1951. The essay, together with Pauli's work on Kepler, was subsequently published in book form.

The only materials I have from 1953 are a few letters from Pauli to Jung; nothing from Pauli or von Weizsäcker or von Franz or Fierz.

At the moment, I'm particularly interested in better understanding the thing Pauli wrote to von Franz in what you sent me: "For me, however, it is much more satisfactory if the laws of nature themselves exclude in principle the possibility even to conceive the disturbances in the observers' own body and own brain connected with his own observations . . . " That really intrigues me! What exactly does he mean by that?

In that regard, let me send you a little compendium I sent to David Mermin, in fact just today. It's pasted below. As you'll see, I'm starting to lean very heavily on an alchemical analogy for building some imagery of what quantum measurement is all about. (I hinted a little about this to you before, but supplied no details.) And the quote you gave me above seems to touch on that in a way I hadn't seen before. This is something I really would love to explore.

Thanks so much again for all this! You're bringing me back to life in these lazy days between Christmas and the New Year.

I hope you and your wife are having a great holiday yourselves.

Hans's Reply, "Translations," 31-12-05

I am happy to translate this and all the other letters, but in order to avoid an infinite regression, we need to establish some ground rules.

1. My primary source for the next year or two will be the Pauli correspondence, with the [....] numbering. This means that unless it is absolutely essential, I will avoid other sources.
2. I am not good at filing, so you are in charge of keeping order.
3. Both of us need to be vigilant about the existence of translations – no use repeating someone else's work. Of course I will make sure to check any translations I find for accuracy. (The art historian Panofsky, Pief's brother I think, considered some of von Franz's translations from Latin, made for Pauli, to be distorted to the point of gobbledygook.)
4. I had decided to start translating Fierz letters, but will start, instead, with the list you sent – i.e., with the selection criterion "detached observer" instead of "Fierz."
5. There will be three types of footnotes: by the writers themselves, by Karl von Meyenn, and by me. I will endeavor to flag them clearly. I will probably skip some parts, and will say so. Any time you want me to fill in the blanks, I'll be happy to do so. Letters to von Franz, for example, often have appended dreams. If these don't seem relevant to the subject matter of the letter, but are simply entries in an ongoing dream-book, I will skip them, but say so.

27-12-05 *Words of Yours I Liked and Didn't* (to N. D. Mermin)

Happy holidays! I've been missing you a lot lately, particularly as Rüdiger was visiting a couple of weeks back, and once again we picked up on our old thread of trying to develop a paper on "certainty"—you don't know how many times your image came to us in the conversations!

I've been meaning to write you, also, to thank you for having a copy of your book sent my way! It is beautiful. Per my promise, I will read it cover to cover; just give me a little time.

I have at least read the preface as of now, and I think I have discovered why you have been so nice to me all of these years (or at least tolerant of me)! Is it because my heart is in the right place, i.e., wanting to see quantum theory reduced to a statement that can be taught in an ordinary high school? I hadn't realized that you had made such an important point of this with Special Relativity. Wonderful!

Now, why am I writing you today in particular? It's because I had insomnia last night and I stumbled across Dennis Overbye's article in the *NY Times*. When I read this,

> In an essay in 1985, Dr. Mermin said that "if there is spooky action at a distance, then, like other spooks, it is absolutely useless except for its effect, benign or otherwise, on our state of mind."

I thought it was sheer genius, and I was ashamed that I didn't remember having read it before. I so wish I could write with your cleverness! Words I liked.

But when I read this,

> "I would say we have to be careful saying what's real," Dr. Mermin said. "Properties cannot be said to be there until they are revealed by an actual experiment."

I thought, "Tsk. Tsk." What trouble I continue to think that way of expressing things makes for our imaginations. Thinking of quantum measurement outcomes as "revealing properties" (whether they are pre-existent properties or not) is, I think, one of the biggest problems getting in our way of making a decent myth for the quantum mechanical world. Words of yours, this time, I didn't like.

By way of saying Happy New Year again, I'll send you three recent emails I wrote to Bas van Fraassen (all pasted below) where once again I'm groping to find the right words to say what quantum measurement "is" and what the clicks it gives correspond to. A quantum measurement outcome (considered on its own, without relation to other issues) is just a "surprise," full stop; it doesn't reveal anything. It's just a primitive reaction within the agent. Or at least that's the myth I'm groping for! (You'll see in the notes below that even I'm guilty of sometimes using the same words that I said "tsk, tsk" to you about. Once again—as always!—I learn from reading even the tiniest things of yours; somehow you cause me to introspect like few others do.)

Happy, happy, happy New Year!

27-12-05 *White Christmas* (to W. G. Demopoulos)

I've been thinking about you most of the holiday season, but am only now getting around to sending out holiday greetings. Happy holidays! The event that seemed to start it off was watching the old movie "White Christmas" (with Bing Crosby and Danny Kaye) sometime early in December. For some reason that I can't put my finger on, I was struck by how the actor who played General Waverly reminded me of you. His name was Dean Jagger in real life, and I don't know if it was his facial features or his voice, but something about him made me think of you throughout the movie.

But, who knows, maybe I was already thinking about you earlier than that! This morning, when I was reviewing some of my old emails from my last discussions with Rüdiger Schack (for a paper we're writing on Wigner's friend), I came across a note I wrote that had these lines in it:

> Quantum theory has no more power within it to say when (quantum) events happen than classical probability theory has the power within IT to say when its own events happen. Maybe this is why some developments of classical probability theory are careful to say that the h's in a probability assignment $P(h)$ are propositions. Propositions don't "happen", they are simply either true or false. And thus, by fiat, one never has to address the question of when h "happens". But we know that we shouldn't try to make that further move (i.e., viewing the h's as propositions with timeless truth values) in the quantum setting. Quantum events do "happen." But that doesn't mean that quantum theory should have the burden on it of explaining or determining "the moment at which 'all is said and done'."
>
> This is ultimately, I suspect, why our view will be greeted with the same revulsion that William James's theory of truth was by Russell and Moore and the like: Because for James, too, truth is something that is made to happen; it is not something that is just there in a timeless way.
>
> > The truth of an idea is not a stagnant property inherent in it. Truth *happens* to an idea. It *becomes* true, is *made* true by events. Its verity *is* in fact an event, a process: the process namely of its verifying itself, its veri-*fication.* Its validity is the process of its valid-*ation.*

When I read this, I thought of the nice walk and talk we had in Maryland a couple of years ago. What I wrote above seems to be the main issue that separates us at the moment in our views of quantum mechanics, but it may be the only one!

All the best, and I hope you have a great New Year.

27-12-05 *Happy Troubles* (to D. Overbye)

I actually got a lot out of reflecting over your article today. So I wanted to say thanks and that I enjoyed it. Particularly, I got a lot out of thinking about David Mermin's sparse remarks that you recorded and then noting an inconsistency in my own ways. I tried to capture the point in an email I wrote to David a couple hours ago. I'll paste it below, as I feel I owe you a little bit too. (David and I are old friends and have been having a discussion on some of these points for a long time.) [See 27-12-05 note "Words of Yours I Liked and Didn't" to N. D. Mermin.]

And since you're not a full-time physicist, I'll give you a special treat: A cartoon version of the whole story! It is attached as a `.jpg` file. (Quantum theory is about all the stuff to the left side of the sparks; the stuff to the right is 'reality,' the partial source of the sparks.)

28-12-05 *Wheeler and the Pleasures of Life* (to D. Overbye)

I'm up again at this annoying hour, and, bringing my chance meeting of you last night to a closure, I read a little more about you on the web. I enjoyed the interview posted on *Edge*. "What else is there? Sex and physics." We might be kindred spirits ... When I first started calling my own view of quantum mechanics "the sexual interpretation of quantum mechanics," one friend's reaction was that the title was of no real content—it was only a cheap way to draw attention to the view—but another friend's reaction was that I was looking for a way to combine my ONLY two pleasures in life ... (The latter friend doesn't think I'm particularly deep.)

More seriously, I also discovered that you seem to be a little bit of a fan of John Wheeler. John has been a huge influence on my scientific life. Before last night, I had not recalled reading anything of yours regarding him, but tonight, searching in this big document I'm putting together "The Activating Observer: Resource Material for a Paulian-Wheelerish Conception of Nature" (which is a compendium of a lot of quotations) I found two entries in your name. I'll place them below for fun. So, you've been writing about Wheelerish stuff since at least 1981!? And apparently I've been reading you since about 1985 (when I started systematically digging up Wheeler stuff)?! Good things to learn.

If you're interested in some funny Wheeler anecdotes, I've got a few compiled in my samizdat (which will soon be published as a real book by Springer) "Notes on a Paulian Idea." (The version with the most complete index presently is posted on my webpage; it's slightly better to go there than `quant-ph`.) For instance, you might get a kick out of the story on page 149, which relates a little to my second quote of you below.

Anyway, as I say, bringing last night's meeting to a closure,

- D. Overbye, "Messenger at the Gates of Time," Science81 **2**(5), 61–67 (1981). This contains some biographical material on John Wheeler. Also, there are some great quotes of John Wheeler:

  > The best way to find oneself outside the ranks of science is to find oneself inside the ranks of mysticism.

  and

If there's one thing in physics I feel more responsible for than any other, it's this perception of how everything fits together. I like to think of myself as having a sense of judgement. I'm willing to go anywhere, talk to anybody, ask any question that will make headway. I confess to being an optimist about things, especially this question about our hopes of being able to understand how things are put together. So many young people are forced to specialize in one line or another that a younger fellow can't afford to try and cover this waterfront—only an old fogey who can afford to make a fool of himself. If I don't, who will?

- D. Overbye, "What Happened Before the Big Bang?," New York Times, 12 March 2002.

> In their dreams, theorists of both stripes [string theory and loop quantum gravity] hope that they will discover that they have been exploring the Janus faces of a single idea, yet unknown, but which might explain how time, space and everything else can be built out of nothing. A prescription for, as the physicist Dr. John Archibald Wheeler of Princeton puts it, "law without law."
>
> Dr. Wheeler himself, the pre-eminent poet-adventurer in physics, has put forth his own proposal. According to quantum theory's famous uncertainty principle, the properties of a subatomic particle like its momentum or position remain in abeyance, in a sort of fog of possibility until something measures it or hits it.
>
> Likewise he has wondered out loud if the universe bootstraps itself into being by the accumulation of billions upon billions of quantum interactions—the universe stepping on its own feet, microscopically, and bumbling itself awake. It's a notion he once called "genesis by observership," but now calls "it from bit" to emphasize a proposed connection between quantum mechanics and information theory.
>
> One implication of quantum genesis, if it is correct, is that the notion of the creation of the universe as something far away and long ago must go. "The past is theory," Dr. Wheeler once wrote. "It has no existence except in the records of the present. We are all participators, at the microscopic level, in making that past as well as the present and the future."
>
> If the creation of the universe happens outside time, then it must happen all the time. The Big Bang is here and now, the foundation of every moment.
>
> And you are there.

28-12-05 *Wheeler and the Pleasures of Life, 2* (to D. Overbye)

Overbye-ism 1: *I am a huge fan of John Wheeler, actually. i wrote a long profile of him in Science Times three years ago. Also he is featured in my book, Lonely Hearts of the Cosmos, currently a Little, Brown paperback, 1999.*

More entries for my compendium! I'm always hungry for more (and hopefully within the next year or so, I'll try to publish the thing). I'll look those things up as soon as I can.

28-12-05 *Grad Research and Quantum Information* (to C. Ududec)

I apologize for taking so very long to reply to you; I have gotten far, far, far behind on my email, and am only now trying to catch up during the holidays.

Cozminism 1: *I'm currently in my last year in a math/physics honours program at the University of Manitoba in Canada, and I'm interested in going on to graduate school and working on something in quantum mechanics and its foundations. I've read a little about different approaches to the measurement and interpretation problems, and I've started reading your 'Quantum Mechanics as Quantum Information' paper. I'd be very interested in learning more about this kind of approach or working on something similar for my graduate studies.*

I was wondering if you have any suggestions for other things I should read, or if there is a good starting point for this topic. I was also wondering if you have any suggestions for schools I could look at, or other people I should talk to.

I would suggest reading anything posted on my website, and maybe supplementing that with

- `http://www.arxiv.org/abs/quant-ph/0404156`
- `http://www.arxiv.org/abs/quant-ph/0404122`.

As for a good place for you to do graduate studies, if you are really interesting in this approach to quantum mechanics, I would suggest studying with Carl Caves at the University of New Mexico or Rüdiger Schack at Royal Holloway University of London.

Cozminism 2: *Also, when you talk about the consequences of an experimental intervention, are they just consequences for the one experimenter's beliefs about the system and about future interventions?*

That is right.

Cozminism 3: *They aren't consequences for all other possible experimenters as well, right?*

Correct. A mantra that came up during Rüdiger Schack's last visit to NJ was, "A quantum state represents one's personal beliefs about the personal consequences of one's personal interventions."

28-12-05 *And a Cartoon* (to H. C. von Baeyer)

And I shouldn't forget to send you the cartoon that goes with the last note I sent you. It is attached as a `.jpg` file. Quantum theory is about all the stuff to the left side of the sparks—i.e., the actions and transformations of the agent. The stuff to the right of the sparks is the 'external reality,' the partial source of the sparks—it is the 'philosopher's stone,' without which the agent would never get transformed. The word 'catalyst' in the cartoon is a little misleading, as anyone with a little chemical training thinks of a catalyst as something that remains unchanged in the reaction; however, I'm thinking here of it in the broader sense of, say, the *American Heritage Dictionary* where a catalyst is simply "an agent that stimulates or precipitates a reaction, development, or change," full stop.

The reason I'm intrigued by the Pauli quote to von Franz is that he says, "For me ... it is much more satisfactory if the laws of nature themselves exclude in principle the possibility even to conceive the disturbances in the observer's own body and own brain connected with his own observations ..." That is, he seems to be talking about something going on to the left of the sparks too, not to the right of the sparks—i.e., just the part I claim quantum theory is about.

31-12-05 *If We Make It Through December . . .* (to G. Musser)

I don't guess you know the old Merle Haggard song, "If we make it through December / / Everything's gonna be all right I know . . . " Well, that's where I am at the moment. Thank you though for prodding me.

I apologize for the delay; it all started out innocently enough, before my interruptions snowballed. The innocent part was that I started to worry some about your words:

Musserism 28 : *One yoke your article will have to carry is that talking of the "subjective" elements of quantum theory sets off alarm bells – people think of Fritjof Capra and get suspicious of a metaphysical agenda. So you might want to state outright that interpretations of quantum mechanics have a somewhat checkered history, but that this shouldn't prevent us from plowing ahead and going where the physics leads us.*

So, I took a little hiatus to learn more about Frank Ramsey's presentation of probability theory—the logic being that Ramsey's view of probability is the *same* as Bruno de Finetti's "radically subjectivistic" interpretation and yet, something about the way he presented the view wasn't nearly as incendiary as de Finetti's way. I wanted to incorporate any presentational insight I could find from him.

But then the snowballing of delay came with 1) Thanksgiving, then 2) Rüdiger Schack's visit, then 3) Chris Timpson's visit, then 4) a long case of Montezuma's revenge, then 5) Christmas . . .

Anyway, the new year is about to start and all these damned holidays will be over. I have to go to a meeting in Snowbird, Utah, Jan 3–6; but I am hoping that that won't slow me down too much. I very much hope to give you something the following week. I've got to stop stalling; it's time to write something serious.

Thanks for pointing out the Zeilinger article too. Somehow it didn't quite register when you wrote me about it (at that time, I was in the throes of the Montezuma thing I told you about), but my curiosity got piqued when I read Overbye's article in the *Times* last week. I ended up sending the note below to Zeilinger, to which I got a cordial response and a copy of the article to finally read. [See 27-12-05 note "A Little Christmas Randomness" to A. Zeilinger.] We are definitely on the same wavelength about some things, as you'll see below.

31-12-05 *Wheeler Meeting at Princeton* (to W. G. Unruh and several others)

Marlan Scully and I are organizing a somewhat impromptu, but nonetheless serious, meeting in Princeton to give a little tribute to John Wheeler, law-without-law, it-from-bit, and quantum information. It'll be a one-day meeting with maybe 10 short talks and a little socializing, held mid- to late-February (or possibly early March) on a Friday. Wheeler has said that he will make an appearance, and we would like to invite you too.

Presently our preferred target date is February 17, but we'll also consider February 23 and March 3 if there are too many scheduling conflicts. Please let me know as soon as possible if you would like to come and how your schedule fits with these possibilities. There are likely to be funds available for your travel expenses too, if you need them.

On this first round of invitations, we're checking on the availability of the following colleagues to see if they can participate: Yakir Aharonov, Carroll Alley, Janos Bergou, Michael Berry, Rob Calderbank, Carl Caves, Leon Cohen, John Conway, Ken Ford, Bas van Fraassen, Danny Greenberger, Hans Halvorson, Lucien Hardy, Mark Hillery, Simon Kochen, Seth Lloyd, Edward Nelson, Ben Schumacher, Yanhua Shih, Bill Unruh, Bill Wootters, Anton Zeilinger, Suhail Zubairy, and Wojciech Zurek. More than likely, we've forgotten other colleagues who would also be very appropriate for this meeting; if you see some glaring absences, give us your suggestions, and we may be able to take them into account on a second round of invitations.

All the best, and a very happy New Year to you and your family,

01-01-06 *Quantum Events and Propositions* (to W. G. Demopoulos)

Demopoulosism 2 : *Maybe this is what separates us: I think an event's happening is strictly analogous to a proposition's being true. Just as events happen or fail to happen, propositions are true or false. So I'm not sure what to make of the idea that props are true or false but events just happen, seeing these as different ways of saying the same thing.*

Actually, I guess I fear that I agree with the ending part of this statement, i.e., that "I'm not sure what to make of the idea that props are true or false but events just happen, seeing these as different ways of saying the same thing." But, I think, the force of it goes in the opposite direction for me than it does for you. That is, I think I think [sic] one of the great lessons of quantum mechanics is that it is a call to arms to rethink what is meant by the truth value of a proposition. Here's the way I put it in one of the proposals I once made:

> Quantum Mechanics as a Powerful Hint. In my opinion, the most profound statement yet to come out of quantum theory is the Kochen-Specker theorem. For it licenses the slogan, "Unperformed measurements have no outcomes." This is just a beginning. If one canvasses the philosophic traditions for one that has significantly developed this slogan, one will find the now mostly-forgotten tradition of pragmatism fathered by William James and John Dewey. As a source of ideas for what quantum mechanics can more rigorously justify, no block of literature is more relevant: The connections between the two fields cry out for systematic study. Quantum mechanics holds the promise of drastically changing our worldview on the wide scale. It is time to let that happen.

Demopoulosism 3 : *On another matter, there is an idea in Pauli that your remark about quantum mechanics and classical probability theory reminded me of, but I can't recall it exactly. Doesn't he say somewhere that what QM does is to give a precise formulation of how the probabilities of propositions all stand with respect to one another without, however, specifying what actually occurs?*

(I've quoted this: "Just as in the theory of relativity a group of mathematical transformations connects all possible coordinate systems, so in quantum mechanics a group of mathematical transformations connects all possible experimental arrangements.")

I don't recall Pauli saying something like in your first version, only your second, but he might well have: I'm a horrible thief at times. Here's the way I put something similar in my anti-Växjö pseudo-paper `quant-ph/0204146`:

> In choosing one experiment over another, I choose one context over another. The experiment elicits the world to do something. To say that the world is indeterministic means simply that I cannot predict with certainty what it will do in response to my action. Instead, I say what I can in the form of a probability assignment. My probability assignment comes about from the information available to me (how the system reacted in other contexts, etc., etc.). Similarly for you, even though your information may not

> be the same as mine. The OBJECTIVE content of the probability assignment comes from the fact that *no one* can make *tighter* predictions for the outcomes of experiments than specified by the quantum mechanical laws. Or to say it still another way, it is the very existence of transformation *rules* from one context to another that expresses an objective content for the theory. Those rules apply to me as well as to you, even though our probability assignments *within* each context may be completely different (because they are subjective). But, if one of us follows the proper transformation rules—the quantum rules—for going to one context from another, while the other of us does not, then one of us will be able to take advantage of the other in a gambling match. The one of us that ignores the structure of the world will be bitten by it!

That is, part of the rational part of quantum mechanics is much like de Finettian or F. P. Ramseyan "coherence": If you gamble this way about this, and you gamble that way about that, etc., etc., then you'd better gamble such way about the other, or you're not being coherent with respect to your beliefs of the properties of the world.

Demopoulosism 4: *I'm back in Canada for the rest of the academic year and perhaps for the foreseeable future. Jeff is supposed to visit PI for several months beginning in February and Itamar should be here in May. Any chance you might be through here? Will you be in Maryland this spring? I plan to be there.*

Yes, I plan to be at the Maryland meeting in the Spring. I don't think I'll be dropping by PI though anytime soon. However, another way I might see you in the next year is that I've thought about organizing a symposium on "subjective probabilities and quantum mechanics" at the next PSA meeting in Vancouver. When I wrote a couple of people in the organizing meeting to see if they'd give me a little time post-deadline to get a proposal in, I wrote this:

> I noticed that you're on the PSA 2006 program committee. The reason I was snooping there is because I had a flash that maybe I'd like to organize a session or workshop at the meeting comparing and *contrasting* epistemic views of the quantum state to Bayesian views of probability. It'd be nice if I could get, for instance, Persi Diaconis or Brian Skyrms and Abner Shimony to give talks, along with, say, maybe you and/or Rob Spekkens and/or Huw Price and/or Itamar Pitowsky and/or Bill Demopoulos, etc., etc.—I'm just starting to think about it all.

They've given me an extension. Now the question is what I might do. What do you think of the idea? Would you be willing to participate in the discussion or give a talk? Do you think Brian Skyrms would be interested? I don't really know him well yet.

02-01-06 *Final Installment* (to W. G. Demopoulos)

Now let me tackle this point of yours

Demopoulosism 5: *I also don't see why we should need something as fundamental as KS to sustain the notion that "unperformed measurements don't have outcomes." I'm being a devil's advocate here because I think what you really mean is that without a measurement of whether the cat is alive, the cat is neither alive nor not alive. But would you put it this baldly? If not, why not?*

in a more longwinded way. For that, I'll paste in an anthology of emails I've had recently with David Mermin and Bas van Fraassen. I think they refer to your point explicitly, but as always I'm still groping to try to get the right language. All the emails are connected, and you can read them linearly from top to bottom.

To answer your question in the best way I know how at the moment, I would say: The transformation that quantum mechanics speaks about, the transformation from a 'superposition' to 'aliveness' or 'deadness', is a transformation *within the agent*, and that transformation cannot take place without some interaction with the external physical system labeled by the word 'cat'. What happens to 'cat' itself (described in a way that makes no reference to the agent)? On that, I think quantum mechanics is silent. With a mantra: Quantum mechanics is a theory for ascribing (and intertwining) personal probabilities for the personal consequences of one's personal interactions with the external world.

Does all this (and particularly the stuff below) go some way toward answering your question?

02-01-06 *The Oblique Pauli* (to H. C. von Baeyer)

Look at this little gem I discovered today. I stumbled across it in the Schilpp volume on Einstein as I was researching for the talk I have to give in Utah Thursday: The topic I got roped into is whether I think Bohr gave an adequate reply to EPR. (My talk's title is, "Why I Never Understood Bohr's Reply to EPR, But Still Liked It.") The quote comes from page 683:

> It may appear as if all such considerations were just superfluous learned hairsplitting, which have nothing to do with physics proper. However, it depends precisely upon such considerations in which direction one believes one must look for the future conceptual basis of physics.
>
> I close these expositions, which have grown rather lengthy, concerning the interpretation of quantum theory with the reproduction of a brief conversation which I had with an important theoretical physicist. He: "I am inclined to believe in telepathy." I: "This has probably more to do with physics than with psychology." He: "Yes." —

Who else could that "important theoretical physicist" be but Pauli! They were certainly discussing these sorts of things at length at that time. Einstein wrote his remarks in 1949 (I think), while Pauli had been visiting Einstein in 1948 (recall how Pauli adjudicated the quarrel between Born and Einstein on quantum foundations during that time).

Also compare the similarity between what Einstein says above and these words of Pauli to Fierz, 10 August 1954:

> All of this then led me onto further, somewhat more phantastic [*sic*] paths of thought. It might very well be that we do not treat matter, for example viewed in the sense of *life*, "properly" if we observe it as we do in quantum mechanics, *specifically when doing so in complete ignorance of the inner state of the "observer."*
>
> It appears to me to be the case that the "after-effects" of observation which were ignored would *still* enter into the picture (as atomic bombs, general anxiety, "the Oppenheimer case" e.g. etc.), but in an *unwanted form.* The well-known "incompleteness" of quantum mechanics (Einstein) is certainly an existent fact somehow-somewhere, but certainly cannot be removed by reverting to classical field physics (that is only a "neurotic misunderstanding" of Einstein), it has much more to do with *integral relationships between "inside" and "outside" which the natural science of today does not contain* (but which alchemy had suspected and which can also be detected in the symbolics of my dreams, about which I believe them specifically to be characteristic for a contemporary physicist).

> With these vague courses of thought I have reached the border of that which is recognizable today, and I have even approached "magic." (From this standpoint observation in quantum mechanics might even appear to someone as a "black mass" after which the "ill-treated" matter manipulates its counter-effect against the "observer," thereby "taking its revenge," as a "shot being released from behind"). On this point I realize well that this amounts to the threatening danger of a regression into the most primitive superstition, that this would be much worse than Einstein's regressive remaining tied to classical field physics and that everything is a matter of holding onto the positive results and values of the *ratio*.

So, I think it's just got to be Pauli that Einstein is referring to!

On another matter, let me come back to something you wrote in your last letter:

von Baeyerism 11: *I had decided to start translating Fierz letters, but will start, instead, with the list you sent – i.e., with the selection criterion "detached observer" instead of "Fierz."*

I apologize for causing trouble. And the more even I think about it, a well defined theme for you is probably called for. How else would you be able to turn your work into a book? I fear a little, however, that "detached observer" may be too narrow, as I think Pauli and Fierz must have discussed all kinds of "mystical" things tangentially related to that topic, from the possibility of physical/psychical neutral language to synchronicity to archetypes, etc., etc. And I think all that stuff is worthwhile to get into the public eye. On the other hand, as my getting carried away has already demonstrated, some of what he wrote to von Franz and others is probably quite interesting too. So, where does that leave you? I hope not an infinite task! Maybe outside of little side ventures of gathering a little background material here and there, maybe indeed it is better to stick with your original plan of tracking the Pauli-Fierz conversation.

Tomorrow I leave for Snowbird and may be out of email contact for a little while.

Happy New Year again!

Hans's Reply

> I think we will come across even more bizarre beliefs of Pauli! For example, he and Fierz were apparently REALLY convinced that the "Pauli effect" was real. That's more than telepathy – that's telekinesis!
>
> Do not worry about my plans. I am retiring, and don't ever have to write a book again. The translations are very slow and arduous, and I'm going to just plunge in and let a theme find me, rather than the other way around. The point, for me, is that translation forces me to try to understand these things very carefully.
>
> B.T.W., did you know that the title of my Anchorage lecture is "How I learned to stop worrying about Schrödinger's cat?"
>
> Have fun in Utah! Me, I'm going to the Bahamas for a few days.

03-01-06 *The Oblique Pauli, 2* (to H. C. von Baeyer)

von Baeyerism 12: *B.T.W., did you know that the title of my Anchorage lecture is "How I learned to stop worrying about Schrödinger's cat?"*

Actually, you did tell me already. It is a great title, and more importantly a great transition!

As it turns out, I wrote a small something about Schrödinger's cat yesterday. It was in a preamble to sending Bill Demopoulos the same collection of letters I sent you in the note titled "Regarding the Detached Observer Attached." I'll place it below for your amusement. [See note to W. G. Demopoulos, dated 02-01-06 and titled "Final Installment."]

Enjoy the Bahamas. I wish I were in your shoes rather than mine.

06-01-06 *The Swedish Bayesian Team* (to A. Y. Khrennikov)

PS. I'm just returning from Marlan Scully's annual big meeting at some ski resort in Utah; there were 220 people there. Roy Glauber, this year's Nobel Prize Winner, gave a talk, and in it he showed a picture of Willis Lamb from 1964. What struck me was how much you and Lamb look alike! (Maybe there's a Nobel Prize in your future?)

09-01-06 *Sunday Reading on Monday* (to A. Cho)

Cho-ism 1: *We met a couple of years ago at the Seven Pines symposium.*

Of course I remember you: I tried to contact you last year to drum up some coverage for our meeting "Being Bayesian in a Quantum World" in Konstanz last August, but never heard back from you. (I notice that your email address has changed; maybe that has something to do with it.) Anyway, you missed a very good meeting with some of the most interesting people in the field of quantum information (Nielsen, Briegel, Mermin, Unruh, Milburn, Wootters, Hardy, etc.,) Have a look at

`http://web.archive.org/web/20090511060206/http://www.uni-konstanz.de/ppm/events/bbqw2005/`;

we would have loved to have you.

Cho-ism 2: *I was hoping you might look at the attached paper (accepted by PRL) and give me your take on its significance and importance in a phone interview.*

In the paper, Francesco De Martini of the University of Rome, "La Sapienza," and colleagues report an experiment in which they've performed a so-called minimal disturbance measurement on one photon by entangling it with a second photon and measuring it. When the two photons are maximally entangled, this effectively results in a von Neumann measurement on the first photon; when the degree of entanglement is lower, the measurement on the second photon produces a smaller disturbance of the first, at the cost of some information about its state. The researchers show that they can trace the optimal trade-off between gaining information about the original photon and disturbing its state, as was calculated in 2001 by Konrad Banaszek.

This strikes me as a very pretty experiment, and I like the fact that it seems to put a quantitative experimental handle on a pretty fundamental theoretical issue. But I'm just a journalist. I'd be most interested in your opinion of the work.

Yeah, I think it is a pretty fundamental theoretical issue; I have ever since Asher Peres and I wrote up the first calculation of this variety in 1995, "Quantum State Disturbance vs. Information Gain: Uncertainty Relations for Quantum Information," `http://www.arxiv.org/abs/quant-ph/9512023` (published as PRA **53**, 2038–2045, 1996). In fact, I have wondered on many occasions whether the effect they explore in this paper may be the single idea upon which all the formal structure of quantum mechanics can be built.

Let me give you some easy Sunday reading to skim before we talk; you may find some of it entertaining, particularly the imaginary conversation with God. First, see the closing section, "The Oyster and the Quantum," of my paper `http://www.arxiv.org/abs/quant-ph/0205039`. Next, look at pages 83–84 and 156 of my book *Notes on a Paulian Idea*, `http://www.arxiv.org/abs/quant-ph/0105039`. It's purely coincidence that those two identifiers differ only by one number. Also maybe look at the letter to Rolf Landauer on pages 190–191. (The book in its present edition is published by Växjö University Press, but a more formal edition will be published this year by Springer.)

Anyway, that's a start for indicating what I think of the importance of the paper you cite. I'm going to be pretty tied up tomorrow, but I should be able to talk Wednesday, any time between 11:00 AM, say, and 5:00 PM. My office phone number is below.

10-01-06 *Quantum Information at Princeton?* (to A. R. Calderbank)

PS. I was intrigued by Richard Jeffrey's remark in his book *Subjective Probability: The Real Thing* that "[Brian Skyrms] is my main Brother in Bayes and source of Bayesian joy. And there are others—as, for example, . . . Ingrid Daubechies, Our Lady of the Wavelets (alas! a closed book to me) but who does help me as a Sister in Bayes . . . ." I bring that up because a large component of my work is devoted to building a Bayesian-like way of viewing quantum information. You or your wife might interested in looking at some of what we accomplished at the meeting I organized last year in Konstanz, "Being Bayesian in a Quantum World"; here's a link:

`http://web.archive.org/web/20090511060206/http://www.uni-konstanz.de/ppm/events/bbqw2005/`.

Nicely, we had some of the most interesting people in quantum information there (Nielsen, Wootters, Briegel, Milburn, Mermin, Smolin, Hardy, etc.). If you have a look at the picture you'll see those guys and maybe some other familiar faces; I'm the guy in the middle with the coffee cup.

10-01-06 *Stones and Glass Houses?* (to L. Smolin)

Today I happened upon your letter in this month's *Physics Today*, which in turn led me back to your June article which I had missed. I found myself largely in agreement with most everything you said and, in particular, very much liked the original article.

However, I was struck by the conjunction of these words of yours in the June issue,

> Some other countries seem to be better at making room for the independent thinkers. . . . Canada has opened the Perimeter Institute, whose specific mandate is to be a home for independent foundational thinkers, and other such projects are in planning stages around the world.

with these words of yours from this month's reply to letters,

> In fact, young people are contributing important new results and ideas to the foundations of quantum theory, but none are working at US research universities. Let me name a few of them: Chris Fuchs, Lucien Hardy, Rob Spekkens, Antony Valentini, and David Wallace.

All I know from my own experience with Perimeter—to which I had dearly wanted to join—is that it was no more supportive of me than any "US research university."

10-01-06 *Subject and Object* (to D. M. Appleby)

Thanks for the note, which I very much enjoyed reading tonight (while listening to Abbey Lincoln and Hank Jones in the background). It did my soul good, and I'll certainly be reading it again.

Let me, however, give you a quick first reaction to this:

Applebyism 9: *I know we agree that physics isn't any kind of mirror. Well: it seems to me that if you start trying to identify some parts of quantum mechanics as "objective" and other parts as "subjective" then you are going back on that.*

In my talk at Konstanz I mentioned the idea of Galileo and Descartes that properties like "redness" don't faithfully depict properties actually in the object, whereas properties like "cuboidal" do. They thought, in other words, that the property of "redness" is subjective whereas the property of being "cuboidal" is objective. And they thought that if one eliminates all the subjective features of the visual field, one will be left with an accurate reflection of things as they are in reality: a mirror of reality. Quite possibly I have misunderstood you. If I have please correct me. But when you talk about identifying the parts of quantum mechanics having objective content it sounds, to my ears, as though you are thinking in a similar way to Galileo and Descartes. Purifying the reflection. Polishing the mirror.

Might I ask you to go back to Sections 4 and 5 (but particularly Section 5) of my anti-Växjö paper `quant-ph/0204146` and tell me whether you think the words in there seem to alleviate any of my sins? I had been planning to use the "It's a Wonderful Life" allusion to open up my *Scientific American* article, so I'd like to know what you think of it in this context. (If you don't know the movie, find a way to rent it and give it a watch.)

Honestly, I'm getting confused on these issues even myself of late. I have been meaning to read Donald Davidson's essay titled "The Myth of the Subjective" and see if that helped me any, but I haven't had the gumption yet.

You're definitely making me think about these things.

11-01-06 *Quantum Information and KS* (to J. H. Conway)

Peter Winkler, whom I was visiting at Dartmouth recently, told me a little (a very little) about your "marvelous free will theorem," as he called it, with Simon Kochen. He suggested that I might contact you to learn more about it. I have a very deep interest in Kochen-Specker type theorems, and would like to learn if there is something new and interesting here that I and collaborators could use in our Bayesian-style approach to the foundations of quantum information.

Winkler also suggested that I send you a CV and a paper or two to demonstrate that I might be worth talking to. I'll do that in the next email. In fact, I'll also send you a little research proposal I wrote up for Caltech the last time I thought about jumping ship from Bell Labs – it makes it clear that I was hoping to build a whole curriculum around the KS theorem! So, I do take it seriously. (Moreover, I take issues about "free will" seriously; thus my side interest in William James, Charles Peirce, and all of pragmatism, which that document also hints of.) At the moment, whatever you have sounds to be awfully intriguing.

I need to come to Princeton next week, in any case, to dig up some old papers. If you'll be around sometime, I'll try to tune my schedule to yours, and I would very much like to have a visit with you to get something of an explanation of all this.

11-01-06 *For the Record* (to N. D. Mermin)

Well, I'm back at home, safely again at Bell Labs, after having spent some time at a meeting in Snowbird, Utah. I am afraid I angered our friend, Prof. Plotnitsky, with my talk. My original title for the talk had been "Why I Never Understood Bohr's Reply to EPR, But Still Liked It"—but I wrote it on two overlapping transparencies so that, at the appropriate moment, I could strip off the part that said "But Still Liked It." (I hadn't originally intended to do that, but it was the only thing I could do with honesty after rereading Bohr.) And so the talk went. I explained how I didn't see much in Bohr's reply that EPR hadn't anticipated in their second- or third-to-last sentence, "... one would not arrive at our conclusion if one insisted that two or more physical quantities can be regarded as simultaneous elements of reality only when they can be simultaneously measured or predicted." (Which is a conception they pretty much simply dismiss.) Then I showed how the EPR criterion of reality can nevertheless be made to implode through a combination of perfect predictability (through entanglement) and KS noncolorable sets. Then I read some long passages from Einstein's autobiographical notes in the Schilpp volume, and claimed that his own logic was flawless: The conclusion being that a quantum state cannot correspond to a "real factual state of affairs"—when Einstein was right, he was really right! Finally I asked, so what is the uncertainty given by a quantum state about? And concluded with a picture that was meant to capture much of what I put in the emails to you a couple of weeks ago.

There's just not a lot you can do by considering only *two* noncommuting variables, and as far as I can tell, that's all Bohr ever really did.

But that's not why I'm writing you—i.e., to make my own record—but rather to get you to come down on the record. I ask because I don't know how many meetings in the last year or two where I've heard people praise the Ithaca interpretation or "correlation without correlata"—this meeting in Snowbird was one of them (Ivan Deutsch being the most recent admirer). And in all cases, I've said, "I don't think Mermin subscribes to those ideas anymore, or at least not fully." But when asked what your problems are with your earlier ideas, I don't know that I've had adequate answers of your own point of view. So, could I ask you again to what extent you now disavow the II and exactly why? I'd like to get it on the record so I don't screw up when trying to represent you.

On another issue, have you ever looked at the section in Max Jammer's book *The Philosophy of Quantum Mechanics* on "relational conceptions of the quantum state"? It seems like there's probably a lot of material in there that would interest you. I myself don't recall ever having noticed that section before last week (though surely I read it before, as I read the whole book cover to cover in the summer of 1984 or 1985), and I found it quite interesting. I also found his section on "latency theories" at the end, where he reports Margenau's view, very useful: In particular, I've started to wonder if, DISREGARDING the part where Margenau thinks of the quantum state as objective, the rest of his view might correspond quite nicely with where Schack and I stand at the moment. Margenau, apparently, views quantum measurement outcomes as secondary qualities in Locke's hierarchy, not primary ones, much like the idea of blueness (which I think you call qualia). I found myself wondering if, in the end, my own view might not just boil down to that. (This, of course, is not unconnected to some points you were trying to make in your "What Is QM Trying to Tell Us?" paper.)

See, I can write a paper on certainty, but I never can be certain myself!

David's Reply

I wish I ran into people who liked the IIQM. Maybe I should go to more meetings. I probably should write some sort of update before the 10th anniversary of the AJP article, but from my perspective it seems vaguely auto-erotic, since I haven't detected anything like the amount of interest in the paper that you describe.

It seems to me that I touched on much of what bothers me (and bothered me even then) in the final section of the AJP paper, reproduced below for your convenience:

> XII. A FEW FINAL REMARKS
>
> At the risk of losing the interest of those who — like myself — read only the first and last sections before deciding whether the rest is worth perusing, I conclude with some brief comments about loose ends.
>
> As noted at the beginning, what I have been describing is more an attitude toward quantum mechanics than a systematic interpretation. The only proper subject of physics is how some parts of the world relate to other parts. Correlations constitute its entire content. The actual specific values of the correlated quantities in the actual specific world we know, are beyond the powers of physics to articulate. The answer to the question "What has physical reality?" depends on the nature of "what." The answer is "Everything!" if one is asking about correlations among subsystems, but "Nothing!" if one is asking about particular values for the subsystem correlata.
>
> This alters the terms of the traditional debates. Traditionally people have been asking what correlata have physical reality. The many different schools of thought differ by answering with many different versions of "Some" while the IIQM answers "None!" The question of what correlations have physical reality, which the IIQM answers with "All!" has not, to my knowledge, been asked in this context. While I maintain that abandoning the ability of physics to speak of correlata is a small price to pay for the recognition that it can speak simultaneously and consistently of all possible correlations, there remains the question of how to tie this wonderful structure of relationships down to anything particular, if physics admits of nothing particular.
>
> At this stage I am not prepared to offer an answer, beyond noting that this formulates the conceptual problem posed by quantum mechanics in a somewhat different way, and suggesting that there may be something to be learned by thinking about it along these lines. I suspect our unfathomable conscious perceptions will have to enter the picture, as a way of updating the correlations. To acknowledge this is not to acknowledge that "consciousness collapses the wavepacket." But it is to admit that quantum mechanics does not describe a world of eternally developing correlation, described by "the wave-function of the universe"!, but a phenomenology for investigating what kinds of correlations can coexist with each other, and for updating current correlations and extrapolating them into the future. This phenomenology applies to any system that can be well approximated as completely isolated.
>
> A skeptic might object that the problem of how to update correlations is nothing more than the measurement problem, under a new name. Perhaps it is, but at least the problem is posed in a new context: How are we to understand the interplay between correlation as the only objective feature of

> physical reality and the absolute particularity of conscious reality? Is something missing from a description of nature whose purpose is not to disclose the real essence of the phenomena but only to track down relations between the manifold aspects of our experience? Is this a shortcoming of our description of nature or is it a deep problem about the nature of our experience?
>
> ... By acknowledging that in our description of nature the purpose is not to disclose the real essence of the phenomena, we free ourselves to construct from the manifold aspects of our experience formal representations of the systems we want to talk about. We have learned how to express their possible correlations by an appropriate state space, and the evolution of those correlations by an appropriate Hamiltonian. By setting aside "the real essence of the phenomena" we also acquire the ability to replace the befuddling spectre of an endlessly branching state of the universe—as disturbing in the self-styled down-to-earth Bohmian interpretation as it is in the wildest extravagances of the many worlds interpretation—with a quantum mechanics that simply tells us how we can expect some of the manifold aspects of our experience to be correlated with others. While this may sound anthropocentric, it is my expectation that anthropos can be kept out of everything but the initial and final conditions, and often—but not always—even out of those. But this remains to be explored.

What can I add to that, 8 years later?

1. You persuaded me quite soon that "objective probability" was problematic. Until I met you I had never taken the notion of subjective probability seriously, or even know very much about it. While I'm still not convinced (sorry) that you've got it right either, I'm much more aware that one of the pillars of the IIQM is much more fragile than I thought.

2. Not unrelated to 1, the notion of "correlation" is not well defined, beyond my assertion that it means nothing more than "joint distribution". But what does it mean to say that joint distributions are fundamental, while conditional distributions, which can be constructed from joints, have no physical meaning? And what are these joint distributions describing? How are they tied down to experience? Which brings us to

3. Consciousness. Although I say that the problem of consciousness should be set aside, when I went around giving physics colloquia on the IIQM in the late 90's, during questions everything kept coming back to conscious perceptions. It ended up being too big a rug to sweep problems under. This is a point in your favor. If probability is subjective, then there is a subject (with conscious perceptions) built in at the beginning, and consciousness becomes the starting point, rather than a completely mysterious add-on.

4. Quantum computation (which I only started studying after writing the paper) made me much more sympathetic to Copenhagen and a purely instrumentalist (positivist?) view of the subject than I had ever been. (See "How I stopped worrying and learned to love Bohr.")

Doubtless there's more, and perhaps I should think about writing something more careful and considered, but since my views have yet to settle down, that still seems premature.

So if you want something to tell these people who you claim exist, I think it's too strong to say that I disavow the IIQM. But I do regard it as at best incomplete (as I think I made clear in the 1998 paper). I guess I was hoping somebody would take up the cause and complete it.

11-01-06 *MY Anthropocentrism vs. YOUR Anthropocentrism* (to I. H. Deutsch)

I've been meaning to write you ever since arriving back in New Jersey, but first I had to clear out a huge backlog of other things. Anyway, I wanted to say I very much enjoyed the long walk and talk we had together. I felt like I got to know you more in those few hours than I had in the last ten years.

Let me clear up a couple of loose ends. Among other things, I wanted to come back to the issue of whether our Bayesian view is more overtly anthropocentric than it ought to be. In that regard, let me attach one of my pseudo-papers that addresses the issue. Whenever you get the time, have a look at Sections 4 and 5. I think they better capture some of what I was trying to get across the other day, even if the whole story is not yet worked out completely.

In the next email, I'll send you a pseudo-paper more particularly devoted to F-theory. In that one it's Sections 6 and 7 that you might want to look at, as your *leisure* time permits.

12-01-06 *It's All Your Fault* (to H. C. von Baeyer)

von Baeyerism 13: *Back from the Bahamas, I find three books from Princeton U. P. in payment for a proposal I reviewed for them.* [One I requested] *on the strength of your blurb: Omnès's Converging Realities.*

Just a quick question: Should I really read it, or were you just being kind to him (them)?

I'm not tellin'. Your interests and taste will decide the first part of your question within the first couple of chapters.

As for Omnès's ability to stir the soul, here's an example of Omnès at his best:

> Perhaps the best way to see what it is all about is to consider what would happen if a theory were able to offer a detailed mechanism for actualization. This is, after all, what the advocates of hidden variables are asking for. It would mean that everything is deeply determined. The evolution of the universe would be nothing but a long reading of its initial state. Moreover, nothing would distinguish reality from theory, the latter being an exact copy of the former. More properly, nothing would distinguish reality from logos, the time-changing from the timeless. Time itself would be an illusion, just a convenient ordering index in the theory. ... Physics is not a complete explanation of reality, which would be its insane reduction to pure unchanging mathematics. It is a *representation* of reality that does not cross the threshold of actuality. ... It is wonderful how quantum mechanics succeeds in giving such a precise and, as of now, such an encompassing description of reality, while avoiding the risk of an overdeterministic insanity. It does it because it is probabilistic in an essential way. This is not an accident, nor a blemish to be cured, since probability was found to be an intrinsic building block of logic long before reappearing as an expression of ignorance, as empirical probabilities. Moreover, and this is peculiar to quantum mechanics, theory ceases to be identical with reality at their ultimate encounter, precisely when potentiality becomes actuality. This is why one may legitimately consider that the inability of quantum mechanics to account for actuality is not a problem nor a flaw, but the best mark of its unprecedented success.

12-01-06 *Sounds of Silence and CBH, 2* (to G. Brassard)

Good to hear from you. I've been meaning to write to you for a while—thanks for reminding me. What I had wanted to write you about is that, as a climax to the van Fraassen / Halvorson seminar, Chris Timpson gave a talk as an invited speaker on the CBH theorem. It was a very, very good talk, and *sadly* very convincing. Particularly, he argued that CBH really, really (despite what Bub says) *make no use of* the no-bit-commitment axiom after all. In other words, they are really only getting the structure of quantum mechanics from 1) C^*-algebras, 2) no-signaling, and 3) no-broadcasting. No-bit-commitment comes for free. Foundationally, I don't see that that is devastating at all—it just means that "no-bit-commitment" doesn't get the airplay you had wanted of it. But as Timpson points out, it does indicate that the C^*-algebraic starting point is doing much, much more work in the derivation than had been expected. My own opinion is that *starting* with algebras like that (even weaker ones like Segal or JB algebras), is just the wrong way to go—one needs a pre-algebraic starting point.

You can read about all this in Timpson's PhD thesis, which can be found here: `http://www.arxiv.org/abs/quant-ph/0412063`. The relevant section is 9.2, and particularly pages 206 onward might interest you.

So, what is the right way to go? That's what our postdoc would work on! It sure would be good if we could scheme something up here.

Brassardisme 20: *I'm trying to emerge but at this point it is clear that I shall fail to do so before I leave for Paris (QIP06). Will I see you there?*

Unfortunately, no. But I just looked up the schedule, and I found that I was licking my lips over a large fraction of the talks. I'm very envious of you!

13-01-06 *Proxy for Dick Jeffrey?* (to B. Skyrms)

We've had a little email correspondence in the past, but I don't know if you remember me.

The reason I am writing you now is that I am thinking very hard about organizing a symposium for the PSA 2006 meeting in Vancouver, November 2–5. My tentative title for the symposium is "Radical Probabilism WITHIN Quantum Mechanics," and I'm guessing that the title is clear enough for you to surmise what the subject will be. I have run over deadline for getting a proposal in, but have had some correspondence with the program committee chairs, and they think it will still be OK if I get something in ASAP. At the moment, I am shooting to get a proposal in by Monday or Tuesday.

I'm sorry to put pressure on you like this (i.e., to give me a very quick reply), but I would very much like you to give us a talk, at least partially as a proxy for Dick Jeffrey. What I mean by this is that I would like you to give a talk with your thoughts on these two papers by Jeffrey:

- R. C. Jeffrey, "De Finetti's Radical Probabilism," *Probabilità e Induzione—Induction and Probability*, edited by P. Monari and D. Cocchi, (Biblioteca di Statistica, CLUEB, Bologna, 1993), pp. 263–275.

- R. Jeffrey, "Unknown Probabilities: *In Memory of Annemarie Anrod Shimony (1928–1995)*," Erkenntnis **45**, 327–335 (1997).

or any thoughts you have that are an extension to what he writes about there. Despite the titles, the two papers (particularly the first one) have very large parts devoted to quantum mechanics.

My own opinion is that he definitely gets the subjective interpretation of quantum states right, but when it comes to what those quantum states are effectively degrees of beliefs about, he shoots off the mark a bit. Nevertheless, his contribution and historical role in the "quantum Bayesian" project deserves to be fleshed out a bit—and I can't think of a better person to do it than you.

What I mean by the quantum Bayesian project is a locus of several new results that, I think, have started to make this way of viewing quantum states very respectable (in fact a hot topic for research). Let me give you a reference to a couple of my own papers that may help orient you:

- "Unknown Quantum States and Operations, a Bayesian View"
  `http://www.arxiv.org/abs/quant-ph/0404156`
- "Quantum Mechanics as Quantum Information (and only a little more)"
  `http://www.arxiv.org/abs/quant-ph/0205039`

Also, you might look at the website (containing all the abstracts) for our meeting last year titled "Being Bayesian in a Quantum World"

`http://web.archive.org/web/20090511060206/http://www.uni-konstanz.de/ppm/events/bbqw2005/`.

Finally you might look at Itamar Pitowsky's paper:

- "Quantum Mechanics as a Theory of Probability"
  `http://www.arxiv.org/abs/quant-ph/0510095`

for another variation on the same theme.

I hope you get the feeling (that I think you should!) that this is now a very large area of research with much promise. And it is an area of research that philosophers of probability can give much to. Thus I hope you will be able to give us a talk, and will let me know of your decision as soon as possible.

Beside you and myself, I'm also hoping to attract Pitowsky to give a talk, and it would be nice if Abner Shimony would serve as a counterpoint to all of us.

13-01-06 *Counterpoint to the Proxy for Dick Jeffrey?* (to A. Shimony)

I just wrote the note below to Bryan Skyrms, asking him if he would participate in a symposium for PSA 2006 that I am hoping to organize. [See 13-01-06 note titled "Proxy for Dick Jeffrey?" to B. Skyrms.] Now, I would like to ask you to participate, in the capacity of trying to keep us all honest: i.e., as a counterpoint to Skyrms, Pitowsky, and me. I know that you have thought very deeply about the subject described below—and I know that you disagree with us—so I hope that you will join us and use your eloquence to explain to the audience why they shouldn't agree with us either!

Please read the note below, and you'll get a feeling for what I have in mind. And if I could hear back from you as soon as possible, I might stand a chance of actually getting this thing organized before the program committee loses patience with me.

I hope that all is well with you, and that your new year has gotten off to a great start!

13-01-06 *Proxy for Dick Jeffrey?, 2* (to B. Skyrms)

Thanks for your note. Well, this is what I get for waiting a month past the last minute! Neither you, nor Shimony, nor Pitowsky even, is in a position to be able to attend! So, I'm not quite sure what I'm going to do—maybe I'll have to drop the project.

I can certainly find others to talk as a "quantum Bayesian" but what was attractive about Pitowsky was that he's a certified philosopher—all the rest I know are physicists by trade. I'll have to think.

But who else but you could really fill the shoes of commenting on Jeffrey's radical probabilism papers? Do you have any suggestions?

Anyway, thanks; I much appreciate your quick reply.

And congratulations by the way on your PSA presidentship.

Brian's Reply

> I believe that Dick liked Stephen Leeds on subjective probabilities and QM. But I don't think that Dick's own views ever got completely developed—especially with regard to measurement.

15-01-06 *Things That Are Outside of Time* (to A. Y. Khrennikov)

Khrennikovism 13: *P.S. My best greetings to your wife! (Did she finish the reconstruction of your house?)*

She will never be finished reconstructing! It would be against her nature ...

16-01-06 *Quantum Information Coincidence?* (to K. T. McDonald)

This morning by chance, playing around, I told my daughter Emma, "Come here; let's see if your name has ever appeared on the internet." So we typed "Emma Jane Fuchs" into Google and got the result in 0.10 seconds. There weren't a whole lot of documents to come up, but what was surprising is that one of them is posted at your website: It's a copy of my samizdat *Notes on a Paulian Idea*! What on earth? I see that you have it stored in a folder called "examples," so I was left wondering "example of what?" I'm almost afraid to hear the answer ...

If for whatever reason you'd like a copy of the paperback version (published by Växjö University Press), let me know and give me a proper mailing address: I have dozens to give away.

16-01-06 *Quantum Information Coincidence?, 2* (to K. T. McDonald)

Thanks for allaying my fears! I feared that you had used the thing as an example of nonsense.

McDonaldism 1: *I'd be pleased to receive a copy of "Notes on a Paulian Idea".*

I sent a note to the secretary in Sweden to send you a copy. It'll probably arrive in a couple of weeks.

Your lecture notes for your quantum computation course are very, very impressive! If this is the norm for a course and I ever do wiggle my way into Princeton, clearly I'll have to adopt a new work ethic!!

McDonaldism 2: *I gather that you stray into quantum metaphysics from time to time, so you might or might not be amused by my brief foray into this realm:*

`http://puhep1.princeton.edu/~mcdonald/examples/evasion.pdf.`

On the whole it's better to leave metaphysics alone, but its temptations are hard for many of us to resist.

Concerning your question of "metaphysics", it depends on what you mean by a "hidden-variable theory" and what you mean by "cloning." If the hidden-variable theory is like Goldstein's version of Bohmian mechanics, which (they say) is empirically equivalent to quantum mechanics for all experiments, then the existence of those hidden variables amounts to nothing beyond their inventors' warm, comfortable feelings—the comfort one usually finds in a religion.

On the other hand, I can think of a perfectly good "unhidden variable theory" that still has a no-cloning theorem: It is simply classical Newtonian mechanics where the question is whether Liouville distributions can be cloned. Since Hamiltonian mechanics is phase-space volume preserving, you can't clone overlapping Liouville distributions any more than you can clone quantum states. (I.e., in my view, quantum no-cloning is not a particularly deep theorem. Certainly not one to get metaphysical about. Save that up for the Kochen-Specker theorem.)

16-01-06 *Bushwhacking* (to H. R. Brown & C. G. Timpson)

The title of this email refers *not* to what I think ought to be done with George Bush's policies (though that's what I think ought to be done), but to some of the content below.

I had a chance to read your new paper after all today, and I very much like it. I even think I agree with most of it. Particularly, I very much agree with this point you make:

> [I]t is worth recalling . . . that the dominant viewpoint in the philosophy of space-time physics over the last few decades puts a very different gloss on Minkowski's contribution to SR. Far from being the basis of a mere algorithm for SR, the current orthodoxy seems to be that Minkowskian geometry provides a constructive dimension to SR (though it is not always put in these terms), and thereby significantly enhances its explanatory power. According to this view, it is the structure of the Minkowski space-time in which they are immersed that ultimately explains why rods and clocks in motion contract and dilate respectively.

As far as I know, that is the dominant viewpoint, and in my own opinion, it is rightly viewed as Minkowski's most important contribution.

This is a point I tried to emphasize in my PSA talk last year; I don't know if Chris remembers it. In the talk, I gave my usual spiel about how we won't ever really clear up the muddle at the foundations of quantum mechanics until we can formulate the essential content of the theory in a couple of crisp, clear, physical statements (drawing on a principle-theory formulation of SR as an *example*). But then, for that particular audience, to make it clear that I set myself apart from Jeff, I included a new transparency to make the point that one shouldn't think of the finding of the principles as the end of the line—rather, they're the real beginning, from whence one can hope to make greater progress. The transparency is attached. I pointed out that from the principles, one finally had a clear enough view to make the leap to Minkowski spacetime—which I see as a unification of the principles and a tentative *ontology* underlying SR. Most importantly, it was only after that tentative ontology was in place, that one had a starting point to move physics forward to General Relativity—namely, to incorporate gravitational phenomena, you curve the manifold.

So I see it with quantum mechanics: first, (convincing) principles rather than Hilbert space rubbish; then, tentative ontology (what I use the word "Zing!" as a placeholder for at the moment); and finally, a test that the ontology has some cash value over-and-above the principle-theory phenomenology: can the ontology be used successfully as a starting point for a broader, more powerful theory? Metaphorically, what happens if you curve the Zing!?

Here's the way I tried to express the sentiment in my old paper `quant-ph/0205039`:

> Our foremost task should be to go to each and every axiom of quantum theory and give it an information theoretic justification if we can. Only when we are finished picking off all the terms (or combinations of terms) that can be interpreted as subjective information will we be in a position to make real progress in quantum foundations. The raw distillate left behind—minuscule though it may be with respect to the full-blown theory—will be our first glimpse of what quantum mechanics is trying to tell us about nature itself.
>
> Let me try to give a better way to think about this by making use of Einstein again. What might have been his greatest achievement in building general relativity? I would say it was in his recognizing that the "gravitational field" one feels in an accelerating elevator is a coordinate effect. That is, the "field" in that case is something induced purely with respect to the description of an observer. In this light, the program of trying to develop general relativity boiled down to recognizing all the things within gravitational and motional phenomena that should be viewed as consequences of our coordinate choices. It was in identifying all the things that are "numerically additional" to the observer-free situation—i.e., those things that come about purely by bringing the observer (scientific agent, coordinate system, etc.) back into the picture.
>
> This was a true breakthrough. For in weeding out all the things that can be interpreted as coordinate effects, the fruit left behind finally becomes clear to sight: It is the Riemannian manifold we call spacetime—a mathematical object, the study of which one can hope will tell us something about nature itself, not merely about the observer in nature.
>
> The dream I see for quantum mechanics is just this. Weed out all the terms that have to do with gambling commitments, information, knowledge, and belief, and what is left behind will play the role of Einstein's manifold. That is our goal. When we find it, it may be little more than a minuscule part of quantum theory. But being a clear window into nature, we may start to see sights through it we could hardly imagine before.

So, as I've already said, I think I agree with you much. However, I wouldn't use the words that you used for Einstein's initial formulation of SR—i.e., as a "strategic retreat"—to describe this methodology (at least in the case of quantum mechanics). Rather, I think of it as an effective method for "clearing out the underbrush"—i.e., making the real lay of the land visible. It's not a strategic *retreat* at all, but rather simply good strategy. I have big dreams for where we might take quantum mechanics, but first we've got to clear out the underbrush of extraneous observer-dependent detail in it. And I see no sure-fire and nonspeculative way of doing that but to <u>first</u> reduce the theory to something like a principle formulation.

Anyway, good paper.

16-01-06 *Lovely Word* (to C. G. Timpson)

By the way, what was that lovely word you used in your lecture at Princeton to describe information's relation to reality? As I recall, it struck me because the idea it conveyed was so similar to the Jamesian phrase I often use in my writings, "numerically additional"—there was an example of that phrase in the note I just sent you and Harvey. Here are some other ways I've used it in various pieces:

> Suppose one wants to hold adamantly to the idea that the quantum state is purely subjective. That is, that there is no right and true quantum state for a system—the quantum state is "numerically additional" to the quantum system. It walks through the door when the agent who is interested in the system walks through the door. Can one consistently uphold this point of view at the same time as supposing ...

or

> William James likes to say that all beliefs are "numerically additional" to the reality they take as their target, even "true" beliefs.

or

> Within quantum mechanics, there is an invariant piece which is common to all of us by the very fact of our accepting the theory. That is what we are in search of because in some sense—which need not pertain to a realistic conception of a theory's correspondence to nature—it is the core of the theory. It is the single part that we agree upon, even when we agree upon nothing else. In the direction I am seeking to explore, the quantum state is "numerically additional" to that core. (That is, the quantum state is a compendium of Bayesian "beliefs" or "gambling commitments" and is thus susceptible to the type of analysis James gives in his "Sentiment of Rationality." Our particular choice of a quantum state is something extra that we carry into the world.)

Would that nice word of yours nicely substitute into these paragraphs? If so, I think I might adopt it.

Chris's Reply

> You know what: I think it might be even better fitted for these contexts than for the ends I had in mind. The term was 'adventitious' adj.: of the nature of an addition from without; extrinsically added, not essentially inherent (OED).

16-01-06 *Little Phrases* (to D. M. Appleby)

A subject and an object, from a physicalist perspective, are simply two objects. Suppose the subject has a belief about something to do with an object (even if only a belief about how some interaction with the object will lead to a certain sensation in the subject). To the extent that the belief is a possession of the subject, and the object need not abide by it, the belief is "subjective." I.e., it is a statement of a property of the subject. To the extent that the belief encodes a statement of the subject's history and composition (perhaps its genetic makeup, the culture in which it was raised, the accidental things that happened to it throughout its life, how much alcohol it had to drink just before the belief, etc.), it is "objective." For, it is a settled and inalienable possession of the actual historical record of that small piece of the world.

Does any of this wordplay have anything to do with settling the issues you wrote me about last week?

17-01-06 *Wheeler Meeting at Princeton* (to several at Princeton University)

Dear colleague in the Princeton community,

Prof. Marlan Scully and I are organizing a somewhat impromptu but nonetheless serious meeting in Princeton to give a little tribute to John Archibald Wheeler and his "law without law" and "it from bit," and also to discuss some recent developments in quantum information. It'll be a one-day meeting with maybe 10 short talks and a little socializing, held Friday, February 24. Wheeler has said that he will make an appearance, and we would like to invite you too.

Please let me know as soon as possible if you would like to come and if your schedule will permit it. Also please say if you would like to give a talk: Tentative titles are encouraged, even if some will have to be eliminated in the end (with a lottery) due to time constraints.

On this round of invitations, we're checking on the availability of the following Princeton locals to see if they can participate: Rob Calderbank, John Conway, Bas van Fraassen, Hans Halvorson, Simon Kochen, Kirk McDonald, and Edward Nelson.

Already from further quarters, we have commitments of participation from: Carroll Alley, Ken Ford, Daniel Greenberger, Mark Hillery, Benjamin Schumacher, Yanhua Shih, William Unruh, William Wootters, and Suhail Zubairy.

It looks to be a promising meeting; we hope you can participate!

17-01-06 *Bushwhacking, 2* (to H. R. Brown & C. G. Timpson)

Brownism 1: *In my opinion, after the weeding, you end up with the wavefunction, or the vector in the Hilbert space. I confess I cannot see why that is 'rubbish'. Maybe you think it is too complicated, too messy. Too many theoretical principles? I am reminded of Einstein's saying about how good it is to simplify as much as possible — BUT NO MORE.*

I'll try to get my hands on your book soon; that'll be fun.

As for your other questions, I'll let Chris Timpson be my proxy if he'll take the task. He'd probably do a better job than I, anyway: What you trim, depends on the first count as to what you see as the more likely solution: that the state vector as 'inherent' to the quantum system or rather 'adventitious' (a lovely word I learned from Chris). Anyway, you two are probably closer to a common pub; and I know you enough already, Harvey, to know that your defenses will have to be down before any of this worldview will ever seep into you.

17-01-06 *Wheeler Meeting at Princeton* (to K. T. McDonald)

McDonaldism 3: *Bill [Brinkman] is very nuts and bolts about bits. He is active in encouraging us to get involved with the implementation of quantum information processing, more than addressing* *theory issues. But I'd hate to see quantum information go the way of high-energy physics in which there's too huge a gap between theory and experiment.*

My own view is that quantum information formalism has gotten way out ahead of lab reality, and that the next phase of hard work is more in the lab than not ...

True, but what else can a theorist do but follow his interests. At least the gap in quantum information theory and experiment is not like the gap between string theory and experiment: There's NO speculation in quantum information, no claims that anything must be right because of 'beauty'—the results are either right or wrong, because after all quantum information is just elementary quantum mechanics pushed a few steps further.

17-01-06 *No 'Plunging Ahead' After All* (to S. Hartmann)

Well, all my hopes for a Bayesian-QM PSA symposium got dashed this weekend: 1) Pitowsky couldn't make it because of teaching duties, 2) Skyrms couldn't give a talk because he'll be giving the presidential address, and 3) Shimony had too many commitments too. I could easily find someone to replace Shimony—he wasn't that crucial—(maybe you would have liked to have spoken too, or maybe Elga as Hans had suggested, or maybe Bill Demopoulos), but without the two headliners of Pitowsky and Skyrms—both of which had ingredients that I couldn't figure out how to replace—there didn't seem much reason to go on. Oh well, c'est la vie; maybe two years from now I'll have a more thought-out plan.

I'm sorry to have troubled you about this, to have it all come to naught.

Hope you are enjoying California. (Outside of the professional part, is there anything to enjoy in Irvine?)

17-01-06 *Diptera* (to D. M. Appleby)

I'm not sure what I did to do it, but it looks like I really angered you. All I guess is that you took very seriously my one (flippant?) use of the work "physicalist," which probably has a lot of connotations for you. I'm not completely sure what it means (other than the Webster definition), but I was trying to search for a word that conveyed the idea that there is no true divide between subject and object in a Kantian or Schopenhauerian sense. What do you call that?

Did you read the Davidson essay "The Myth of the Subjective"? What would you call that kind of idea? Maybe not physicalism, but then what?

You write, "You are probably thinking that the physicalist perspective you ask me to adopt ..." But I didn't ask you to adopt anything. I ASKED, "Does any of this wordplay have anything to do with settling the issues you wrote me about last week?" It was my meager attempt to see if that was what was at issue; it was a (lame?) attempt to clarify things to my mind.

18-01-06 *New York Times Quote* (to me)

Betty Friedan in *The Feminine Mystique*:

> Down through the ages man has known that he was set apart from other animals by his mind's power to have an idea, a vision, and shape the future to it ... when he discovers and creates and shapes a future different from his past, he is a man, a human being.

18-01-06 *What I Must Have Meant* (to D. M. Appleby)

I searched my memory on and off though my sleeping/sleepless hours last night to see if I could find a clue to why I had used the word "physicalist" in my note to you.

Well, I found it: It came to me through Rorty. "Nonreductive Physicalism" is what he calls his view and what he calls Davidson's in the "The Myth of the Subjective" and other places. So, I finally read Davidson's essay, and I RE-read Rorty's essay "Non-reductive Physicalism" in his book *Objectivity, Relativism, and Truth*. And I think that view approximates to some extent the direction I'd like to go.

Did you ever read Rorty's introduction to that volume, like I had once suggested to you? (I'll place my old note suggesting that below.) He states quite clearly there what he means by antirepresentationalism—I think it is a view that approximates our own two views (i.e., yours and mine). Yet, later in the book Rorty has this essay "Non-reductive Physicalism," and he certainly doesn't see it at cross-purposes with his introduction. So my question is, what do you think of it? Is it a meaning for the word "physicalism" that you could accept?

18-01-06 *Integers and Real Numbers* (to D. M. Appleby)

Regarding this piece of your note:

Applebyism 10: *I suppose one might argue, with some plausibility, that the integers are a purely logical structure, devoid of physical content. But I have doubts even about that. Not only does the concept of an integer originally arise in the context of counting sets of physical objects. That is the still the way it is defined in axiomatic set theory. And I would say that the concept of an object is a physical concept, which embodies assumptions about the world. Ditto the concept of a set. Furthermore, it seems to me that there is something very classical about the concept of a set. The concepts of object and set clearly have an approximate, everyday phenomenological validity. But it seems to me that they have "human", in fact "primitive human", stamped all over them. I see no reason to assume that objects and sets exist in ultimate reality. Indeed, to my mind quantum mechanics rather suggests the opposite.*

Below is a note that Danny Greenberger once wrote me, which I liked a lot. Maybe you'd be interested in reading it in this connection. (And maybe I'll cc this note to Mermin, as he and I once had a discussion on the integers—I think it was in Capri—and I took the stubborn position that even they don't exist by themselves ... much like you seem to suspect. I'm not sure I ever shared Danny's note with David.) [See 06-12-02 note titled "Enjoyed" to Greenberger.]

18-01-06 *Wheeler Meeting at Princeton* (to E. H. Lieb)

Good to finally meet you; I've been a fan for many years. (For a while, when I was working on my PhD, I thought the key to all the secrets of the universe might be found in one of your papers on operator-Schwarz inequalities.)

Liebism 1: *Marlan suggested a review of strong subbadditivity, but this is well known stuff, or is it? Probably you have more up to date material in mind.*

Well, the meeting is a bit of a hodgepodge of younger and older guys—the only common thread really being John Wheeler's influence on quantum foundational thought in the past. Certainly, strong subadditivity is old stuff to some of the guys in my side of the invitation list—say, Schumacher, Wootters, maybe Unruh, etc. But I doubt Greenberger, Alley, and others (including Marlan!) know anything about it. So, I think it couldn't hurt to give a talk about it. Maybe you could squeeze statements of some of your newer theorems in as asides … but the talks will probably be pretty short if we try to get 10 of them in in one day.

19-01-05 *The Wheeler Meeting* (to D. B. L. Baker)

Well the holidays came and went and I didn't write you a thing. I thought I would, and maybe send you some new pictures, but time just slipped away—it always seems to slip away now.

But I found myself thinking about you again yesterday, particularly that incident in 1984 when John Wheeler called your mom because you hadn't turned in a term paper for his class. John was, I think, 73 then.

He's almost 95 now. I've been involved in organizing a little conference for him at Princeton, and so all kinds of memories have been coming to me. In this connection, I got the nice note (and attachment) below from Ken Ford, John's biographer and former student, that gives some sense of what the man is like now. It was Ken's line about "courtliness" that made me think about John's calling your mother. I hope you have MS Word installed, so that you can read the attachment; if you don't let me know and I'll put the words into a plain text file.

Mostly, Ken's closing lines got to me. It kind of reminded me of that Joan Baez – Kris Kristofferson duet, "Hello in There". I think the song was written by John Prine. Do you know it? If you don't, some approximation to the lyrics can be found here:

`http://www.cowboylyrics.com/lyrics/prine-john/hello-in-there-10843.html.`

I hope you and the family are all doing well.

19-01-06 *Elevator Stories* (to A. Cho)

Let me send you one last little thing to read while it's on my mind. You might enjoy looking at the introduction and conclusions to this paper: `http://www.arxiv.org/abs/quant-ph/0404122` (particularly the elevator stories). Anyway, this has to do with the question you asked near the end of the phone conversation about what I would like to see experimentally explored next—this paper talks about that optimal alphabet I was telling you about.

Good luck with your writing.

22-01-06 *QCMC, Hirota, and Giacometti* (to O. Hirota)

Thank you for the invitation to serve on the advisory committee for QCMC; I graciously accept.

It is a funny coincidence that I open my email to find a note from you this morning. The reason is because, before turning on my computer, I had planned to write you a note myself this morning!! This is really true. Last week, I took my older daughter Emma to the New York Metropolitan Museum of Art to celebrate her 7th birthday. All week, I have been meaning to tell you about how we saw two pieces of Alberto Giacometti's work there! Did you see those pieces when you visited New York? One was a sculpture, called "Three Men Walking" I think. And the other was a painting of his mother, I believe. They were striking!

I very much look forward to QCMC this year. It has now been several years since I have been to Japan; I miss it very much.

I hope you will sometime come to visit us in our new home in New Jersey. It is a big old Victorian home (from 1895) that my wife has been reconstructing wildly. Most recently she painted it orange!! (I will attach two pictures.) It would be wonderful to talk of quantum information and noncausality within these orange walls with you! And, Kiki will cook for you grandly!

22-01-06 *Stranger Still!* (to O. Hirota)

Me again. Reviewing some of my old emails to you, I discovered something stranger than the coincidence I wrote you about this morning! I discovered a whole set of coincidences with you. Note, for instance, what I wrote you on 1 June 2004:

> It was a coincidence that you wrote me today. I had been meaning to write you again about the QCMC award—and I was going to do it today!

or as another example what I wrote you 27 May 2003:

> It was an interesting coincidence that I would get your book today. Just this morning, the secretary in Sweden told me that she mailed off several copies of my samizdat *Notes on a Paulian Idea*. You were in the list of recipients. So it should be arriving soon.

Non-causality!!

25-01-06 *Beyond QM and So On* (to A. Y. Khrennikov)

Khrennikovism 14: *And finally: I got again the proposal from AIP to publish Conf. Proc. Would you like to be one of the Editors? It would be natural (then at the end you should write about people from your team in the preface and make selection of papers related to quantum information).*

As for my being an editor, that will be fine. And yes, I will write an introduction for my team.

By the way, I met Simon Kochen for the first time Monday, and had an extended discussion with him (2.5 hours). The main point I got from him is that he thinks the essence of quantum mechanics is that it is a *contextual probability theory*, and he thinks that he and John Conway have some strong mathematical results that support that claim. I thought of you as he told me all that.

26-01-06 *Some Words to Use, Maybe?* (to R. E. Slusher)

The great advantage of the controlled cold collision technique for optically trapped neutral atoms is the ease and simplicity with which it can generate Raussendorf-Briegel "cluster states" over any number of qubits [1]. These are entangled quantum states with the remarkable property that they are a *universal* resource for quantum computing [2]. If a technique can produce these states deterministically, then the remainder of any quantum computation amounts to simply performing single qubit measurements thereafter. Moreover, the complexity class structure of this type of computation may be somewhat better than the older unitary gate style (or circuit model) of quantum computation because it allows for many of the measurements required of an algorithm to be performed in parallel—this is something the circuit model cannot support [3]. The discovery of the cluster-state method of quantum computation should not be underestimated: It is among the top four theoretical discoveries in the history of the field (up there with the factoring algorithm, database search, and the existence of quantum error correction and fault tolerance).

However, beyond the technology-enabling universality property already discussed, cluster states are also of significant raw physical interest [4]. For instance, among the class of entangled states over N qubits, there is a sense in which cluster states have the most persistent entanglement: A user must perform measurements on at least $N/2$ qubits of the original N before the entanglement in the remainder is completely depleted. This is a property that Bell, GHZ, and error-correcting code states do not have. Also, cluster states have the interesting property of being maximally connected: By performing local measurements, one can teleport between any two sites in the array. This physical phenomenon that has not been demonstrated in an array before. Finally, the cluster-state model of quantum computation provides a test-bed for quantum foundational studies that take quantum measurement as the primary nonclassical feature of quantum mechanics [5], for, among other things, they show that even unitary evolution is ultimately representable in measurement and entanglement terms alone [6].

[1] Recently, there have been a few experiments producing $N = 4$ cluster states (and possibly $N = 5$ in unpublished work)—see, for instance, P. Walther, et al., "Experimental One-Way Quantum Computing," Nature **434**, 169 (2005); P. Walther, et al., "Experimental Violation of a Cluster State Bell Inequality," Phys. Rev. Lett. **95**, 020403 (2005). However the production of these states rely on down-conversion techniques that cannot produce cluster states *deterministically.* Moreover, the experimental results reported are always of the post-selected variety: I.e., the cluster state must be destroyed before it can be said to have *been* there.

27-01-06 *Wheeler Quantum Information Meeting, February 24–25* (to the Wheelerfest participants)

Dear Colleague,

If you are receiving this email, it means that I have heard back from you with a firm or tentative yes that you will be able to participate in the "Wheeler – Quantum Information Meeting" that Marlan Scully and I are organizing at Princeton. The final dates for the meeting have now been set: The meeting will run all day Friday February 24, reconvening Saturday morning February 25 for a further session (until noon). Friday night, we will have a conference dinner.

If you have not done so yet, please send me a tentative title for your talk.

Presently we are either hoping for or expecting talks from: Carroll Alley, Rob Calderbank, Ken Ford, Chris Fuchs, Danny Greenberger, Hans Halvorson, Mark Hillery, Simon Kochen, Elliot Lieb, Stephen Lyon, Kirk McDonald, Edward Nelson, Wolfgang Schleich, Ben Schumacher, Marlan

Scully, Robert Seiringer, Yanhua Shih, Bill Unruh, William Wootters, Suhail Zubairy, Wojciech Zurek, and maybe John Conway and Anton Zeilinger. Also, there will likely be some local students and postdocs giving talks.

Attached are instructions for making your hotel reservation and suggestions for how to get from the local airports to the hotel; we strongly suggest you fly into Newark airport if you are flying. For the Friday of the meeting, all talks and the conference dinner will be held at a conference center near the Hyatt hotel; shuttle service from the hotel to the conference center will be provided by grad students. The Saturday morning session will convene at a lecture hall on Princeton University campus; again shuttle service will be provided.

The present plan is that John Wheeler will be attending the Friday morning part of the meeting. To give some sense of what John is (still) interested in, I'll also a attach a nice article that Ken Ford wrote recently for the Princeton Physics Department Newsletter.

Marlan and I look forward to seeing you all. And I will be communicating with you all again before the date with further details.

27-01-06 *Monday or Tuesday Meeting* (to H. Halvorson)

Halvorsonism 5: *Thanks for coming to Princeton yesterday. I really did appreciate the fairly comprehensive overview of your current perspective. By the way, regarding upcoming meetings, I could also come up your way sometime, or we could try to find a midpoint meeting place. In any case, I would like to try to maximize the chances that we will meet again soon and often.*

I enjoyed it too, and it was nice to learn a little more about the things you're thinking and about our common ties through Davidson. Thanks for your nice offer too; I'll certainly take you up on it sometime.

In the meantime, though, I was thinking about coming to Princeton Monday or Tuesday (if everything continues to go OK with my step-dad): My in-laws are visiting, and I thought my father-in-law might like to explore a little of the town and campus. So to kill two birds with one stone, maybe I could have a meeting with you while he's entertaining himself. Would you have any time Monday or Tuesday?

By the way, I thought of something I should tell you with regard to Hardy's axioms. You said you were particularly interested in Hardy's continuity axiom. But that axiom, at least within the context of the other ones, is particularly weak. In its place, Hardy could have inserted almost any distinction between classical probability theory and quantum mechanics, and it would have still done the trick. For instance, instead of requiring the existence of a continuous transformation between pure states, he could have outlawed broadcasting. That would have been just as effective for narrowing him down to quantum mechanics (as all one needs in that spot is a statement that works in the quantum case but not the classical one). Thus, his axiom structure is not particularly tight.

27-01-06 *Degrees of Freedom / Distinguishable States* (to H. Halvorson)

Also, I spent a little time this morning trying to search my archive of mumbles to see if I could find something that decently expressed my distaste for taking "the number of degrees of freedom" or "the maximum number of distinguishable states" as the foundation for Hilbert-space dimension.

Unfortunately, I wasn't as successful as I had hoped I would be: Maybe it means my memory is failing, and I haven't really yet written a clear statement of what I'm thinking.

So, let me give you the pointers that I could find in the meantime:

- "On the Quantumness of a Hilbert Space," `quant-ph/0404122`
- pages 159–160 of *Quantum States: W.H.A.T.?*

I want Hilbert-space dimension to denote not (a priori at least) number of distinguishable states, but rather something to do with a quantum system's sensitivity to the touch or its creative power. And that's partially what I am trying to get at with ideas like "quantumness".

30-01-06 *Loose Ends and Pedagogy* (to K. T. McDonald)

It took me quite a while, but I finally found it. I'm talking about the John Wheeler passage on $\hbar$ that I mentioned to you. Let me paste it here:

> The quantum, $\hbar$, in whatever correct physics formula it appears, thus serves as a lamp. ...
>
> Giving us its as bits, the quantum presents us with physics as information.
>
> How come a value for the quantum so small as $\hbar = 2.612 \times 10^{-66}$ cm^2? As well as ask why the speed of light is so great as $c = 3 \times 10^{10}$ cm/s! No such constant as the speed of light ever makes an appearance in a truly fundamental account of special relativity or Einstein geometrodynamics, and for a simple reason: Time and space are both tools to measure interval. We only then properly conceive them when we measure them in the same units. The numerical value of the ratio between the second and the centimeter totally lacks teaching power. It is an historical accident. Its occurrence in equations obscured for decades one of nature's great simplicities. Likewise with $\hbar$! Every equation that contains an $\hbar$ floats a banner, "It from bit". The formula displays a piece of physics that we have learned to translate into information-theoretic terms. Tomorrow we will have learned to understand and express *all* of physics in the language of information. At that point we will revalue $\hbar = 2.612 \times 10^{-66}$ cm^2—as we downgrade $c = 3 \times 10^{10}$ cm/s today—from constant of nature to artifact of history, and from foundation of truth to enemy of understanding.

I certainly agree with significant pieces of that. Particularly, through quantum information theory I think we are already seeing strong hints of how to formulate the essence of quantum mechanics without ever making mention of $\hbar$. The idea is to let finite dimensional Hilbert spaces lead the way to telling what is really quantum and what is not.

It probably won't add much to that statement, but let me record that I really believe it by attaching a teaching proposal I wrote for Caltech the last time I thought about jumping ship from Bell Labs (a couple years ago). At the time, there was a small chance of an interdisciplinary position between physics, philosophy, and engineering (through their Information Science and Technology initiative), and the proposal was written with that mix-match in mind. The relevant part for you is the section on "Innovative Undergraduate Quantum Mechanics." It took a little nerve to write that stuff, but I think it needs to be said.

I've been meaning to write you since returning from NIST, but I wanted to find the Wheeler quote first. That meeting really fired me up for this DTO proposal we're writing. Let me ask you this. As you get a chance, have a look at: O. Mandel, *et al.*, "Controlled Collisions for Multi-Particle Entanglement of Optically Trapped Atoms," *Nature* **425**, 937–940 (2003). If we (Lucent) could use our MEMS spatial light modulators to create 50,000 individually movable atom traps for enacting these controlled cold collisions—as we think we can in the near-term future—to set the scene for cluster-state quantum computation, would that count in your mind as "doing physics" within quantum information? I'm just trying to get a feeling for the sorts of distinctions you seemed to be making at lunch the other day.

30-01-06 *Loose Ends and Pedagogy, 2* (to K. T. McDonald)

McDonaldism 4: *Your teaching proposal to Caltech looks like it might find better reception in a philosophy department than in a physics department.*

Well, yes. The potential position was explicitly to be interdepartmental if it materialized (it didn't materialize at the time). I guess you're telling me my proposal looks to have left out the other half ... ... ouch.

McDonaldism 5: *A clarification. I have somehow (without being well informed) come to associate "Bayesian" with the notion that there is no such thing as intrinsic randomness in Nature.*

I hope that this term means something different to you.

McDonaldism 6: *But I am a bit worried by the quotation: "Bayesian Statistics offers a rationalist theory of personalistic beliefs in contexts of uncertainty, with the central aim of characterizing how an individual should act in order to avoid certain kinds of undesirable behavioral inconsistencies."*

I interpret this as implying that Bayesian Statistics provides a kind of deprogramming for those misguided souls who take too seriously the claims that intrinsic probability plays a key role in Nature.

I'll consider how to best respond to your other queries over the rest of the day. In the meantime, let me ask if Sections 3, 4, and 5 of [`arXiv:quant-ph/0204146v1`] don't already answer your questions relatively directly? And within that maybe pay particular note to the discussion near the ALL-CAPPED "reality" on page 6 and the last two paragraphs of page 8 for your question on "intrinsic randomness."

30-01-06 *Wheeler Accuracy?* (to J. Preskill)

Marlan Scully and I are organizing a little impromptu meeting for John Wheeler and quantum information at Princeton Feb 24 & 25, and I think I want to open my talk with that story you once told me about the flying equations. It's recorded at the top of page 149 of my *Notes on a Paulian Idea*, which you can get off my webpage below. I wonder if I could ask you to check that write-up for accuracy, and tell me any other tidbits you remember that might be of use for setting the mood of the story. I just want to make sure I get the dramatic effect right.

After that intro I will spend some time talking about our Bayesian view of QM: That the formal structure of quantum mechanics should not be viewed as some kind of mathematical mirror image of the real world, but rather as a layer on top of Bayesian probability theory (molded by the real world). It represents how an agent should tie together his gambles when the subject matter is the agent's "kicking" the external world and waiting for the reaction it produces within him (formerly known as quantum measurement). Then, to end with making a connection back to John, I want claim that the disconnect between the "real world" and "QM as normative theory of gambling" is precisely the sort of space one needs to get the kind of flight John was talking about—no space, no flight.

I'm surely responsible for all the errors in the latter part of the talk, but I hope you can help me to be as historically accurate as possible in the first part of it.

By the way, if you're interested in coming (and/or talking), please do come. I could send you the logistical information if you're interested. John will make an appearance for two or three hours the Friday morning. So far, outside of the Scully crew, I've only been inviting his old students and Princeton locals; but now that I think of it, you might possibly be interested too. I'll paste in the tentative speaker list below. I think everybody in the list will be coming except (probably) Zeilinger, Zurek, and Schleich—I just don't have talk titles yet from most (only previous confirmations).

John's Reply

> Well, the moral of the story is correct. The course was actually called Honors Physics and it was for sophomores intending to major in physics. It started with Goldstein *Classical Mechanics*, but actually we also did E&M, relativity, statistical physics and quantum physics, all from a rather idiosyncratic perspective.
>
> My recollection is that he didn't ask us for "all the equations" but for the ones we thought were most important and fundamental, the ones that succinctly sum up the known laws of physics. Otherwise, though, you have captured the moment pretty well, to the best of my recollection. The phrase "But the universe flies" had just the right tone of wonder, and there was a dramatic pause following, to let it sink in for a few seconds.
>
> The meeting sounds like fun. Sorry I can't be there.

30-01-06 *Locus of Free Will* (to H. Barnum)

In August 1999 you wrote me this:

Barnumism 15: *Ah! I have come to understand (or remember, perhaps) the importance of leaving a place for free will in your views on the foundations of qm. . . .*

Here's a caricature, so feel free to object: Bell's worry about the foundations of QM has been: that we have "measurement" as an "unanalyzed primitive" of the theory. Everett shows us how to get around that. You don't like Everett's resolution because you want *to have an unanalyzed primitive around so it can be the locus of free will.*

and I just thought of your writing it via our correspondence a few minutes ago in conjunction with a note I had written John Preskill a few minutes before that. I'll place the note to Preskill below. [See 30-01-06 note titled "Wheeler Accuracy?".]

Have you ever read the Wheeler story I refer to? Anyway, it struck me that maybe I'm still talking about that same locus!

30-01-06 *Island of Misfit Toys* (to K. T. McDonald)

McDonaldism 7: *Looking over your anti-Växjö note, I infer that I am much less concerned with the relation of human beings to quantum theory than you. So I doubt that I will be of much use to you as a sparring partner.*

Yeah, you're probably right.

McDonaldism 8 : *Instead, I'm led to infer that your view is that physics = psychology.*

I must be a horrible expositor if that is what has come through to you.

McDonaldism 9 : *Probability arises in situations involving people.*

No, it is that probability theory is as much prior to empirical science and the peculiar properties of the objective, physical, man-independent world (which I have no doubt is out there) as number theory and mathematical logic are. That is why we can practice probability theory (just as we can mathematical logic) without knowing anything necessarily of physics.

McDonaldism 10 : *People have lots of subjective impressions.*

They do, and I'm gaining one.

McDonaldism 11 : *Therefore, the notion of probability is probably subjective.*

Non sequitur.

The Bayesian view of probability, as developed for instance in

- E. T. Jaynes, *Probability Theory: The Logic of Science*, edited by G. L. Bretthorst (Cambridge University Press, Cambridge, 2003).
- J. M. Bernardo and A. F. M. Smith, *Bayesian Theory* (Wiley, Chichester, 1994).
- L. J. Savage, *The Foundations of Statistics* (Dover, New York, 1972).

is that one's *initial* probabilities (for anything) are largely beyond one's control. For they depend upon one's particular history, the accidents of one's learning, even the bad lessons one might have received in college. So, in that sense, probabilities are "subjective." Initial probabilities are like the initial conditions of a pendulum in a physics problem; their origins are left unanalyzed as a matter of principle. The best one can do is trace back the initial condition of a pendulum to the initial condition of some larger system (whose origin again goes unanalyzed), and so similarly with probability—the best one can do in analyzing the origin of some prior probability is to trace it back to some further prior (whose own origin then goes unanalyzed).

What is *not* subjective and not dependent on history in Bayesian probability theory, however, is how probabilities *should* fit together. As an example, if you gamble with odds $P(A)$ for some event A, and $P(B)$ for some event B, and gamble with odds $P(A \vee B)$ for the disjunction of A and B, and with $P(A \wedge B)$ for the conjunction of A and B, then it had better be the case that your numbers fit together according to this relation

$$P(A \wedge B) = P(A) + P(B) - P(A \vee B)$$

or you will lay yourself open to a sure loss. (This is called the Dutch book argument.) Thus it is the transformation rules between probabilities that are *objective*—the edict that one should strive to make sure that one's probability assignments meet the constraints of all Dutch book arguments is something that does not depend on the peculiarities of one's actual history. In that sense, the transformation rules are not "subjective," but rather "objective."

McDonaldism 12 : *A clarification. I have somehow (without being well informed) come to associate "Bayesian" with the notion that there is no such thing as intrinsic randomness in Nature.*

I hope that this term means something different to you.

Your association is the common one. A. J. M. Garrett, for instance, expresses it very eloquently,

> The nondeterministic character of quantum measurement can, and should, be taken to imply a deeper 'hidden variable' description of a system, which reproduces quantum theory when the unknown values of the variables are marginalised over. Differences in measurements on identically prepared systems then represent differences in the hidden variables of the systems. Not to seek the hidden variables, as the Copenhagen interpretation of quantum mechanics arbitrarily instructs, is to give up all hope of improvement in advance, and is contrary to the purposes of science.

But Caves, Schack, Appleby, Peres, Leifer, I (and I hope a few others) are renegades from that. If what you mean by "intrinsic randomness" is that quantum measurement outcomes do not preexist the measurement process—that they are made "on demand"—and that there is no fact of the matter in the universe that will determine which way they will go, then Caves, Schack, Appleby, Peres, Leifer, and I all accept that.

But that does not contradict the main Bayesian point, which I attempted to express in the section above: That initial probabilities are *subjective*, while the transformation rules and the way probabilities tie together are not—they are *objective*. Garrett-style hidden variables, regardless of what Garrett might say, are thus not necessary for a Bayesian view of quantum probabilities.

Which leads to this point:

McDonaldism 13: *But I am a bit worried by the quotation: "Bayesian Statistics offers a rationalist theory of personalistic beliefs in contexts of uncertainty, with the central aim of characterizing how an individual should act in order to avoid certain kinds of undesirable behavioral inconsistencies."*

I interpret this as implying that Bayesian Statistics provides a kind of deprogramming for those misguided souls who take too seriously the claims that intrinsic probability plays a key role in Nature.

Quantum measurement is a "context of uncertainty"—and it is *because* of "intrinsic randomness," as defined idiosyncratically (but carefully) above. As far as I can tell, that has nothing to do with psychology—that is now a statement about our empirical world. But that has no implication that quantum probabilities have to be any more objective than Bayesian ones—they are still as much dependent on the gambling agent's peculiar history as any agent's probabilities in *any* context (because even the quantum states one ascribes to a system depend on unanalyzed prior probabilities).

What Bernardo and Smith are talking about in that quote is the *objective* content of Bayesian Statistics: It is that one should strive to be invincible to a Dutch book. (Not being invincible is what they mean by "undesirable behavioral inconsistencies.") The point that Caves, Schack, and I are attempting to develop is that the *transformation rules* of quantum mechanics *too* are of just such an *objective* flavor. That is, if a gambling agent bets this way on the outcomes of this measurement, and that way on the outcomes of that measurement, and so on and so on, for a complete or overcomplete set of quantum observables, and yet that gambling agent does not relate his probabilities in the way quantum mechanics prescribes (through the transformations between operators), then the world will be able to smite him down as certainly as any Dutch bookie can.

So, far from saying that physics is psychology, our Bayesian program is a careful attempt to ferret out the objective content of quantum mechanics at the same time as accepting "intrinsic randomness" (in the sense above). Only *part* of quantum mechanics is about the gambler-independent world, and that part still calls for a full identification. This task of separating the wheat from the chaff is the price one must pay if one accepts the idea that quantum *states* are of essence information—luckily it is a task that stands a chance of bearing fruit (and already has born fruit). To say 'every physical system is a quantum computer' adds nothing to existing physics—you would have been better to stick with the tautology that a physical system is a physical system, full stop. Using the terminology you do only anthropomorphizes things that shouldn't have been anthropomorphized in the first place. It erases the very distinction that one wants to make in order to get at an objective statement.

OK, enough.

I have strived to use the word peculiar as many times as possible in this note.

30-01-06 *Not Quite Enough* (to K. T. McDonald)

And I still need to reply to this:

McDonaldism 14: *As I sketch in my blurb, the issue as I see it is that the so-called classical world (with its unexplained long-lived bound states) is largely due to the quantum character of Nature. . . . The challenge is to understand better how the classical view arises out of the quantum world.*

It may be that in your way you are addressing this challenge. If so, I need a little more help from you to be able to follow your thinking on this.

Indeed, I think that is a valid and important question (the part I quoted at least). And, yeah, I do think that what Caves, Schack, the rest and I are doing is an important movement toward that goal. Or, at least, I hope so.

But there's no sense in attempting to say anything about our efforts along these lines unless/until I can first instill a little respect in you for the substructure that supports our approach. I.e., you have to have a little respect for the basics first—and I fear that we may not get there.

30-01-06 *Krugman on Reality* (to me)

From Paul Krugman, "A False Balance," *New York Times*, 30 January 2006:

> "How does one report the facts," asked Rob Corddry on *The Daily Show*, "when the facts themselves are biased?" He explained to Jon Stewart, who played straight man, that "facts in Iraq have an anti-Bush agenda," and therefore can't be reported.
>
> Mr. Corddry's parody of journalists who believe they must be "balanced" even when the truth isn't balanced continues, alas, to ring true. The most recent example is the peculiar determination of some news organizations to cast the scandal surrounding Jack Abramoff as "bipartisan."

30-01-06 *Exponentiation* (to K. T. McDonald)

In the words of Scarlett O'Hara, "Tomorrow is another day." A cooler head always prevails on the day after with me; maybe the process is already starting. It was just—and you should know it—that I found some of your choices of words insulting. I don't mind a skeptic raising doubt—being challenged to make our point of view consistent is what keeps the view moving along and making progress: You can find any number of notes in my archives with polite and patient explanations, and plenty of evidence that I find the challenges I receive to be very useful. But to use phrases like "what little I can reconstruct from your note . . . " and "I'm led to infer that your view is that physics = psychology"—you've got to admit—had the feel of throwing down a gauntlet. What physicist would not find it insulting that his work is seen as trying to say "physics = psychology"?

I'll let the issue rest, and actually thank you for firing me up: I did rather like some of the formulations I used in the longer note I sent you—they will be useful in the future, in a calmer context.

I look forward to seeing you again at the Wheeler meeting.

01-02-06 *Measurement Based Quantum Computation* (to H. Halvorson)

While I'm thinking of it (because of the grant proposal I happen to be working on), let me give you references to my three favorite papers on measurement-based quantum computation:

- Measurement-based quantum computation with cluster states
  Authors: R. Raussendorf, D. E. Browne, H. J. Briegel
  `http://www.arxiv.org/abs/quant-ph/0301052`

- Cluster-state quantum computation
  Author: Michael A. Nielsen
  `http://www.arxiv.org/abs/quant-ph/0504097`

- An introduction to measurement based quantum computation
  Author: Richard Jozsa
  `http://www.arxiv.org/abs/quant-ph/0508124`

That computational model strikes me as a veritable goldmine for exploring how the notion of "measurement" I've been talking to you about (i.e., action on a system, followed by unpredictable reaction in the agent) is given *meaning* in the workaday sense. Maybe a way to put it is: Quantum measurements don't "inform," rather they "enable." And I think the Raussendorf-Briegel computational model starts to give that slogan some precision.

01-02-06 *Enabling Alchemy* (to R. E. Slusher)

Below, let me place three notes for you to look over. The first one contains the slogan I just told you about. The second one (somewhat about alchemy—don't tell anyone) provides some background for why I would say something like that. The part that comes closest to a technical paragraph—and the part that you should take away in your memory—is the fourth paragraph from the bottom of it. Finally, in the third note (to van Fraassen), I expand on how one should *not* think of quantum measurements as informative of anything. [See 01-02-06 note "Measurement Based Quantum Computation" to H. Halvorson, 19-06-05 note "Philosopher's Stone" to G. L. Comer, and 14-11-05 note "Questions, Actions, Answers, & Consequences" to B. C. van Fraassen.]

Let me also attach one illustration of the idea (hand drawn of course).

03-02-06 *Red Spears* (to D. B. L. Baker)

It was the strangest thing to my ear when you called him Red in your note to me the other day. I hadn't heard him called that in so long—it kind of came back to me, "That's right; people used to call him Red Spears."[85]

Red passed away this morning, about an hour ago. It was during his sleep. A pretty good way to go in the end, I suppose.

08-02-06 *The Quotes* (to D. B. L. Baker)

Here's the quote that'll be going in the revised edition of the *American Heritage Dictionary of American Quotations* (though it has been bought by Oxford and will be renamed the *Oxford Dictionary blah blah blah*):

> There is no one way the world is because the world is still in creation, still being hammered out.

It originally appeared in one of my samizdats, then made its way into a *Scientific American* article by George Musser, and I guess this will be its final resting place. Actually, I'm very proud of this little accolade (probably more than any of the other ones in my career); I'm a little surprised I had not already told you about it. The fuller context of the quote is reproduced below.

It was so good seeing you again. Your company is one of the very few reasons I would ever want to come back to Texas—otherwise, the place is a kind of desert to me.

At the moment, I'm finally on a plane bound for Newark and waiting for my two little bottles of red wine. I was originally supposed to be home by 5:30 today; now I'm scheduled to arrive in Newark just at 10:00, where/when I'll have to catch a taxi home rather than be greeted by my family. [...]

OK, well that exhausts all the quotes I could find tonight. And it seems I'm not so good at holding my two little bottles of wine at 32,000 feet anymore. Maybe I'll drift into one of those reveries like old John Wheeler.

15-02-06 *Discussion* (to S. J. van Enk)

Yeah, I still feel awful; I don't know why. I've been in bed most of the day. It's a constant mild nausea, but no other symptom. I suppose it could be a stomach virus.

Anyway, you are right that in a certain sense, the only thing one ever *learns* (in the common sense of the word) from a "quantum measurement" are the consequences of one's actions. Another way to put it is that, strictly speaking, measurement is nothing other than the changing of a prior state to a posterior state—and the only means the quantum formalism gives for enacting such a change is when one takes an action (i.e., a "measurement") on a system.

To say that one learns something in the common sense (i.e., of becoming aware of which of a set of alternatives is already there), one has to give up treating a system (or part of a bipartite system) quantum mechanically. That is effectively what one is doing when one says that a sender "prepares" one state or another. If one had treated everything quantum mechanically, then there would simply be one quantum state in the picture (circumscribing the preparer and the smaller system), as you point out.

[85] My curriculum vitae presently includes this passage in it: "To the present date, I have given over 175 invited lectures and seminars. Beyond traveling through or over most states in the United States, this has allowed me the opportunity to visit Australia, Austria, Belgium, Canada, China, Denmark, England, Finland, France, Germany, Greece, Hungary, Ireland, Israel, Italy, Japan, Mexico, The Netherlands, New Zealand, Northern Ireland, Poland, Portugal, Scotland, South Africa, Spain, Sweden, Switzerland, and Wales. This is my tribute to my stepfather W. T. Spears, who would say, 'Chris, travel is the best form of education.'"

Have another look at the "clipping" of the note to van Fraassen that I sent you a little while ago. [See "Questions, Actions, Answers, and Consequences."]

Does any of this help your worry?

Steven's Preply

> If you're not too sick to read email, let me ask you a question about yesterday's discussion:
>
> We discussed only very briefly the case where someone, Alice, prepares some qubit A in a state ρ in a particular way (say, tossing a coin, and preparing $|0\rangle$ or $|1\rangle$ depending on the result of that coin toss). It seemed you were going to say then that a measurement by you on system A does teach you something, namely about the preparation.
>
> But I don't see how that would be consistent: after all, you might as well consider Alice + the coin + qubit A as one quantum system consisting of $N \gg 1$ qubits, and assigning as state (in oversimplified but obvious $N \gg 1$ form)
>
> $$|0\rangle^N + |1\rangle^N$$
>
> to Alice + coin + qubit A. But then you would say that you learn nothing from a measurement on A ...
>
> Isn't it consistent to say you never ever learn anything??
>

15-02-06 *Free Will* (to S. J. van Enk)

van Enkism 7: *I also thought of another paradoxical statement about counterfactuals: "If a counterfactual statement could be experimentally tested, it wouldn't be a counterfactual statement, would it?"*

I like that one.

On another subject, could I challenge you to write down in an email what you seemed to like in the discussion yesterday? I'd like to be able to look over it and absorb it better. You characterized how you thought we quantum Bayesians were saying something different than Bohr's position. Could you repeat that?

I also liked the way you said something like we always include the observer in the counterfactual. But I can't quite reconstruct what you really said.

Of myself, I also liked the little characterization I gave of how barring counterfactuals in the way we do is equivalent to the very idea that "measurements" are always generative of their outcomes. But just as I can't reconstruct what you said, I can't seem to reconstruct what I said either! Feel free to jump in if you've got a pithy way to say it.

It would be great if any of this clarifies the Hardy paradox for you. Might it finally be time for another van Enk – Fuchs paper?

Steven's Reply

> [CAF wrote:] *You characterized how you thought we quantum Bayesians were saying something different than Bohr's position. Could you repeat that?*

I thought that Bayesians think they get out of paradoxes related to Bell inequalities etc. by the observation that

> 1) Alice's measurement changes something about *her* description of Bob's state, but nothing for Bob's description

True, that leaves nothing nonlocal but it avoids the "real" paradox which occurs when Alice and Bob get together, compare their measurement results and wonder what the heck they would have found had they chosen different measurements. And

> 2) Both Bohr and Bayesians say: but quantum mechanics gives you all the probabilities you need for actually performed measurements, and you should not even ask the question what would have happened if something else had been measured.

So, again, what I like about yesterday's discussion is that now you *do* say something very clear about what would have happened if you had measured something else: If you assign ρ to some system, and measure E_a, with result a_0, what would you have found had you measured F_b instead? Answer: You ignore the result a_0 and assign probabilities $p(b) = \mathrm{tr}(\rho F_b)$.

So, I guess that disproves my impression about what Bayesians say, but I still would guess that Bohr, if he were still alive [yep, another one!] would still insist on not giving an answer to counterfactual questions.

> [CAF wrote:] *I also liked the way you said something like we always include the observer in the counterfactual. But I can't quite reconstruct what you really said.*

Darn, I tried many different ways, but I can't say clearly what I meant! I'll think about it more.

> [CAF wrote:] *Of myself, I also liked the little characterization I gave of how barring counterfactuals in the way we do is equivalent to the very idea that "measurements" are always generative of their outcomes. But just as I can't reconstruct what you said, I can't seem to reconstruct what I said either! Feel free to jump in if you've got a pithy way to say it.*

I agree you said that, and I think I agree with the content. Isn't it this: Suppose a measurement does reveal some preexisting property of a system. Then my counterfactual statements about that system would be affected by that knowledge. In particular, had I done a very similar measurement on the system, then I would have found a very similar measurement result. And conversely, if a measurement generates the outcome, then if I had done a slightly different measurement, the outcome could have been very different, since it is as if you're doing a new measurement which will generate a new outcome from scratch. Anyway, obviously that's not the way you said it yesterday but it's how I understand it now.

> [CAF wrote:] *It would be great if any of this clarifies the Hardy paradox for you.*

I still think it does! The paradox arises there only if you consider 2 counterfactuals: if both Alice and Bob had done a different measurement then they would have found

1. something that will never occur in an experiment, if you use the "standard" rule for counterfactuals
2. exactly what will occur in an experiment if you use the new great rule for counterfactuals.

And again, the only change I need to get rid of the paradox is change how I answer a counterfactual question!

> [CAF wrote:] *Might it finally be time for another van Enk – Fuchs paper?*

Yes! But only if it does not fall in the same category as "Entanglement is super ... but not superluminal!"

16-02-06 *Back from the Silence* (to H. C. von Baeyer)

Thanks for the notes of 2/1 and 2/6. I'm sorry to take so long to write back to you: My stepdad became quite ill in late January and finally passed away February 3. Between trips to Texas and all else, I got quite behind.

First off, I'm glad to hear that your AAPT talk went well! I wish I could have seen it. And I like the idea of this B3 diagram—it's good to have a trademark; it focuses people's attention.

Second off, thanks for showing me your first installment in the translation project! I read it on the plane back from Texas the other day; so I should have just written you then, but I guess I was too exhausted. I like your system for the endnotes. One thing: I detected a couple of typos. How should we handle things like this in the future? Would you like me to write a short note indicating them, or would you like me to simply insert the corrections directly into your Word file and send it back? I could flag them by writing them in boldface or red or something.

Finally, let me apologize to you for a bad oversight on my part. Marlan Scully and I have organized a little meeting at Princeton next Friday and Saturday in honor of John Wheeler. In my invitations, I only approached old (quantum-oriented) students of John and Princeton locals for giving talks. But I should have thought of you too, at least for participation! It's probably too late for you now, but if you're interested, you're certainly welcome to come. I'll attach the meeting program so you can get a feel for what it'll be like. John himself, too, will make an appearance — either for the first two or three hours Friday morning, or for the dinner Friday evening, we don't know which yet. If I'm not mistaken, he'll soon turn 95. John is very frail now, and almost completely deaf, but Ken Ford has said that he will be able to understand that the meeting is in honor of him, and he will recognize some faces. If you're interested, let me know and I'll send you all the logistical information.

Within my "Pauli Project" folder on my computer, I have now started a subfolder titled "von Baeyer" to hold your translations and the like. I can imagine my hard drive, if it could talk, saying, "Now that's some comfortable real estate in my landscape."

Hans's Preply, "AAPT Conference Talk," 01-02-06

> Here is an unanticipated fallout from my Anchorage lecture. I am heartened to see the Bayesian view taking hold in Europe and Australia (is New Zealand part of that continent?), and also in industry and the elementary physics lab.
>
> The "B3 triad" is a triangle with the words psi, information, and probability at its vertices, and the names Bayes, Born, and Bohr, respectively, along their opposite sides.

My talk was well received by many, including my old friend Stuewer, who mentioned you.

Hans's Preply, "First Installment," 06-02-06

Here is the first instalment of a translation. You can regard it as a finger exercise of the kind piano students play. I don't know yet what will develop.

Endnotes are labeled E, A, and T, for editor, author, and translator, respectively. Letters are numbered in square brackets [. . .]. References to the book's extensive bibliography are in curly brackets {...}.

[1286] Pauli to Fierz.

Zurich, 3 October 1951

Dear Mr. Fierz!

I have now read your essay[86] and thank you also for the written addendum. Of course the psychology of the unitary versus dualist theories of electricity were very interesting to me, representing, as it does, a special case of the psychology of the development of scientific theories (since the empirical facts to be explained were the same for both theories.) Furthermore I was particularly interested in your written addendum about trinitarian and quaternarian scholars (the latter are sometimes non-thinkers), where you count Spinoza and Leibniz among the former, Voltaire and Kant among the latter. (Your positive attitude toward Voltaire is very congenial to me.)

I came upon Kepler as trinitarian, and upon *Fludd* as quaternarian – and felt inside myself, with respect to their polemics, the resonance of an inner conflict. I have certain traits from both, but now, in the second half of my life, I ought to change over to the quaternarian position. The problem is that the positive values of the trinitarian position must not be sacrificed in the process. (Mr. Panofsky in Princeton, who loves wordplay and bad puns, once wrote to me so amusingly: "Today you can no longer pour out the Kepler with the Fluctibus[87]!")[88]

By the way, I would like to remark that once upon a time (in Hamburg) my route to the exclusion principle was concerned with the difficult transition from 3 to 4: namely with the necessity to ascribe to the electron instead of *three* translations another *fourth* degree of freedom (which soon thereafter was explained as "spin".) To wrestle my way to the realization that, contrary to the naive "view", the fourth quantum number is also a property of one and the same electron (just like the known *three* quantum numbers now called n, l, and m) — this was really the *principal effort.* (I had to fight so hard against the then current theories that had ascribed the fourth quantum number to the *rest of the atom* or core).

When I began to work on Kepler's trinitarian point of view, I did not yet know anything about Fludd's polemic, and even less that the quaternity hat

[86]E1. Fierz had sent Pauli his essay *The development of the science of electricity as an example of physical theory making*, which had been published as a brochure by the University of Basel {1951b}.

[87]T1. Latin for Flood.

[88]E2. Pauli's remark in letter [1278] to Panofsky.

such an essential symbolic meaning for Fludd (the relevant longer passage is repeated and translated in my essay) — I only knew that for Kepler the Pythagorean tetraktys, which he knew well, had *no* symbolic meaning.[89] In this way, by following a psychological line, I happened *again* upon the problem of the transition from 3 to 4. In both cases Mr. C. G. Jung had certainly not suggested this to me, nor did I have the intention from the start to wrestle with the problem 3 and 4, of all things.

Therefore I am pretty sure that *objectively* an important psychological problem, and perhaps one of natural philosophy, is related to these numbers.

In general I am completely in agreement with everything you said. The question is, however, whether one should *add* several things — perhaps on another occasion when you want to publish this matter. (I have the feeling that in that case the work should be longer.)

For example, one should note and explain that Dirac's hole theory is a not entirely successful new attempt to interpret the relativistic quantum mechanics of the electron in the sense of a unitarian theory of electricity.

Then on to the problem of opposites: in physics there are *compensatory pairs of opposites* (represented by positive and negative quantities like the two electrical charges) and *complementary pairs of opposites* (represented by non-commuting quantities like p and q).[90] This is a very important distinction, because it my personal conviction that it has a counterpart in the realm of psychology: A compensatory pair of opposites seems to me – as it does to you – to be good and evil, a complementary pair, on the other hand, conscious – unconscious[91] (in Chinese the corresponding pair is Yang and Yin.) In my opinion analytical psychology is hitherto suffering severely from the absence of this distinction (which is related to the insufficient mathematical-scientific training of its representatives.) (See below.) I would be very glad if, in your essay, you insisted pedantically on this conceptual differentiation.

This matter brings me to another subject that is also treated in your essay: The fundamental difficulty of the "field" concept. On page 14 you very beautifully describe the *assumption* of the reality of the field: "But Faraday thought that the field had to be there, whether we prove it or not, just as we believe that the moon is there, whether we look at it or not." One might add: "just as we assume that the motion of the moon is the same whether we look at it or not" (which goes far beyond its mere existence.)[92] This is of course the cloven hoof itself, both with respect to physics (*quantum* field theory) and to the psychological analogy.

I have a slightly different opinion from you in that I do not ascribe the same significance to the impossibility of empty space in quantum field theory as you do. In my opinion the cloven hoof remains *exactly the same* in quan-

[89]E3. In his later letters [1383] and writings Pauli often worked on the special role of the tetraktys or quaternity which the Pythagoreans had already emphasized. This interest had been awakened by Jung, who pointed in his 1937 *Terry Lectures on Psychology and Religion* {1940, chapter 2} to the psychological meaning of the number four, or quaternity, which appeared also in Pauli's dreams.

[90]E4. Cf. the preceding commentary to letter [1286].

[91]T2. I use the word "unconscious" rather than "subconscious" to preserve the German distinction between "Unbewusstsein" and "Unterbewusstsein".

[92]A1. I might call this "the classicistic idea of objective reality in the universe."

tum field theory as in the unquantised classical theory: A field without the test bodies required for its measurement should not even be *thinkable* according to mathematics and logic. Actually, however, in today's theory things stand as follows: if you put $e = 0$, and thus describe light fields, then these are, regardless of whether they are classical fields or photons, mathematically possible *without* charges; if one puts $e \neq 0$ and describes electrons, positrons, or photons (Schwinger), then these are mathematically possible *without* the heavy masses in the measurement devices that are necessary in order to measure fields or charge densities in small spaces (of order $h/2\pi mc$, $m =$ electron mass). As for the true complementarity relation between the possibility of regarding *the same* physical objects as fields or test bodies (measuring devices) (the former when *other* objects function as measuring devices), this choice is *not* expressed in today's formalism. (N.B. What good is it to me that *no* empty space is possible?)

Now to switch to the psychological analogy of the physical field concept, it seems to me to reside in the concept of the *unconscious.* The latter cropped up, and was applied practically, approximately simultaneously with the former. The "unconscious" also "assumes" a reality — in particular, just as in the physical field, an *invisible reality* (in the sense of everyday life) *which mediates a connection between spatially (and perhaps also temporally) distant events.* For this reason it seems to me that there is here a more profound similarity than a mere analogy. Consciousness corresponds to the test bodies. And this conceptual correspondence between field and unconscious extends further to the fact that both exhibit the corresponding cloven hoof. The concept of the unconscious was initially also used in analytical psychology as though one could observe it without changing it. And although its representatives occasionally admit the opposite, many of their assertions about the unconscious are still much too close to what I called above "the classicistic idea of objective reality in the universe." This seems to me to be especially the case when C. G. Jung tries to find law-like assertions about the sequence of "archetypes" (he calls this the "dynamics of the self")[93] — which are supposed to be valid regardless of the intervention of human consciousness. These statements remind me in their type too much of Maxwell's classical equations. An analogy to the quantum mechanical-complementary description does not exist yet, which seems to correspond to the absence of a satisfactory quantum field theory.

This last paragraph is my personal opinion and probably not yet sufficiently demonstrable to be publishable. But the correspondences between psychological and quantum mechanical concepts in general (I mention similarity, acausality, experimental set-up, correspondence, pairs of opposites, and holism – these concepts are used in both disciplines, although they were formulated independently of each other) — this correspondence is too striking not to believe in a more profound meaning of their *simultaneous* appearance in the history of ideas.

And that is exactly what your essay wanted to show, using different ex-

[93]E5. In the chapter XIV of his new book *Aion*, which Pauli had mentioned in his preceding letter [1285] to M.-L. von Franz, Jung dealt with the *Structure and Dynamics of the Self.*

amples from different times.

I will be very interested in hearing your opinion of my ideas!

Once more, many thanks for last Sunday at noon, and greetings to you and your wife.[94]

Editorial comment on letter [1286] from Pauli to Fierz, 3 October 1951

The significance for the history of ideas of the problems of opposites, such as light-dark, warm-cold, one-many [1209, 1212], male-female [1391], good-evil [1291, 1364, 1373], idealism-materialism [1395], physical-psychic [1291, attachment], matter-form [1363, 1391], chance and necessity [1497], causal and acausal [1388], as well as their central role in Jung's psychology, henceforth begin to occupy Pauli more and more.[95] Jung considered the *Self*, which included the conscious as well as the unconscious psyche, as the center of the spirit (*das seelische Zentrum*). It was made manifest by a unification of opposites (*coniunctio*) which "joins the temporal with the eternal and the specific with the most general." [96]

The parallel appearance of such pairs of opposites in modern physics was for Pauli another hint of the profound relationship which he assumed to exist between physics and psychology [1179, 1180]. As Pauli said in his radio lecture on the occasion of the centenary celebration of Columbia University in 1953,[97] the biggest impression upon him was made precisely by the fact that "in physics there are real pairs of opposites, such as particle v. wave, location v. momentum, energy v. time, whose contradiction can only be resolved in a symmetrical way." The special property of these novel pairs of opposites was that "one partner is never eliminated in favor of the other, but both are taken over into a new kind of physical law, which expresses the complementary character of the pair in an appropriate way."[98]

His interest as physicist was directed primarily toward the psychology of the creation of scientific concepts.[99] He paid particular attention to the development of the concept of matter, which was created in analogy with the doctrine of *privatio boni* in Platonism, which Pauli had aptly called the *Hole Theory of Evil* [1029,1278], after Dirac's hole theory. Since Evil is defined here by the absence of the Good, matter, which is governed by a dark principle, is supposed to be explained by a deficiency of the spiritual [1283].[100] A more positive expression was given to the concept of matter by Aristotle and his successors by calling matter, or *hyle*, something which actually existed because

[94] E6. Pauli had evidently been invited to lunch by Fierz.

[95] E1. The problem of pairs of opposites, and their resolution (by unification or conjunction), for which Pauli mentioned quantum mechanics as physical paradigm, also plays a central role in Pauli's later letters to Jung. Cf., for example, Pauli's letter to Jung dated 27 February 1953 [1526].

[96] E2. Jung, *Alchemie und Psychologie*, 1972, p. 34.

[97] T1. Actually, the year was 1954, and the celebration was the bicentennial.

[98] E3. Cf. Pauli {1961/84, p. 8}.

[99] E4. Cf. Pauli's *Bemerkungen zur Psychologie der naturwissenschaftlichen Begriffsbildung* in the biographical collection PLC Bi 67 in his literary estate. Cf. also von Meyenn {1994, pp. 18–23}.

[100] T2. In this 1951 letter to Panofsky, Pauli writes: "The Christian theology of the '*summum bonum*' and the '*privatio boni*' is both absurd and historically unique. To call the entire *material* world 'evil' is consistent; but to define the material as an 'absence of the spiritual' would be absurd."

it was possible, and thus accessible to conceptual thinking.[101]

According to Pauli's opinion, the negative assessment of everything material, by its commingling with the ethical pair of opposites good-evil[102], thus entered into the European history of ideas, and through Fludd and the Platonism of the Renaissance permeates all Western thought.[103]

However, compared to the doctrine of the *privatio boni*, Pauli was more impressed by the more symmetrical 'conceptions of the whole' of the gnostics [1270] and by the ideas of Plotinus about the 'problem of the one v. the many' [1236, 1278]. These ideas anticipated certain aspects of Bohr's notion of complementarity.

In the letter to Fierz below [1286] Pauli seeks to clarify even further the difference between the two conceptions, by differentiating between *compensatory* (or polar) and *complementary* pairs of opposites.[104] As paradigms of complementary opposites he considers of course the non-commuting quantities p and q of quantum mechanics, which have already been mentioned. Compensatory opposites, on the other hand, are quantities that cancel each other when they meet. Pauli points out good-evil and conscious-unconscious as their psychological counterparts.

But what Pauli was striving for in these thoughts about pairs of opposites was the far more significant effort at a *comprehensive coniunctio (umfassende Coniunctio)*, as he put it in a commentary on a dream he had had on 20 December 1952 on the occasion of his visit to Bombay.[105] "I want to try," he explained there, "to say somewhat more clearly what I really wanted to say in the last part of my Kepler essay[106]: A firm grip on the *tail*, i.e. physics, provides me with unexpected means which may perhaps be useful in the larger enterprise, *to grasp the head*. For it seems to me that the *complementarity in physics*, with its solution of *wave-particle duality*, is a kind of *model or paradigm for this other, more comprehensive coniunctio*. The smaller *coniunctio* in terms of physics, the quantum or wave mechanics constructed by physicists, shows, quite without the intent of its inventors, certain characteristics which might turn out to be useful in the resolution of other pairs of opposites."

To this, Pauli further added the following epistemological explanations: "By admitting events and making use of possibilities which can no longer be considered pre-determined and existing independently of the observer, the quantum mechanical manner of explaining nature comes into conflict with the old ontology, which was able to state simply: *Physics is the description of reality* (words of *Einstein*), in contrast to, say, *the description of that which one merely imagines* (words of *Einstein*). *Being* and *Non-being* are not unique characterizations of properties which can only be checked by statistical series of experiments with different set-ups, which may, in certain cases, exclude

[101]E5. The Aristotelian concept of *hyle* was later translated into the Latin *materia*. Cf. also Happ {1971}.

[102]E6. Cf. remarks in the letters [1354, 1357, 1362–1364, 1366, 1373, 1376, 1391, and 1396].

[103]E7. Cf. the attachment to letter [1328]. Pauli also presented his ideas on the development of the concept of matter in his "*sermon*" to the *International Conference of Scholars* in Mainz, March 1955. Cf. Pauli {1961/84}.

[104]E8. Pauli had already mentioned this subject in 1948 in his *Background Physics*. Cf. Meier {1992, p. 182}.

[105]E9. Cf. also the comment on Letter [1489].

[106]E10. Pauli {1952, p. 155}.

each other."

Hans's Reply, 16-02-06

Thanks for the nice email and your kind invitation. Your attachment is ominously labeled "newsletter blurb... doc.suspect" and my computer haughtily rejects it. But no matter — I cannot get away on this short notice. I wish you and your friends, including John Wheeler, a wonderful weekend. I happened to sit next to Ken Ford at the Anchorage banquet.

The comment and Pauli letter are background for Fierz's reply, which is so important that it comes in multiple drafts – my next instalment. I am grateful for all corrections, and would prefer a little email note about them, so I can make sure we are on the same page. I am now in correspondence with Atmansbacher, and will probably visit him in the summer. Furthermore, Roger Stuewer told me that one of his students had written a good thesis about Pauli's mysticism (my phrase), but has not emailed about it yet. I must remind him.

Hans's Reply, "Trivium," 08-03-06

I have been sick in bed and unable to translate, but things are better now. I am reading a good thesis by John Gustafson, Roger Stuewer's student, claiming that contrary to conventional scholarship, Pauli became "Jungian" well before he met Jung. Here is a bit I thought you might enjoy:

> There would have been many good reasons for Pauli's father to leave Prague, to seek his fortune in nearby Vienna, to leave his family religion, and to embrace the Roman Catholic faith. The Pascheles home at No. 7 on Prague's Old Town Square (Altstädter Ring), had been a Paulan convent earlier, which may have been the reason he changed the family name to Pauli.

Did you learn anything, or teach anything, at the Wheelerfest?

16-02-06 *Synchronicity* (to H. C. von Baeyer)

von Baeyerism 14: *Cheers from sunny Williamsburg, where the total number of snowflakes during the recent storm was 17.*

Interesting number, since it turns out that throughout my yard I fairly evenly measured 17 inches. First Fierz and Pauli, and now the two of us!

16-02-06 *Many Worlds Does Not Explain Much* (to B. C. van Fraassen)

Thanks for sending your notes. I enjoyed reading them (twice actually), and I think I get your point. I don't know that I have much to add at the moment by way of endorsement or, alternatively, criticism, but your ideas are tumbling around in my head—maybe something will eventually emerge.

Let me only point out a couple of connections that you evoked in me. First, I liked the way you put this:

> In retort it will perhaps be suspected that I yearn for a classical understanding of the world, if I'm not willing to count the 'many worlds' answer as explanatory. Quite the contrary, I would say: as I see it, quantum theory does leave unexplained why the actual outcome of a measurement is this rather than that one among the possible outcomes. Yearning for a classical understanding means yearning for an explanation of all that this theory leaves – and legitimately leaves – unexplained.

Its tone reminded me mildly of something David Mermin said in his lecture notes for his quantum computing course:

> There are nevertheless some who believe that all the amplitudes α_x have acquired the status of objective physical quantities, inaccessible though those quantities may be. Such people then wonder how that vast number of high-precision calculations (10^{30} different amplitudes if you have 100 Qbits) could all have been physically implemented. Those who ask such questions like to provide sensational but fundamentally silly answers involving vast numbers of parallel universes, invoking a point of view known as the many worlds interpretation of quantum mechanics. My own opinion is that, imaginative as this vision may appear, it is symptomatic of a lack of a much more subtle kind of imagination, which can grasp the exquisite distinction between quantum states and objective physical properties that quantum physics has forced upon us.

[Actually the source of this quote is `quant-ph/0207118`.]

The other thing you evoked in me was a memory of an article by Markus Fierz that I reprinted in my *Notes on a Paulian Idea* with the title: "Does a physical theory comprehend an 'objective, real, single process'?" I read it again, between my two readings of your note. I think you too will enjoy the piece, and particularly near the end of it, see some similarity to what you have written in your paragraph above. Tell me if I am on the money? For your convenience, I'll paste in the whole article below; I hope the remnants of LaTeX code in it won't bother you too much.

Finally let me remark on these words of yours:

> A beautiful program for the interpretation of quantum mechanics has lately received new life as new results, new techniques, and other approaches have been mined to aid in its elaboration. The excitement in such work is its own reward.

My own feeling is that all their purported progress is illusory. It is a lot of technical-looking huffing and puffing (which builds a shield of seeming protection), but in the end doesn't amount to much. At a crucial point they make the identification "weight = probability" for no other reason than that they know that's what they have to do to get the answer they want. Here's the way my friend Howard Barnum put it recently:

> The basic idea is that the Wallace argument is just some version of a Laplace's symmetry principle argument in another guise ... and that I think all these arguments have things backwards: our belief that there is a "physical symmetry" just about IS the invariance of our preferences under the relevant transformation ...

Basically, I say beware of giving the New Everettians too much credit!

16-02-06 *Wheelerfest Program, User-Friendly Version* (to the Wheelerfest participants)

Dear Wheelerfesters,

Many of you have had trouble opening the MS Word document I sent out previously with the program for our upcoming meeting. Thus, I have cut and paste the information directly into the present email. The formatting is not quite as nice as it was before, but at least you can (without doubt) read the information this way.

Please note that there have been some changes to a couple of titles, and the final session has been shortened by one talk.

Banquet will be held in the evening of Feb. 24, 2006 at the Conference Center at 6:00 pm.

17-02-06 *Free Will Again* (to S. Kochen)

Now that I've got a few bureaucratic burdens off me, I'm hoping to finally get a chance to skim this free-will manuscript you gave me over the weekend. Free will at last! Maybe we can talk about this a bit Monday.

I'm not sure you got this impression from me when we were talking a few weeks back, but I think this theorem may be deeply important for the Bayesian tack on quantum probability that Caves, Schack and I want to develop. And your partial Boolean algebra view may not be so unrelated to our trains of thought either. The paragraphs below taken from my pseudo-paper `http://www.arxiv.org/abs/quant-ph/0204146`, I think, give some decent indication of how seriously I take this "measurement context dependence" view. Also, I'll excerpt from a recent email to Kirk McDonald on this subject.

Let me give you a couple of other pointers to our work. I think these are the best things we've put together yet on our quantum foundational ideas:

- "Quantum Mechanics as Quantum Information (and only a little more)"
  `http://www.arxiv.org/abs/quant-ph/0205039`
- "Unknown Quantum States and Operations, a Bayesian View"
  `http://www.arxiv.org/abs/quant-ph/0404156`

See you Monday. Quotes below; maybe this will give us a little more to talk about.

17-02-06 *Incompletely Knowable vs 'Truth in the Making'* (to W. G. Demopoulos)

Now I have to apologize to you again for a long silence: Soon after the new year my stepfather became very ill, finally passing away a couple of weeks ago. It has been very tough on the family, and I am only now catching myself back up.

However, don't think that throughout all that, your ideas have not been on my mind. Indeed I enjoyed another re-reading of your 'incompletely knowable domain' paper—it lifted me on my sad flight back from Texas—and I tried to think hard about whether there really is a substantial distinction between us or not.

Let me try to consider a situation and 1) try to imagine what you would say of it (but probably in my idiosyncratic language), followed by 2) what I think I would say of it ... and then see if there is a substantial distinction.

Start with a finite dimensional Hilbert space, say of dimension 3, and imagine it indicative of some real physical system within an observer's concern. From that Hilbert space, let us form all possible sets of three mutually orthogonal one-dimensional projection operators. That is, let us consider all possible sets of the form $\{P_1, P_2, P_3\}$.

What is it that you would say of those sets? If I understand you correctly, it is this. Each such set $\{P_1, P_2, P_3\}$ corresponds to a set of mutually exclusive properties that the system can possess. At any given time, one of those projectors will have a truth value 1 and the other two will have values 0. Now consider a potentially different such set $\{Q_1, Q_2, Q_3\}$; again, at any given time, one of those projectors will have a truth value 1 and the other two will values 0. What is interesting in your conception, if I understand it, is that even if two elements happen to be identified between those two sets—for instance, if $P_1 = Q_3$—there is *no requirement* that P_1 and Q_3 need have the same truth value; P_1 might have the truth value 0, whereas Q_3 might have the truth value 1. Another way to say this is that the truth-value assignments depend upon the whole set and not simply the individual projection operators. For you, all the identification $P_1 = Q_3$ amounts to is that the *probability* for the truth value of P_1 within the set $\{P_1, P_2, P_3\}$ is the *same* as the *probability* for the truth value of Q_3 within the set $\{Q_1, Q_2, Q_3\}$. (If you were a Bayesian about probabilities—though I don't think you are—you would say, "Well P_1 has whatever truth value it does, and Q_3 has whatever truth value it does (each within their appropriate set of mutually exclusive triples), but my degree of belief about the truth value of P_1 is the same as my degree of belief about the truth value of Q_3. That is the rule I am going to live by.") Then it follows from Gleason's theorem that there exist no probability assignments for the complete (i.e., continuously infinite) set of triples that are not of the quantum mechanical form. In particular, one can never sharpen one's knowledge to a delta function assignment for *each* triple. This is how you cash out the idea of an 'incompletely knowable domain.'

That is a novel idea, and if I understand it correctly, I like it.

However, now let me contrast my characterization of you with what I think has been my working conception. I prefer not to think of the triples $\{P_1, P_2, P_3\}$ as sets of mutually exclusive *properties* inherent within the system all by itself, but rather *actions* that can be taken upon the system by an external *agent*. Each *set* of such projectors corresponds to a distinct action; what the individual elements within each set represent are the (generally unpredictable) *consequences* of that action. What are the consequences in operational terms? Distinct sensations within the agent. The reason I insist on calling them consequences, rather than "sensations" full stop, is because I want to make it clear that the domain of what we are talking about is sensations that come about through the action of an agent *upon* the external world.

The essential idea of the sexual interpretation of quantum mechanics is that no element of a set $\{P_1, P_2, P_3\}$ has a truth value before the action of the agent. Rather the truth value—if you want to call it that (maybe it is not the best terminology)—is generated (or given birth to) in the process. At the point, one of the P_i stands in autonomous existence (within the agent), whereas the other two fall.

I hope I have characterized both of us accurately!

Here is the question that has been troubling me. Is there any real distinction (one that makes an pragmatic difference) between our views? You say the truth value is there and revealed by the measurement, and I say it's made by the measurement and wasn't there beforehand. So what?

If there is a pragmatic distinction, Steven van Enk and I through discussions this week have come to believe that it may show up most clearly in how you and I would treat counterfactuals with regard to measurement. Let us take a situation where an agent ascribes a quantum state ρ to the system; contemplating the measurement $\{P_1, P_2, P_3\}$, we know that he will ascribe probabilities according to the Born rule $\mathrm{tr}(\rho P_i)$ for the various outcomes. Suppose he now performs that measurement and actually gets value P_2.

What does getting that outcome teach him about the quantum system? I think you would say it reveals which of the three mutually exclusive properties the system actually had. On the other hand, I would say it teaches him nothing about the system per se; the outcome P_2 is just the consequence of his action. What is the implication of this on counterfactuals? Here's at least one.

Suppose after you get your outcome, you contemplate magically having performed a distinct measurement $\{Q_1, Q_2, Q_3\}$ instead. I think you're careful to point out in your paper that the knowledge of P_2 carries no implication for what you would have found with this other imaginary measurement. But what happens if you conceptually transform this measurement $\{Q_1, Q_2, Q_3\}$ to one closer and closer to the original, i.e., to $\{P_1, P_2, P_3\}$? In the *limit* when the two are identical again, I think you would say that knowledge of the outcome P_2 in the original case implies that P_2 will also be the outcome in the limiting counterfactual case. But what would I say? From my conception, there is no reason at all to believe that the limiting counterfactual case will give rise to the same outcome P_2. The best one can do, either in the original case or the counterfactual case, is to say that an outcome i will arise with probability $\mathrm{tr}(\rho P_i)$. In fact, a counterfactual analysis with this kind of result may be the very meaning of the idea that quantum measurements are generative of their outcomes.

At least that is a potential distinction Steven and I see at the moment. We are toying with the idea that this may have some implications on the analysis of Hardy-type paradoxes, etc., where counterfactuals abound, and if anything comes of that, we'll let you know. In the meantime, would you say that we have given you a fair characterization?

17-02-06 *Dutch Book Presentation!* (to R. Schack)

In that talk, I'm going to try to say some of those things I told Kirk McDonald when I got pissed off. I think our project when we get together in Sweden ought to be to try to make some of this business rigorous: What is this extra "coherence" that quantum mechanics forces upon us significatory of? The more I think about it, that has to be the content of the Born rule—that our probability assignments for seemingly distinct measurements are linearly related.

Before that of course, we have to finish the certainty paper …

Let me hope I survive this week and next. (Monday I give the Princeton applied mathematics colloquium; Friday and Saturday are the Wheelerfest; and in the middle there is certainty, certainty, certainty.)

18-02-06 *Two Questions* (to W. G. Demopoulos)

Here are two questions that came up in the discussions with Steven. I probably won't have a chance to think about your answers too deeply until the week after next (I've got to give the Applied Maths Colloquium at Princeton and then run the Wheelerfest there Thursday and Friday ... and I've got a million things to do for both). But let me throw the questions on the table anyway.

1) Almost by definition, what you are proposing is a contextual hidden variable theory. But what is its status with regard to locality? At different times (while driving, taking a shower, etc.), I've been able to convince myself that a constraint of *locality* can be placed upon the truth values, but then I get confused. What can you say on the matter?

2) Take two triads of one dimensional projectors, $\{P_1, P_2, P_3\}$ and $\{Q_1, Q_2, Q_3\}$, as in my last note to you. And as before, suppose $P_1 = Q_3$. However this time, let us be careful to assume that P_1 and Q_3 differ in truth value in their respective sets. What happens now when we consider nonelementary propositions of the form $\{P_1, \neg P_1\}$ and $\{\neg Q_3, Q_3\}$ where by $\neg P_1$ I mean the orthocomplement of P_1, etc. Presumably you still want to view these sets as representative of mutually exclusive properties inherent within the quantum system. However, by construction the sets are identical: $\{P_1, \neg P_1\} = \{\neg Q_3, Q_3\}$. How does one decide on a truth value assignment here, given the previous truth value assignments for $\{P_1, P_2, P_3\}$ and $\{Q_1, Q_2, Q_3\}$?

21-02-06 *London Overnighter* (to R. Schack)

I had a pathetic long talk with John Conway at Princeton about Dutch book yesterday (about three hours). He buys none of it. Can you believe this is the man who wrote the Atlas of Finite Groups (and actually has all that in his head ... as far as I can tell and as is rumored there). Yet, a simple argument like Dutch book can't pierce his preconceptions.

John Nash was also at my talk: I think he never blinked once, and he looked a million miles away. I couldn't help but remember the passage in *A Beautiful Mind* where he says that it was thinking about quantum foundations that pushed him over the edge.

21-02-06 *Poetry* (to S. Kochen & J. H. Conway)

I enjoyed the sparring yesterday, and I think just before we parted from the lounge Si had a good summary of a hefty aspect of what I'm shooting for. So, thanks for the understanding, if not the agreement. (Some of that stuff, Si, in case you haven't read it, is in the last note I sent you "Free Will Again"—hopefully I'm a little clearer there than I was in person.)

While it's on my mind, let me come back to the part of the discussion where we had three different ways of talking about "measurement", going from left to right written on the board. Recall John changed the word "action" to "interaction." At about that time, I said something that made you both cringe.

With your indulgence, I want to say it again using the words I used at my Caltech summer school lectures last summer. [See 17-06-04 note "Preamble" to H. Mabuchi.] I'm sure it'll still make you cringe, but maybe you'll enjoy the pentameter of this version. Like always when I talk, it emphasizes the distinction between ontology ("the quantum world")—i.e., the exciting part—and epistemology ("*part* of quantum theory")—i.e., the dull but necessary part. Luckily, as I see it, in an oblique way, the epistemology is teaching us something about the ontology. Maybe that's enough to leave us a little room for further discussion.

21-02-06 *Heaping the Poetry* (to J. H. Conway)

Conwayism 1: *Well, it ended before it began. Yeah, yeah. JHC*

It's a general problem; that's why I keep at it year after year.

I won't have the time to reply to you in depth until I get all the planning for this Wheelerfest done, but don't you worry, eventually I'll be back in full force: I, of course, think I have a reply to your last note that will run you in a circle. But I want to spend some time writing it delicately.

In the meantime, let me give you a little something related to your present note that I happen to have in my archives. (Menand's book was my very favorite of 2001, and I've recommended it to a lot of people.) You should see the relevance to our discussion very quickly into the quote. For me, a probability is like a beak: That is all I am saying. To that extent, probabilities are real in nature, but only to that extent. Free decisions—as you call them—may be part of the fundamental furniture of nature (I'm willing to bet that)—that is, they are of a more respectable status than beaks—but it is going to be hard to convince me that probabilities are.

Still, I am a somewhat logical being, and as such I will give your arguments a hard go.

As I say, I'll be back eventually (sooner, rather than later).

From L. Menand, *The Metaphysical Club*, (HarperCollins, London, 2001):

> The world is filled with unique things. In order to deal with the world, though, we have to make generalizations. On what should we base our generalizations? One answer, and it seems the obvious answer, is that we should base them on the characteristics things have in common. No individual horse is completely identical to any other horse; no poem is identical to any other poem. But all things we call horses, and all things we call poems, share certain properties, and if we make those properties the basis for generalizations, we have one way of "doing things" with horses or poems—of distinguishing a horse from a zebra, for example, or of judging whether a particular poem is a good poem or a bad poem. These common properties can be visible features or they can be invisible qualities; in either case, we create an idea of a "horse" or a "poem," or of "horseness" or "poetry," by retaining the characteristics found in all horses or poems and ignoring characteristics that make one horse or poem different from another. We even out, or bracket, the variations among individuals for the sake of constructing a general type.
>
> Darwin's fundamental insight as a biologist was that among groups of sexually reproducing organisms, the variations are much more important than the similarities. "Natural selection," his name for the mechanism of evolutionary development that he codiscovered with Alfred Russel Wallace, is the process by which individual characteristics that are more favorable to reproductive success are "chosen," because they are passed on from one generation to the next, over characteristics that are less favorable. Darwin regretted that the word "selection" suggested an intention: natural selection is a blind process, because the conditions to which the organism must adapt in order to survive are never the same. In periods of drought, when seeds are hard to find, finches that happen to have long narrow beaks, good for foraging, will be favored over finches with broad powerful beaks: more of their offspring will survive and reproduce. In periods of abundance, when seeds are large and their shells are hard, the broad-beaked finches will hold the adaptive advantage. "Finchness" is a variable, not a constant.
>
> Darwin thought that variations do not arise because organisms need them (which is essentially what Lamarck had argued). He thought that variations occur by chance, and that chance determines their adaptive utility. In all seasons it happens that some finches

are born with marginally longer and narrower beaks than others, just as children of the same parents are not all exactly the same height. In certain environmental conditions, a narrower beak may have positive or negative survival value, but in other conditions—for example, when seeds are plentiful and finches are few—it may make no difference. The "selection" of favorable characteristics is therefore neither designed nor progressive. No intelligence, divine or otherwise, determines in advance the relative value of individual variations, and there is no ideal type of "finch," or essence of "finchness," toward which adaptive changes are leading.

Natural selection is a law that explains *why* changes occur in nature—because, as Darwin and Wallace both realized after reading, independently, Thomas Malthus's *Essay on the Principle of Population* (1798), if all members of a group of sexually reproducing organisms were equally well adapted, the population of the group would quickly outgrow the resources available to sustain it. Since some members of the group must die, the individuals whose slight differences give them an adaptive edge are more likely to survive. Evolution is simply the incidental by-product of material struggle, not its goal. Organisms don't struggle because they must evolve; they evolve because they must struggle. Natural selection also explains *how* changes occur in nature—by the relative reproductive success of the marginally better adapted. But natural selection does not dictate *what* those changes shall be. It is a process without mind.

A way of thinking that regards individual differences as inessential departures from a general type is therefore not well suited for dealing with the natural world. A general type is fixed, determinate, and uniform; the world Darwin described is characterized by chance, change, and difference—all the attributes general types are designed to leave out. In emphasizing the particularity of individual organisms, Darwin did not conclude that species do not exist. He only concluded that species are what they appear to be: ideas, which are provisionally useful for naming groups of interacting individuals. "I look at the term species," he wrote, "as one arbitrarily given for the sake of convenience to a set of individuals closely resembling each other .... [I]t does not essentially differ from the term variety, which is given to less distinct and more fluctuating forms. The term variety, again, in comparison with mere individual differences, is also applied arbitrarily, and for mere convenience sake." Difference goes all the way down.

21-02-06 *Rényi Distinguishability Measures* (to E. H. Lieb)

It was good meeting you yesterday. I only wish I had had a chance to extend the discussion: I've got loads of mathematical problems I'd love to get some expert input on!

Here's the reference where you can read a little about the quantum Rényi overlaps I was telling you about: `http://www.arxiv.org/abs/quant-ph/9601020`. The place to look is pages 60–64. (Also pages 16–19 explain why this kind of quantity even comes up in the classical context.) I had plenty more inequalities than that related to the quantity, but I never published them and they burned up in the Los Alamos fire. In any case, none of them were probably very interesting, as they weren't tight and the thing I really wanted was the infimum.

22-02-06 *Hollow Eyes* (to S. J. van Enk)

Oh, let me tell you a funny little story, and then I should go. During my Princeton talk, there was one of the oddest looking fellows in the audience. His eyes just looked so hollow—I don't know how to describe it. He hardly blinked the whole talk, and his face was completely expressionless. After it was all over, I kept thinking, "He looks familiar; who is that?" Well the next morning in the shower, I got a hunch and checked it out on Google: It was John Nash! After discovering that, I amused myself by remembering how he claimed that it was his thinking about quantum foundations that pushed him over the edge to schizophrenia! And I hoped I didn't push him over the edge again!

22-02-06 *Tutorial* (to J. E. Sipe & R. W. Spekkens)

T3 Current Interpretations of Quantum Mechanics
Organizer: Rob Spekkens, Perimeter Institute for Theoretical Physics,
Room 302, Baltimore Convention Center ...
Instructor: Professor John Sipe, University of Toronto

Too bad the pseudo-Bayesian view of Caves, Schack, Appleby, Fuchs and few others isn't a current interpretation of quantum mechanics ...

... ☺

P.S. Below is a nasty note I wrote a while ago. I kind of like the way I put some of the things in it (the explanatory things that is, not the nasty things)—I think they represent a little more mature way of putting things than I may have expressed to you two before. Maybe you'll enjoy it for the content. [See 30-01-06 note "Island of Misfit Toys" to K. T. McDonald.]

22-02-06 *Probably More Than I Should Send* (to J. E. Sipe)

Sipesm 2: *Anyway, I haven't yet decided what (or where in the presentation) to say something about your approach. So this is a good chance for me to ask a couple of questions.*

I hope you didn't take me too seriously; your tutorial title just looked like a good set-up to abuse you two, and I couldn't resist.

Sipesm 3: *As the saying goes, I didn't have time to write you a short letter so I wrote you a long one ... apologies for the verbiage!*

You ought to know that *I* am more guilty of this than *anyone*! I practically make a living of it.

If you can wait 'till Sunday or so, I'll write you some more delicate and specific answers to all your questions—at the moment, I'm struggling to get everything finished up for the Wheelerfest this weekend (including my own talk).

But let me send you two or three older emails in the meantime that I think fairly directly answer a couple of your questions. Rob calls the ontology being spoken of (more accurately, dreamed of) here "F-theory," where the F can be interpreted a couple of ways.

I'll come back to the issue of why I'm not very open-minded on hidden variables theories in the next note after the Wheelerfest, and I'll (probably) resculpt the partial answers that I'm sending you at the moment to be more in the shape of your present questions while I'm at it.

BTW, you and Rob have great gifts: you both write very, very clearly, even in your hastily composed emails. Your letter was a joy.

See notes below on "F-theory" and (what I don't view as) "instrumentalism." [See 21-02-06 note "Poetry" to S. Kochen & J. H. Conway, 19-06-05 note "Philosopher's Stone" to G. L. Comer, 14-11-05 note "Questions, Actions, Answers, & Consequences" to B. C. van Fraassen, and 17-02-06 note "Incompletely Knowable vs 'Truth in the Making'" to W. G. Demopoulos.]

John's Preply

Well, I'm still writing the tutorial. It's supposed to be four hours long. As you can imagine, this is not an easy task. In some ways (counting the slides that have to be made, for example!), four hours is dreadfully long. But in another way it is too short to do much justice to anything. My main goal in this is to "first, do no harm" in presenting the different views. We'll see how well I do ...

Anyway, I haven't yet decided what (or where in the presentation) to say something about your approach. So this is a good chance for me to ask a couple of questions. First, I am glad to see statements like:

> To say that 'everything is information,' as Zeilinger does, or to say 'every physical system is a quantum computer,' as you and Lloyd do, adds nothing to existing physics—you would have been better to stick with the tautology that a physical system is a physical system, full stop.

I certainly feel that statements like Zeilinger's likely convey nothing, but only propagate buzz-words and probably, by their implicit over-hyping, do science no good in the long run. I also have a lot of sympathy for statements like:

> Only *part* of quantum mechanics is about the gambler-independent world, and that part still calls for a full identification. This task of separating the wheat from the chaff is the price one must pay if one accepts the idea that quantum *states* are of essence information—luckily it is a task that stands a chance of bearing fruit (and already has born fruit).

I gather from this that you see the ultimate task to be the identification of just what is the part of quantum mechanics that is "about the gambler-independent world." The Bayesian analysis is a strategy, as I understand it, to identify that task and undertake it. It is a means, not an end.

But if I understand this correctly I am puzzled to see statements like:

> If what you mean by "intrinsic randomness" is that quantum measurement outcomes do not pre-exist the measurement process—that they are made "on demand"—and that there is no fact of the matter in the universe that will determine which way they will go, then Caves, Schack, Appleby, Peres, Leifer, and I all accept that.

Why could it not be that there is a "fact of the matter in the universe" that will determine the outcome of (maybe just some) measurements. You say that

> Garrett-style hidden variables, regardless of what Garrett might say, are thus not necessary for a Bayesian view of quantum probabilities.

Fair enough. But might it not be that the "gambler-independent world" is in fact described by a hidden-variable theory of some sort? For example, why would you (immediately!) rule out a Bohm - de Broglie universe (or a modified one, with the usual distribution over configuration space being a kind of 'equilibrium distribution' that we might someday be able to overcome, such as Valentini suggests) simply because of your Bayesian strategy in trying to identify just what that "gambler-independent world" is? Could it not be that Bohm and de Broglie have really identified the "fact of the matter in the universe," or that some such approach would? At least, must not this possibility be seriously considered? How does a Bayesian strategy immediately rule it out? By rejecting even the possibility that some quantum measurement outcomes may pre-exist the measurement process, do you not prejudge the outcome of the larger quest, for which the Bayesian viewpoint is not a goal but a strategy?

Perhaps I simply have read too much between the lines of what you say, or perhaps I truly misunderstand your views. In any case, (and to make sure in this tutorial I don't confuse somebody about what you really do hold!) could I get you to see if the way I describe your approach below is (a) basically right, (b) partly right but with major flaws, or (c) totally screwed up? Below I am going to phrase things in the kind of language I'm going to use in the tutorial. Please bear with me; I realize this is not the way you might want to frame the issues, and I really am not wedded to this as necessarily the 'best way' to phrase the issues. But for better or worse it's the one I've adopted for the tutorial, and so it's the one in which I have to somehow (and hopefully without too much damage) fit the thoughts of Chris Fuchs.

Here we go.

I use the term "interpretation" of a modern physical theory to mean an identification of just what it is to which the abstract elements in the theory purportedly refer. A "type of interpretation" identifies the type of things to which the abstract elements in the theory refer.

The abstract elements in quantum mechanics are density operators, POVMs, etc., etc. A "realist" type of interpretation identifies the abstract elements with stuff that purportedly really exists in the world, the "furniture of the universe." An "operationalist" type of interpretation identifies the abstract elements with tasks in the laboratory, such as preparations, transformations, and measurements. And so on. An "instrumentalist" type of interpretation says that abstract elements don't refer to anything at all, except perhaps in the way a hammer refers to a nail. That is, theories are just (only) tools for coping in the world.

Admittedly these categories are not as hard-and-fast as the language implies, but let's take them as a rough guide to thinking about these things. Now you and your colleagues hold

> "the idea that quantum *states* are of essence information"

and the obvious question a beginning student would ask—and undoubtedly someone will ask if I say something like this in the tutorial—is "information about what?" Perhaps one could argue that this question has no meaning, but I don't see how that view can be sustained. In any case, from the talks I have heard you give I came away with the impression that, at least in the short term and from the point of view of our current work-a-day physics, you take this to be information, broadly speaking, about the impact and results of future tasks in the laboratory, such as measurements. On the basis of this it seems to me you are in the "operationalist" camp.

Now within this camp there are various tribes. Some feel that any talk about underlying "furniture of the universe" is meaningless, or at least not worthwhile. They are "hard core operationalists." Gadgets and tasks for them are ultimate primitives in their theorizing, and for them an operationalist physics is all there can ever be, at least if it is to be what they would consider a proper physics.

I take you to be in a different tribe, whose members feel that ultimately we want a physics that does indeed talk about the furniture of the universe, the "gambler-independent world." Indeed, you refer to that as the "wheat," as opposed to the "chaff." But that "gambler-independent world" has not yet been identified. In the interim you argue that the abstract elements of quantum mechanics should be understood operationally, and the predictions and statements of quantum mechanics subjected to a kind of "Bayesian rack" to clarify exactly what beyond the objective rules of probability actually exists in them. This analysis then provides a firm footing for the search for the actual "furniture of the universe," whatever it is. Ultimately you want a theory that does describe this furniture; I would guess you are uncertain as to whether quantum mechanics (sufficiently purified by Bayesian analysis) would provide that, or whether a successor theory would be required. But in any case in your heart of hearts you hope someday for a realist science, or at least hope that that hope makes sense.

OK, that's my take. How close to your thoughts is it? It may be a while before I can respond to anything you say, because I am at a conference in Germany, but I really would appreciate some comments!

P.S.: As the saying goes, I didn't have time to write you a short letter so I wrote you a long one ... apologies for the verbiage!

22-02-06 *Wheelerfest* (to D. Overbye)

Here is something I should have told you about a good while back, but—I have to apologize—I didn't think about you until this morning. Since you're such a fan of John Wheeler, you might be interested.

Marlan Scully and I have organized a little meeting in Princeton in honor of John Wheeler to discuss quantum foundations and quantum information. It'll be held Friday Feb 24 and Saturday Feb 25; on the Friday it'll be at a certain conference center in Princeton, and on the Saturday it'll be on campus. I'm sorry for the very, very short notice.

I'll place the meeting schedule below, so that you'll have some indication of what it's all about. [See 16-02-06 note titled "Wheelerfest Program, User-Friendly Version".] If you're interested in coming let me know.

John himself will join us Feb 24, the Friday, between 5:00 PM and 6:00 PM (and maybe a little longer, depending upon his stamina) to be greeted by former students, etc. There'll be a conference dinner Friday evening at the same conference center (starting at 6:00), but we don't think John will stay all the way through that. However, you're welcome to come—choice of prime rib or salmon.

22-02-06 *Wheelerfest, 2* (to D. Overbye)

Overbye-ism 2: *I am a huge fan of Wheeler's and would love to have been at this meeting. Unfortunately I'm already committed to going to Pennsylvania for my mother-in-law's 80th birthday. I am especially intrigued by at least the title of Conway's talk about free will. Is that John Conway, the inventor of Life? Sorry I can't be there but the weekend has long been taken.*

Too bad! I'm so sorry I didn't think about contacting you before today. Yeah, that's John Conway—the inventor of "life" and a much more famous mathematician than that for his *Atlas of Finite Groups* and many other things. He's a very lively character. The theorem he'll be talking about is one by Simon Kochen and him, that is a stronger, newer version of the sort of thing first proven by Kochen and Specker. I would say it this way: That quantum mechanical measurement outcomes do not pre-exist the process of measurement; nature makes a choice when forced to the point. Or, another way I would put it is, that a quantum measurement forces a little act of creation (or birth). They claim it's the strongest hidden-variable no-go theorem yet. It's hasn't been published yet, but there has been plenty of press coverage due to Conway's talks.

23-02-06 *John Wheeler's Visit* (to L. Wheeler Ufford)

Thank you for your greeting. It has been a pleasure to organize this. John has long been one of my heroes, ever since I took a first-year college course with him in 1984. Almost every paper I have written in physics has concerned one or more of the problems he brought to my attention way back then. So, this is really a very small gesture in return.

I look forward to meeting you, your husband, Jackie and, of course, John tomorrow. (It will be the first time I have seen him since 1994.)

Letitia's Preply

> I am John Wheeler's older daughter and with Jackie Fuschini, his secretary, I and my husband will be bringing him to your Fest, hoping to arrive there a little before 5 p.m. I look forward to meeting you and thanking you for arranging such a happy and encouraging event for him.

27-02-06 *Wheelerfest, Thanks* (to M. O. Scully)

I wanted to write you a note to try to express my heartfelt thanks for supplying the resources that made this meeting happen. There is nothing that tickles me more than seeing our understanding of quantum mechanics advance, and meetings like this one are crucial in that regard. In fact, I think on one of the things John Wheeler wrote in that letter to Carroll Alley that I read at the beginning of the meeting:

> Expecting something great when two great minds meet who have different outlooks, all of us in this Princeton community expected something great to come out from Bohr and Einstein arguing the great question day after day—the central purpose of Bohr's four-month, spring 1939 visit to Princeton—I, now, looking back on those days, have a terrible conscience because the day-after-day arguing of Bohr was not with Einstein about the quantum but with me about the fission of uranium. How recover, I ask myself over and over, the pent up promise of those long-past days?

I hope we fulfilled a little of John's dream: Though the time was short, we did have a very impressive array of "great minds with different outlooks" arguing the great question.

Particularly, for me, I got a lot out of the interaction. My favorite talks were yours and Unruh's (with which I heartily agreed) and Conway's and Kochen's (which stretched me to a new level). Furthermore, Schumacher took my "Dutch book" challenge seriously, and, I think, may have already provided a very nice solution to it. Finally, Hardy stayed at my house over the rest of the weekend and we got a good bit of conceptual work done with regard to his "causaloid" framework. So, this conference turned out to be nothing but pleasure for me!

28-02-06 *Foundational Cost Cutting?* (to A. Wilce)

Are you planning to go to the "New Directions in the Foundations of Physics" meeting, April 28–30? If so, would you be interested in having a roommate to cut down on costs? My travel budget is tiny this year, and I'm trying to do everything I can to stretch it.

Let me know what you think, or if you have any other suggestions.

01-03-06 *Foundational Cost Cutting?, 2* (to A. Wilce)

Too bad. OK, either I'll try to look for another roommate, or I might even drop the plan of going myself. I'm wishy-washy anyway: Something deep inside me has been telling me that I've been going to too many foundational conferences (the payoff doesn't seem so big anymore).

06-03-06 *Be Forgiving* (to G. L. Comer)

Comerism 11: *I'm very much convinced that the historical approach to teaching special relativity is very much a disservice to the subject. It gives precisely the wrong foundational point-of-view.*

I think you ought to be a little forgiving to something like a historical process for thinking about the foundation of the theory—or, at least admit that it may have its place. It may not be the best pedagogy for students, but it may have its place elsewhere.

What I'm thinking of here particularly is how one might incorporate quantum mechanical ideas into the scene. If one starts the analysis off—crucial words, "starts the analysis off"—with spacetime before rods and clocks (or clocks and maybe some stand-in for light rays), then the only natural progression one can take may end up being to try to "quantize gravity" in the usual sorts of ways (for instance, wave functions over three-geometries and variations of that program).

On the other hand, a more operationalistic approach—one that doesn't assume spacetimes or wave functions of spacetimes at the outset—may be just what is needed to free up the conceptual playground enough to make good progress. For instance, if a quantum measurement event helps set the very notion of causal structure in the first place, then maybe it is best to rethink where along the lines of earlier thinking one could make the conceptual leap to "metric is fundamental." In the quantum world, maybe one cannot make that conceptual leap—and thus maybe that is not a good starting point.

On a different subject:

Comerism 12: *I mean not discussing the metric as fundamental is like presenting quantum mechanics without mentioning the wave function.*

You see, but that is what I would ultimately like to do! For, for me, wave functions are always about *someone's* degrees of belief. And what we (quantum Bayesians) would like to get at is a gambling-agent-independent account of what is up in the quantum world. As long as one invokes a wave function, one is always *explicitly* talking about an observer. See transparency #12 in my talk "Being Bayesian in a Quantum World" posted at the bottom of my webpage. It talks to that point directly!

08-02-06 *Counterfactual* (to S. J. van Enk)

I'd like to soon get back to the Demopoulos issue. Particularly, I would like to record better the change you pointed out in how we quantum Bayesians must be treating counterfactuals. I wish there were a whole paper in that idea. I guess I came back to the issue today as I was reading Thomas Marlow's paper, "Relationalism vs. Bayesianism" `gr-qc/0603015`. I couldn't really understand it, but he did drive one point home that you've been driving at with me for a while:

> It is often stated that EPR and Bell-like theorems are avoided (not disproved but just avoided) by using Bayesian probability theory (this is often the major reason people invoke Bayesian reasoning in quantum theory [6]), but rarely is it explicitly stated how

> the invocation of Bayesian probabilities overcomes arguments for causal nonlocalities. We shall attempt to argue why this is the case and why arguments that claim the opposite are lacking.

Ref. [6] refers to me. Unfortunately, as I've already hinted, I didn't get his argument. But his sentiment is good (and seems to second yours). So, if by recording the conversation you and I have been having, we can provide a little service to the community, it might be worthwhile.

14-02-06 *Notwithstanding* (to D. Bacon)

Steven van Enk pointed out to me the award you recently bestowed upon us on your blog. [See `http://dabacon.org/pontiff/?p=1189`.] Well, thanks—I'm honored. (If I could only figure out a way to put it in my CV.)

Not completely unrelated (but mostly so), here's something that might tickle your fancy. Once upon a time, Steven told me a story that he had heard from Klaus Mølmer. It went that Bohr needed to write a paper for a conference proceedings and insisted on starting it off with the word "notwithstanding." Thereafter, for a day or two, Bohr was absolutely stumped and didn't write a word until he could compose his first sentence!

Well Steven and I, wanting to learn from the master, decided that we too would compose a paper around the word "notwithstanding." The result was a little paper titled, "Entanglement is Super … but not Superluminal!," that appeared in a book of collected papers on spooky action-at-a-distance. We were so embarrassed with the paper that we never posted it on `quant-ph`! But for you, since you've earned it with your kind accolades to us, here is its opening sentence:

> Notwithstanding its wonderful potential for enhancing and extending our capabilities within the realm of communication technology—through applications like quantum cryptography, quantum superdense coding, and quantum teleportation—quantum entanglement as a physical resource falls far short of being the feast the hungry seekers of superluminal communication would hope it to be.

22-02-06 *The Way the Cookie Crumbles* (to H. C. von Baeyer)

Thanks for the note. As I just wrote to Marcus Appleby, "At the moment, I am scrambling to get something together for the Wheelerfest meeting I organized at Princeton this weekend. I gave my talk the title 'The Equations of Quantum Mechanics Already Do Fly,' but honestly I don't yet have a clue what I'm going to say. I hope I get some inspiration before tomorrow morning, so that I'll have time enough to put it together before Friday morning!" But I want to get caught up on some emails too!

Just a couple of comments on your note:

von Baeyerism 15: *Translating Fierz's sentence: "As is often the case, when you don't understand anything, you think of all sorts of things that you feel are connected, but whose connection you cannot express clearly" inspires me to speculate as follows.*

How did the Greeks discover atoms? By reasoning from the observation of steam that water could not possibly retain its characteristics under arbitrary dilution unless those characteristics were stored in tiny, finite lumps.

How did Schrödinger invent molecular genetics? By reasoning that living organisms could not possibly retain their characteristics over millions of years unless those characteristics were stored in tiny, material, finite lumps.

In both cases the argument was that the cookie would crumble into chaos unless its parts were quantized.

It seems to me that this is the basis of Zeilinger's principle. Information would dissolve into ignorance if it were not quantized into bits – even though it is carried by qubits. Conversely, if you add analyticity to bits, you get qubits (Hardy). (This does not imply that information is material.)

With regard to the part about Hardy (which reminds me that I had wanted to invite him to my house this weekend—thanks), see the note below that I wrote to Hans Halvorson a few weeks ago. [See 27-01-06 note "Monday or Tuesday Meeting" to H. Halvorson.]

von Baeyerism 16: *So if Spekkens had a toy model in which the ontic content was continuous, and the epistemic content countable, he would have quantum mechanics.*

OK, as far as I know he doesn't have that. But he and Terry Rudolph and Steve Bartlett do have one in which the ontic content is continuous. See their talk at the APS March meeting; here is their abstract. (Or at least I think that's the same toy model he told me about before, and as far as I understood, there was a continuous set of epistemic states allowed.) [Though, now see `http://arxiv.org/abs/1111.5057`.]

> **3:30PM D40.00004**
>
> Liouville mechanics with an epistemic restriction and Bohr's response to EPR
>
> TERRY RUDOLPH, Imperial College, STEPHEN BARTLETT, University of Sydney, ROBERT SPEKKENS, Perimeter Institute
>
> We introduce a toy theory that reproduces a wide variety of qualitative features of quantum theory for degrees of freedom that are continuous. Specifically, we consider classical mechanics supplemented by a constraint on the amount of information an observer may have about the motional state (i.e. point in phase space) of a collection of classical particles – Liouville mechanics with an epistemic restriction (This may well be how Heisenberg initially understood the Uncertainty Principle). We develop the formalism of the theory by deriving the consequences of this "classical uncertainty principle" on state preparations, measurements, and dynamics. The result is a theory of hidden variables, although it is not a hidden variable model of quantum theory because of its locality and noncontextuality. Despite admitting a simple classical interpretation, the theory also exhibits the operational features of Bohr's notion of complementarity. Indeed, it includes all of the features of quantum mechanics to which Bohr appeals in his response to EPR. This theory demonstrates, therefore, that Bohr's arguments fail as a defense of the completeness of quantum mechanics.

In addition though, I'm pretty sure I don't agree with what you're hoping for here. That is because, toy models, at least as conceived along the original Spekkens line, have the property of noncontexuality (which gives rise to the fact that in these models, the measurement 'outcomes' are already alive before the measurement actually takes place—i.e., they pre-exist). In that sense, these are still detached-observer models. One paper that I don't think I have recommended to you before, but that you might enjoy is this:

> The Bell-Kochen-Specker Theorem
> Authors: D. M. Appleby
> Comments: 22 pages
> Journal-ref: Stud. Hist. Philos. Mod. Phys. **36** (2005) 1
> `http://www.arxiv.org/abs/quant-ph/0308114`

von Baeyerism 17: *In any case, I feel (wish?) that we are very close to understanding the quantum. Maybe somebody will figure it out in Wheeler's lifetime.*

I can't disagree with that!

27-02-06 *Wheeler* (to W. P. Schleich)

No, thank YOU very much for coming. I was very much impressed by the humanity I saw in you; I had not got to know you so well before as I did this weekend.

John continues to be an inspiration for me — as I hope my talk conveyed.

I hope that one day we'll get a chance to sit down and talk about this representation of (finite dimensional) quantum states in terms of true-blue probability distributions, which I mentioned briefly in my talk. My own understanding of it is long in development, and I suspect there are some insights I could glean from Mr. Phase Space's view on it. Schumacher, by the way, provided a nice "Dutch book" argument over the weekend, fulfilling the challenge I put at the end of the talk. So, on the technical end even (i.e., even outside of the opportunity to see John honored), this meeting was quite useful to me. It was a real pleasure to see it come together.

27-02-06 *Convex Sets / Algebras Tutorial?* (to H. Halvorson)

I very much enjoyed your talk at the Wheelerfest, the parts of it I understood at least—I'm terribly primitive when it comes to mathematics.

To continue our mutual quest, I wonder if the logical next step might be for you to help bring me up to speed on the connection between convex sets and algebras if you would? That is definitely an important connection which I need to understand. It would be great if I could pull a tutorial from you that a) concerned itself only with the finite dimensional case, and particularly b) used only the language of the finite dimensions in its presentation. My mind gets unusually distracted when I hear terms like Hausdorff and compactification, and if you could help me get to the truly essential points (which I view always as the finite dimensional issues), I think it would help both of us exponentially (you from the teaching, me from the learning).

Might you have some time early next week?

27-02-06 *Dutch Book* (to D. M. Greenberger)

I'm sorry I never answered your question about Dutch book after my talk. Maybe the simplest solution is for me to just point you to the nice notes Carl Caves put together on it:

> `http://info.phys.unm.edu/~caves/reports/dutchbook.pdf`.

Another place to look is the appendix in our paper:

> "Conditions for Compatibility of Quantum State Assignments"
> Authors: Carlton M. Caves, Christopher A. Fuchs, Rüdiger Schack
> `http://www.arxiv.org/abs/quant-ph/0206110`

It was good seeing you at the meeting; you had me laughing and laughing with your quips.

27-02-06 *Wheelerfest* (to K. W. Ford)

Thanks for the note. I'm glad you enjoyed the meeting, and I'm particularly glad that you think John enjoyed it. Seeing him at this late stage of life was just as inspiring for me as seeing him, and thinking about his thoughts, at every other stage. He is an amazing man.

You're right about the gender balance issue, and your note helped promote it a little further to the top of my consciousness (and conscience). I'll try to think harder next time when I work on an invitation list.

I hope you got something out of my talk. I'm a little disappointed with it myself: I tried to squeeze both too much history and too much technicality to get any live points across effectively. (I was pleased though that Schumacher took my "Dutch book" challenge seriously over the weekend; I think he has provided a very nice solution to it!) Your question at the end was a very good one. It's one of the crucial issues—and I wish I had a much better answer for you by this stage. As best I can put it at the moment, I think the issue is not consciousness at all; but the distinction between an "inside description" and an "outside description"—analogous to one of the points Conway brought up in his talk about the "free will theorem" (which unfortunately you missed). Maybe a way to put it is this: What we call quantum theory has sadly been misidentified all these years as a "description from the outside," when in fact it is almost completely a "description from the inside." There is a hint of the outside in it—through these very powerful theorems of Kochen and Specker (and now Conway and Kochen)—and that is our best handle for getting at our next big step in physics, but the first thing we've really got to disabuse ourselves of is confusing the inside with the outside. Quantum states, and their changes, live only on the inside; the "acts of creation," the "clicks," that trigger those changes live on the interface between the inside and outside—thus they should be viewed as distinct from the quantum-state changes themselves. When we really get that cleared up (as I hope our Bayesian program is doing), then we'll be ready for some serious progress.

Let me paste in couple of notes below that go a little further along these lines. [See 19-06-05 note "Philosopher's Stone" to G. L. Comer and 17-06-04 note "Preamble" to H. Mabuchi.] But you can see I've got a long way to go in my understanding before I'll be able to drop the poetry and put in its place a little clarity.

If you weren't able to recover the manuscript I gave you from the conference center, let me know and I'll send you another copy if you'd like one.

28-02-06 *Our Special Sauce* (to L. Hardy)

I'm just back from a mandatory "Bell Labs town meeting." It seems that the over-riding purpose of the meeting was to remind all the researchers here that they and their thoughts are just part of the food chain. Here were some of the words and phrases that caught my attention:

> "competition makes you stronger," "value proposition," "territory," "what do we have to do to win," "our special sauce," "where do we want to compete to win," "ways to attack certain verticals to win," "attack," "kickin' some butt," "organic ways to win," "where the puck is moving," "we drive value," "new competitive landscape," "we need to develop stickiness," "or else we don't eat," "monetize the core product strategy," "early alignment around our value proposition."

This note seemed like a good opportunity to record them all. Coming back to our conversation on the drive to the airport, I think it is this culture that is the main thing getting me down.

Your visit was a breath of fresh air. Thanks for coming. I've had the early Einstein arguments on my mind ever since, and I think you're on to something.

Concerning the Boston meeting, as I work on my schedule this afternoon, I think I probably ought to bow out: I really can't afford it, both because of my travel budget and because of my time. I leave for Lisbon March 27, and this would put me away from home immediately beforehand for still more days. You go there, and remind them that decoherence, many worlds, and nonlocality really aren't all that interesting or creative.

Attached is a picture of Cap'n Hardy and ye maties.

28-02-06 *Quantum Causal Structure* (to L. Hardy)

I'm back again: I had forgotten that when Rob Spekkens was here last, I put together a little collection of some of my wilder speculations on the connections between quantum and GR. Let me share that file with you too. I think it made little effect on Rob, but—given all the stuff you told me the other night—you might find more of use in it. (Well, probably nothing of use, but maybe some food for thought.)

Particularly, for me, one of the phrases you used the other night has gotten me excited that it may be possible to give some true-blue substance to those old thoughts of Mead near the end of the document. I.e., that taking account of "this" event may change the "causal structure" of all the rest:

> [T]he greatest lesson quantum theory holds for us is that when two pieces of the world come together, they give birth. They give birth to FACTS in a way not so unlike the romantic notion of parenthood: that a child is more than the sum total of her parents, an entity unto herself with untold potential for reshaping the world. Add a new piece to a puzzle—not to its beginning or end or edges, but somewhere deep in its middle—and all the extant pieces must be rejiggled or recut to make a new, but different, whole. That is the great lesson.

I'm very attracted to that, and to some extent I took the imagery from Mead and his musings on time.

I will be studying your paper thoroughly, and rethinking old Einstein again.

28-02-06 *Stupider Chris* (to T. Rudolph)

Rudolphism 9: *I really like that second paragraph you quoted,*

> Is the entirety of existence ... built upon billions upon billions of elementary quantum phenomena, those elementary acts of "observer-participancy," those most ethereal of all the entities that have been forced upon us by the progress of science? — John Wheeler

although to be honest I'm somewhat skeptical of the overriding sentiment (I suspect things are ultimately a little more mundane, the history of science is littered with the corpses of the Anthropocentricians).

Yeah, that's too bad: Unfortunately, I agree with you. However, I continue to wonder if one could de-anthropocentrify John's idea and still make something of it: I.e., that the big bang is here, rather than way back there. That part of it very much intrigues me.

Below is a daisy-chain of notes demonstrating my latest flailing for the right imagery. [See 27-02-06 note "Wheelerfest" to K. W. Ford.]

07-03-06 *Invitation to Grinnell and Talk Titles* (to W. B. Case)

Thanks for the invitation; I am flattered. What is a Squire Lecturer? It sounds like an honor (and even Bell Labs people think that $800 sounds like good money). I would very much like to come, but April is pretty much already filled up for me. Would it be possible to come in May? How long of a visit were you thinking?

Titles? Maybe for the undergraduate talk:

> "Drawing a Qubit in a Tetrahedron"

And how about this for the general talk:

> "Quantum Information and the Malleable World"

They're just ideas. If you don't like them, send me back to the drawing boards.

07-03-06 *April* (to N. C. Menicucci)

Menicuccism 1: *I would really like to talk to you about Bayesianism in QM. Howard Wiseman from Griffith University gave a talk recently where he called the Bayesian approach 'solipsism' – i.e., that there is no external world, only one's own mind. We eventually convinced him that that was crap and not true of the interpretation, but he never really seemed to "get it": How can there be an external world if all quantum states are states of my knowledge? Well, I told him, they're states of your knowledge about the external world. Somehow that didn't make sense. This really got my goat because I think this interpretation might be one of the only ways of correctly looking at quantum theory, since it embraces the paradigm shift the theory inspires (although being a paradigm shift, it's hard for me to pin down in words), but Howard* **completely** *missed the point and made it sound like all Bayesians are looney. I tried to defend the position, but I was at a loss for words.*

What you tell me is very sad. A solipsist, it seems to me, would have no reason whatsoever to do physics, much less try to understand quantum mechanics.

I append a little story below from my "Quantum States: What the Hell Are They?" about solipsism. [See 21-07-01 note "The Reality of Wives" to A. J. Landahl & J. Preskill.] (If you give me a mailing address, and you want a copy, I'll have a copy of the VUP edition of *Notes on a Paulian Idea* sent to you.)

07-03-06 *Some Reading* (to N. C. Menicucci)

Going back to solipsism, I could point you to a lot of things I've written on this annoying issue, but let me start with this: `http://www.arxiv.org/abs/quant-ph/0204146`. Do Sections 4 and 5 help any already?

08-03-06 *A Little Wheelerfest Report* (to H. C. von Baeyer)

von Baeyerism 18: *Did you learn anything, or teach anything, at the Wheelerfest?*

Indeed I got a lot from the meeting. And had many ridiculous fights with John Conway, who is afraid of the Bayesian idea of probability. Such a great mind; such a great prejudice!

Particularly useful for me in preparing my own talk was the *strong* realization that the Born rule is not at all about setting probabilities but transforming them! Its role really is that of a transformation rule. There are hints of that in my writings before, but finally I feel it with all my heart and soul—that's what I meant by the "strong realization." Anyway it indicates that maybe one can get at the content of the Born rule through some Dutch-book-like arguments. Thus I posed that as a question at the end of my talk. Very nicely, Schumacher took the challenge and has started to make progress in that direction.

I sort of like the talk I put together for this—even though it goes out on the limb more than usual (even for me). I will try to scan in a copy soon (and send to you), and I will probably give an expanded variation on it in Sweden.

09-03-06 *Carl Again, a Few More Words* (to R. E. Slusher)

In the last three years, Carl has posted 13 papers to the quant-ph archive (with his students and postdocs).

The 5 papers I personally found the most interesting are:

- `quant-ph/0304083` [abs, ps, pdf, other] :
  Title: Physical-resource demands for scalable quantum computation
  Authors: Carlton M. Caves, Ivan H. Deutsch, Robin Blume-Kohout

- `quant-ph/0306179` [abs, ps, pdf, other] :
  Title: Gleason-Type Derivations of the Quantum Probability Rule for Generalized Measurements
  Authors: Carlton M. Caves, Christopher A. Fuchs, Kiran Manne, Joseph M. Renes
  Journal-ref: Found. Phys. 34, 193 (2004)

- `quant-ph/0310075` [abs, ps, pdf, other] :
  Title: Symmetric Informationally Complete Quantum Measurements
  Authors: Joseph M. Renes, Robin Blume-Kohout, A. J. Scott, Carlton M. Caves
  Journal-ref: J. Math. Phys. 45, 2171 (2004)

- `quant-ph/0404137` [abs, ps, pdf, other] :
  Title: Minimal Informationally Complete Measurements for Pure States
  Authors: Steven T. Flammia, Andrew Silberfarb, Carlton M. Caves

- `quant-ph/0409144` [abs, ps, pdf, other] :
  Title: Properties of the frequency operator do not imply the quantum probability postulate
  Authors: Carlton M. Caves, Ruediger Schack
  Journal-ref: C.M. Caves and R. Schack, Ann. Phys. 315, 123–146 (2005)

All of the papers are cut from the same cloth: They are devoted to developing a technical apparatus for getting at what is quantum about quantum information. Particularly, Carl's worldwide impact has been in his efforts to develop a view of quantum information along Bayesian lines—in fact he is the very father of that field. To get some indication of the number of serious quantum information theorists willing to take this line of thought seriously, one can look at the participation list for the meeting "Being Bayesian in a Quantum World" for which Caves was a co-organizer:

`http://web.archive.org/web/20090511060206/http://www.uni-konstanz.de/ppm/events/bbqw2005/`

You'll see Hans Briegel, Lucien Hardy, David Mermin, Gerard Milburn, Michael Nielsen, John Smolin, Bill Wootters, and many others there.

Caves is a behind-the-scenes worker, a kind of theorist's theorist. The press may not know him so much (because he's not a weird, journalist-attracting recluse like David Deutsch) nor may the funding agencies (because he's not a flamboyant stage actor like Seth Lloyd), but anyone in this field who is worth his salt knows of Caves's intellect and influence.

10-03-06 *Opening of My APS Talk* (to R. E. Slusher)

Your story of how you opened your MIT talk inspired me for the opening of my own talk at the APS meeting Monday.

I'm going to start off by reading this quote of William James:

> Metaphysics has usually followed a very primitive kind of quest. You know how men have always hankered after unlawful magic, and you know what a great part in magic *words* have always played. If you have his name, or the formula of incantation that binds him, you can control the spirit, genie, afrite, or whatever the power may be. Solomon knew the names of all the spirits, and having their names, he held them subject to his will. So the universe has always appeared to the natural mind as a kind of enigma, of which the key must be sought in the shape of some illuminating or power-bringing word or name. That word names the universe's *principle*, and to possess it is after a fashion to possess the universe itself.

Then I'm going to show a big $|\psi\rangle$ and say we finally know its *name*: It is "expectation"—raw, unmitigated expectation with no further need for justification. If we take that name and that idea seriously, we will "possess the universe itself."

I'm going to Princeton this morning to work with Halvorson a bit. Depending upon when that finishes, I may or may not come in to Bell Labs. If you really need me around, drop me a note.

10-03-06 *Probably More Than I Should Send, 2* (to J. E. Sipe)

My post-Wheelerfest days have passed away, and it has just been one thing after another. Now the APS meeting is upon us! Time, time, time; what has become of me!

Still, I wouldn't mind writing you something today: Never pass up an opportunity to expose a colleague to Bayesian ways of thought! But I have to go to Princeton this morning to work with Halvorson. May I ask, what is the last time you'll be checking email before leaving for Baltimore (if you haven't already left for Baltimore)? You know, if there's a carrot in front of the horse, he'll pull the cart!

I'll plan my afternoon according to you.

10-03-06 *Isms* (to J. E. Sipe)

Sipesm 4: *I'll be checking email until about 5PM today (Friday); I fly to Baltimore tonight, and hope to be checking email there, but I'm not sure that'll be possible until the conference starts, and my tutorial is Sunday morning!*

Ouch, I've run out of time for all those delicate and carefully constructed answers I wanted to give you! My fault—you deserve much better than me. It's now almost 3PM, and I'm just finished talking to Hans. Now I'm in a Panera Bread in Princeton, having a cup of coffee before my drive home. Let me send you a very little note answering some of your questions, and maybe we can talk more next week.

I certainly liked the way you posed your questions.

Sipesm 5: *I gather from this that you see the ultimate task to be the identification of just what is the part of quantum mechanics that is "about the gambler-independent world." The Bayesian analysis is a strategy, as I understand it, to identify that task and undertake it. It is a means, not an end.*

But if I understand this correctly I am puzzled to see statements like: ... [blah blah blah measurements create outcomes]

Fair enough. But might it not be that the "gambler-independent world" is in fact described by a hidden-variable theory of some sort? For example, why would you (immediately!) rule out a Bohm - de Broglie universe (or a modified one, with the usual distribution over configuration space being a kind of 'equilibrium distribution' that we might someday be able to overcome, such as Valentini suggests) simply because of your Bayesian strategy in trying to identify just what that "gambler-independent world" is? Could it not be that Bohm and de Broglie have really identified the "fact of the matter in the universe," or that some such approach would? At least, must not this possibility be seriously considered? How does a Bayesian strategy immediately rule it out? By rejecting even the possibility that some quantum measurement outcomes may pre-exist the measurement process, do you not prejudge the outcome of the larger quest, for which the Bayesian viewpoint is not a goal but a strategy?

Here is the way I once answered Jeff Bub when he asked a similar question. Jeff asked:

> You want to take quantum mechanics as a theory of the way information is represented and the limitations on the communication of information, and not a description of the behavior of particles, as in classical mechanics. Granted, the way the world is hard-wired might impose limitations on the gathering of information and the exchange of information – limitations expressed precisely by the 'limited sort of privacy' we have (i.e., secure kd, but no secure bc), hence by science necessarily taking the form of quantum mechanics. But how does it follow from this that we must interpret quantum mechanics as a theory of information, and not as a descriptive theory in the sense of classical mechanics?

My reply was:

> It doesn't. You're completely on track there. Do you remember my slide where I listed the axioms of quantum mechanics in Montréal? In my presentation I said how I'm always struck by the stark contrast between that list of axioms and the ones we take for our other cornerstone theory of the world (referring to special relativity): (1) the speed of light is constant, and (2) physics is the same in all frames. The debate over the foundations of quantum mechanics will not end until we can reduce the theory to such a set of crisp physical statements—I believe that with all my heart. However, just as special relativity will always be interpretable in Lorentz's way, quantum mechanics will likely always be interpretable in Bohm's way. There's nothing we can do about that.
>
> What I'm really searching for is just a polite way to say, "Ahh, blow it out your butt. You can believe that Lorentzian way of looking at things if you want to, but why when have this absolutely simple alternative conceptual structure?"

> What I'm looking for is just a couple of crisp physical statements—contradictory appearing even, just as Einstein's—that can characterize what quantum mechanics is all about. Something like (but more precise than):
>
> 1. The effects of our interventions into the world are nondiminishable. And,
> 2. But still we have science; all the world is not simply a dream of our own concoction.
>
> Once we get that cleared up, we'll finally be ready to move to the next stage of physics, much like Einstein was ready to move on to general relativity once he had reduced the Lorentz contractions to the two statements above.

That's the best answer I think I can give you at the moment. Even a Bayesian approach to quantum mechanics cannot DISPROVE nonlocal, noncontextual hidden variables theories. It just emphasizes that they don't smell right.

The "proof" of any approach will ultimately be in what new physics it gives rise to.

Now for your most important question:

Sipesm 6: *In any case, (and to make sure in this tutorial I don't confuse somebody about what you really do hold!) could I get you to see if the way I describe your approach below is (a) basically right, (b) partly right but with major flaws, or (c) totally screwed up? ...*

I use the term "interpretation" of a modern physical theory to mean an identification of just what it is to which the abstract elements in the theory purportedly refer. A "type of interpretation" identifies the type of things to which the abstract elements in the theory refer.

The abstract elements in quantum mechanics are density operators, POVMs, etc., etc. A "realist" type of interpretation identifies the abstract elements with stuff that purportedly really exists in the world, the "furniture of the universe." An "operationalist" type of interpretation identifies the abstract elements with tasks in the laboratory, such as preparations, transformations, and measurements. And so on. An "instrumentalist" type of interpretation says that abstract elements don't refer to anything at all, except perhaps in the way a hammer refers to a nail. That is, theories are just (only) tools for coping in the world. ...

Now you and your colleagues hold "the idea that quantum STATES are of essence information" and the obvious question a beginning student would ask – and undoubtedly someone will ask if I say something like this in the tutorial – is "information about what?" Perhaps one could argue that this question has no meaning, but I don't see how that view can be sustained.

In any case, from the talks I have heard you give I came away with the impression that, at least in the short term and from the point of view of our current work-a-day physics, you take this to be information, broadly speaking, about the impact and results of future tasks in the laboratory, such as measurements. On the basis of this it seems to me you are in the "operationalist" camp.

Now within this camp there are various tribes. Some feel that any talk about underlying "furniture of the universe" is meaningless, or at least not worthwhile. They are "hard core operationalists." Gadgets and tasks for them are ultimate primitives in their theorizing, and for them an operationalist physics is all there can ever be, at least if it is to be what they would consider a proper physics.

I take you to be in a different tribe, whose members feel that ultimately we want a physics that does indeed talk about the furniture of the universe, the "gambler-independent world." Indeed, you refer to that as the "wheat," as opposed to the "chaff." But that "gambler-independent world" has not yet been identified. In the interim you argue that the abstract elements of quantum mechanics should be understood operationally, and the predictions and statements of quantum mechanics subjected to a kind of "Bayesian rack" to clarify exactly what beyond the objective rules of probability actually exists in them. This analysis then provides a firm footing for the search for the actual *"furniture of the universe," whatever it is. Ultimately you want a theory that does describe this furniture; I would guess you are uncertain as to whether quantum mechanics (sufficiently purified by Bayesian analysis) would provide that, or whether a successor theory would be required. But in any case in your heart of hearts you hope someday for a realist science, or at least hope that that hope makes sense.*

I think my way of looking at the terms *within* quantum mechanics runs the whole gamut from instrumentalism to realism, and there's no way to put it into one single category.

1. When I posit a physical system about which I will speak (by assigning it a Hilbert space, etc.), I am doing that in an almost naïve realistic way. I.e., the $\mathcal{H}$ I write down, represents a piece of the world that is out there independently of me.

2. When I assign a dimension d to that Hilbert space, I am hypothesizing an inherent *property* of that system. I might be right, or I might be wrong, but d is something I hypothesize of it, even if only provisionally. Realism again.

3. When I draw a quantum state out of the space of operators defined by $\mathcal{H}$, however, I am expressing a bundle of my expectations. These are not properties inherent in the system. They are subjective expectations that I bring into the picture (presumably because they have served me well in the past, or at least done me no harm). If I were to conceptually delete myself from the picture, these expectations would disappear with me. To that extent, the view might sound a little like—or at least be confused with—idealism (but that's only if one—as Howard Wiseman often does—forgets elements 1 and 2 above and one of the further elements below.)

4. The subject matter of those expectations, i.e., what they are about, refers both to me and the system I posit. They are MY expectations for the consequences (for ME) of MY interactions with the system. That, you might think is a kind of operationalism: For if I were to conceptually delete myself from the picture, those interactions would disappear too.

5. On the other hand, the reason we use the formal structure of quantum mechanics to bundle our expectations, to manipulate and update them, to do all that we do with them, is to better cope with the world. It is a means to help our species to survive and propagate. That is a kind of instrumentalism. That part of quantum mechanics is a tool like a hammer; it can be used to fix a lot of things, or simply as an aid to help defend ourselves.

6. Still one can never forget the ultimately uncontrollable nature of each quantum measurement outcome—and through Kochen-Specker, at least the way I view it, the non-pre-existence of those "outcomes". That smacks of realism in the oldest, most time-honored way. The world surprises us and is not a creation of our whims and fancies. Back to realism ... but the twist is quantum mechanics, as used by each individual user, only refers to the outcomes HE helps generate. (That smacks of alchemy ... dangerous to say so, but I call it like it is.)

7. Nevertheless, having learned a little from Copernicus, it seems we should ultimately try to abstract away from these personal encounters with the world (having learned what we could from the formalism concerned with gambling on them). If a tiny little system and I create something new in the world when we get together—i.e., we give rise to a birth or new fact—so must it be likely, it seems to me, that any two things give rise to a birth when they get together. That is "F-theory" or the "sexual interpretation of quantum mechanics" ... but you'll have to wait for the movie if you question me any further on that ...

I hope that answers you a little. It took me a cup and a half of coffee, and I think I just barely made deadline.

Have a safe trip. It'll be fun talking to you next week.

10-03-06 *Isms, 1* (to H. Halvorson)

I didn't explain in the last note why I didn't leave Princeton until 4:00. What happened was that I owed John Sipe a note before his leaving for the APS meeting to give a four-hour tutorial on quantum foundations Sunday—he wanted a little explanation of our Bayesian point of view so that he might incorporate it into the tutorial. Well, after leaving Marx Hall, I started thinking, "I don't quite know when he'll be leaving, so I'd better check my email." Thus I popped in to Panera's Bread, and sure enough I found out that he'd soon be checking his email for the last time before his flight. So, I quickly composed the note below. [See 10-03-06 note "Isms" to J. E. Sipe.]

The part that might interest you is the list at the end explaining the various isms that my view of the quantum mechanics seems to cross. The list is incomplete: I think I hit even more isms than that, but maybe this is a good starting point for categorization.

Another note on relevant isms coming after I get a chance to search the web.

Still a silent house!

10-03-06 *Isms, 2* (to H. Halvorson)

The other thing I wanted to write you about isms is this. Here is the paper by Huw Price that I was telling you about:

> "Naturalism without Representation"
> `http://www.usyd.edu.au/time/price/preprints/naturalism-final.pdf`

The abstract for the paper is below. I recall liking the paper very much. And to the extent that I understand the term, I believe I can classify myself (presently) as what Huw calls a "subject naturalist."

I wonder how you would characterize a) yourself, and b) your other colleagues in your department, in these terms.

> Abstract: I begin with a distinction between two ways of taking science to be relevant to philosophy. The first ("object naturalism") is a ontological thesis – it holds that what exists, what we should be realists about, is the world as revealed by science. The second ("subject naturalism") is a prescription for philosophy, based on the belief that we humans (and in particular, our thought and talk) are part of the natural world. What is the relationship between these two kinds of naturalism? Contemporary naturalists are apt to think that the latter view is a mere corollary of the former. I argue that there is an important sense in which the priority is the other way around: object naturalism depends on "validation" from a subject naturalist perspective – in particular, on confirmation of certain "representationalist" assumptions about the functions of human language. Moreover, I maintain, there are good reasons for doubting whether object naturalism deserves to be validated, in this sense. Thus, an adequate naturalistic philosophy threatens to undermine what most contemporary philosophers have in mind, when they call themselves philosophical naturalists.

10-03-06 *Singularities and Evolutionary Laws* (to H. Halvorson)

Below are the three quotes I have by Poincaré concerning the subject above. The quotes seem horribly inadequate now (with respect to what I remember of the niceness of the article); I wish I had more extensive quotes in the computer. Always too much to do ...

From: H. Poincaré, "The Evolution of Laws," in his book *Mathematics and Science: Last Essays (Dernières Pensées)*, translated by J. W. Bolduc, (Dover, New York, 1963), pp. 1–14.

> Mr. Boutroux, in his writings on the contingency of the laws of Nature, queried, whether natural laws are not susceptible to change and if the world evolves continuously, whether the laws themselves which govern this evolution are alone exempt from all variation. ... I should like to consider a few of the aspects which the problem can assume.

and

> In summary, we can know nothing of the past unless we admit that the laws have not changed; if we do admit this, the question of the evolution of the laws is meaningless; if we do not admit this condition, the question is impossible of solution, just as with all questions which relate to the past. ...
>
> But, it may be asked, is it not possible that the application of the process just described may lead to a contradiction, or, if we wish, that our differential equations admit of no solution? Since the hypothesis of the immutability of the laws, posited at the beginning of our argument would lead to an absurd consequence, we would have demonstrated *per absurdum* that laws have changed, while at the same time we would be forever unable to know in what sense.
>
> Since this process is reversible, what we have just said applies to the future as well, and there would seem to be cases in which we would be able to state that before a particular date the world would have to come to an end or change its laws; if, for example, our calculations indicate that on that date one of the quantities which we have to consider is due to become infinite or to assume a value which is physically impossible. To perish or to change its laws is just about the same thing; a world which would no longer have the same laws as ours would no longer be our world but another one.

and

> No doubt many readers will be dismayed to note that I seem constantly to substitute for the world a system of simple symbols. This is not due simply to a professional habit of a mathematician; the nature of my subject made this approach absolutely necessary. The Bergsonian world has no laws; what can have laws is simply the more or less distorted image which the scientists make of it. When we say that nature is governed by laws, it is understood that this portrait is still rather lifelike. It is therefore according to this description and this description only that we must reason, or else we run the risk of losing the very idea of law which was the object of our study.

12-03-06 *The Spirit of Stevie Ray* (to G. L. Comer)

Boy you sure send a lot of pictures of your guitar! Handsome picture of the singer though—you're right, you do look authentic.

I'm just off to the APS March meeting in Baltimore … where our little efforts in physics has finally been recognized with a topical group all of its own. Sessions all week long. I chair the one on entanglement tomorrow morning, and then give my talk in the session on quantum foundations in the afternoon.

Just made a transparency of this William James quote:

> Metaphysics has usually followed a very primitive kind of quest. You know how men have always hankered after unlawful magic, and you know what a great part in magic *words* have always played. If you have his name, or the formula of incantation that binds him, you can control the spirit, genie, afrite, or whatever the power may be. Solomon knew the names of all the spirits, and having their names, he held them subject to his will. So the universe has always appeared to the natural mind as a kind of enigma, of which the key must be sought in the shape of some illuminating or power-bringing word or name. That word names the universe's *principle*, and to possess it is after a fashion to possess the universe itself.

I'm gonna read that to the audience, and then put up a transparency with a big $|\psi\rangle$ and nothing else on it. Then I'll say that since the beginning of quantum mechanics, the debate has been over what this thing actually is. But now we know its name: it is "expectation." Raw expectation. (A better word than "information" I think.) And now that we finally possess its name, we will after a fashion possess the universe itself.

Then I'll bombard them with too many equations … as one is expected to do in a physics talk.

20-03-06 *The Rest of the Story?* (to J. E. Sipe)

Sipesm 7: *Regardless of the strategy, the quantum world of this interpretation is a fixed, static thing. It is a frozen, changeless place. Dynamics refers not to the quantum world, but only to our actions, our experiences, and our beliefs as agents. Or, more poetically (à la Chris), life does not arise from our interventions; it is our interventions.*

Just like in our conversation, I think I'm pretty sympathetic with your description … until we get to here.

It is the substrate (and catalyst) that is changeless, but it is being written upon like a writing pad with the construction of a story. And that part of the process seems to me to be as important as anything else. In fact, I personally consider it a crucial part of the ontology. I want to better understand your de-emphasis of it.

Let me give you a little material below to react to. The first three passages represent what I have been calling the "Paulian Idea"—they are almost literal quotes from Pauli himself, but not quite, as I had to compress them somewhat to fit on the transparencies I was using for my presentation (at the Wheelerfest). I am not in complete agreement with these—for instance, sometimes he forgets his own emphasis that the measurement device should be considered as a prolongation of the agent—but maybe they can help get your gears turning, before I turn to more radical stuff.

Following Pauli, I'll put one version of Wheeler's 20-question story that was influential on me.

Finally I'll end with one excerpt from my *Notes on a Paulian Idea* and a couple of excerpts from my "Anti-Växjö Interpretation of Quantum Mechanics." These pieces emphasize, why I think the unpredictable outcome of a quantum measurement should be included in the ontology.

Do you see these things as consistent with your description above, or do you see them as contradictory? I would like to get that straight, because as I say, I like much in your description previous to that. (I'll come back to some more minor technical points in it later.) And who knows, maybe I've been misunderstanding my own view! It, like the world, is malleable after all.

Paulian Idea, 1

[Einstein and I] often discussed these questions, and I invariably profited very greatly even when I could not agree with Einstein's views. "Physics is after all the description of reality," he said to me, continuing, with a sarcastic glance in my direction, "or should I perhaps say physics is the description of what one merely imagines?" This question clearly shows Einstein's concern that the objective character of physics might be lost through a theory of the type of quantum mechanics, in that as a consequence of its wider conception of objectivity of an explanation of nature the difference between physical reality and dream or hallucination become blurred.

The objectivity of physics is however fully ensured in quantum mechanics in the following sense. Although in principle, according to the theory, it is in general only the statistics of series of experiments that is determined by laws, the observer is unable, even in the unpredictable single case, to influence the result of his observation—as for example the response of a counter at a particular instant of time. Further, personal qualities of the observer do not come into the theory in any way—the observation can be made by objective registering apparatus, the results of which are objectively available for anyone's inspection. Just as in the theory of relativity a group of mathematical transformations connects all possible coordinate systems, so in quantum mechanics a group of mathematical transformations connects the possible experimental arrangements.

Einstein however advocated a narrower form of the reality concept ...

Paulian Idea, 2

It seems to me appropriate to call the conceptual description of nature in classical physics, which Einstein so wishes to retain, "the ideal of the detached observer". To put it drastically, the observer has according to this ideal to disappear entirely in a discrete manner as hidden spectator, never as actor, nature being left alone in a predetermined course of events, independent of the way in which the phenomena are observed. "Like the moon has a definite position" Einstein said to me last winter, "whether or not we look at the moon, the same must also hold for the atomic objects, as there is no sharp distinction possible between these and macroscopic objects. Observation cannot *create* an element of reality like a position, there must be something contained in the complete description of physical reality which corresponds to the *possibility* of observing a position, already before the observation has been actually made." It is this kind of postulate which I call the ideal of the detached observer.

In quantum mechanics, on the contrary, an observation changes in general the "state" of the observed system in a way not contained in the mathematically formulated *laws*, which only apply to the time dependence of the state of a *closed* system. I think here on the passage to a new phenomenon by observation which is taken into account by the so called "reduction of the wave packets." As it is allowed to consider the instruments of observation as a kind of prolongation of the sense organs of the observer, I consider the impredictable change of the state by a single observation to be *an abandonment of the idea of the isolation (detachment) of the observer from the course of physical events outside himself.*

Paulian Idea, 3

Like an ultimate fact without any cause, the *individual* outcome of a measurement is, however, in general not comprehended by laws. This must necessarily be the case, if quantum mechanics is interpreted as a natural generalization of classical physics, which takes into account the finiteness of the quantum of action. . . .

The significance of this development is to give us insight into the logical possibility of a new and wider pattern of thought. This takes into account the observer, including the apparatus used by him, differently from the way it was done in classical physics. In the new pattern of thought we do not assume any longer the *detached observer*, occurring in the idealizations of this classical type of theory, but an observer who by his indeterminable effects creates a new situation, theoretically described as a new state of the observed system. In this way every observation is a singling out of a particular factual result, here and now, from the theoretical possibilities, thereby making obvious the discontinuous aspect of the physical phenomena.

Nevertheless, there remains still in the new kind of theory an *objective reality*, inasmuch as these theories deny any possibility for the observer to influence the results of a measurement, once the experimental arrangement is chosen. Therefore particular qualities of an individual observer do not enter the conceptual framework of the theory.

Wheelerish Idea, 1

But if I could have asked Bohr, how did he think the Universe came into being, and what is its substance, what would he have said?

It is too late to ask. The plan is up to us to find.

The Universe can't be Laplacean. It may be higgledy-piggledy. But have hope. Surely someday we will see the necessity of the quantum in its construction. Would you like a little story along this line?

Of course! About what?

About the game of twenty questions. You recall how it goes—one of the after-dinner party sent out of the living room, the others agreeing on a word, the one fated to be a questioner returning and starting his questions. "Is it a living object?" "No." "Is it here on earth?" "Yes." So the questions go from respondent to respondent around the room until at length the word emerges: victory if in twenty tries or less; otherwise, defeat.

Then comes the moment when we are fourth to be sent from the room. We are locked out unbelievably long. On finally being readmitted, we find a smile on everyone's face, sign of a joke or a plot. We innocently start our questions. At first the answers come quickly. Then each question begins to take longer in the answering—strange, when the answer itself is only a simple "yes" or "no." At length, feeling hot on the trail, we ask, "Is the word 'cloud'?" "Yes," comes the reply, and everyone bursts out laughing. When we were out of the room, they explain, they had agreed not to agree in advance on any word at all. Each one around the circle could respond "yes" or "no" as he pleased to whatever question we put to him. But however he replied he had to have a word in mind compatible with his own reply—and with all the replies that went before. No wonder some of those decisions between "yes" and "no" proved so hard!

And the point of your story?

Compare the game in its two versions with physics in its two formulations, classical and quantum. First, we thought the word already existed "out there" as physics once thought that the position and momentum of the electron existed "out there," independent of any act of observation. Second, in actuality the information about the word was brought into being step by step through the questions we raised, as the information about the electron is brought into being, step by step, by the experiments that the observer chooses to make. Third, if we had chosen to ask different questions we would have ended up with a different word—as the experimenter would have ended up with a different story for the doings of the electron if he had measured different quantities or the same quantities in a different order. Fourth, whatever power we had in bringing the particular word "cloud" into being was partial only. A major part of the selection—unknowing selection—lay in the "yes" or "no" replies of the colleagues around the room. Similarly, the experimenter has some substantial influence on what will happen to the electron by the choice of experiments he will do on it; but he knows there is much impredictability about what any given one of his measurements will disclose. Fifth, there was a "rule of the game" that required of every participator that his choice of yes or no should be compatible with *some* word. Similarly, there is a consistency about the observations made in physics. One person must be able to tell another in plain language what he finds and the second person must be able to verify the observation.

Flying Equations Story

Good holidays to you. This morning, as I was driving to work, it dawned on me that roughly this day 10 years ago, I was conferred my degrees at the University of Texas. Time does fly.

It made me think of a little anecdote about John Wheeler that I heard from John Preskill a few days ago. In 1972 he had Wheeler for his freshman classical mechanics course at Princeton. One day Wheeler had each student write all the equations of physics s/he knew on a single sheet of paper. He gathered the papers up and placed them all side-by-side on the stage at the front of the classroom. Finally, he looked out at the students and said, "These pages likely contain all the fundamental equations we know of physics. They encapsulate all that's known of the world." Then he looked at the papers and said, "Now fly!" Nothing happened. He looked out at the audience, then at the papers, raised his hands high, and commanded, "Fly!" Everyone was silent, thinking this guy had gone off his rocker. Wheeler said, "You see, these equations can't fly. But our universe flies. We're still missing the single, simple ingredient that makes it all fly."

Merry Christmas.

Växjination, 1

The situation of quantum mechanics—I become ever more convinced—illustrates this immersion of the scientific agent in the world more clearly than any physical theory contemplated to date. That is because it tells you you have to strain really hard and strip away most of the theory's operational content, most of its workaday usefulness, to make sense of it as a reflection of "what is" (independent of the agent) and—importantly—you insist on doing that for all the terms in the theory. . . .

So, I myself am left with a view of quantum mechanics for which the main terms in the theory—the quantum states—express nothing more than the gambling commitments I'm willing to make at any moment. When I encounter various other pieces of the world, if I am rational—that is to say, Darwinian-optimal—I should use the stimulations those pieces give me to reevaluate my commitments. This is what quantum state change is about. The REALITY of the world I am dealing with is captured by two things in the present picture:

1. I posit systems with which I find myself having encounters, and
2. I am not able to see in a deterministic fashion the stimulations (call them measurement outcomes, if you like) those systems will give me—something comes into me from the outside that takes me by surprise.

Växjination, 2

Yes there is certainly a kind of realism working in the back of my mind, if what you mean by "realism" is that one can imagine a world which never gives rise to man or sentience of any kind. This, from my view, would be a world without science, for there would be no scientific agents theorizing within it. This is what I mean by realism: That man is not a priori the be-all and end-all of the world. (The qualification "a priori" is important and I'll come back to it later.)

A quick consequence of this view is that I believe I eschew all forms of idealism. Instead, I would say all our evidence for the reality of the world comes from without us, i.e., not from within us. We do not hold evidence for an independent world by holding some kind of transcendental knowledge. Nor do we hold it from the practical and technological successes of our past and present conceptions of the world's essence. It is just the opposite. We believe in a world external to ourselves precisely because we find ourselves getting unpredictable kicks (from the world) all the time. If we could predict everything to the final T as Laplace had wanted us to, it seems to me, we might as well be living a dream.

To maybe put it in an overly poetic and not completely accurate way, the reality of the world is not in what we capture with our theories, but rather in all the stuff we don't. To make this concrete, take quantum mechanics and consider setting up all the equipment necessary to prepare a system in a state Π and to measure some noncommuting observable H. (In a sense, all that equipment is just an extension of ourselves and not so very different in character from a prosthetic hand.) Which eigenstate of H we will end up getting as our outcome, we cannot say. We can draw up some subjective probabilities for the occurrence of the various possibilities, but that's as far as we can go. (Or at least that's what quantum mechanics tells us.) Thus, I would say, in such a quantum measurement we touch the reality of the world in the most essential of ways.

20-03-06 *Replies to Sipe* (to R. Schack)

The history of the conversation with John Sipe goes like this. After reading the abstract for his tutorial at the APS meeting, I sent he and Rob Spekkens this little quip (and asked Matt Leifer if I embarrassed him by using his name in some of the attached material):

> T3 Current Interpretations of Quantum Mechanics
> Organizer: Rob Spekkens, Perimeter Institute for Theoretical Physics
> Room 302, Baltimore Convention Center
> ...
> Instructor: Professor John Sipe, University of Toronto
>
> Too bad the pseudo-Bayesian view of Caves, Schack, Appleby, Fuchs and few others isn't a current interpretation of quantum mechanics ...

That got John to asking questions, but also Matt replied:

> I think that in Rob and John's terminology the Bayesian approach is not a "current interpretation" but an idea for an interpretation. They are careful to distinguish the two in their book. A full blown interpretation is required to account for all of nonrelativistic quantum mechanics and to make precise what the ontology of the interpretation is. I don't think we have all agreed upon a consistent answer to the latter question yet.

I tend to take Matt's point seriously, and I worry about losing the ground we've gained with Sipe. It was for this reason that I really tried to shy away from the issue of Hamiltonians when Carl and I were talking to him the other day ... though Carl really wanted to put it front and center.

Similarly I might say about a possible corrective to his description of "measurements as [objectively described] tasks [via the formal assignment of a POVM]." Which is what I think you were getting at with your words:

Schackcosm 89: *One point that surprises me is that he got the impression that there is a fundamental difference in the way we look at preparations and measurements. How on earth did that happen?*

Partially it happened by my choosing to be silent on the issue.

Below I'll place the part's of John's description that I myself consider problematic, ... either because it doesn't convey properly our current unified thinking, or because it may pinpoint an area our current disagreement.

How to reply to him further, *if at all*, I am not yet clear on.

I've got to do a bunch of stupid company things today, but I really, really, really hope to start writing you two some detailed notes on the paper tomorrow.

Oh, also concerning Sipe, did you already get from Carl the one thing I did send him in reply a few days ago? I'm somewhat timid to send it over the airwaves again, as Carl has already pointed out its exorbitant length ...

— — — — — — — — — — — — — — — — —

Things from Sipe's note and small comments.

> Thus, while the abstract elements in the theory associated with measurements are identified with tasks in the laboratory, as in operationalism, the abstract elements in the theory associated with preparations are identified with beliefs of the agent, signaling a kind of empiricist perspective.

I understand Rüdiger's worry, but there is some small truth in this and I think it worth nurturing at this stage in his thinking (without overwhelming him). Yes, from our view, writing down a quantum state and writing down a set of effects is, in both cases, the writing down of beliefs. But they are beliefs of different things. And John carries the hint of that in his description. A POVM represents the agent's belief about the action he will take on the external world; a quantum state represents his belief about which of the consequences will come about from his action.

> In contrast, a usual Stern-Gerlach device oriented along the z direction does not, in this interpretation of quantum mechanics, reveal the z-component of angular momentum, or for that matter anything else. The particular outcome of one experimental run is simply a consequence of performing the experiment.

Agreed.

> Nonetheless, repeated experimentation does reveal that the electron associated with the atom passing through the device should be taken as a spin-1/2 particle. Here the attribute under consideration is taken to be internal angular momentum, and the instance – the irreducible representation appropriate to the particle of interest – spin-1/2.

This passage highlights the difference in ways that Carl and I talk. Carl would say that a system's attributes of this nature—say the system's Hamiltonian—are set intrinsically. The Hamiltonian (again, for instance) gives the system identity across time. Whereas, I would say that such identity is set by a subjective judgment.

It is my judgment that I should write down a constant Hamiltonian through time for such and such system: Measurement cannot reveal the TRUE Hamiltonian. To the extent that it can, one is making a judgment analogous to exchangeability. Because of the quantum de Finetti theorem, we know there is only the illusion that measurement can be used to infer the one true quantum state. Similarly I would say of the one true Hamiltonian.

On the other hand, I appreciate Carl's point that measurements (and their outcomes) have to be given meaning by some means. (This is what John was trying to get after with his phrase "anchors of belief.") But I lean much more on the agent's initial involvement in that term than Carl. The bureau of standards measurement, however abstract, does the trick for me. Its intention is to make clear that as long as an agent ascribes internal meaning to the outcomes of one measurement, then the meanings of all the rest are set too. But it's no deeper than choosing a standard meter stick. We have no right to say that the meter stick is the one true meter in nature's eyes, and similarly for the timeless quantum attribute. We set it, and thereafter, the practice of quantum mechanics is in trying to being consistent (coherent) with that initial call.

Which leads us to this:

> The role of an "instance of an attribute" in this interpretation is not to specify one of a number of possible expressions of existence, as it is in realist classical mechanics, but rather to specify one class of possible beliefs – the one that the theory recommends – about the consequences of future interventions of a particular type.

which I can again accept, with emphasis on "class of beliefs," before disagreeing with this for the reasons above:

> The point of physics is to identify these nondynamical variables. Repeated interventions by experimentalists, and the careful noting of the range of consequences that those interventions elicit, is how these fixed instances are discovered.

Finally, I've already told John and Carl know my strong dislike of this (and maybe it's been forwarded to Rüdiger):

> Regardless of the strategy, the quantum world of this interpretation is a fixed, static thing. It is a frozen, changeless place. Dynamics refers not to the quantum world, but only to our actions, our experiences, and our beliefs as agents.

but as I reread it, maybe I'm willing to find a grain of truth in its emphasis too. John puts the formal structure on one side of a dividing line, and the extra-formal stuff (like the indices on a POVM) on the other side. What we may be disagreeing over may only be whether the latter stuff is allowed to be called part of quantum mechanics.

— —

In all, after writing all this, I find myself wondering even more about how much of all this should be brought to John's attention. Maybe it is best to leave John's temporary happiness as it is (he'll eventually come out of it anyway) and leave our internal arguments as a family matter for the moment.

21-03-06 *The Unchanged Changer* (to R. Schack)

Schackcosm 90:

***Sipesm 8*:** *But in your interpretation some of the abstract elements of the theory do describe something that "actually exists"; it is these "frozen" elements, your Bureau of Standards measurement results, which might be called the scaffold of our experiences.*

Am I right that he has misunderstood something?

I'm not sure at what level you're asking this question. Is you question concerning the part about "in your interpretation some of the abstract elements of the theory do describe something that 'actually exists' "? Or rather the part about "your Bureau of Standards measurement results, which might be called the scaffold of our experiences"?

Since you know that I'm pragmatist about theories (and only willing to talk about "objective with respect to a theory"), let me guess that your concern is with the second issue. If that's the case, then let me rather focus on this passage of his:

Sipesm 9: *The results of your Bureau of Standards measurements, existing in some Platonic heaven at some time in the future, are "once and for all." Carl would say that the irreducible representation of a spin-1/2 particle is the same today as it always was and always will be.*

He's got the bit about the attributes being frozen in time right, for both Carl and me (or, at least, as I understand Carl). That is one of the reasons I call the quantum system a "catalyst" in the attached diagram (which John would never look at in our conversation the other day)—it is the unchanged changer (at least at this level of our understanding).

Where he flubs things is where he attributes to me the idea that, "The results of your Bureau of Standards measurements, existing in some Platonic heaven at some time in the future, are 'once and for all.' " I don't at all imagine the results as existing at some time in the future. For no measurement results pre-exist an actual measurement process; or to say it better, without the actual action, there is no actual reaction. Instead, to the extent that an agent judges that he is always thinking of the same system, he will fix a single B of S measurement with which to make reference (which in turn fixes an irreducible representation, as in Carl's version). It is only that that is timeless in the way John is thinking, not any putative outcome for the Platonic measurement.

More generally about the note, he seems to have the flavor of the "phenomenalism" wrong that he attributes to Bohr and Pauli (those two for sure), but also the one he attributes to me. There is something about his description that seems to leave it disconnected from the quantum formalism. Whereas I would say that I have come to this point precisely because of Kochen-Specker and Gleason, which surely rely on the quantum formalism. The categories and their motivations just can't be separated so cleanly as he would like.

22-03-06 *Web Page, Second Draft* (to R. E. Slusher)

1.5.6 Fundamentally New Science and Technology

Quantum Computing, Communication, and Cryptography at Bell Labs

Quantum mechanics, as a branch of physics, has been with us since the late 1920s, and it can be safely said that without it our modern technological society would not exist. Quantum effects power almost all that we know, from transistors, to lasers, to medical imaging, to nuclear weapons and much, much more. However, only in the last 10-15 years has it been realized that the most arcane features of quantum mechanics—ones not presently used in any technology—can be harnessed for computing and communication tasks unimaginable within classical physics. This is not so much because quantum devices can be made smaller and faster, but because the language of quantum mechanics allows the writing of new algorithms that simply cannot be written in classical terms. The most famous algorithms in this respect are Peter Shor's prime factorization algorithm (which, if implemented, would make RSA public key cryptography insecure) and Lov Grover's quantum search algorithm, both of which were discovered here at Bell Labs. Finding ever new uses for these arcane quantum effects and implementing them in real technologies is an active and lively field, known as Quantum Information.

Present work at Bell Labs ranges the field: On the theoretical side, we specialize in algorithms, topological quantum computation, fundamental aspects of quantum information, quantum error-correcting codes, and supporting technologies calculations. On the experimental side, we are participating in a large effort to implement quantum computation in scalable micro-ion-traps and scalable optical-lattices for cold trapped atoms. As well, we have a strong effort to implement multi-channel gigahertz-rate quantum cryptography. All our experimental efforts make crucial use of Lucent's expertise in MEMS device technologies, with fabrication of ion traps and spatial light modulators through the New Jersey Nanotechnology Consortium.

23-03-06 *A Review of General Covariance* (to G. L. Comer)

Waking up very slowly. Silly, after an almost sleepless night. All night long I tossed and turned obsessing over the same thought/question:

> An 'action' is defined by the set of its 'consequences.' However the only consequences I can see in a quantum measurement are the refinement of one's expectations. But some actions lead to identical sets of refined expectations with differing probabilities. So they must be different actions after all. But that contradicts the first part. Repeat. Repeat. Repeat. What's going on? Repeat. Repeat. The only consequences of quantum measurement should be refined expectations. What's going on?

Somewhere around 6:00, I said, "Aha, it's 'likelihoods' that are the consequences." I still don't really understand that, but somehow it was enough to let me finally fall asleep. But then it was almost time to get up.

24-03-06 *On Certainty, Quantum Outcomes, Subjectivity, Objectivity, and Expanding Universes, Part 1* (to R. Schack & C. M. Caves)

Amazing, how hard it is to write this paper and even discuss these things internally between the three of us. When we started this debate on certainty in August 2001, I had no grey hair; now

I've got lots of it. ... OK, maybe the real problem has been Lucent all along (which, as of this morning, may soon be Alcatel), but still it's been a tough paper to write. Luckily—and despite all that—I do think Rüdiger's outline/draft is pretty good. Major chunks of it, to my mind, are certainly very usable. It is a valiant attempt and certainly something I haven't been able to do.

But, there are some things in the present draft and in the latest discussion between you two that, I think, go in the wrong direction, or at least diverge from all the progress I thought we had made in confronting the Wigner's friend issue in December. Maybe it was illusory, but I don't want to think so.

So, let me try to get this on paper before having a phone conversation about it. (I know you two like to talk rather than write all this email; you find it more efficient. But I don't most of the time. I can pain over my sentences and pause as much as I want without getting ridiculed or sidetracked or rushed along, and that is pretty important for me.)

But even now, where to start?

Maybe a good place is these two sentences from Rüdiger (even if one or both are outdated by now ... and I think at least one of them is):

Schackcosm 91: *There is a* quantum *reason for certainty being subjective, which does not apply in the classical case.*

and

Schackcosm 92: *I agree, reluctantly. The category distinction doesn't buy as much as I hoped it would.*

I don't believe I had ever thought of it that way. I.e., that the category distinction between the elements of the event space and the probability function over the event space would ever 1) "buy us" something new—I only saw it as something that had to be emphasized to patch up a perceived inconsistency in our Bayesian position—, or 2) be such that there could be additional, specifically quantum reasons for invoking it.

The problem is, without a *philosophical* category distinction of some sort between the x and the $P()$ in $P(x)$—and not just the mathematical one—the Bayesian view of probability runs the risk of collapsing into a kind of solipsism or mysticism (as Howard Wiseman and Wayne Myrvold indeed, and sometimes Bill Unruh, seem to think it does). That risk is already there without quantum mechanics.

One of our main contributions, I thought, was in emphasizing (like no one else ever had) that this category distinction *must* be maintained even in the limiting case of $P(x) = 1$. Then, after doing so, we would leverage that to say the Penrose argument carries no weight after all. And partially this has been carried out in the draft.

But here's where I think things have gotten off track. I'm seeing language of this order traveling between the two of you: "certainty never implies a fact," "knowledge of a fact h can, however, compel the assignment $P(h) = 1$," "some probabilities are objective after all." More colloquially, at some far off meeting, I think I even heard someone say this, "this 'category distinction' business is a red herring." These may not be precise quotes, but I think they capture the sorts of phrases that are going around. And I think that is very dangerous business.

We had a clean point (or at least we were groping toward one); let's not lose it.

Part of the trouble, I think, is coming from derailed uses of the terms 'subjective' and 'objective' creeping back into this draft, and then starting a snowball effect. Let me try to expand on that. When I finish, I will come back to give specific replies to:

1) this thing that Carl said:

Cavesism 72 : *my concern is that the category distinction loses some of its force. The original idea, I believe, was to say that facts never determine beliefs (i.e., probabilities), either classically or in qm. We can still say that, but the important distinction between realism and qm will be different: in a realistic world, knowledge of facts can dictate delta probabilities, but in qm knowledge of facts cannot dictate quantum states. What do you think?*

2) this thing that Rüdiger said:

Schackcosm 93 : *And you should make the point in this way when you talk to Chris ... Let's say X is "up" in a spin measurement. Agents A and B agree about everything concerning the setup and the precise conditions under which you would call X true. The measurement is performed, and they both agree that X is true. Then $P(X) = 1$ for both of them. This P is objective.*

and 3) this thing Carl said:

Cavesism 73 : *I am now thinking that it would be a mistake to get into distinguishing "facts" from "knowledge of facts," since that is not the distinction we want to make. Rather we want to say that "knowledge of facts" can never compel a pure-state assignment, whereas it would seem that we are saying that "knowledge of facts" can compel a delta probability assignment.*

In all three cases I have a bone to pick. In 1), it is in hinging too much on the nonoperational term 'knowledge,' which I would like to banish in any case. In 2), it is in a definition of 'objective' that I do not like anymore, and I think runs into trouble or at least becomes confusing in the places where we need it most. And ultimately in 1) and 3), I think this is just the wrong distinction, and, in any case, it is not true.

— — — — — —

I'll go ahead and send you this much now, to show you that I wasn't lying when I said that I've been thinking of these things, but before going on, I've got to go home to satisfy an urge to try to catch some squirrels.

Recommended reading: Item #7, "Epistemology Probabilized," by Richard Jeffrey, at `http://www.princeton.edu/~bayesway/`.

27-03-06 *Block of Ice-Nine* (to C. M. Caves)

Cavesism 74 : *We should never have let Sipe get away with the ice-nine characterization of the Bayesian interpretation. He is right that we posit a changeless world of attributes that physics is trying to get at, but this is less than half the story. The rest of the story is the evolving universe in which we participate. He would say that the only dynamics that occurs is the dynamics of our beliefs (or the descriptions based on our beliefs), but there is a world out there, which we are trying to describe as best we can, and the evolution of our beliefs is our best attempt to capture what's happening in the world.*

Cavesism 75 : *It's a Vonnegut novel, in which all the water in the world follows a tiny seed into a solid thermodynamic state called ice-nine.*

Thanks for the definition.

I hate it when I can't pin down all my rantings. I remember one day going off on someone (maybe it was Howard Barnum or maybe Jeremy Butterfield, but probably someone completely different) about how the many-worlds conception is of a universe that's a big block of ice. And I became so tickled with that phrase that I just kept saying it over and over.

Rüdiger, if you remember, come to my rescue. I remember us talking about this sort of thing when we were talking about that guy's book, *The Paradox of Cause*.

Nothing more distasteful than a block-universe view.

Looking through my emails, I'm surprised by how little I've used the phrase "block universe"! And even more shocked that I couldn't find the phrase "block of ice." I was going to send you some examples ... but I see I've now got to go catch my plane.

Ice-nine, I like it.

> I go up and I go down when it comes to speaking the words gravity and quantum in the same sentence. At times I find myself thinking that general relativity and quantum mechanics express two absolutely incompatible worldviews. The general relativistic universe is a "block universe" in William James's sense: It's just there. One can talk about foliations and dynamics, etc., *within* the 4-manifold, but in the largest view—the view from nowhere—the world and all its history is just there. It is a universe without life (in the creative sense). In contrast, the quantum world strikes me as a malleable world—one that is still in formation, and in particular, one for which it is impossible to get such a "view from nowhere" (as Nagel would call it).

30-03-06 *The Sqrt Operation* (to W. K. Wootters)

What are you doing up so early?! I'm in Lisbon at the moment; so at least that's my excuse for reading your email at this time!

Woottersism 14: *You probably know the answer to this question. Consider any POVM. Depending on how one implements the POVM, the system being measured could end up in many different states, even for a specific outcome of the POVM. (I'm assuming that the system survives the operation.) One very easy case to consider, at least mathematically easy, is the case in which the final state of the system is given simply by $\sqrt{\Pi_j}$ applied to the original state, where Π_j is the POVM element. Is there any precise sense in which this particular implementation of a POVM is the* least disturbing *to the system's state? (I suppose there will have to be some sort of averaging over all the possible initial states. Some will be disturbed more than others.)*

Yeah, you've got it exactly right. If the input is promised to be a random pure state (wrt unitarily invariant measure), and the measure of disturbance is 1-fidelity between input and output, then the operation you describe for a fixed measurement is the least disturbing on average. This issue came up around 1996 and the proof was harder than one might think. Howard Barnum has a large bit about it in his PhD thesis. I think he finally published it here: `http://www.arxiv.org/abs/quant-ph/0205155`.

04-04-06 *Title* (to S. J. van Enk)

"Had We Found a Better Title, We Would Have Chosen It" [See 09-05-08 note "Change of Plan" to S. J. van Enk.]

19-04-06 *Church of the Smaller Hilbert Space* (to M. S. Leifer)

I love it!

Almost semi-seriously, it'd be nice if you'd hone that and present it in Växjö.

Matt's Beautiful Preply: "The Church of the Smaller Hilbert Space"

I can't believe I wasted a whole hour writing this thing, and I can't even post it on my office door because some god-fearing member of the public might see it.

TEN COMMANDMENTS OF THE CHURCH OF THE SMALLER HILBERT SPACE

With apologies to Charlie Bennett and, of course, God.

1. I am ρ, your state, who brought you out of wavefunction realism, the place of orthodox dogmatism.
2. Do not have any other states except Me. Do not represent states by false purifications, conceived as ontological states of the Platonic forms above, of reality below, or of the space-time foam underlying reality. Do not bow down to such states or worship them. I am ρ your state, a state that demands exclusive belief.
3. Do not announce your state ρ in vain. ρ will not allow the one who announces it in vain to go unpunished by a Dutch bookie.
4. Remember the CP-map $\mathcal{E}$ to keep dynamics meaningful. You can work things out using six different Kraus decompositions or Steinspring dilations and do all your tasks. But the CP-map $\mathcal{E}$ is an equivalence class to ρ your state. Do not do anything that attaches meaning to the arbitrary tools you choose to work with. This includes your Hilbert Space basis $\{|j\rangle\}$, your purifications $|\Psi\rangle$, your Kraus decompositions $\{E_j\}$, $\mathcal{E}(\rho) = \sum_j E_j \rho E_j^\dagger$, your Steinspring dilations U, $U^\dagger U = UU^\dagger = I$, your Naimark extensions P_j, $P_j P_k = \delta_{jk} P_j$, your path integral decompositions and your virtual particles. It is for perturbation theory calculations in QED that ρ is supplemented by the Feynman diagrams, the path integrals, the Greens functions, and all that is in them, but the true evolution of ρ rests on the CP-map. ρ therefore blessed the CP-map E and made it meaningful.
5. Honor your forefathers by using the Hilbert space algorithm they handed down to you to calculate your expected utilities. You will then live long on the land that ρ your state describes your beliefs about.
6. Do not commit murder, since there is no other "branch of the wavefunction" in which your victim will survive.
7. Do not adulterate the Schrödinger equation by adding nonlinear terms designed to cause collapse.
8. Do not steal from classical physics by insisting that particle position or field configuration variables must evolve deterministically.
9. Do not testify as a false witness to the existence of histories of events that do not appear in the empirical records.
10. Do not be envious of your neighbor's state σ. Do not be envious of your neighbor's dynamical CP-map $\mathcal{F}$, his POVM elements $\{N_j\}$, his update CP-maps $\mathcal{F}_j$, his Kraus operators F_{jk}, his donkey, or anything else that is your neighbor's, for they only describe his beliefs (except for the donkey), which naturally differ from yours.

20-04-06 *Always Quantumness!* (to M. Sasaki)

Thank you too for your other kind offer. With friends like you, I am spiritually wealthy! But do not break your back trying to realize an invitation for me if your budget is tight—certainly take care of important things first!

I hope things are going well for you scientifically. A couple months ago, I talked about our quantumness again, for the first time in quite a while. It was for the colloquium of the Applied Mathematics Dept. at Princeton University. It was quite well received, in fact, as generating some interesting questions in mathematics. In the audience there were Rob Calderbank (a coding theorist), Ingrid Daubechies (inventor of wavelets), Simon Kochen (a famous logician, particularly for the Kochen-Specker theorem in quantum mechanics), ... and even the super-famous John Conway ("Atlas of Finite Groups" and the cellular automaton "Life") and John Nash (Nobel Prize in economics). I'll place the abstract of the talk for you below.

Anyway, there are many things still to be done with the concept, and I hope that one day we will get a chance to work on it together again. If the world of quantum information picks up here at Bell Labs in the next year (after the merger), I hope that I can reciprocate on your kind invitation.

> Title: Math Problems from the Far Side of Quantum Information
>
> Abstract: The field of Quantum Information has recently rightly attracted great interest for the technological fruits it may bear. But there is a sect of its practitioners who think it stands a chance to bring us much more than that—namely, that its theoretical tools will give us a means for exploring what quantum mechanics is really all about and for settling some of the deepest problems in physics. The roots of this optimism come from a very old thought: that a quantum state has more to do with representing its user's information, than any inherent physical property of the system to which it is ascribed. What is new and nice is that quantum information teaches us how to formulate this idea precisely and even check its consistency. Nicer still for the mathematics community is the number of juicy mathematical problems the consistency-checking process poses. In this talk, I will review some of the history of this and then quickly settle on a sample problem that has been annoying me a lot lately: the question of the existence of symmetric informationally complete positive-operator-valued measures for finite dimensional Hilbert spaces. I'm not alone—it turns out to be equivalent to a 30-year-old problem in coding theory—but I will say some things about it that you may not have heard before.

20-04-06 *Church of the Big-Enough Hilbert Space, 1* (to M. S. Leifer & D. Bacon)

In contemplating the genius of Matt's commandments (and being especially motivated from watching the old Charlton Heston movie with my seven-year-old this weekend), I took a trip down memory lane tonight. I found the passage below in my *Notes on a Paulian Idea*:

> I had a very nice conversation with Charlie on the drive back to Wendell from your house, that, I think, has allowed me to sharpen what I think about things in quantum mechanics. In particular, I would like to work on a point of view that substitutes in place of the "Church of the Larger Hilbert Space," something along the lines of "Church of the Big-Enough Hilbert Space." However, it'll require some writing for me to get it down coherently.

It led to the question is big-enough bigger than smaller—maybe, maybe not: probably depends upon who you're kneeling with. Anyway, I hope it's bigger than empty.

On another subject, I've also been contemplating dumping another 500 pages onto `quant-ph` May 10 (for the fifth year anniversary of my last big dump). Experienced bloggers that you both are, what do you think of the idea? Do you think it goes too far, given my earlier foray?

20-04-06 *Church of the Big-Enough Hilbert Space, 2* (to D. Bacon)

Baconism 1: *Whoever first framed the words "Church of the Larger Hilbert Space" was a genius.*

Yes, John Smolin is a genius, and for many reasons.

Baconism 2: *I mean, it makes other interpretations just seem silly!*

But this point worries me. You do realize that Matt's manifesto, despite the humor is semi-serious? It captures many of the essential points of what he, Carl Caves, Rüdiger Schack, I and a few others, are trying to get at with our Bayesian view of quantum probabilities. Particularly take head of his second commandment:

> Do not have any other states except Me. Do not represent states by false purifications, conceived as ontological states of the Platonic forms above, of reality below, or of the space-time foam underlying reality. Do not bow down to such states or worship them. I am ρ your state, a state that demands exclusive belief.

He means it. And that statement is the antithesis of what Charlie Bennett and John Smolin are thinking when they invoke their church.

Thanks for endorsing another dump. I'll take your vote into account as I make this painful decision ... (One day I'll have to tell you about the advice William James once wrote to his brother Henry concerning the latter's hygienic habits.)

25-04-06 *My Title and Abstract* (to A. Y. Khrennikov)

I'm not sure what title I sent you before, but let us now go with the one below. It is a talk I gave at Princeton for their Applied Math Dept colloquium one week ago—I hope you don't mind if I recycle it, but I've run out of time for something new.

> Title: Math Problems from the Far Side of Quantum Information
>
> Abstract: The field of Quantum Information has recently rightly attracted great interest for the technological fruits it may bear. But there is a sect of its practitioners who think it stands a chance to bring us much more than that—namely, that its theoretical tools will give us a means for exploring what quantum mechanics is really all about and for settling some of the deepest problems in physics. The roots of this optimism come from a very old thought: that a quantum state has more to do with representing its user's information, than any inherent physical property of the system to which it is ascribed. What is new and nice is that quantum information teaches us how to formulate this idea precisely and even check its consistency. Nicer still for the mathematics community is the number of juicy mathematical problems the consistency-checking process poses. In this talk, I will review some of the history of this and then quickly settle on

a sample problem that has been annoying me a lot lately: the question of the existence of symmetric informationally complete positive-operator-valued measures for finite dimensional Hilbert spaces. I'm not alone—it turns out to be equivalent to a 30-year-old problem in coding theory—but I will say some things about it that you may not have heard before.

01-05-06 *Conversations with God* (to W. B. Case)

Attached are the two excerpts from my samizdat "Notes on a Paulian Idea" that I told you about last night.

From a 23 January 2000 note to Gilles Brassard, "I See Why Bit Commitment"

Let me just say that I had a bit of an epiphany in the shuttle bus at Dulles Airport: for the first time I have understood why you want to take *both* the EXISTENCE of secure key distribution and the NONEXISTENCE of bit commitment as pillars in your sought-after derivation of QM. You have been thinking more deeply than me since the beginning!

Let me place at the end of this note a little piece from my samizdat. [See letter to Greg Comer, 22 April 1999, titled "Fuchsian Genesis."] It sort of presents what I've been trying to get at in a dramatic way: it may be my best presentation of the idea of why quantum key distribution has something to do with the foundations of quantum mechanics. But more to the present point, let me tell you about a second way I use to get the point across. I've used this slide in a few talks. It consists of five frames with the following little story.

> In the first frame God starts to speak to Adam at a time just before Genesis, "Adam, I am going to build you a world. Do you have any suggestions?"
>
> **Adam**: Mostly I don't want to be alone. I want to have friends ... and enemies to spice things up ... and generally just plenty of people to talk to.
>
> **God**: Done. I'll give you a world populated with loads of other people. But you ask for a bit of an engineering feat when you ask to be able to talk to them. If you want to communicate, the world can't be too rigid; it has to be a sort of malleable thing. It has to have enough looseness so that you can write the messages of your choice into its properties. It will make the world a little more unpredictable than it might have been for me—I may not be able to warn you about impending dangers like droughts and hurricanes anymore—but I can do that if you want.
>
> **Adam**: Also God, I would like there to be at least one special someone—someone I can share all my innermost thoughts with, the ones I'd like to keep secret from the rest of the world.
>
> **God**: Now you ask for a tall order! You want to be able to communicate with one person, and make sure that no one else is listening? How could I possibly do that without having you two bifurcate into a world of your own, one with no contact whatsoever with the original? How about we cut a compromise? Since I'm already making the world malleable so that you can write

your messages into it, I'll also make it sensitive to unwanted eavesdropping. I'll give you a means for checking whether someone is listening in on your conversations: whenever information is gathered from your communication carriers, there'll be a reciprocal loss in what you could have said about them otherwise. There'll be a disturbance. Good enough? You should be able to do something clever enough with that to get by.

> **Adam**: Good enough!

> **God**: Then now I'll put you in a deep sleep, and when you awake you'll have your world.

> **Adam**: Wait, wait! I overlooked something! I don't want an unmanageable world, one that I'll never be able to get a scientific theory of. If whenever I gather information about some piece of the world, my colleagues lose some of their information about it, how will we ever come to agreement about what we see? Maybe we'll never be able to see eye to eye on anything. What is science if it's not seeing eye to eye after a sufficient amount of effort? Have I doomed myself to a world that is little more than chaos as far as my description of it goes?

> **God**: No, actually you haven't. I can do this for you: I'll turn the information-disturbance tradeoff knob just to the point where you'll still be able to do science. What could be better? You have both privacy and science.

> So Adam fell into a deep sleep, and God set about making a world consistent with his desires. And, poof(!), there was QUANTUM MECHANICS.

That's the tale. But now I see the crucial spot of outlawing bit commitment within it. God could have supplied Adam with a set of impenetrable boxes (and keys to open them) where he could place his information whenever he wanted some secrecy. A bit commitment protocol could certainly be used in that secondary fashion. But God chose to make all information open for all the world to see: he just left the possibility of an imprint whenever someone has a look.

From a 22 April 1999 note to Greg Comer, "Fuchsian Genesis"

> In the beginning God created the heaven and the earth. And the earth was without form, and void; and darkness was upon the face of the deep. And the Spirit of God moved upon the face of the waters. And God said, Let there be light: and there was light. And God saw the light, that it was good; and God divided the light from the darkness. And God called the light Day and the darkness he called Night. And the evening and the morning were the first day. ... [Day 2], [Day 3], [Day 4], [Day 5] ... And God saw everything that he had made, and behold, it was very good. And there was evening and there was morning, a sixth day. Thus the heavens and the earth were finished, and all the host of them.

But in all the host of them, there was no science. The scientific world could not help but STILL be without form, and void. For science is a creation of man, a project not yet finished (and perhaps never finishable)—it is the expression of man's attempt to be less surprised by this God-given world with each succeeding day.

So, upon creation, the society of man set out to discover and form physical laws. Eventually an undeniable fact came to light: information gathering about the world is not without a cost. Our experimentation on the world is not without consequence. When *I* learn something about an object, *you* are forced to revise (toward the direction of more ignorance) what you could have said of it. It is a world so "sensitive to the touch" that—with that knowledge—one might have been tempted to turn the tables, to suspect a priori that there could be no science at all. Yet undeniably, distilled from the process of our comparing our notes with those of the larger community—each expressing a give and take of someone's information gain and someone else's consequent loss—we have been able to construct a scientific theory of much that we see. The world is volatile to our information gathering, but not so volatile that we have not been able to construct a successful theory of it. How else could we, "Be fruitful, and multiply, and replenish the earth, and subdue it?" The most basic, low-level piece of that understanding is quantum theory.

The *speculation* is that quantum theory is the unique expression of this happy circumstance: it is the best we can say in a world where *my* information gathering and *your* information loss go hand in hand. It is an expression of the "laws of thought" best molded to our lot in life. What we cannot do anymore is suppose a physical theory that is a direct reflection of the mechanism underneath it all: that mechanism is hidden to the point of our not even being able to speculate about it (in a scientific way). We must instead find comfort in a physical theory that gives us the means for describing what we can *know* and how that *knowledge* can change (quantum states and unitary evolution). The task of physics has changed from aspiring to be a static portrait of "what is" to being "the ability to win a bet."[107]

This speculation defines the large part of my present research program.

09-05-06 *The Bayesian Big Bang* (to H. Barnum)

Wow, that's some report! Thanks for sending me all that. It sounds like I really did miss a thought-provoking time.

I wouldn't know what to suggest to put in a note to Albert.

Barnumism 16: *Incidentally, the discussion with Albert ended with him saying "so you don't believe parts of the early universe do work on other parts even though there is no subject who is using its knowledge to extract work. . . " I was rather tired, so called a pause there and will deal with that later. I think it can be dealt with, the main point being that WE understand parts of the early universe as doing work on other parts [. . .], perhaps, because OUR KNOWLEDGE of those parts is the same kind of knowledge (canonical ensemble at some temperature, blah-de-blah) that would allow us, given large enough apparatus etc. . . , to extract that much work. . . because some of the processes that actually go on in the early universe are (I guess. . .) similar to various kinds of thermodynamic processes of putting stuff in pistons and expanding, etc. [. . .] [N]evertheless I believe this is basically right. . . our description of early-universe processes in thermodynamic terms is because we have the same kind of knowledge about it that we have about gases and liquids being boiled and compressed etc. . . "The radiation background was at XX degrees Kelvin when it decoupled from matter" is a statement of what we think we know about it, not a property of its microstate at the time.*

[107]The nice phrase "physics is the ability to win a bet" is due to J. R. Buck (a grad student at Caltech) circa 19 February 1999.

I've told you my wacky idea that for all Bayesians there must be a big bang, haven't I? In case not, the idea is this. Consider my beliefs about yesterday's events. If we were to lump all of them into a big joint probability distribution, it would have some entropy. Now consider my beliefs about the events the day before that. They too could be lumped into a distribution. However, since I'm probably less sure about the things that happened the day before last than I am about the things that happened yesterday, the latter distribution should have more entropy. And so on we could go further back in time. Assuming I lose effectively all predictability as I conceptually reach back to some finite time (based on the size of my brain and my processing capability), I should end up with a distribution of effectively infinite entropy. Associating (somehow) this distribution with one of canonical form—that's one of the hard steps—I find an effectively infinite temperature in the finite past.

Just another way of saying the universe came into existence (at least with regard to my ability to extract work from it).

Homework Problem: Given reasonable models of a typical brain's inferential powers and the resolution of human senses, estimate the number of years since the big bang.

17-05-06 *Beautiful Passage* (to G. L. Comer)

Most of my work tonight though has been on going through your files—I'm up to December 2002 at the moment, so there's still a long way to go. But it's been very enlightening to read our correspondence between each other again. And so nice to read your poems again. I feel like there's so much I want to tell you—about all the clarifications that have come to me about the transformation rules in quantum mechanics in the last year, about the disanalogy I start to see with relativity (relativity connects disparate observers, the transforms in quantum mechanics connect the gambles one single observer is willing to make, much like Dutch-book consistency), and about how so much of these thoughts probably find their origins in the things you were bringing to my attention in 2002. But all of that is going to require new notes, not old! So you have to wait old friend.

19-05-06 *Spring Is in the Air . . . MUBs Are in the Air* (to W. E. Lawrence)

It dawned on me today that it was about this time last year that you visited us and gave us a talk about MUBs and phase space. There must be something about the time of year! As it turns out Bill Wootters will visit us next week, and give the talk below. What is it about the Spring?

Hope all is well with you.

> RESEARCH TALK –
>
> Phase Space for Qubits
> Prof. William K. Wootters
> Williams College
>
> Wednesday – May 24, 2006
> 11:00 AM
> MH 1D-224
>
> Abstract:
> For a single particle moving in one dimension, the particle's quantum state can be rep-

resented as a real function of position and momentum, the Wigner function, which has certain properties that make it useful for state reconstruction. In this talk I show how a system of binary quantum objects (qubits) can be represented by a closely analogous function, a discrete Wigner function, on a discrete phase space. The two axis-variables of the discrete phase space, that is, the analogs of position and momentum, are associated with two "conjugate" bases of the state space, and are labeled by the elements of a finite field (in the algebraic sense of "field"). The use of a finite field is by no means arbitrary: one finds that the structure of the field accords remarkably well with certain features of the complex-vector-space structure of quantum mechanics.

01-06-06 *Cirac Has Been Deservedly Awarded* (to M. Pérez-Suárez)

Thanks for the letter. I'm sorry to hear that staying in the US put you in a funk, though. Ignacio is a great guy; it is great to hear he has won such an award. I talked to him for almost three hours at the APS March meeting, mostly about de Finetti theorems and SIC-POVMs, and it was such an exhilarating experience. He is lightning fast and simply understands everything almost immediately.

Congratulations too on your book. Thanks so much for sending me a copy. I'll put it with pride on my shelf (even if I cannot read it).

We will miss you in Sweden. I hope it is a productive meeting and actually expect it will be. I will talk on recent things Bill Wootters and I have discovered on SIC-POVMs—that they are not all unitarily or anti-unitarily equivalent—also, I will frame better what I mean by saying that the Born rule for calculating quantum probabilities is really a kind of transformation rule (along the lines of a de Finettian coherence principle). It would have been nice to have your critical input at the talk.

Send me your thesis as it comes together.

01-06-06 *Critical Paper* (to J. Bub)

Thanks for sending the paper! It looks interesting. I've just printed it out and will be taking it with me to Sweden tomorrow. I'll send you my comments hopefully early in the week.

I didn't think there was any real difference between the Ramseyan and de Finettian views of probability (other than perhaps emphasis). There may, however, be a difference between how you and I think of "truth"—particularly in the quantum context. I'll flesh out my thoughts to you just as soon as I can and give you feedback on your paper.

BTW, I've also printed out your most recent paper on quantum computation from quant-ph to take with me. That looks very exciting.

02-06-06 *Enjoyable Paper* (to J. Bub)

As I wrote you earlier, I'm on my way to Sweden today (though I didn't tell you about how roundabout of a way I'm taking). Anyway, I'm in Chicago at the moment and will board the next plane soon.

But I wanted to tell you that I used the first flight to read, take notes on, and contemplate your paper. It was quite enjoyable. And certainly I'm glad to see you making a movement in the Bayesian direction!

If I had known about your thinking along these lines, I would have certainly invited you to this meeting. With the funding I had, I put together what I've been calling the "Swedish Bayesian Team" (Schack, Leifer, Appleby, Pitowsky, and Caticha), so that hopefully we'll have a very focused discussion on some of the technical aspects of this subject (as opposed to the impasse that I mostly viewed the Konstanz meeting as). You would have been a great contributor.

Anyway, as a proxy for not having you physically present, I'll be writing you this week. I have plenty of comments and queries about your paper.

13-06-06 *Little Chocorua* (to L. Simon)

I am a research physicist at Bell Labs doing quantum information theory and quantum foundations for a living, but have a great side interest in William James and pragmatism in general. I even pride myself—probably incorrectly—on having the largest personal library on pragmatism in New Jersey! (About 420 volumes.)

Anyway, I write to you because it dawned on me that you may be able to help me in a silly little quest. My wife is constructing a playhouse for our daughters from 12 doors she recovered from an 1896 house being demolished near our home. (Our own house is an 1896 Victorian, and the coincidence of the years gave her this clever idea.) Of course it's one more door than James' home in Chocorua had, but nonetheless we've decided to call the playhouse "Little Chocorua"—the kids seem to like the name and we've run with it.

This is where you come in: Do you know of any good sources of pictures of the original Chocorua home? Or do you perhaps have any of your own that you have scanned into your computer? We're hoping to get ideas on how to give the playhouse some final touches so it fits its name even better.

The only picture of the Chocorua home that I have ever seen comes from your book. (Wonderful book, by the way; I very much enjoyed it.) But I also know from an interview with you on the web that I read a few months back, that you have physically visited the home. Perhaps you took some pictures then.

Sorry to bother you with such a strange request … but I thought it might be novel enough that you would be interested in helping us out.

P.S. If you are interested in seeing how some of James's idea strike me as having an intimate connection with quantum foundations issues, download the big document posted at the bottom of my webpage titled "Cerro Grande II". Then simply do a search on "William James" within it, and maybe you'll find an interesting idea or two. There is a link to my webpage below.

Linda's Reply

> Dear Christopher Fuchs, your playhouse sounds wonderful, but I don't have photos. I was able to see the house because it was on the market at the time (Janice Hamel was the realtor) and I think it has since gone on the market again. Through the years, owners made lots of updates. It may be that the historical society, which I think is housed in the Chocorua Public Library, might be able to come up with some historical photos. Or maybe the realtor has some from when she handled it.
>
> Thank you so much for your interest in my book and, of course, in James. I DO think you have a record number of books on pragmatism.
>
> Good luck with the playhouse!

19-06-06 *Report* (to Fellowships)

This is an excellent proposal and I wholeheartedly recommend that it be funded. Recent advances in quantum information theory have made it quite respectable within the physics community to view quantum states as representing agent-centered information about quantum systems, rather than as intrinsic physical properties for those systems. Concomitant with these advances has been a reawakening in the philosophy-of-physics community for the need to study and develop philosophical systems that can support such an idea. Pragmatism in one guise or another (Jamesian, Deweyian, Putnamian) seems to fit the bill, and there has been a flurry of activity in this direction. Particularly nice so far has been the work of Prof. Michel Bitbol. I see the present proposal [of a younger researcher] as a continuation down this line. Novel to this approach is a melding of pragmatic and Kantian (or transcendental) lines of thought—this sort of work is long overdue, and I give it my highest recommendation. It will have direct impact on the philosophical discussion of quantum foundations and direct impact on theoretical methods in quantum information science.

10-06-06 *Title and Abstract—Special Treat* (to G. M. D'Ariano)

I apologize for not getting the title and abstract to you yesterday as I had promised: From my hotel in Copenhagen, I could not get a connection to the internet (something to do with my wireless "location profiles list" being full, and I could not figure out how to fix it). Now, though, I am in the Chicago airport, and can send you mail by my usual routes.

I know it was a further delay, but at least it allowed me the time to come up with something of a new abstract for you. The result is below. If you feel that your name ought properly to be in the list with the other guys, feel free to take out the part "(maybe D'Ariano?)" and replace it with your name in the earlier list right after Caves (alphabetical order).

I'm looking forward to much better understanding your axiom system. It looks indeed very promising—I am quite excited. This is going to be a great trip.

I will take care of the whatever needs to be done in the other emails you wrote me, right after the weekend.

> **Title:** Where Is the Reality in a Bayesian View of Quantum Mechanics?
>
> **Abstract:** In the neo-Bayesian view of quantum mechanics that Appleby, Caves, Pitowsky, Schack, the author and others (maybe D'Ariano?) are developing, quantum states are taken to be compendia of partial beliefs about potential measurement outcomes, rather than objective properties of quantum systems. Different observers may validly have different quantum states for a single system, and the ultimate origin of each individual state assignment is taken to be unanalyzable within physical theory—its origin, instead, ultimately comes from probability assignments made at stages of physical investigation or laboratory practice previous to quantum theory. The objective content of quantum mechanics (i.e., the part making no reference to observers) thus resides somewhere else than in the quantum state, and various ideas for where that "somewhere else" is are presently under debate—there are adherents to the idea that it is purely in the "measurement clicks," there are adherents to the idea that it is in intrinsic, observer-independent Hamiltonians, there are adherents to the idea that it is in the normative rules quantum theory supplies for updating quantum states, and so on. This part of the program is an active area of investigation; what is overwhelmingly agreed upon is only the opening statement of this abstract—that quantum states are

compendia of beliefs. Still, quantum states are not simply Bayesian probability assignments themselves, and different representations of the theory (in terms of state vectors or Wigner functions or C^*-algebras and the like) can take one further from or closer to a Bayesian point of view. It is thus worthwhile spending some time thinking about which representation might be the most propitious for the point of view and might, in turn, carry us the most quickly toward solutions of some of the open problems. In this talk, I will explore various issues to do with the above and explain why I prefer a representation of quantum mechanics that makes crucial use of a single probability simplex.

12-06-06 *Grover's Alg and Temporal Bell Inequalities* (to L. K. Grover)

By the way, I met a really interesting young man in Sweden, who gave an excellent talk on some ideas surrounding your algorithm. Here is the paper he presented:

Title:	Information-theoretic temporal Bell inequality and quantum computation
Author:	Fumiaki Morikoshi
Journal-ref:	Phys. Rev. A **73**, 052308 (2006)

It's on the archive at: `http://www.arxiv.org/abs/quant-ph/0602011`.

The basic idea is that he shows that your algorithm violates a certain kind of temporal Bell inequality. Further he speculates that something like this might be at the heart of the speedup in all quantum algorithms. It was certainly a thought provoking thought.

Anyway, I think he is very interesting and amiable, and he was very articulate in English too for a Japanese. Also, he was very keen to talk and work with you. If you want to see his full list of publications, go here: `http://arxiv.org/find/quant-ph/1/au:+Morikoshi/0/1/0/all/0/1`.

If you have any money left for visitors, I think this guy could be a winner for you. His excitement was so high for visiting you and Bell Labs, that I suspect he would jump at the chance, even if you could only give him partial support.

21-06-06 *Hoan Dang* (to A. P. Ramirez)

Thanks. At the moment, I'm planning to have Hoan work on one of these Wigner-function type representation of quantum mechanics, to see where the power of quantum computing comes from. There have recently been some encouraging results along these lines. See for instance,

- `http://www.arxiv.org/abs/quant-ph/0506222`
- `http://www.arxiv.org/abs/quant-ph/0405070`.

Also, I'd like to see if we can translate those results into the particular q-function-style representation that I've been working on the last year. There, the key issue wouldn't be negativity, but something else.

It all goes back to a mostly forgotten point made in Feynman's original paper on quantum computation—I think there's a lot of life in the idea and everyone has gotten carried away talking about entanglement and multiple universes.

Anyway, some meaty mathematical problems, and I'll probably try to use his programming skills to simulate a lot of things. (Mabuchi at Caltech wrote me some very good things about his abilities.)

22-06-06 *Triangles* (to H. C. von Baeyer)

I was just taking care of some administrative things to do with the Växjö conference, and it dawned on me that I haven't yet written you since the conference's end. I was surprised to find you gone already by the Wednesday. I hope you didn't become ill or something. It was also too bad to see you gone especially as I think you missed three of the most interesting talks of the meeting: Bengtsson, Leifer, and D'Ariano. For your reference, here are the two papers associated with Leifer's and D'Ariano's talks:

- `quant-ph/0606022`
  Title: Quantum Dynamics as an Analog of Conditional Probability
  Author: M. S. Leifer

- `quant-ph/0603011`
  Title: How to Derive the Hilbert-Space Formulation of Quantum Mechanics From Purely Operational Axioms
  Author: Giacomo Mauro D'Ariano

The D'Ariano construction, to me, really starts to smell right from the Paulian perspective—so, I'm quite pleased with it. It still could use a good bit of Bayesianization, but the mathematics, I think, is starting to get in place. Saturday, I'm off to Italy for a little meeting that D'Ariano put together; it'll be another good opportunity to delve into these things.

Below, I'll paste in the fragment of the note I started to write you in March. One of these days, I should finish that up.

I hope all is well with you, and that you got something out of your Växjö experience.

— — — — — — — — — — — — — — — —

> Dear Hans,
>
> I hope you're better by now. I'm between meetings once again: Last Friday I got back from the APS March meeting in Baltimore, and this coming Monday I zip off to Portugal.
>
> While in Baltimore at dinner one evening, as we were waiting for our crabs, somehow your name came up, and I ended up drawing your B3 diagram:
>
> **von Baeyerism 19:** *The "B3 triad" is a triangle with the words psi, information, and probability at its vertices, and the names Bayes, Born, and Bohr, respectively, along their opposite sides.*
>
> (though I accidentally inverted the vertices and sides).
>
> I was trying to explain why I thought the B3 idea was pretty catchy. However, as we—that is, Rob Spekkens, Matt Leifer, Carl Caves, Hideo Mabuchi, and I—discussed it, I found myself slowly morphing the content of your diagram to better fit my predilections. Here was the result, which was left on a sheet of butcher paper in Obrycki's Crab House:
>
> > A triangle with the names Bayes, Pauli, and Gleason at the vertices, and $p(x)$, "contextuality", and $|\psi\rangle$ along the opposite sides.
>
> It won't be as catchy and memorable, I know (what small fraction of physicists have ever heard of Gleason, and what even smaller fraction have ever heard of "contexuality"?). But let me explain the reasons.
>
> At first it was just that I was dissatisfied with ...

24-06-06 *Notes on "What are Quantum Probabilities"* (to J. Bub)

ABSTRACT: Jeff says, "Chris Fuchs presents a different analysis of the status of the projection postulate as Bayesian updating, associated with a very different account of quantum probabilities as degrees of belief than the view I want to argue for here. . . . But this rather complicated analysis misses the essential point." Chris says, "No. It may not be perfect, but it captures the essential point it was meant to capture. It just so happens that that essential point is different from the one Jeff wants to make."

Abstract

Bubism 5: *I distinguish between the measurement problem of quantum mechanics, which is a problem about truth, and a problem about probabilities.*

I like that strategy and think it is an important step forward. It has been my strategy since 1995, though I didn't know it in these terms then. In July 2001, I learned a little about James, Dewey, and pragmatist theories of truth, and realized that that's what I had been on about with respect to quantum measurement. But I started to take the Bayesian step toward quantum probabilities long before that.

At this stage, I doubt very much that you'd be happy to think that you might ultimately be led to a pragmatist notion of truth (in the quantum measurement setting at least), but the distinction you make is—in my eyes—the first step toward it. In any case, there is certainly nothing to be lost by starting to make a distinction between the "issue of quantum measurement" and the "problem of quantum-state collapse." I will certainly admit that the former is not refined or understood well enough for my own tastes at this stage, but I think worrying about the latter anymore is just a waste of time—I think the evidence is simply overwhelming.

Here's the way I put the distinction of the concepts to Oliver Cohen in December 2003. I will quote the passage at decent length because it helps set the stage for the particular points I want to make with regard to your own paper.

> I'm writing you because I've been reading your paper "Classical Teleportation of Quantum States" this week. It's a nice paper, and I very much like the simplicity of your scheme and the point you make with it. I am in complete agreement.
>
> In fact it took me a little down memory lane. You see, Asher Peres and I had used teleportation as an example in our March 2000 *Physics Today* article, "Quantum Theory Needs No 'Interpretation'," precisely to illustrate the sensibility of the conception of a quantum state as a "state of knowledge, rather than a state of nature". When the paragraph peaked in clarity (i.e., before the editor's knife), it went like this:
>
>> The peculiar nature of a quantum state as representing information is strikingly illustrated by the quantum teleportation process. In order to teleport a quantum state from one photon to another, the sender (Alice) and the receiver (Bob) need a pair of photons in a standard entangled state. The experiment starts when Alice receives another photon whose polarization state is unknown to her, though known to some preparer in the background. She performs a measurement on her two photons, and then sends Bob a classical message of only two bits, instructing him how to reproduce the unknown state on his photon. This economy of transmission appears remarkable because to completely specify the state of a photon, namely one point in the Poincaré

> sphere, we need an infinity of bits. However, the disparity is merely apparent. The two bits of classical information serve only to transfer the preparer's information, i.e., his *state*, to be from describing the original photon to describing the one in Bob's possession. This can happen precisely because of the previously established correlation between Alice and Bob.

… The conclusion you draw, I think, is particularly important: the phenomenon of quantum teleportation only looks surprising and remarkable if one takes an ontic view of the quantum state. In fact, in the past, I have accused some of my friends (some of whom were authors on the original teleportation paper) of sticking with an ontic interpretation of the quantum state precisely because it is the only way to keep the phenomenon surprising and newsworthy. …

If you are interested in seeing the struggle Asher and I had in constructing the paragraph above see … Maybe the main lesson in those discussions is how difficult it is to give up an objectivist language when using quantum states, even for a recalcitrant positivist like Asher, and even in an example intended to be illustrative of why quantum states should be viewed as states of knowledge, rather than states of nature. (The philosophy being: if quantum mechanics looks too very mysterious, then you're probably being wrong-headed about it. Case in point: if teleportation looks mysterious, then you're probably being wrong-headed about it too.)

The sense I get from your paper is that you are much more neutral about the lesson than I am. You say simply: "[O]ur classical version of teleportation is just as impressive as the original protocol, if we think of quantum states as representing states of knowledge. … If, on the other hand, we think of a quantum state as having ontological content, …, then our classical version of teleportation is not equivalent to the quantum case," and leave it at that. However, there is a spate of evidence starting to come out that a significant fraction of some of the most 'remarkable' phenomena in quantum information theory can be mocked up with classical toy models just as your own. The only requirement for seeing it is that one must focus on the epistemic states (i.e., the states of knowledge) in such models rather than the ontic states (like the actual H or T in your own model). For instance, Rob Spekkens has a toy model which he has presented in several conferences and which he is writing up presently as a paper, "In Defense of the Epistemic View of Quantum States: A Toy Theory," in which he can reproduce the following quantum mechanical and quantum information-theoretic type phenomena in a pretty NON-REMARKABLE way: the noncommutativity of measurements, interference, a no-cloning theorem, … and many others. (In particular, he gets teleportation too, just like you do.) As Rob puts it in his abstract:

> Because the theory is, by construction, local and non-contextual, it does not reproduce quantum theory. Nonetheless, a wide variety of quantum phenomena have analogues within the toy theory that admit simple and intuitive explanations. … The diversity and quality of these analogies provides compelling evidence for the view that quantum states are states of knowledge rather than states of reality, and that maximal knowledge is incomplete knowledge. A consideration of the phenomena that the toy theory fails to reproduce, notably, violations of Bell inequalities and the existence of a Kochen-Specker theorem, provides clues for how to proceed with a research program wherein the quantum state being a state of knowledge is the idea upon which one never compromises.

So, given that your paper is an independent and particularly notable link in that, and as opposed to his paper, your result is not buried within over 70 pages (and counting) of text, I very much endorse it. I think the lesson is this: A good lot of quantum information theory is simply regular probability theory and information theory applied in ways that had not been deemed interesting before. *What is interesting and unique to the quantum itself, thus, must be something else.*

In my paper `quant-ph/0205039`, "Quantum Mechanics as Quantum Information (and only a little more)," I tried to give the community to a call to arms by saying this:

> This, I see as the line of attack we should pursue with relentless consistency: The quantum system represents something real and independent of us; the quantum state represents a collection of subjective degrees of belief about *something* to do with that system (even if only in connection with our experimental kicks to it). The structure called quantum mechanics is about the interplay of these two things—the subjective and the objective. The task before us is to separate the wheat from the chaff. If the quantum state represents subjective information, then how much of its mathematical support structure might be of that same character? Some of it, maybe most of it, but surely not all of it.
>
> Our foremost task should be to go to each and every axiom of quantum theory and give it an information theoretic justification if we can. Only when we are finished picking off all the terms (or combinations of terms) that can be interpreted as subjective information will we be in a position to make real progress in quantum foundations. The raw distillate left behind—minuscule though it may be with respect to the full-blown theory—will be our first glimpse of what quantum mechanics is trying to tell us about nature itself.

What your work and Spekkens' work does, from my perspective, is give the best illumination yet of what I was hoping for when I was speaking of "combinations of terms" in that passage. Teleportation—being a certain combination of uses of the axioms of quantum mechanics—is nevertheless a purely probabilistic or information-theoretic effect. As such, it tells us very little about the ontology behind quantum mechanics.

My own view—and the thrust of my research program presently—is that these examples help us to realize that what is unique in quantum mechanics is not the probabilities (i.e., the quantum states) but what the probabilities are applied to. There, I think, lies the essence of quantum mechanics: It is localized in the Kochen-Specker theorem. "Unperformed measurements have no outcomes," as Asher Peres likes to say. That is to say, where quantum mechanics gets its uniqueness is from *breaking* with the old idea that a probability (as a subjective state of knowledge) must be knowledge about a pre-existent reality. Instead, probabilities can just as fruitfully be applied to capturing one's knowledge of "what will come about due to one's actions." The predominant issue becomes how to formalize the difference between probability theory as applied to pre-existent facts and probability theory as applied to "creatables" (for want of a better word). ...

Bubism 6: *I show that the projection postulate can be interpreted as a probability updating rule, and I argue for a subjective Bayesian interpretation of quantum probabilities as rational degrees of belief, in the sense of Ramsey rather than de Finetti.*

I would certainly call it a probability update rule too—so, if I have missed an "essential point" it is certainly not that. On the other hand, I think you're hoping that there is an essential distinction between Ramsey and de Finetti, where as far as I can tell there is none. However I'll have much more to say about both of these subjects later.

Introduction

From Classical to Quantum Mechanics

Bubism 7: *Faced with the conceptual puzzles of quantum mechanics, there is a temptation to begin with a blank slate. It seems, then, that if one were only careful enough with implicit assumptions about physical theory and measurement, the characteristic features of the theory could have been foreseen before classical mechanics.*

I think this view is entirely mistaken.

I am in agreement with your last sentence. Attempts like the former effectively erase the empirical content (or contingency) of quantum mechanics, and I just don't see that. When I myself invoke the slogan "Quantum Mechanics is a Law of Thought," I only do it partially tongue in cheek, quickly correcting myself. For if quantum mechanics were *only* law of thought, it would be like one of Kant's a priori categories of the understanding. On the other hand, I come dangerously close to viewing "probability theory" (i.e., the theory of coherent gambling) in such a Kantian kind of way. And, indeed, it is partially because of this that I would not want to view quantum mechanics as a *generalized* probability theory.

Bubism 8: *The transition from classical to quantum mechanics involves replacing the representation of properties as a Boolean lattice, i.e., as the subsets of a set, with the representation of properties as a certain sort of non-Boolean lattice.*

The? I would rather say *one possible way of looking at* the transition from classical to quantum mechanics involves blah, blah, blah. And, you partially recover from this a few paragraphs later where you write:

Bubism 9: *Of course, other ways of associating propositions with features of a Hilbert space are possible, and other ways of assigning truth values, including multi-valued truth value assignments and contextual truth value assignments. Ultimately, the issue here concerns what we take as the salient structural change involved in the transition from classical to quantum mechanics, and this depends on identifying quantum propositions that take the same probabilities for all quantum states.*

But let me hang on this point for a moment despite your partial recovery. For when you say things like, "Fuchs misses the essential point," you should realize that that judgement (at most) comes from within a context very different from the one I am working in.

I would, for instance, never say "the representation of properties in quantum mechanics involves as a certain sort of non-Boolean lattice." That is just not the context I'm working in. Similarly, I would not say, as you say in the next section, "Somehow, a measurement process enables an indeterminate property, that is neither instantiated nor not instantiated by a system in a given quantum state, to either instantiate itself or not with a certain probability."—i.e., I would not say that a measurement process instantiates any *property* at all for a quantum system.

Instead, the setting for our quantum Bayesian program (i.e., the particular one of Caves, Schack, and me), is one where all the *properties* <u>intrinsic</u> to a quantum system are timeless and have no dynamical character whatsoever—moreover, those properties have nothing to do with particular quantum state assignments or particular quantum measurement outcomes. In that way, the idea of a non-Boolean lattice simply doesn't apply to them.

John Sipe recently made a nice write-up of our view for his book that, I think, brings this one difference between you and me into pretty stark relief. Maybe it's worthwhile to quote it at length, as it may lay the groundwork for a good bit of our later discussion:

> This interpretation shares some features with operationalism. *Measurements*, for example, are understood in a manner close to that adopted by an operationalist. They are characterized by POVMs, and those abstract elements are associated with tasks in the laboratory undertaken with gadgets that are part of the primitives of the theory. The result of any such measurement is simply one of a possible number of outcomes, and there is no talk of these measurements "revealing" the value of any variable, in the sense that an arbitrarily precise position measurement in classical mechanics is often described as revealing the position of a particle. Yet, compared to the operationalist's quiet, unassuming terminology of "tasks" and "outcomes," advocates of this interpretation adopt a more active manner of speaking, referring to "actions" (or even "interventions") undertaken by an agent, and the "consequences" that those actions elicit.
>
> This indicates a role for the observer (or agent) in this interpretation that is more significant than the role played by such a person in operational quantum mechanics. The significance of that role becomes clear when we consider the reference of density operators in this interpretation. Density operators do not refer to sets of tasks that define *preparations*, as they do in operational quantum mechanics. Rather, a density operator is taken to encode the beliefs of an agent concerning the probabilities of different consequences of possible future actions. While these beliefs may be *informed* by knowledge of the tasks involved in setting up the particular gadgetry associated with a preparation, they are not *determined* by it. Hence there is not a unique, "correct" density operator necessarily associated with each preparation procedure, as there is in operational quantum mechanics. In the present view two different researchers, one more skilled in quantum mechanics than the other, could adopt different density operators after being identically informed of the details of a particular preparation procedure. One density operator might be more successful than the other in predicting the possible consequences of future actions, but each would be the correct density operator *for that agent* insofar as it correctly encoded that agent's beliefs.
>
> Thus, while the abstract elements in the theory associated with measurements are identified with tasks in the laboratory, as in operationalism, the abstract elements in the theory associated with preparations are identified with beliefs of the agent, signaling a kind of empiricist perspective.
>
> So in contrast to operational quantum mechanics, where density operators are necessarily updated following a measurement — since the combination of the previous preparation and the measurement constitutes a new preparation, and an operationalist associates the new density operator with *that* — in this view there is no necessary updating of a density operator in the light of measurement outcomes, since there is no *necessary* connection between the consequences of an agent's action (more prosaically, "measurement outcomes") and his or her beliefs. After all, foolish researchers, like foolish men and women more generally, could choose not to modify their beliefs concerning the consequences of future actions despite their knowledge of the consequences of recent ones. And note that even wise researchers will not update their beliefs concerning future actions until they *know* the consequences of recent ones; hence a wise researcher's

"personal density operator" (the only kind of density operator there is in this view!) will not change until that researcher is actually aware of a measurement outcome.

Other abstract elements in the theory, such as the dimension of the Hilbert space, and the dimensions of various factor spaces, are actually associated with instances of attributes of physical objects. Hence with respect to the reference of *these* abstract elements this interpretation is realist. The manner in which this works can best be seen by first reviewing the role measurement outcomes play in revealing aspects of the universe in realist classical mechanics, and then comparing that with the role such outcomes play in this interpretation of quantum mechanics.

An arbitrarily precise position measurement of a bead moving along a wire, in realist classical mechanics, reveals the position of the particle, the instance (say, $x = 10$ cm) of a particular attribute (bead position) of a physical object (bead) that actually exists in Nature. In contrast, a usual Stern-Gerlach device oriented along the z direction *does not*, in this interpretation of quantum mechanics, reveal the z-component of angular momentum, or for that matter anything else. The particular outcome of one experimental run is simply a consequence of performing the experiment. Nonetheless, repeated experimentation *does* reveal that the electron associated with the atom passing through the device should be taken as a spin-1/2 particle. Here the attribute under consideration is taken to be *internal angular momentum*, and the instance – the irreducible representation appropriate to the particle of interest – *spin-1/2*. The role of an "instance of an attribute" in this interpretation is not to specify one of a number of possible expressions of existence, as it is in realist classical mechanics, but rather to specify one class of possible beliefs – the one that the theory recommends – about the consequences of future interventions of a particular type.

Note that, at least within nonrelativistic physics, the instances of the attributes in this interpretation are fixed. A spin-1/2 particle remains a spin-1/2 particle. Thus there are no dynamical variables in this theory, only nondynamical variables analogous to the mass of a particle in nonrelativistic classical mechanics. The point of physics is to identify these nondynamical variables. Repeated interventions by experimentalists, and the careful noting of the range of consequences that those interventions elicit, is how these fixed instances are discovered.

In this interpretation of quantum mechanics, with its mix of operationalist, empiricist, and realist identification of abstract elements in the theory, these fixed instances specify the [[agent independent features]] of the "quantum world," and it is the business of physics to figure them out. This is done by experimentation, and the theoretical linking of basis vectors in the appropriate Hilbert space with various measurements, providing an "anchor" for those basis kets to our experience, the consequences of our actions. Particularly significant is the Hamiltonian operator and its basis kets [[in Caves' particular version of all this]]. As time evolves during what is colloquially described as "unitary evolution," we have the option to modify our beliefs or to modify the anchors of those beliefs; the first strategy corresponds to the usual Schrödinger picture, the second to the Heisenberg picture.

Regardless of the strategy, the [[properties intrinsic to the]] quantum world of this interpretation [[are]] a fixed, static thing. [[This aspect of the quantum world]] is a frozen, changeless place. Dynamics refers not to the quantum world, but only to our actions, our experiences, and our beliefs as agents. Or, more poetically (à la Chris), life does not arise from our interventions; it is our interventions.

John doesn't represent us correctly in every detail of this presentation—for the purpose at hand, it only seemed essential to modify him in a few instances, which I have have marked with double brackets [[·]]—but I would say he is roughly on track, and he certainly gets it that we are not concerned with the usual way of ascribing properties to quantum systems via the values of measurement outcomes or probability-1 predictions (i.e., the eigenvector-eigenvalue link).

Which brings me back again to your paper:

Bubism 10: *For a quantum state, the properties represented by Hilbert space subspaces are not partitioned into two such mutually exclusive and collectively exhaustive sets: some propositions are assigned no truth value. Only propositions represented by subspaces that contain the state are assigned the value 'true,' and only propositions represented by subspaces orthogonal to the state are assigned the value 'false.' This means that propositions represented by subspaces that are at some non-zero or non-orthogonal angle to the ray representing the quantum state are not assigned any truth value in the state, and the corresponding properties must be regarded as indeterminate or indefinite: according to the theory, there can be no fact of the matter about whether these properties are instantiated or not.*

You see, my way of looking at things wouldn't even allow me to say what you say here. It is just a very different world that I am working in.

To try to make this point, let me quote a couple of emails I wrote to Bas van Fraassen a few months ago. It started with my saying this:

> The way I view quantum measurement now is this. When one performs a "measurement" on a system, all one is really doing is taking an ACTION on that system. From this view, time evolutions or unitary operations etc., are not actions that one can take on a system; only "measurements" are. Thus the word measurement is really a misnomer—it is only an action. In contradistinction to the old idea that a measurement is a query of nature, or a way of gathering information or knowledge about nature, from this view it is just an action on something external—it is a kick of sorts. The "measurement device" should be thought of as being like a prosthetic hand for the agent—it is merely an extension of him; in this context, it should not be thought of as an independent entity beyond the agent. What quantum theory tells us is that the formal structure of all our possible actions (perhaps via the help of these prosthetic hands) is captured by the idea of a Positive-Operator-Valued Measure (or POVM, or so-called "generalized measurement"). We take our actions upon a system, and in return, the system gives rise to a reaction—in older terms, that is the "measurement outcome"—but the reaction is in the agent himself. The role of the quantum system is thus more like that of the philosopher's stone; it is the catalyst that brings about a transformation (or transmutation) of the agent.
>
> Reciprocally, there [[may]] be a transmutation of the system external to the agent. But the great trouble in quantum interpretation—I now think—is that we have been too inclined to jump the gun all these years: We have been misidentifying where the transmutation indicated by quantum mechanics (i.e., the one which quantum theory actually talks about, the "measurement outcome") takes place. It [[may]] be the case that there are also transmutations in the external world (transmutations in the system) in each quantum "measurement", BUT that is not what quantum theory is about. [[Quantum mechanics]] is only a hint of that more interesting transmutation. [[Instead, the main part of quantum mechanics is about how]] the agent and the system [[together bring about]] a little act of creation that ultimately has an autonomy of its own—that's the sexual interpretation of quantum mechanics.

which led to the following dialogue:

> **van Fraassenism 8 :** *Writers on the subject have emphasized that the main form of measurement in quantum mechanics has as result the value of the observable at the end of the measurement – and that this observable may not even have had a definite value, let alone the same one, before.*
>
> Your phrase "MAY NOT even have a definite value" floated to my attention. I guess this floated to my attention because I had recently read the following in one of the Brukner/Zeilinger papers,
>
> > Only in the exceptional case of the qubit in an eigenstate of the measurement apparatus the bit value observed reveals a property already carried by the qubit. Yet in general the value obtained by the measurement has an element of irreducible randomness and therefore cannot be assumed to reveal the bit value or even a hidden property of the system existing before the measurement is performed.
>
> I wondered if your "may not" referred to effectively the same thing as their disclaimer at the beginning of this quote. Maybe it doesn't. Anyway, the Brukner/Zeilinger disclaimer is a point that Caves, Schack, and I now definitely reject: From our view all measurements are generative of a NON-preexisting property regardless of the quantum state. I.e., measurements never reveal "a property already carried by the qubit." For this, of course, we have to adopt a Richard Jeffrey-like analysis of the notion of "certainty"—i.e., that it too, like any probability assignment, is a state of mind—or one along (my reading of) Wittgenstein's—i.e., that "certainty is a tone of voice"—to make it all make sense, but so be it.

and

> **van Fraassenism 9 :** *Suppose that an observer assigns eigenstate $|a\rangle$ of A to a system on the basis of a measurement, then predicts with certainty that an immediate further measurement of A will yield value a, and then makes that second measurement and finds a. Don't you even want to say that the second measurement just showed to this observer, as was expected, the value that A already had? He does not need to change his subjective probabilities at all in response to the 2nd measurement outcome, does he?*
>
> It is not going to be easy, because this in fact is what Schack and I are actually writing a whole paper about at the moment—this point has been the most controversial thing (with the Mermin, Unruh, Wootters, Spekkens, etc., crowd) that we've said in a while, and it seems that it's going to require a whole paper to do the point justice. But I'll still try to give you the skinny of it:
>
> - Q: He does not need to change his subjective probabilities at all in response to the 2nd measurement outcome, does he?
> - A: No he doesn't.
> - Q: Don't you even want to say that the second measurement just showed to this observer, as was expected, the value that A already had?
> - A: No I don't.
>
> The problem is one of the very consistency of the subjective point of view of quantum states. The task we set before ourselves is to completely sever any supposed connections

between quantum states and the actual, existent physical properties of the quantum system. It is only from this—if it can be done, and of course we try to argue it can be done—that we get any "interpretive traction" (as Chris Timpson likes to say) for the various problems that plague QM. [[...]]

This may boil down to a difference between the Rovellian and the Bayesian/Paulian approach; I'm not clear on that yet. [[...]] Rovelli relativizes the states to the observer, even the pure states, and with that—through the eigenstate-eigenvalue link—the values of the observables. I'm not completely sure what that means in Rovelli-world yet, however.

I, on the other hand, do know that I would say that a measurement intervention is always generative of a new fact in the world, whatever the measurer's quantum state for the system. If the measurer's state for the system HAPPENS to be an eigenstate of the Hermitian operator describing the measurement intervention, then the measurer will be confident, CERTAIN even, of the consequence of the measurement intervention he is about to perform. But that CERTAINTY is in the sense of Jeffrey and Wittgenstein above—it is a "tone of voice" of utter confidence. The world could still, as a point of principle, smite the measurer down by giving him a consequence that he predicted to be impossible. In a traditional development—with ties to a correspondence theory of truth—we would then say, "Well, that proves the measurer was wrong with his quantum state assignment. He was wrong before he ever went through the motions of the measurement." But as you've gathered, I'm not about traditional developments. Instead I would say, "Even from my view there is a sense in which the measurer's quantum state is WRONG. But it is MADE WRONG by the ACTUAL consequence of the intervention—it is made wrong on the fly; its wrongness was not determined beforehand." And that seems to be the main point of contention.

Particularly this is going to be a key point when I finally come to the analysis in Section 7 of your paper.

The Probability Problem

Bubism 11: *The orthodox answer is that the probability assigned to a property of a system by a quantum state is to be understood as the probability of finding the property in a measurement process designed to ascertain whether or not that property is instantiated. I will defend this proposal later in the paper, but a little thought will reveal that it is rather problematic. When the system is represented by a quantum state that assigns a certain property the probability 1/2, say, this property is indeterminate. Physicists would say that ascribing the property to the system in that state is 'meaningless.' But somehow it makes sense to design an experiment to ascertain whether or not the property is instantiated by the system. And in such a measurement, the probability is asserted to be 1/2 that the experiment will yield the answer 'yes,' and 1/2 that the experiment will yield the answer 'no.' Clearly, a measurement process in quantum mechanics is not simply a procedure for ascertaining whether or not a property is instantiated in any straightforward sense. Somehow, a measurement process enables an indeterminate property, that is neither instantiated nor not instantiated by a system in a given quantum state, to either instantiate itself or not with a certain probability; or equivalently, a proposition that is neither true nor false can become true or false with a certain probability in a suitable measurement process.*

I found this paragraph interesting. Particularly as I could both agree and disagree with the last sentence! The difference comes at the semi-colon. That is, I disagree with this: "Somehow, a measurement process enables an indeterminate property, that is neither instantiated nor not instantiated by a system in a given quantum state, to either instantiate itself or not with a certain probability." But I agree with "A proposition that is neither true nor false can become true or false with a certain probability in a suitable measurement process." The trouble comes in at the connective "equivalently." I don't believe those separate thoughts are equivalent at all. The saving grace of the second of the two clauses for me is that you don't explicitly mention what the proposition is about. In the first clause, on the other hand, you are talking about properties of the system.

The Measurement Problem

Bubism 12: *In classical theories, we measure to find out what we don't know, but in principle a measurement does not change what is (and even if it does change what is, this is simply a change or disturbance from one state of being to another that can be calculated on the basis of the classical theory itself). In quantum mechanics, measurements apparently bring into being something that was indeterminate, not merely unknown, before, i.e., a proposition that was neither true nor false becomes true in a measurement process, and the way in which this happens according to the theory is puzzling.*

Here again, I can agree. You nicely did not say anything about what the proposition refers to. For instance, with your wording here—as long as I am careful to take the paragraph out of context!—I am free to think that the proposition that gains a truth value with the process of measurement refers to MY sensations, not a property of the system at all.

Indeed, I rather like the very next sentence:

Bubism 13: *The standard measurement problem of quantum mechanics is fundamentally* a problem about truth *. . . , distinct from the probability problem.*

as long as I am not forced to refill the ellipses with your parenthetical "(or the instantiation of properties)." I think this is the fundamental problem—it is about *truth*—and I am very happy that you're saying that much. When you say things in the philosophy-of-science community people listen. It is quite important to make a careful distinction between the problem of probability and the problem of truth, and not many people are doing that presently.

My own conviction that the measurement problem is fundamentally a problem about truth explains my fascination with James, Dewey, Schiller, Rorty, and Putnam, and the whole pragmatist framework for truth. Here is something I wrote Carl Caves in 2001:

> Today I focused on rounding up some more William James, John Dewey, Percy Bridgman material. I think James is taking me over like a new lover. I had read a little bit of him before, but I think I was more impressed with his writing style than anything. But I was drawn back to him by accident, after reading Martin Gardner's *Whys of a Philosophical Scrivener*. Gardner devoted a lot of time knocking down James' theory of truth, because it is just so much easier to accept an underlying reality that signifies whether a proposition is true or false, rather than saying that the knowing agent is involved in eliciting the very proposition itself (along with its truth value). And something clicked! I could see that what James was talking about might as well have been a debate about quantum mechanics. He was saying everything in just the right way. (Let me translate that: he was saying things in a way similar to the way I did in my NATO "appassionata.") And things have only gotten better since.

My recommendation—tongue in cheek—I like the direction your paper starts to move in, but I think you could take a good dose of James!

Here's a little dialogue I had with Bill Demopoulos earlier this year:

> **Demopoulosism 6:** *I also don't see why we should need something as fundamental as KS to sustain the notion that "unperformed measurements don't have outcomes." I'm being a devil's advocate here because I think what you really mean is that without a measurement of whether the cat is alive, the cat is neither alive nor not alive. But would you put it this baldly? If not, why not?*
>
> To answer your question in the best way I know how at the moment, I would say: The transformation that quantum mechanics speaks about, the transformation from a 'superposition' to 'aliveness' or 'deadness', is a transformation *within the agent*, and that transformation cannot take place without some interaction with the external physical system labeled by the word 'cat'. What happens to 'cat' itself (described in a way that makes no reference to the agent)? On that, I think quantum mechanics is silent. With a mantra: Quantum mechanics is a theory for ascribing (and intertwining) personal probabilities for the personal consequences of one's personal interactions with the external world.

Bubism 14: *The most sophisticated formulation of Everett's interpretation is probably the Saunders-Wallace version (Saunders, 1998; Wallace, 2003). Here the preferred basis is selected by decoherence, and probabilities are introduced as rational degrees of belief in the Bayesian sense via a decision-theoretic argument originally due to Deutsch (Deutsch, 1999).*

Sophisticated in the sense of being complicated, yes. Sophisticated in the sense of hiding things in layer upon layer. See our original criticism of Deutsch—Barnum *et al.*, "Quantum Probability from Decision Theory?," Proc. Royal Society London A **456**, 1175–1182 (2000), and `quant-ph/9907024`—which still stands, as well as some new nice stuff by Huw Price, `quant-ph/0604191`. Or talk to Jos Uffink, who's got some very good replies.

Bubism 15: *Of course, quantum mechanics could be false, but it seems wildly implausible that a modification of quantum mechanics whose sole motivation is to solve the measurement problem will survive fundamental advances in physics driven by other theoretical or experimental questions.*

I like this point very much.

Solving the Probability Problem

Bubism 16: *[T]he physical world is* nonlocal*, in that spacelike separated systems can occupy entangled states that persist as the systems separate.*

This language hints of an ultimately ontic view of quantum states.

Bubism 17: *Solving the probability problem* without reducing the problem to a solution of the measurement problem (the truth problem)*, amounts to treating quantum mechanics as a theory of information, in which no measurement outcomes are certified as determinate* by the theory*. Rather, measuring instruments are sources of classical information in Shannon's sense, where the individual occurrence of a particular distinguishable event produced stochastically by the information source lies outside the theory. In this sense, a measuring instrument, insofar as it functions as a* *classical information source, is ultimately a 'black box' in the theory. So a quantum description will have to introduce a 'cut' between what we take to be the ultimate measuring instrument in a given measurement process and the quantum phenomenon revealed by the instrument. The 'cut' is just a reflection of the fact that quantum mechanics is a* theory about the representation and manipulation of information *constrained by the possibilities and impossibilities of information-transfer in our world, rather than a theory about the ways in which nonclassical waves and particles move.*

I like much of this of course, if not not literally all.

Bubism 18: *If we set aside the measurement problem, the Gleason probabilities cannot be intelligibly interpreted as the objective chances or relative frequencies that dynamical variables take determinate values, and the only viable option is a subjective Bayesian interpretation of the quantum probabilities as rational degrees of belief.*

Why? Of course, I like the sentiment of this, but it'd be nice to see in your words an extended discussion of this point. As it is written right now, I think this represents a weak point of the paper.

On the other hand, I don't agree with any of this:

Bubism 19: *To show that quantum mechanics can 'stand on its own feet' as a theory of probability, i.e., as theory of information, we need to take account of the phenomenon of decoherence: an extremely fast process that occurs in the spontaneous interaction between a macrosystem and its environment that leads to the virtually instantaneous suppression of quantum interference. What happens, roughly, is that a macrosystem like a measuring instrument or Schrödinger's cat typically becomes correlated with the environment—an enormous number of stray dust particles, air molecules, photons, background radiation, etc.—in an entangled state that takes a certain form with respect to a preferred set of basis states, which remain stable as the interaction develops and includes more and more particles. It is as if the environment is 'monitoring' the macrosystem via a measurement of properties associated with the preferred states, in such a way that information about these properties is stored redundantly in the environment. This stability, or robustness, of the preferred basis, and the redundancy of the information in the environment, allows one to identify certain emergent structures in the overall pattern of correlations—such as macroscopic pointers and cats and information-gatherers in general—as classical-like: the correlational information required to reveal quantum interference for these structures is effectively lost in the environment. So it appears that the information theoretic constraints are consistent with both (i) the conditions for the existence of measuring instruments as sources of classical information, and (ii) the existence of information-gatherers with the ability to use measuring instruments to apply and test quantum mechanics, given a characterization of part of the overall system as the environment. That is, by selecting a preferred basis, decoherence provides an explanation for the emergence of classical information in a quantum correlational structure.*

This is just Zurekian obfuscation. You have already invoked the black-box concept for measurement, explaining the need for this if quantum mechanics is to be viewed as a theory of information. You did that nicely. Why back off and re-ontologize all the ideas to try to *explain* the existence of classical observers? WHO is writing down these decohering wavefunctions? In an information theoretic approach to quantum mechanics (by that I mean a non-ontic approach to wave functions), it is not fair to give in to temptation at the last moment and invoke God in the quad.

Bubism 20: *If something like the above account of decoherence is acceptable, then the probability problem reduces to showing that the probabilities assigned to measurement outcomes by these information-gatherers, in the subjective Bayesian sense, are just the Gleason probabilities.*

Again, why? It seems you're being very short on the key points you want to make here (i.e., this point and the last point above where I said, "Why?").

The Projection Postulate as Bayesian Updating

Bubism 21: *An analysis of quantum probabilities as measures of ignorance in the Bayesian sense, i.e., as degrees of belief measured by rational betting behaviour, has been developed by Schack et al. (2001), and Caves et al. (2002). In Pitowsky's formulation (Pitowsky, 2002, 2005), the structure of 'quantum gambles' encoded in the subspace structure of Hilbert space imposes nonclassical probabilistic constraints that define a logic of partial belief in the sense of Ramsey.*

What is this explicit distinction between Ramsey and de Finetti that you keep invoking? Can you articulate it?

Here is a quote by Keynes on Ramsey. How do you react to it?

> The application of these ideas [regarding formal logic] to the logic of probability is very fruitful. Ramsey argues, as against the view which I had put forward, that probability is concerned not with objective relations between propositions but (in some sense) with degrees of belief, and he succeeds in showing that the calculus of probabilities simply amounts to a set of rules for ensuring that the system of degrees of belief which we hold shall be a *consistent* system. Thus the calculus of probabilities belongs to formal logic. But the basis of our degrees of belief—or the *a priori*, as they used to be called—is part of our human outfit, perhaps given us merely by natural selection, analogous to our perceptions and our memories rather than to formal logic.

And here is a long quote by Sandy Zabell, "Ramsey, Truth, and Probability." How do you react to it, along with my parenthetical comment?

> The key point is that previous attempts to explain induction had attempted to model the process by a unique description of prior beliefs [[references]], or by a very narrow range of possibilities [[references]]. De Finetti realized that because probability is a logic of consistency, one can never—*at a given instance of time*—uniquely dictate the partial beliefs of an individual; at most one can demand consistency. The essence of inductive behavior, in contrast, lies not in the specific beliefs that an individual entertains at any given point in time, but the manner in which those beliefs evolve over time. [[In this way it is exactly like classical logic: One is not judged as irrational for starting with the incorrect truth value for some proposition in one's considerations; one is judged irrational only if one makes an incorrect inference in the proof process.—CAF]] Let us pause briefly over this point.
>
> I change my mind slowly; you do so with rapidity; you think I am pigheaded, I think you are rash. But neither of us is of necessity irrational. Disagreement is possible even if we share the same information; we may simply be viewing it in a different light. This is what happens every time the members of a jury disagree on a verdict. Of course it can be argued that the members of the jury do not share the same body of facts: each brings to the trial the sum total of his life experiences, and one juror tries to persuade another in part by drawing upon those experiences and thus enlarging the background information of their fellow jurors. It is the credibilist view of probability that if you knew what I knew, and I knew what you knew, then you and I would—or at least should—agree.

> Such a metaphysical stance may well be, as I. J. Good says, “mentally healthy”. But it is an article of faith of no real practical importance. None of us can fully grasp the totality of our own past history, experience, and information, let alone anyone else’s. The goal is impossible: our information cannot be so encapsulated.

Bubism 22: *Here I want to show that the quantum rule is in fact just a noncommutative version of the classical rule.*

The next three pages give a very nice treatment! (And I’m serious about that.) Why would I—Bayesian to the core—ever want to find to find a different analogy between quantum collapse and Bayesian conditionalization than the one you present here? In a quick word, the idea of a POVM (even a standard von Neumann measurement) as an analog of an indicator function goes in the wrong direction for what I want to squeeze out as the essential structure of quantum mechanics. Indicator functions carry the baggage of thinking about quantum measurement as a process of revealing pre-existent values. But I’ll come back to this in a longwinded way, as you can guess.

Bubism 23: *The prior probability assignment of an observer about to make a measurement on a quantum system S is given by an initial density operator $\rho_S \in \mathcal{H}_S$. What should an observer take this density operator to be?*

Here we go again ... You sure have some dangerous remaining objectivist tendencies when it comes to probabilities and quantum states.

Bubism 24: *Suppose the universe $U = S + E$ is in an initial pure state $|\psi\rangle \in \mathcal{H}_R$.*

Whose pure state? Is the state information (in the sense of Bayesian probability theory), or is it not?

Quantum Probabilities as Rational Degrees of Belief

Bubism 25: *Now, Fuchs points out (Fuchs, 2002b, p. 34) that the state change following a quantum measurement of a POVM $\{E_d\}$ can be presented as a 2-state process:*

I think you meant “2-stage” here.

Bubism 26: *In the case of a projective measurement $\{E_d\} = \{E_d = |d\rangle\langle d|\}$, where the E_d are projection operators, the state change on measurement with outcome d is a collapse corresponding to a readjustment by the unitary operator $U_d = |d\rangle|\psi\rangle$.*

There’s a typo at the end of the sentence here; an operator is not a state. Here is the way I said it in the final version of the paper (after I had fixed my own typo at this very spot!):

> In particular, when the POVM is an orthogonal set of projectors $\{\Pi_i = |i\rangle\langle i|\}$ and the state-change mechanism is the von Neumann collapse postulate, this simply corresponds to a readjustment according to unitary operators U_i whose action on the subspace spanned by $|\psi\rangle$ is
> $$|i\rangle\langle\psi| \; . \tag{46}$$

Finally, we come to the real point of contention:

Bubism 27: *Fuchs concludes from this analysis that quantum collapse can be regarded as a noncommutative version of Bayes's rule. But this rather complicated analysis misses the essential point. It is precisely the 'violent' collapse transition (17), where measurement is only disturbance, that has to be explained as a noncommutative variant of Bayes' rule and not merely the 'gentle' selection from an initial density operator of a term corresponding to the outcome of a measurement.*

"When a distinction in concepts can be made, a distinction in concepts should be made." I thought that methodology was the working bread and butter of the philosopher? Let me try to better explain what I did, and why I did it. I made a distinction; I followed through with the implications; I tried to learn a lesson.

The distinction, when it was found, was made because of this: I am working in a quantum foundational context that is trying very hard to dispel that idea that quantum "measurement" has anything *a priori* to do with information gathering about things intrinsic to the quantum system. I tried to give you ample evidence and explanation of that above. Still, though, let me give one last point of reference in that regard. It comes from the same email discussion with van Fraassen that I referenced before. Then I'll return to giving an account of the "distinction" I've alluded to.

> **van Fraassenism 10:** *I thought I would after all not follow you in replacing the term "measurement", despite all the bad effects old connotations have had in various discussions. We need to bracket the old connotations such as that a measurement result reveals a pre-existing value for the measured observable. But I think we can do that because: ...*
>
> *[T]here is a certain kind of retrodictive inference possible also on the basis of qm measurements. For a long time the paradigm was a source preparing a stream of particles in a certain state – measurements on samples taken from the stream give a good basis for conclusions about just what state the source was preparing, and these conclusions can then be used to predict the outcomes of further measurements made on later samples of the stream.*
>
> This is what we in quantum information call quantum-state tomography. One can indeed think of a quantum measurement outcome as *giving information* in the old standard sense in that case and not simply being the "unpredictable consequence of one's action." But then "giving information" is quantified by Shannon's "mutual information," $I(X,Y)$ and not simply by his entropy function $H(Y)$. That is, one has two random variables in the game—one treated classically, namely the "unknown preparation" X, and the other one purely quantum mechanical, the result Y of the measurement interaction. Those two variables have quite different roles, and one indeed would not want to think of X as the "consequence of one's interaction." On the other hand, without making explicit mention of X one has no means for thinking of the elicitation of Y as giving information about anything at all. Before seeing the value of Y, one can expect to be *surprised* to the extent quantified by $H(Y)$, but that's where the story stops.
>
> [For a more detailed Bayesian-like development of this point, you might have a look at our paper "Unknown Quantum States and Operations, a Bayesian View," `quant-ph/0404156` and some of the references therein. Particularly the Introduction and Concluding section might be of some interest to you with regard to the present discussion.]
>
> The only point I want to make to you with regard to your remark above is that, for these reasons, I would say it has no bearing on the issue at debate: I.e., the debate

of whether it is better to think of a "quantum measurement" as simply an action with an unforeseeable consequence, or rather as a kind of "question-asking" or "information-gathering." It is tangential.

So, what is this distinction that I was trying to capture in my formalism that it seems your way of viewing quantum conditionalization does not take into account? Take a single quantum system, for which some quantum-state assignment ρ has been made. Now imagine performing a quantum "measurement" on the system and updating the quantum state to some new value ρ_d, consequent to the measurement's outcome. One can write that update in the usual Kraus way or in my idiosyncratic way. Let's even take the special case where the update is just the Lüders rule—noting that it too can be viewed in both ways.

You have a state change; I have a state change. In the end, they're identical of course. But whereas you have a change that looks *solely* like an application of Bayesian conditionalization, I don't. I have a handle for making a distinction—and in fact it is a distinction I want to make. You write, "It is precisely the 'violent' collapse transition (17), where measurement is only disturbance, that has to be explained as a noncommutative variant of Bayes' rule and not merely the 'gentle' selection from an initial density operator of a term corresponding to the outcome of a measurement."

No. It doesn't need to be, and I don't want it to be. I want it to remain a distant, maybe unrecognizable addition to Bayes, not a variant at all. It quantifies the extent to which my previous opinion changes radically (as compared to the change it would have made solely through Bayes) upon the receipt of the data. It gives me a handle for exploring a new issue. If a quantum "measurement" is not merely the receipt of data with regard something pre-existent, why should it look like a learning process at all? Well, in truth, the consequence of the measurement may allow me a refinement in predictions for the next round of measurement. But to some extent it is simply new input into my beliefs that my previous opinion could not take into account.

In the end, where I think I want to go with this kind of thing is this. Sandy Zabell puts it nicely in his essay on Ramsey.

> Ramsey did consider the question of the dynamic evolution of belief. Conditional probability is defined in terms of conditional bets; it states the odds that someone "would now bet on p, the bet only to be valid if q is true." This approach has since been adopted as the basis of the commonly accepted subjectivist definition (see, e.g., de Finetti, 1972, p. 193); but of course it does not address the relation that conditional probabilities—thus defined—may have to the actual degrees of belief one holds after the observation of an event. And here we run up against an apparent inconsistency in Ramsey's views. Initially, Ramsey notes there is no reason to automatically identify the two quantities:
>
> > the degree of belief in p given q is not the same as the degree to which a person would believe p, if he believed q for certain; for knowledge of q might for psychological reasons profoundly alter his whole system of beliefs.
>
> But further on in the last section of his essay Ramsey writes: ...
>
> Clearly the emphasized portion of the quotation completely ignores the profound insight of the preceding quotation; perhaps this second passage represents a portion of the text written at an earlier stage.

(OK, I'm too lazy to copy the second passage of Ramsey, which has no relevance to my argument.) Anyway, this idea of Ramsey's has been developed at great length in the work of van Fraassen, Skyrms, and Richard Jeffrey—in fact it is the standard fare of what Richard Jeffrey calls "radical probabilism." Standard conditioning in the probabilistic setting is NOT always the way to go. (The precise statement is that diachronic Dutch book arguments *always* need supplementary assumptions that the synchronic ones don't need.)

I want to fit quantum conditioning into that framework, if possible, and this distinction I draw—i.e., splitting the quantum state change into two components—gives me some handle on that. I regret some of the phrases in my original description of this now—all this business about "gut-wrenching violence"—(remember, that was 4 years ago!), and I am sorry it may have caused confusion about my motivations, but the technical result is still exactly where I want to go.

Bubism 28 : *The above analysis simply illustrates the way the projection postulate works in quantum mechanics. It does not explain it, in the sense of showing how quantum collapse can be understood as a noncommutative version of Bayes' rule for updating states of belief. What Fuchs' analysis in terms of POVM's shows is that the relevant features of my example are quite general. But, again, this in itself does not demystify quantum collapse as a noncommutative version of Bayes' rule.*

Well, I didn't think I had claimed to demystify the particular form of the quantum collapse rule so much as quantify it in a new way (one more in line with the point of view I am trying to build). If my bad writing style confused you, again I apologize.

Bubism 29 : *Fuchs' Bayesian interpretation of quantum probabilities follows de Finetti rather than Ramsey and reflects de Finetti's instrumentalism.*

When I get back home, I'll send you a reading list on Ramsey. The divergence is not as drastic as you think. The only difference I have ever made note of is that Ramsey was willing to call "intersubjective agreement" on a probability assignment "objective chance." But mixing the logical and empirical realms, Ramsey did not do or advocate. I'll bet money on that.

Bubism 30 : *For de Finetti, science is just an extension of common sense and cannot inform the 'logical' aspect of probability formalized in the probability calculus through the notion of coherence. So it would not make sense to regard quantum mechanics as a nonclassical probability theory or theory of information, where the formal features of this new theory encode objective structural relations about the physical world. Physics can only be relevant to the extra-logical and context-dependent evaluation of probabilities.*

That is pretty much correct. And it strikes me as exactly what one would want if one were a *realist*! There is our reasoning about the world, and then there is the world itself. When one starts to mix those two ingredients, that's when one is becoming an instrumentalist!

Yes, I definitely want to see the essence of quantum mechanics being born out as an extra-logical and context-dependent (let me say empirical) addition to probability theory. It is a layer on top of probability (for instance the restrictive region that I always draw on the simplex), and in that way quantum reality (whatever that is) keeps its autonomy from my thought.

Bubism 31 : *What Fuchs takes himself as establishing is that quantum states represent subjective degrees of belief . . .*

Yes, my paper was meant to be a foray in that direction. But, the remainder of your sentence

Bubism 32 : *. . . and that quantum collapse is Bayesian conditionalization* in the standard sense.

not at all. Besides this blatantly contradicts the remaining sentences in your paragraph:

Bubism 33: *What the* physics *tells us is summed up in his statement ...: 'The world is sensitive to our touch.' That is, there is an irreducible nonclassical disturbance that occurs whenever we probe the world. But this enters into the* readjustment *of the observer's probabilistic beliefs* after *the application of Bayesian updating, which is a straightforward refinement of prior degrees of belief in the usual sense.*

And finally,

Bubism 34: *The difference, ultimately, is between an instrumentalist approach to quantum mechanics with the application of a strictly classical Bayesian theory of probability, and an interpretation of quantum mechanics as a nonclassical theory of information, in which the structure of quantum gambles, considered as an objective feature of reality, informs the correlational structure of quantum probabilities.*

No, no, a million times, no! My point of view is in no form an instrumentalism. With each of our theories we are making direct or indirect statements of what we believe of the objective, external world. The quantum Bayesian view of Caves, Schack, Appleby, me, and whoever else to quantum mechanics is no less so. On the other hand, imagining melding empirical statements into the very structure of the laws of thought—as you and Itamar seem to do—represents a real danger with regard to the realist-instrumentalist divide.

Maybe more later, but I'll stop now and print this out.

06-07-06 *Try This* (to R. E. Slusher)

Supercomputers of the Future

These quantum computers, for some problems, would be unimaginably faster. For, increasing a problem in size by a factor of 2, can often make it 4 times as hard to solve on a regular computer. But not so with a quantum computer—there the problem only becomes 2 times as hard to solve.

Quantum Computers Vs. Current Computers

Instead of classical bits, a quantum computer would work with qubits. A qubit is a single atom, or a smaller subatomic particle, whose spin works like an oracle for a bit. The oracle doesn't make up its mind until it is asked a question.

Depending on how it is *found* spinning, a qubit signifies a "1" or a "0." It does not make up its mind before the process of observation.

Why Quantum Computers Could Be So Powerful

Pairs of qubits can be much more powerful as computational components than pairs of bits because of a strange quantum feature called entanglement. In a regular computer, if one were to stop it in its tracks and learn the values of some of its bit, this often is of only limited value for guessing the remaining bits. But in a quantum computer, knowing the answers of some oracle calls can give a seemingly unnatural amount of information about other oracle calls. This makes the logical operations of a quantum computer more tightly connected than in a classical computer, effectively allowing a quantum computer to skip computational steps that a regular computer has to meticulously strain to go through one by one.

06-07-06 *College Keys!* (to G. M. D'Ariano)

D'Ariano-ism 3 : *You didn't give back the keys of the college room at S. Caterina.*

I'm so sorry about doing that! When I read your note, I looked into my backpack and there they were! In any case, I have mailed them straight off; I hope it won't take the keys too long to get there.

I have been meaning to write you for several days now, but ever since returning to the US I have had constant things to do because of Bell Labs (and this large nanotech meeting I am organizing for next week). Anyway, I want to thank you again for inviting me; I very much enjoyed my time there and got a lot out of the interaction. My discussions with you in particular will certainly make me rethink terminology, but more than that. I'm not lying when I say I like the smell of your axiom system—it starts to seem right in a way that the others have not. Ultimately, though, my desire is to get out of pure operationalism—i.e., to take a good look at the quantum formalism and distill from it some statement about the world that makes no direct appeal to the notion of an experiment taking place in the world. I view your axiom system (what I understand of it) as a crucial step in that trek.

07-07-06 *Markus Fierz, RIP* (to H. C. von Baeyer)

von Baeyerism 20 : *Today I asked Klaus Hepp (ETH Zurich), who happens to be a distant cousin, whether Fierz is still alive, and he emailed back that he died one week ago at 94.*

I'm always annoyed to hear news like this. I think, "Why on earth did I not seek out a way to talk to the person when I had a chance." I've had an interest in Fierz for 11 years. If I had sought him out in 1995, when I was already traveling the world, I might have caught him at a fresh, relatively young, 83, and might have learned so many things.

von Baeyerism 21 : *I looked at D'Ariano's paper, but found it pretty hard to understand. However, if some of his postulates about "informationally complete observables" and "symmetric faithful states" can be rendered into English, they might indeed be promising. Is the limitation of information that nature allows us to collect about a quantum system explicit or implied in his approach?*

I go up and I go down about the work, particularly after all the fights I had with him last week about terminology. Might sound silly, but I think it reveals some serious underlying philosophical differences. Certainly, I see "purely operational axioms" as a stopgap measure (though a necessary first step), whereas he may (probably) view it as the end of the line. Still, I think leaning heavily on informationally complete measurements (and their properties) in an axiomatization is the way to go.

To answer your question, yes it has to be. It is somehow already buried in the idea of an informationally complete measurement. But ferreting the direct connection out may be a big problem.

In any case, this has been a very exciting summer for me foundationwise. Itamar Pitowsky presented a very nice result at the Pavia meeting that is worth serious study, to do with a kind of pseudo-Dutch-book argument for the quantum probability rule. (I say pseudo-Dutch-book because it had empirical elements in it—to do with Kochen-Specker things—that a straight-up Dutch book argument cannot have.) He told us that the lecture is posted at his homepage, but I could not find it. When I learn the exact coordinates, I will send them your way.

Attached are some notes I put together while in Pavia to comment on a draft of a paper that Jeff Bub is writing. [See 24-06-06 note to Bub titled "Notes on 'What are Quantum Probabilities'".] The notes are certainly more about my point of view than what Jeff is actually writing about. But I felt I had to do that, since part of his paper was strictly intended to be contra-me. Still, for my discussions with you—on Pauli, Fierz, and alchemy—even though you've already seen various pieces of what I tell Jeff, it may be useful for you to see these various pieces of the description all tied together in one place.

08-07-06 *Cerro Grande II* (to H. C. von Baeyer)

von Baeyerism 22: *In passing I noted that "Hans" accused you of the view that the world does not exist. (If, surprisingly, I happen to be the only Hans in this context, then I am that Hans. If there's another, my comment is moot.) The trouble is, I don't remember accusing you of such a drastic view. I always thought of information as the go-between that mediates between the thing and the mind, and that we have no direct evidence of the material world. Which doesn't mean it isn't there.*

If I really said those things, fine. Even if I didn't, I don't mind helping you out as a straw-man. But did I say them? Only one person comes to mind who really did say them: the editor Hervé Poirier in Science et Vie*. I recall that I was uncomfortable when he wrote that, but didn't object because I didn't know what your real views were.*

Anyway, I am not in the least offended. I'm just following your lead in trying to be as accurate as I can – which is difficult with a lousy memory.

Indeed it wasn't you. But you should know that people accuse me of that "drastic view" all the time. Literally all the time. Here's a partial list that comes to mind: Wayne Myrvold, Michael Nielsen, Andrew Landahl, Abner Shimony, Philippe Grangier, Matthew Donald, Hans Halvorson of course (though he doesn't any more), Simon Saunders, Todd Brun, Bob Griffiths, Wojciech Zurek, and untold numbers of people in the audiences of so many of these meetings I've gone to over the years.

Apparently it is a very thin line we are walking—thin at least with respect to the coarse-grained perceptions and views of the people who pipe up with said accusation.

12-07-06 *Notation for Inspiration* (to H. C. von Baeyer)

von Baeyerism 23: *And what of the future? What notational revolutions can we expect, and what new understanding will they bring about? We have to await a future Leibniz, Dalton, or Feynman to tell us – but I can suggest a couple of areas in which a notational innovation would be welcome. [...]*

Quantum mechanics itself presents another opportunity for better notation. The original version of the theory developed in 1925/26 includes two different ways in which atomic systems develop in time – a smooth, predictable evolution according to well established rules, interspersed with abrupt random changes called quantum jumps or quantum leaps. The two processes might be represented respectively by the steps and risers of a staircase, and both are well understood. To describe an atomic process, physicists usually have to deal with two or three steps up and down the stairs. In recent years, much effort has gone into trying to understand the puzzling interface between the quantum world of the atom, and our own, macroscopic experience. [...] Eventually I hope that an evocative notation will suggest a better way to understand how the world as we experience it, and as it is described by histories, arises from its quantum mechanical substrate.

Thanks for sending me your article on notation. I enjoyed it very much. Do you know I've had Yates' book[108] on my shelf for several years now—ever since picking it up at a charity flea market—but have never read it.

The idea is simple and good. Particularly, you are right in that we need a better notation for making sense of what quantum measurement is all about.

My own favorite image of what quantum measurement is all about is the one attached, which you have seen many times now. But how to turn that image into an effective notation? And notation to do what? I don't really know.

Here's maybe an actual notational innovation in our field of quantum computation: `quant-ph/0504097`. If you haven't read about the Raussendorf-Briegel model of quantum computation yet, this may be a good place to start in any case. Quantum computation enacted solely by quantum measurement and no unitary time evolution at all. That thrills me to no end. For myself, it makes me take the idea of "measurement" as "action" even more seriously.

It's all about philosopher's stones. But how to put that into notation? Your article did get me thinking.

16-07-06 *Edward Lear?* (to A. Shimony)

NOTE: For an amusing story of one of the unintended consequences of this note, see the Abner Shimony story in the introduction, "How to Stuff a Wild Samizdat," of my Cambridge University Press book *Coming of Age with Quantum Information*.

I wonder if you're not in transit to Waterloo yet?

I am looking forward to your celebration and have been gearing up mentally for it in several ways. One is I have just read Brent's biography of C. S. Peirce, so that I might get to know the man a little better. (You know that my talk is titled "Peirce, James, and the Quantum Bayesians"?) What a tough thing to do, to read that book! And actually what a depressing thing to do: I couldn't help but note some of the parallels between his life and mine. Though I lack his genius, I have certainly brought some of the same troubles upon myself.

Particularly now though, I'm writing you because I have just spent a frustrating hour on the web trying to hunt down the words of the poem you recited a little in Vienna last year. The key line as I recall was "going to sea in a sieve". It wasn't Edward Lear's "The Jumblies", was it? What you read seemed so much more serious. Anyway, I'd like to use the lines you actually did recite in my own talk in Waterloo. (I'll use them in the obvious way … to make fun of myself.) If you're out there in email-land still, could you let me know? If I don't hear from you, I'll use some of the lines from Edward Lear—they're certainly appropriate!

Can't wait to talk with you again.

Abner's Reply

> It was very good hearing from you and hearing that you would be at the conference in Waterloo. Also that you are reading Peirce and about him, though your dark statements about parallels between his life and yours were disturbing.
>
> The poem you enquired about is by Lear, and the first line is "They all went to sea in a sieve, they did / In a sieve they went to sea." I don't know whether the poem is called "The Jumblies", though that name occurs in the poem. Most poetry books have indices not only by title but by first line.

[108] Frances A. Yates, *The Art of Memory*, (U. of Chicago, 1966).

18-07-06 *Story about Peirce and Habits* (to J. Christian & L. Hardy)

Here's the story about Peirce and linear time from Louis Menand's *The Metaphysical Club*:

> One of the first things Peirce did after he arrived at Hopkins in the fall of 1879 was to start a Metaphysical Club. It was open to faculty and graduate students from any department, and it met once a month to discuss papers presented, usually, by the members themselves. ...
>
> At one meeting, presided over by Morris, Dewey heard Peirce read a paper called "Design and Chance," and joined in the discussion afterward. The paper is the germ of Peirce's later cosmology, and it sums up in a few pages what was probably the substance of the yearlong class Dewey had chosen not to take. Peirce's subject was the laws of nature—the laws that Newtonian physicists believed explained the behavior of matter and that physiological psychologists believed explained the behavior of minds—and he began with a simple question: Does the principle that everything can be explained have an explanation? Or, as he also put it: Does the law of causality (which is another name for the principle that everything can be explained) have a cause? ...
>
> Summarizing Peirce's Metaphysical Club paper on "Design and Chance" is ... not quite the same thing as paraphrasing it. The argument begins with the point James Clerk Maxwell had made with his imaginary demon: that a scientific law is only a prediction of what will happen most of the time. Even "the axioms of geometry" said Peirce, "are mere empirical laws whose perfect exactitude we have no reason whatever to feel confident of." The decision to treat a particular law as absolute is a pragmatic one: sometimes we feel that questioning it will only lead to confusion, and sometimes we feel that questioning it is necessary in order to try out a new hypothesis. A law, in Peirce's pragmatic view (derived, of course, from Wright), is essentially a path of inquiry. It helps us find things out—as the law of gravitation, for example, helped us discover Neptune—and Peirce's first rule as a philosopher of science was that the path of inquiry should never be blocked, not even by a hypothesis that has worked for us in the past.
>
> Maxwell's view was that laws are fundamentally uncertain because there is always a chance that the next time around things will behave in an improbable (though not an impossible) way—a chance that all the fast molecules will congregate on one side of the container. Peirce's point was that a chance occurrence like this can change the conditions of the universe. His illustration was drawn from classic probability theory: in a game with fair dice, a player's wins and losses will balance out in the long run; but if one die is shaped so that there is an infinitesimally greater chance that after a winning throw the next throw will be a losing throw, in the long run the player will be ruined. A minute variation in what seemed a stable and predictable system can have cosmic consequences. In the natural world, Peirce said, such minute variations are happening all the time. Their occurrence is always a matter of chance—"chance is the one essential agency upon which the whole process depends"—and, according to probability theory, "everything that can happen by chance, sometime or other will happen by chance. Chance will sometime bring about a change in every condition." Peirce thought that even the terrible second law of thermodynamics—the law of the dissipation of energy—was subject to reversal by such means.

As Peirce acknowledged, this was a Darwinian argument: "my opinion is only Darwinism analyzed, generalized, and brought into the realm of Ontology," he said. What he meant was that since nature evolves by chance variation, then the laws of nature must evolve by chance variation as well. Variations that are compatible with survival are reproduced; variations that are incompatible are weeded out. A tiny deviation from the norm in the outcome of a physical process can, over the long run, produce a new physical law. Laws are adaptive.

Pragmatically defined, variations are habits. They constitute a behavioral tendency —for if they had no behavioral consequences, they would have no evolutionary significance. Bigness in beak size is whatever big beaks do for you (if you are a finch), just as (to use an example from "How to Make Our Ideas Clear") "hardness" is just the sum total of what all hard things do. What Peirce proposed in "Design and Chance" was that natural laws are also habits. This was not a new thought for him. There is a story, attributed to William James, about a meeting of the original Metaphysical Club in Cambridge, in which the members waited patiently for Peirce to arrive and deliver a promised paper.

> They assembled. Peirce did not come; they waited and waited; finally a two-horse carriage came along and Peirce got out with a dark cloak over him; he came in and began to read his paper. What was it about? He set forth ... how the different moments of time got in the habit of coming one after another.[109]

It sounds like a joke, but the story is probably true. Peirce's paper must have been an extrapolation from the nebular hypothesis—the theory that the universe evolves from a condition of relative homogeneity, in which virtually no order exists, not even temporal order, to a condition of relative heterogeneity, in which, among other things, time has become linear. How did time get straightened out in this way? By developing good habits. In "Design and Chance," Peirce put it this way:

> Systems or compounds which have bad habits are quickly destroyed, those which have no habits follow the same course; only those which have good habits tend to survive.
>
> Why ... do the heavenly bodies tend to attract one another? Because in the long run bodies that repel or do not attract will get thrown out of the region of space leaving only the mutually attracting bodies.

If you are a heavenly body, in other words, gravitational attraction is a good habit to have, in the same way that if you are a proto-giraffe, a long neck is a good attribute to have. It keeps you in the system. When gravitational attraction becomes the habit of *all* heavenly bodies, then we can speak of "the law of gravity," just as when all surviving proto-giraffes have long necks, we can speak of a giraffe species, and (presumably) when all moments of time have the habit of following one another, we can speak of past, present, and future. But the law of gravity did not preexist the formation of the universe, any more than the idea of a giraffe did. It evolved into its present state while the universe was evolving into *its* present state. Gravity was a chance variation that got selected. Objects that didn't have the gravitational habit didn't survive.

[109] See M. H. Fisch, "Was There a Metaphysical Club in Cambridge?," in *Studies in the Philosophy of Charles Sanders Peirce, Second Series*, edited by E. C. Moore and R. S. Robin (U. Massachusetts Press, Amherst, MA, 1964), p. 11. The words are attributed to Dickinson Miller. [Fuchs: Compare this to John Wheeler's story of the Pecan Street Cafe grafitto.]

18-07-06 *The Real Peres Number* (to J.-Å Larsson)

For the Peres 33-ray example, you once told me how many rays and bases it would take if the jumble were to be completed into full sets of bases (i.e., no basis elements missing). Could you tell me those numbers again? (I guess the number of bases is 16—if I have that right—but what is the total number of rays when everything is counted properly?)

As before, I'm asking because I'm guessing you have these numbers at the top of your head. If you don't, don't kill yourself—I just thought it might be nice to mention them in passing when I mention the KS theorem (in passing) in this week's talk. (Actually, I'm going to put a lot of different material than usual in this one; wish you were here at the Abnerfest to discuss these things.)

Jan-Åke's Reply

> The 33 vectors form 16 triads. But to do the proof for these you need to modify the "two ones and a zero" to "maximum one zero in a pair", sometimes you go via a rotation from one triad to a pair of vectors and then to another triad. Completing to triads only I counted to a total of 57 vectors, forming 40 triads interconnected by 96 rotations.
>
> A table for different KS sets is in `quant-ph/0006134`.

19-07-06 *My Draft* (to C. M. Caves & R. Schack)

OK, I have read it all again, and now at least I agree with everything that is actually said in the paper. At this stage, in preparation for printing it out tomorrow morning to hand off to Mermin, the only changes I have made to Carl's latest draft are [. . .]

As I said, now I at least agree with everything that is actually said in the draft. That is progress. That is not to say, however, I still wouldn't like to make some small additions. There are the ones already marked for me to say something—and, I'm sorry again, but I haven't taken care of that yet. But also,

1) I am a little worried that we have not defined the word "objective" all that well. "Subjective" is OK, but "objective" is left a little dangling. I worry about how to do that in a way we will all agree with and so as not to stir up a new hornet's nest.

2) The present paragraph on the "fundamental conceptual difficulty" in the Principal Principle in the coin-toss case is good, but we really didn't give any argument against it in the quantum case. We simply said "the Bayesian contends . . . " I don't think that is adequate, as much of the point of our paper is premised on the idea that "objective probability" is worthless. The Lewisian says, "Why worry about this category distinction business when both terms—the probability function and its argument—are simply objective in the quantum case? It is a different thing than the classical Bayesian case. There is the objective event and its objective propensity; no category distinction called for."

3) I think it could be useful to end on a more rounded out note on the meaning of the Born rule. What is the meaning of the Born rule if it is not specifying a probability by fundamental physical law? Why do we all use the darned thing? We give a negative answer to the first question—i.e., that despite appearances, quantum probabilities are not specified by law itself—but we never give a positive answer. My own contention is that the sum total meaning of the Born rule is that it is a rule of transformation. It tells us how to take our probability assignment for the outcomes of *this* informationally complete measurement (or set of measurements) and transform it

into a probability assignment for the outcomes of *that* measurement. Thus it is the transformation rule that is specified by "fundamental physical law" (a kind of empirical addition to Dutch-book coherence), not the probability assignment itself. [. . .]

5) An equation or two might be called for at the discussion "The quantum operation depends, at least partly, on an agent's beliefs about the device that executes . . . " For instance, something like what Rüdiger and I put in our tomography-volume paper:

> For any trace preserving completely positive map Φ on a system, one can always imagine an ancillary system A, a quantum state σ for that ancillary system, and unitary interaction U between the system and the ancilla, such that
>
> $$\Phi(\rho) = \mathrm{tr}_A\Big(U(\rho\otimes\sigma)U^\dagger\Big) ,$$
>
> where tr_A represents a partial trace over the ancilla's Hilbert space. The Bayesian should ask, "Whose state of belief is σ?"

6) This one may not be for here—i.e., another can of worms thing that we probably don't want to get into for the present paper—but I want to record that I'm also a little worried about our dual use of "facts" and "propositions". Appleby has already called me on it during his reading in Pavia. It could be a serious point, and it has come up in our conversation before. For instance, the present dual use probably contradicts the usage I proposed in several of those old notes to you and Mermin. See for instance, 04-09-2001 "Note on Terminology," in my letter collection.

Appleby's particular point is that our category distinction is really a logical distinction, and one should therefore stray away from any presentation that doesn't make it seem as such. (But I'd probably have to work more than I have the time for now, and quote Wittgenstein and such, to make this mean much to you. So, I won't go into it any further than this.)

If you tell me which, if any of these, you agree with, and you yourself think is important, I will try to oblige. Realistically though (even without any of the changes above) I don't see how we can post anything before Carl returns from vacation. I can promise to do my very best to stop my sinning of trashing deadlines, and see what I can work up to have waiting on your desks when you return August 6.

19-07-06 *Quick Early Reaction* (to C. M. Caves & R. Schack)

Cavesism 76: *God save us from Wittgenstein. We're writing this for physicists. I do think we want to be addressing things other than propositions, because most physicists would think physics has to do with things other than propositions.*

Believe it or not, I am not making this up. (I may be vindictive, but I am not *that* vindictive.) I just had lunch with Mermin and the first thing he said was that he could not get past our first page. He got hung up on the words "proposition," "data," and "fact"—how they were potentially meant to be the same thing, or how they might possibly be different. He didn't know which. The word he was the most comfortable with was "proposition." When I told him that "acquiring data" was meant to be the becoming aware of the truth value of a proposition, he was OK with that too and happier. However, with the word "fact" we made no great progress. He said he might be happier if we didn't have to use the word in our presentation. At the very least, we should be more careful about the distinctions and identities.

. . . just quoting him to the best of my ability. I hope he'll move on to page 2 now.

I know there have been plenty of times when Carl has said that I am not a physicist. (Though I certainly can't blame him: Clearly it's an opinion shared by all the physics departments I've interviewed with.) But do you really want to say that David Mermin is not a physicist?

I think we're going to need some more precision. At least Appleby and Mermin are a sympathetic readership; what's it going to be like when we hit someone who is nasty?

20-07-06 *Capacity for Creation* (to J. E. Sipe)

That's the phrase I should have used. That is what I would like to think of as permanent and unchanging for a quantum system. (As far as I understand, it is not crucial for my ontology at this stage, but it is an idea I am testing out and intrigued by.)

The essay collection "Delirium Quantum" is attached. [See `arXiv:0906.1968v1`.]

For the bit I read you tonight about how

> Our quantum measurements in the present never tell us about the past. They only tell us about the consequences of the past for any of our other measurements in the present.

you can go to the present (incomplete) compilation of the new samizdat. [See 23-09-03 note "The Trivial Nontrivial" to S. Savitt.]

Thanks for the conversation tonight! It was very useful to me.

26-07-06 *Another Question* (to J. E. Sipe)

Thanks for the note. I think it really goes to the heart of the matter (though, I recognize it is what you already brought up in our till-midnight conversation the other day). In fact, it goes to the heart of the matter so much so that I had better search my soul before writing you more. Your question is a really important one, and—I cannot lie to you—I am learning a lot by your forcing me on this point.

At the moment, I am inclined to say that I lean toward being a "dualist Bayesian," though I don't think that definition (i.e., falling within a mere trichotomy) captures the right sense of distinction that should be made. There is a whole spectrum of things that I think I would allow, and "classical Bayesians" and "consequence Bayesians" are just two points in that space (not necessarily extreme points).

Certainly I am sometimes in the habit of thinking of Hilbert-space dimension as akin to a classical property (something that one hypothesizes of a system). Thus if one were to write down a probability distribution for the dimensionality of a system, one would be committing a type of "classical Bayesianism," as opposed to "consequence Bayesianism." What else could I mean by it? On the other hand, I sometimes think of the distinction between dimensionality and a particular state vector as a *logical* distinction (one of the *level* of subjectivity).

See for instance the note "04-07-03 Solid Ground, Maybe? (to G. L. Comer)" starting on page 209 of Cerro Grande II. Particularly the remark on page 301 about levels of subjectivity. Also have a look at the note "25-07-03 Relative Onticity (to R. Schack)" starting on page 314. Finally—though this may confuse things more than help things (because it is spiraling outward from your particular point)—if you have some extra time, *maybe* look at "28-07-03 Your Newest Turn (to R. Schack)" starting on page 316.

Anyway, as I say, you deserve a thorough answer to this one, and it will be a good exercise to me to figure out my own opinion!

Let me now, if you don't mind, turn this note to a different kind of soul searching that I've been going through, and I hope you will give me an honest, straight-up opinion in reaction … no matter what the reaction is. One of my friends at the PI meeting, whose opinion I respect very, very much, absolutely hated my talk—so much so that he took me aside on a private walk to let me know. The kinds of words that came out as a description of the talk were, e.g.: "too vague," "not focused," "irrelevant cartoons," "doing a disservice to this otherwise interesting research program," [i.e., the quantum Bayesian program], overhearing people say that I'm a nut, things like that. It was pretty devastating, and maybe I needed to hear it. On the other hand, from another group of people at the conference, I thought—but maybe it was just wishful thinking—I got the opposite impression. If I'm not mistaken Wayne Myrvold, for instance, said it was the clearest talk he had ever heard from me, and I remember some similar (though maybe not as extreme of) reactions from some of the other philosophers (and Bernstein, Greenberger, and Zeilinger). When I encounter things like this, my head spins and I feel like a lost little sheep; in some ways I am very fragile. All I care to do is get these ideas conveyed, and I have had a tendency to keep simplifying and simplifying to try to get this (what I view as a) rather simple message across: In going from classical to quantum, the notion of probability and its import stays the same, but what changes is the notion of event ("consequence Bayesian"). At the same time, one does not "renounce the enterprise of physics" (as Geoffrey Hellman said explicitly in his talk). Our program, in fact, is exactly what is needed to get back on track in physics. That's the message. But maybe my talks are of absolutely the wrong strategy, and I am doing the program a great disservice after all.

Here's where I'd like your straight-up opinion. Please be brutally honest. I've been devastated once; it is bound to be much easier to be devastated a second time around, and I am prepared for it. Do you think my talks on this subject would benefit by going heavier on technical details—quantum de Finetti theorems, senses of compatibility of quantum state assignments, POVM Gleason theorems, that kind of stuff? I.e., that my method of speaking is way off key, even for a foundational meeting like the Abnerfest? Taking Paul Busch's very clear talk—which I myself enjoyed immensely—as an example, do you think speaking more along the lines of that style would be of greater benefit to the quantum Bayesian program?

John's Preply

> Let me try to me a bit more articulate about one of the questions I was trying to ask in our discussion at Perimeter.
>
> Bayesians, as I understand them, take probability statements to be statements of beliefs. The obvious follow-up is the question "beliefs about what?" As I understand your view, in quantum mechanics you take this to be an agent's belief about the consequences of future actions, and you have shown how the ket can be understood as encapsulating those beliefs through, for example, your "bureau of standards" approach.
>
> Now suppose a Bayesian is not doing quantum mechanics, but rather paleontology, and is discussing the dinosaurs. If probabilities entered in his or her paleontology — and presumably they would because of the kind of central significance that Bayesians give to probabilities — those probabilities would again be taken to be statements of belief. Again one can ask "beliefs about what?" The man-in-the-street Bayesian (if such a person exists, but by the term I mean one not terribly familiar with quantum mechanics) might take those beliefs to be about when particular dinosaurs lived, what their physiology was like, what they ate, what caused their extinction, etc., etc. That is, the "x" in $P(x)$ would be the usual kind of proposition about "the external world" — in this case, "the world of dinosaurs" — that is common in, say, usual readings of

classical mechanics.

This would be different than the "x" in $P(x)$ that appears in your quantum mechanics, for there "x" is a proposition concerning the consequences of your actions, and not concerning "the quantum world."

In contrast to this, one could also imagine a Bayesian who insisted on using the same kind of "x" in paleontology as in quantum mechanics. That is, the "x" would refer to consequences of actions, such (as what we would colloquially describe) as "seeing a fossil of such-and-such a type upon digging down one more layer at such-and-such a site." Any talk about dinosaurs existing, fighting, eating, etc., would be taken just to be heuristic devices for helping one think about the actual consequences of doing such fieldwork in paleontology, and the work of the discipline itself would understood to be properly concerned not with someone's heuristic thoughts of 'dinosaurs' but rather with the fieldwork.

This leads to the point that, even if one is a fully-committed Bayesian, it seems to me that there are a number of types of which one might be a representative. Here are three:

- A thorough "consequence Bayesian," for whom the "x" in *any* $P(x)$ refers to the consequence of an agent's action.
- A "dualist Bayesian," for whom the "x" in $P(x)$ *sometimes* refers to statements about the external world of the type common in the usual readings of classical mechanics, and *sometimes* refers to the consequence of an agent's action.
- A "classical Bayesian," for whom the "x" in $P(x)$ *always* refers to statements about the external world of the type common in the usual readings of classical mechanics.

That is, simply committing to a "belief understanding" of probabilities does not in itself commit you to a particular view of to what kind of entity the "x" in $P(x)$ refers.

You would help me a lot if you would answer the question: In your view, what is the nature of the x's in *all* the $P(x)$ that arise in science? Do they *all* just identify consequences of actions of the agent? Or can some of them identify propositions about the external world? And if some of them identify propositions about the external world, what is the rule for establishing when that is possible? And if none of them identify propositions about the external world, paleontology is not about dinosaurs!

27-07-06 *A Probability Calculus for density Matrices* **(to M. Warmuth)**

Thank you for drawing my attention to your paper with Kuzmin. To the moment, I have only given it a cursory look, but it looks very interesting!

In fact, I hope that you will post both this paper and the other one on the `quant-ph` archive, `http://www.arxiv.org/archive/quant-ph`. It is effectively the main "journal of quantum information and computing" with most of us in the field looking to see what's new there daily. It would be good for your results to be posted there for discussion and debate and building upon—this is certainly a community interested in such things.

Anyway, as I say, I look forward to understanding your papers. There are indeed now several distinct things that one might be tempted to call a "quantum Bayes rule." Exploring the realm of possibilities is good exercise and will lead to a better understanding of all that quantum mechanics has to offer.

My own preferred direction *at the moment* is actually *not* to think of density operators as "generalized probabilities" as you do in your papers, but rather as *single* (normal, usual, classical, whatever you want to call them) probability distributions for the outcomes of a fixed, fiducial measurement (an informationally complete POVM). Then, the probability distributions for the outcomes of all other measurements can be thought of as coming about through a kind of coherence condition (analogous to Dutch book, but empirical in nature). That is to say, the import of the Gleason theorem is that it tells us how to interrelate (or transform) probability distributions, not how to set them.

Caves, Schack, and I will make some remarks on this in our newest paper, which we hope to post soon. However, let me give you a couple of existing pointers that at least broach the subject:

- "Quantum Mechanics as Quantum Information (and only a little more)"
  `http://www.arxiv.org/abs/quant-ph/0205039`
  (See particularly, Subsection 4.2 and Section 6.)

- "Unknown Quantum States and Operations, a Bayesian View"
  `http://www.arxiv.org/abs/quant-ph/0404156`

By the way, I already like the prettiness of this matrix operation you define in your Eq. (1). (Though I was certainly aware of a similar operation used by Cerf and Adami—maybe though they used it in a more restrictive way—once upon a time, you helped bring it from the recesses of my memory.) For your enjoyment (and contrast!), you might have a look at the monstrosity I once constructed to draw out some perceived similarity between quantum conditioning and Bayes' rule. (The idea at the time was that the initial (pre-measurement) quantum state ρ fulfills both the role of $P(h)$ and $P(d)$ in an application of Bayes' rule $P(h|d) = P(h)P(d|h)/P(d)$.) You can find the thing at page 90 of `http://www.arxiv.org/abs/quant-ph/0105039` in the subsection titled "Where Did Bayes Go?"

27-07-06 *Course Adjustment?* (to W. L. Harper)

It was good to finally meet you last week! I greatly enjoyed our discussions, and I hope we'll pick them up again sometime.

For the moment though, I wonder if I might ask you a (probably difficult) question. I hope you will give me your honest, straight-up opinion ... no matter what the opinion might be. The reason I'm picking on you in particular is because it seems you got something out of my talk (I'm basing this on a couple of comments you made at the end) and because I don't think you've ever heard me speak before. Thus perhaps you're a little more blank-slate for the question at hand than someone else I might ask.

OK, here goes.

One of my friends at the PI meeting, whose opinion I respect very, very much, absolutely hated the talk—so much so that he took me aside afterward to let me know. The kinds of words that came out in his description of the talk were, e.g.: "too vague," "not focused," "irrelevant cartoons," "doing a disservice to this otherwise interesting research program," [i.e., the quantum Bayesian program], overhearing people say that I'm a nut, things like that. It was pretty devastating, and maybe I needed to hear it. On the other hand, from another group of people, I thought—but maybe it was just wishful thinking—I got the opposite impression. For instance, if I'm not mistaken Wayne Myrvold said it was the clearest talk he had ever heard from me (though maybe he was just being facetious). Anyway, I certainly got some positive reactions from a few other people.

When I encounter opposite impressions like this, my head spins and I feel like a little lost sheep. All I generally care to do in these quantum foundational talks is get the main "quantum Bayesian" message across, and I have had a tendency to keep simplifying and simplifying to try to get that done. But maybe my talks are of absolutely the wrong strategy, and I am doing the program a great disservice after all, as my friend thought.

Here's where I'd like your straight-up opinion. Please be brutally honest. I've been devastated once; it is bound to be much easier to be devastated a second time around. Do you think my talks on this subject would benefit by my going heavier on technical details—quantum de Finetti theorems, senses of compatibility of quantum state assignments, POVM Gleason theorems, that kind of stuff? I.e., that my method of speaking is way off key, even for a foundational meeting like the Abnerfest? Taking Paul Busch's very clear talk as an example, for instance, do you think my speaking more along the lines of that style would be of greater benefit to the quantum Bayesian program? Or do you think it would be just the opposite, at least for someone's (like your own) first encounter with me?

I am truly perplexed, and if you could give me another data point to work with, that would be most useful for how I adjust my course. Maybe I'll cc this note to Wayne, so he'll know what kinds of things I'm saying to his colleague (particularly if I'm misquoting him!).

28-07-06 *Bad Reality Creation* (to G. L. Comer)

I don't know if you read Paul Krugman in the *NY Times*, but I wanted to have a recorded of the closing lines of today's column. So, I'm going to send the whole column to you if you don't mind (in case you wanted to understand the context). This is a very perplexing situation indeed—I've been scratching my head over it for six years!

From Paul Krugman, "Reign of Error," *New York Times*, July 28, 2006:

> The climate of media intimidation that prevailed for several years after 9/11, which made news organizations very cautious about reporting facts that put the administration in a bad light, has abated. But it's not entirely gone. Just a few months ago major news organizations were under fierce attack from the right over their supposed failure to report the "good news" from Iraq — and my sense is that this attack did lead to a temporary softening of news coverage, until the extent of the carnage became undeniable. And the conventions of he-said-she-said reporting, under which lies and truth get equal billing, continue to work in the administration's favor.
>
> Whatever the reason, the fact is that the Bush administration continues to be remarkably successful at rewriting history. For example, Mr. Bush has repeatedly suggested that the United States had to invade Iraq because Saddam wouldn't let U.N. inspectors in. His most recent statement to that effect was only a few weeks ago. And he gets away with it. If there have been reports by major news organizations pointing out that that's not at all what happened, I've missed them.
>
> It's all very Orwellian, of course. But when Orwell wrote of "a nightmare world in which the Leader, or some ruling clique, controls not only the future but the past," he was thinking of totalitarian states. Who would have imagined that history would prove so easy to rewrite in a democratic nation with a free press?

31-07-06 *To the Memory of Walter Philipp* (to A. Y. Khrennikov)

That is very sad news. Do you know any details of how Walter passed away? Was it a hiking accident or something? Amazing how a person can be with you one day and gone the next. There should be an object lesson in that which stays in the backs of all our minds.

31-07-06 *Hi* (to W. E. Lawrence)

Lawrencesm 3: *The Conference* [“Quantum Reality, Relativistic Causality, and Closing the Epistemic Circle: An International Conference in Honour of Abner Shimony,” July 18–21, 2006, Perimeter Institute, Waterloo, Canada] *looked as if it would be wonderful. What's your impression of it? — actually, before you answer — I've got a mind to call you up and ask “in person,” as it were. But if you still want to answer …*

Good to hear from you. It was a fun conference. I got quite a bit from the talks, and the “dialog” between Lee Smolin and Abner Shimony one night in the Black Hole Bistro was particularly fun.

For myself, I gave a sadly polarizing talk: At the end of it, one of the philosophers came up to me and said it was the best talk he had ever heard from me. On the other hand, one of the physicists (one whose opinion I respect very, very much) came up and said it was the worst talk I had ever given. Unfortunately, I suspect the disparity in those comments indicates something deep! Something I'd really rather live in denial about.

Anyway, you shouldn't feel that you completely missed the meeting. You can still view the talks by going to this website: `http://pirsa.org/`. At the very least, you should enjoy the “Bistro Banter” that I mentioned above.

02-08-06 *Collaboration?* (to L. K. Grover)

Seeing your note to Bill coming by reminded me that I'd like to eventually discuss a possible collaboration if you're interested. I was intrigued by some of your remarks at the July 11 meeting in the auditorium here, about how the $\pi/3$-phase-shift problem had a more understandable picture in terms of the evolution of probabilities rather than amplitudes. That made me wonder how the Grover algorithm and all its variants would look if written in terms of this representation of quantum mechanics I've been developing — where state vectors are replaced by probabilities for the outcomes of a certain informationally complete measurement.

Would you be interested in seeing if we could translate your algorithms into those terms?

I'm working rather steadily with my student Hoan on this representation until he leaves Sept 1. But after Sept 1, I should be free to start another big project like the one above. My hope is that it could give us some real insight into another way of looking at your algorithm.

06-08-06 *The Story of Little Chocorua* (to J. B. Lentz & S. J. Lentz)

> [[Flashback to three months before the present note:]] Kiki's gone freakier than usual on me. A couple of weeks ago, she found a hundred year old Victorian that's going to be torn down, and she convinced the owner to let her have all the doors. So, I've got 16 doors (solid, mind you, and historical), but still 16 doors, stacked up in my garage. Final destination: She's going to make the walls for the girls' playhouse from them.

> Too much time on her hands and certainly too much imagination for her good (or at least for the good of our relationship). I told her she's got a month to get them out of my garage.

I guess I have to admit that Kiki is a true blue carpenter now, and that I'm quite proud of her product. The playhouse is fantastic. And she's a pretty good salesman too, calling it Little Chocorua (after William James's weekend home in Chocorua, NH). Did she tell you the story? James was so proud of the fact that there were 11 doors leading outside at his home; he could walk out and look in any direction on his land. Well, the count of doors on Little Chocorua is 12. I tell everyone we've done William James one better.

By the way, here was another ploy of Kiki's for softening me up. The big green patch on the right front door is chalkboard paint; I don't know if you knew. Kiki says to the kids, "You should think about how much you'd charge Dad for renting out Little Chocorua as a conference center. He could bring his colleagues over and they could have small seminars around the chalkboard, if you'd rent your space out." That certainly did get me to start thinking, "Hmm. This might really be a good place for a small quantum information conference." She's a professional I tell you!

You two made quite a daughter.

06-08-06 *Kiki's Wacky House* (to M. D. Sanders & D. B. L. Baker)

Let me give you a follow-up on the hair-brained scheme of Kiki's that I told you about a couple months ago.

I wrote the note below to Kiki's parents today since it's Kiki's birthday—it tells a little more of the story of the house—and included some pictures. [See 06-08-06 note "The Story of Little Chocorua" to J. B. Lentz & S. J. Lentz.] Before stripping the pictures out of Outlook (so the `.pst` file doesn't get too big), I thought I might send them to you too. In the end, I'm pretty proud of the damned thing, and Kiki too. She built every inch of the place all by herself—from the foundation to the frame to the roof—not one ounce of help from me or anyone else. And even with the old ship's porthole window and the fire pole on the inside, the total cost was less than $350.

Anyway, admitting that maybe she's not so crazy after all (to all the people I had told she was quite crazy) is part of my birthday present to her.

15-08-06 *Drink the Kool-Aid* (to C. H. Bennett)

I have to apologize: After our horse play the other day, I got carried away with some bureaucratic duties, and then simply *forgot* to come back to your note. Pathetic. Then Kiki, the kids, and I took a long weekend of sailing and amusement parks, etc.

I hope I'm not writing you back so late that the reply will be irrelevant.

Bennettism 27: *I thought first of Jonestown, but according to Wikipedia the Jonestowners drank a less well-known brand of grape drink. "Drink the Kool-Aid" is said to have originated earlier, in the 1960's, from Ken Kesey's use of it as a vehicle for LSD. Thus I can be said to have drunk the Kool-Aid of Many Worlds. I thought that Lucent, like IBM, had drunk the Kool-Aid of DTO funding.*

But what about basing QM on Yes QKD and No BC? I am trying to write a piece on conceptual foundations of quantum crypto. As I recall there was some difficulty with this program, and at one *point it had evolved to no-broadcasting and no superluminal communication, without mentioning bit commitment.*

Yeah, the Bub, Clifton, Halvorson stuff wasn't too very convincing after my initial excitement wore off. First, by starting off in a framework of C^*-algebras, they were effectively invoking quantum mechanics to begin with—or at least I always felt that way. Then, it was pointed out that "No BC" wasn't doing any work for them at all. And the last report I heard from Halvorson was that "no superluminal" was mostly redundant too. A good explanation/critique comes in Chris Timpson's PhD thesis: `http://philsci-archive.pitt.edu/archive/00002344/`. See pages 196–225; it's easy reading.

In the end, I don't think those early ideas of Gilles' and mine go very far toward getting at the essence of quantum mechanics. The best counterexample, I think, is in the form of Rob Spekkens' toy model: `quant-ph/0401052`. It appears to have "Yes QKD" and "No BC", and much more (like a no-broadcasting principle and correlation monogamy) but it sure ain't quantum mechanics. Instead it relies "merely" on an information limitation with regard to some hidden variables (i.e. pre-existing values).

I find that work of Spekkens tremendously exciting because I learned so much from it. It didn't lessen my conviction that the essence of quantum mechanics has to do with the intricate connection between observer and observed in the quantum world—in fact I think it is the best demonstration yet that quantum states are expressions of information, rather than stand-alone properties of the systems (or the universe) themselves—but it did help me to understand how much more interesting the story has to be. Spekkens' toy model is based on the very pre-existence of measurement values (for that is what drives his combinatorics), but in the quantum world (because of Bell-Kochen-Specker), measurement values don't pre-exist the measurement process. I now think it is that that is primary in quantum mechanics, and things like NO BC, YES QKD, no-broadcasting, teleportation, etc., are all secondary.

If you have any more questions, I promise to be more attentive this time.

Charlie's Reply

> We miss you too. Why don't you come up and visit us more often, so we can pretend to throw your computer away like in the old days? Or we'll come down and visit you. I thought of you when I was visiting my late mother's best friend Cynthia, 89 years old, the other day, along with her daughter Sally, my sister's best childhood friend, and her grandson Will (in his 20's). Sally said "quantum mechanics – that must be hard to understand". Her mother said, "We'll I'm taking a course in it for seniors, emphasizing the history and concepts, without the math". I said, "Good for you. The history is rather lively. For example one of the greats, Schrödinger, was a notorious womanizer, and historians are trying to figure out which mistress he was with when he came up with the Schrödinger equation". Sally said, "for a while they even thought of calling it condom mechanics."

18-08-06 *Aqualung* (to C. M. Caves & R. Schack)

> Feeling like a dead duck –
> Spitting out pieces of his broken luck.
> Sun streaking cold –
> An old man wandering lonely.
> Taking time
> The only way he knows.
>
> — Jethro Tull, "Aqualung"

Attached is a draft where I made most of the changes I had suggested before. Mostly I niggled a lot with some of the phrases to do with "facts" and "the world", in an attempt to be a little more careful, and so as not to give an impression that we do not think the agent is part of the world. If you would like to get a better feeling for all the places I made changes (even trivially small ones), I could fax you my marked up manuscript.

The main thing that I regret not having touched very much is the discussion of objective chance and the weakness of the Principal Principle and such. That really is the weakest point of the paper, and I wish we could do something better. I suspect it is because of the weakness of that section that Carl's students came out swinging. (Will they like this version better? I did try to keep them in mind, particularly in the closing statements.) And I also suspect that it is the weakness of the chance section that is going to lead to our most trouble in the future (particularly with the philosophical set, which is an annoying, but undeniable, fraction of our audience—I hate to say it, but they're the ones who at least take us more seriously than anyone else).

23-08-06 *My Revision* (to C. M. Caves & R. Schack)

Cavesism 77: *I think I understand why "ascertaining" was replaced by "ascertaining or prompting" in the second paragraph of the Intro: "Gathering new data—i.e., ascertaining or prompting the truth values of various propositions—allows the agent to update his probability assignments, generally by using Bayes's rule." It is probably meant to deal with the impression that ascertaining gives of finding out something that pre-exists. I'm sympathetic to that, but suspect that the prompting will puzzle many readers. Still, I don't want to change it.*

Yes, that was the motivation. And, yes, you are probably right that a reader will be puzzled. And finally, I'm happy that you don't want to change it. But, I don't see that a small footnote with one sentence of explanation could hurt. Might that be an effective analgesic?[110]

I think we're good to go on all else. I'll certainly accept Rüdiger's kind offer of making all submissions. With all my computer problems, I barely have a functional office (still can't pin the problems down).

Cavesism 78: *In other words, here independent does not modify the verb demands, which would call for an adverb, but is a predicate adjective in a clause that has been abbreviated.*

[110] Afterward, Carl added this footnote to the paper: "We introduce 'prompting' here because 'ascertaining' has the connotation of determining a preëxisting property, which is in conflict with the central point of our paper. Having made the point, however, we banish this connotation from the use of 'ascertaining' and use it for the remainder of the paper." Later, he further changed 'prompting' to 'eliciting'; see my 16-10-06 note to Caves below.

In my professional career, I have always felt intellectually second-class whenever I'm in the presence of people who invoke terms like "algebraic geometry" or "diffeomorphism invariance" when speaking of a problem. (Howard Barnum still frightens me to no end when I compare notes with him on any subject that I've been thinking about for some time.) But ever since meeting Charles Bennett and Carlton Caves, I have realized that my greatest inadequacy is actually English grammar.

Cavesism 79: *It's always a privilege to write a paper with Chris (frustrating, but a privilege), partly because the references make one look so much more learned than one really is.*

The intent of the "one" can be read in at least two ways. It's probably psychologically useful to me to believe that it is the more innocent of the two.

23-08-06 *NATO Workshop Gdansk 10-13.09.2006* (to M. Żukowski)

Well, I've had no luck finding a speaker from the U.S. who could carry the torch of "quantum states are information, not physical properties." But I have pinpointed a colleague from the U.K. who would do the point some serious justice, and in a technically important way.

It is Prof. Rüdiger Schack at U. London, Royal Holloway. He would talk about recent work of he and Carlton Caves, that is some of the most important I've seen in our quantum-Bayesian effort in a while: It is an analysis of "quantum random number generators" from our perspective. The work ultimately connects to the precise meaning of how quantum cryptography can be more secure than classical cryptography even in this Bayesian view of quantum probabilities. The differences from the naive view—which amounts to little more than blithely saying, "it's secure because of physical law," which is an almost empty statement—are pretty striking.

So, I hope that piques your interest. He would be a very good representative of our effort, and I saw the talk earlier this summer and know that it's excellent.

I know that he is from the U.K., but he would be talking about collaborations with his U.S. colleagues (Caves and me). Do you think you can do it? Would NATO allow it?

I apologize again for not being able to attend myself. It looks like I am going to miss a really good and really important meeting.

31-08-06 *My Two Cents* (to J. Finkelstein)

Finkelsteinism 7: *It seems to me that to say that a detector has clicked is to make a statement about the state of that detector (or about the state of the device which records the clicks, which comes to the same thing). Since you take seriously the fact that experimental devices are necessarily quantum systems, I would have expected you to say that a statement about the state of a detector is a statement of subjective belief, not of objective fact.*

To put it somewhat differently, in your paper you argue that since a preparation device is itself a quantum system, objective facts about that device do not determine the prepared quantum state. But since the preparation device is a quantum system, how, in your view, could there be any objective facts about it?

The way I would put it is to say that the cut is not three-way as you outline—that is, between the quantum system, the detector, and the agent—but rather two-way: In our scenario there is only the agent and the external world. The way one should think of the measurement device is the same way one should think of a prosthetic hand—it is an extension of the agent.

"Detector click" is shorthand for *sensation* in the agent, and in my personal view, that is all it is. The value of the "detector click" is beyond the control of the agent; it is not a function of his beliefs or his desires. His interaction with the external world gives the class of potential sensations, but it does not set the value.

Thus, the value of the detector click—call it d—is objective for the agent. (There is one sentence in the paper where adopted almost that phraseology "an event is a fact for the agent," and it might have been wise to adopt it more consistently.) What is subjective from our view—i.e., a function of the agent and not the data or external world alone—is the POVM associated with those potential values. That is, the set of operators E_d.

I expand on this in the essay "Me, Me, Me," [in this collection], which I still think is worthwhile reading. Let me also attach a file I wrote a couple of months back in response to some issues of Jeff Bub's (it's maybe a little more up to date). [See 24-06-06 note "Notes on 'What are Quantum Probabilities'" to J. Bub.] Particularly relevant to the present discussion are the points I make right after Bubisms 9, 10, and 13. I'll also attach my favorite way of illustration of the point (in the form of a `.jpg` file.) There is an agent, there is an external world, there is an interaction between the two—the agent acts on the external world, it causes a reaction back in him (sensation). As far as he is concerned that reaction is not subjective; it's as real as anything he's ever seen.

To make it clear: I'm not speaking for Carl or Rüdiger with these paragraphs. They may disagree with one or another nuance of what I've said. We tried to write the paper in a neutral way that didn't do a disservice to any of our particular views (though I think they are mostly aligned, except for particular choices of words).

11-09-06 *My Swerves and Yours* (to M. S. Leifer)

Leiferism 2: *For now, I'll just leave you with one comment. I think a better name for "Zing" would be "the swerve", in deference to Epicurus. That's the earliest reference I can think of to any similar sort of notion.*

I've thought about "swerve" before (in the context of the old atomists and within our own), but I don't think the word really captures whatever it is I'm trying to get at. For instance, somewhere in my first samizdat, you'll find this sentence:

> The quantum mechanical indeterminism doesn't come about from an indiscriminate swerve in the path of an atom; it comes from the point of contact between the theory and the world—the measurement.

In my quantumness of a Hilbert space paper, I also remember writing this:

> Associated with each quantum system is a Hilbert space. In the case of finite dimensional ones, it is commonly said that the dimension corresponds to the number of distinguishable states a system can "have." But what are these distinguishable states? Are they potential properties a system can possess in and of itself, much like a cat's possessing the binary value of whether it is alive or dead? If the Bell-Kochen-Specker theorem has taught us anything, it has taught us that these distinguishable states should not be thought of in that way.
>
> In this paper, I present some results that take their *motivation* (though not necessarily their interpretation) in a different point of view about the meaning of a system's dimensionality. From this view, dimensionality may be the raw, irreducible concept—the single *property* of a quantum system—from which other consequences are derived

> (for instance, the maximum number of distinguishable preparations which can be imparted to a system in a communication setting). The best I can put my finger on it is that dimensionality should have something to do with a quantum system's "sensitivity to the touch," its ability to be modified with respect to the external world due to the interventions of that world upon its natural course. Thus, for instance, in quantum computing each little push or computational step has the chance of counting for more than in the classical world.

Zing is meant to capture something intrinsic to the system. The bit of indeterminism that comes about in a quantum measurement I don't think of as intrinsic to any one thing. Rather, it is more along the lines of the relational stuff you PI people always talk about—it is a function of two objects, not one.

18-09-06 *Seeking Advice* (to L. Hardy, R. W. Spekkens, G. M. D'Ariano, R. Schack, D. M. Appleby, and M. S. Leifer)

Dear Friends and Acquaintances of the epistemic quantum state,

I wonder if I can ask your advice on the following subject—I'd like to get your opinions before making a decision myself. I let the distribution list in sight, so you could see who else I was consulting, but please write back to me privately—I will keep your opinion in confidence.

Marlan Scully has given me the opportunity to have a plenary talk at his annual "Physics of Quantum Electronics" Conference in Snowbird, Utah (January 2–6), and more importantly, associated with that, the chance to organize a session around the subject with 4 or so other invited talks. The thing I'm wondering is whether it would be worthwhile for our community for me to follow through with this? If I were to organize a session it would be to highlight recent work (and potential applications) of epistemic/operational/Bayesian views of the quantum state. Thus, this is why I'm writing to you.

It is decent sized meeting; I think there were over 300 people there last year, including a couple Nobel prize winners (Glauber, and I can't remember the name of the other one). You can go to this website if you want to get a feel for what the line-ups the last few years have looked like: `http://www.pqeconference.com/`. Old programs since 2001 are posted there.

Anyway, the good I can see coming from this is that we would have a captive audience from a set of people who normally have far more to do with the applied side of physics than the ones we are usually around. Maybe that would be useful for raising recognition of the promise of recent research in quantum foundations and its uses for the wider physics community. The downside is that this is a very expensive conference, and there is no financial aid for it: Registration is $350 USD, hotel comes to $180/night (though that could be halved by doubling up in rooms for anyone who cares to), meals are *not* included, and the only restaurants available are the ones of this resort hotel. Not cheap. They say the skiing is great (and the conference shuts down every afternoon for it), but for me personally, that is of very little consequence.

I would like to know your opinion of the value of such a get together before following through with this or not following through with this. Also, would you yourself come?

18-09-06 *Big Expensive Conferences* (to J. E. Sipe)

Sorry, I still owe you that note on the extent of my "consequence Bayesianism." These are heady waters and I took a couple months off from foundational chit-chat to do some hard calculating while

I had a good summer student. Plus, after the Shimony meeting, I think my system needed a good purge. However, I will come back, and probably soon (as we're starting to get referee reports on `quant-ph/0608190`, and some of their points concern the one you're also getting at). But I don't feel too terribly guilty—you yourself never called me, after bringing up the possibility twice.

18-09-06 *Another Topic* (to M. S. Leifer)

Leiferism 3: *On a completely different topic, I wanted to ask you a question in your role as chief expert on distinguishability measures in quantum theory. Do you know if anyone has done any work on axiomatic approaches to distinguishability measures, along the lines of the axiomatic approach to entanglement measures? Specifically, I have in mind that a distinguishability measure would be defined as a functional of two states that is monotonically decreasing under CP maps, with perhaps a few other regularity conditions, and then that two such functionals could be found that provide upper and lower bounds on all such measures.*

You can look at Jozsa's *J. Mod. Optics* article for a first pass. But the real powerhouses in this regard are Uhlmann and Petz. They have plenty written on the axiomatics of the subject. Particularly, monotonicity has always been an essential ingredient. A good place to get a start in the literature is probably the reference list in Ohya and Petz's book; or maybe flipping through Petz's web page: `http://www.math.bme.hu/~petz/`.

18-09-06 *New Course: Einstein's Universe* (to G. L. Comer)

Word of warning on other matters: Never ever get involved with 30 year old mathematical problems if you can help it. They'll destroy your career just as surely as not doing any research at all will. It's "performance review" time for us at Bell Labs this week, and I've got nothing at all to show for this last year. God pity my mortgage.

Comerism 13: *I think I have you beat: I'm working on dissipation in general relativity, which has now about a 100 year history. Maybe more physics than math, but still unresolved.*

Ah, but do you have something to show for your last year of work? I'll bet I've got less than you! (Steven van Enk once told me about a competition he saw where the contestants were each trying to see who could blow a noodle from his nose the farthest.)

18-09-06 *Nonbayesian Musings* (to R. D. Gill)

Gillism 1: *I've made a first rough write up of some zen/frequentist quantum philosophy thoughts:*

`http://www.math.leidenuniv.nl/∼gill/waveparticle.html`
`http://www.math.leidenuniv.nl/∼gill/fifthposition.html`
`http://www.math.leidenuniv.nl/∼gill/BetterBell.pdf` *(Gdansk talk)*

Thanks for the coordinates (all of them). Apparently though, I already had your new email address in my book—don't know how it got there. Congratulations on your move to Leiden; I hope you fill Lorentz's shoes well!

Taking a look at your Gdansk talk, I noticed isn't there a contradiction in these two sentences in your closing transparency:

1) "I think that only detector clicks in the past are real."

2) "The probabilities are for real, the past is real, the wave function is objective ..."

Specifically, if "*only* detector clicks in the past are real" how can there be room for the probabilities to be real TOO? I'll say (tongue in cheek): Make up your mind!

19-09-06 *Werner and Misrepresentation* (to R. D. Gill)

I read this line in your Gdansk talk: "Recall the quantum information open problems site of Reinhard Werner (and let's wish him a speedy recovery too)." What has happened to Reinhard?

And I read this line in one of your other pages:

Gillism 2 : *Contrary to the currently popular Bayesian interpretations of quantum physics, there is an objective reality (again: the past).*

That is simply a gross misrepresentation. You grant reality to detector clicks; we grant reality to detector clicks. And I certainly grant reality to the past. I go further: I grant reality to quantum *systems* (even when they're not in interaction with detectors) and their associated Hilbert-space dimensionality. And Carl Caves among us, for instance, grants reality to the "intrinsic" Hamiltonians associated with quantum systems. There are lots of things within the theoretical structure of quantum theory that we quantum Bayesians are willing to grant reality to.

The main things we *are not* willing to grant an intrinsic reality to (i.e., a reality outside a gambling agent that makes use of them) are *probabilities* and *quantum states.* But that is a far cry from a position that "there is no objective reality," as you effectively attribute to us above.

It's almost insulting that you cannot seem to get this simple, little point.

But you're not all bad, Richard. I've always liked you. And in the present instance, I very much like this sentence of yours: "As the present moves relentlessly forward the 'past' crystallizes out of it, randomly." I am very much attracted to that idea, and have spent some time thinking about it myself. If I understand your sentence correctly, the ideas are along the lines of those of George Herbert Mead's at the turn of the last century. I'll paste in a little review of his ideas below. [See quote in 23-09-03 note to Steve Savitt, titled "The Trivial Nontrivial".]

22-09-06 *Chutes and Ladders* (to D. M. Appleby & H. B. Dang)

Thanks for the sympathetic note.

I spent a tossy-turny night having all kinds of wacky thoughts ... and trying to suppress them so that I might get some sleep. The main thing I kept coming back to is: Might we find some way of combining the first phase of this summer's work with the second? Could we get any traction from that?

What I mean by the first phase is our general study of type-E matrices.[111] Particularly our reduction (under the assumption of Appleby form) to finding a set of d^2 phases so that a certain $d \times d$ matrix is rank-1 (the matrix given by Eqs. (11) and (12) in SIC-Notes C, 10 August). Phase

[111]Let us call a $d^2 \times d^2$ matrix "type-E" if it is Hermitian and has $1/d$ on the diagonal and $1/d\sqrt{d+1}$ times various $e^{i\phi}$s for all the off-diagonal elements. There is no restriction that a type-E matrix be positive semi-definite. SIC Gram matrices (up to a scale factor) are special cases of the type-E matrices—they are simply type-E matrices that are rank-d projectors. For all type-E matrices E it automatically holds that $\mathrm{tr}E = \mathrm{tr}E^2 = d$. Thus if E is a type-E matrix and $\mathrm{tr}E^3 = \mathrm{tr}E^4 = d$, then E is a "SIC-projector".

2 was when we started thinking about minimizing the frame potential and/or explicitly solving the equations for a SIC-generating fiducial vector.

How to combine these two phases?

Here's one, almost surely useless idea. (But it gives an indication of the sorts of things my mind was getting hung up on.) Start with a Weyl-Heisenberg Gram matrix generated from some arbitrary fiducial state. Next, find the nearest (in matrix norm) type-E matrix. It won't be positive semi-definite or rank-1, but it will probably be closer to being such than an arbitrary choice. So, next, find the nearest WH Gram matrix to this type-E matrix. It generally won't be the original WH Gram matrix; it'll be a different one ... presumably being nearer to type-E form than the original. And on we go iteratively. A far-fetched question is: Might one prove that this process generically converges to a sought-for SIC Gram matrix? I.e., we just climb a ladder to get to it.

Sounds tough to me; the idea's probably a chute, rather than a ladder. But mostly I'm interested in how we might combine our two separate trains of thought.

Here was another question that crossed my mind. Might anything shake loose if we stopped thinking about the Gram matrices themselves (in the WH case), but the difference between the Gram matrices and our target. Might this give us the tools to start considering small deviations from the target ... possibly getting a set of quadratic equations (rather than quartic)?

This is off the beaten track, but I remember Holevo's technique for proving his bound on accessible information. He didn't try to prove the bound directly, but rather he started with an arbitrary ensemble of states and considered a one-parameter deviation from them. Then he found the second derivative of the information with respect to that parameter. The second derivative was relatively easily bounded, and then he just integrated back up. I think you can read about the technique in my old paper "Mathematical Techniques for Quantum Communication Theory" (`quant-ph/9604001`).

Just thinking out loud ...

26-09-06 *Something Significant* (to D. M. Appleby & H. B. Dang)

I just wrote you a very quick and dirty note. The result is below. I have no idea why these simplifications seem work, and have not made any attempt to prove them analytically yet. But I am very, very pleased that they appear to be true. You will see below.

I hope all is well with you. I haven't had a chance to read your note from yesterday. I've been sick in bed most of the day with a stomach virus. I'll look at your note soon after this.

Recall that the frame potential in the Weyl-Heisenberg case is given by

$$F = d^3 \sum_{jn} \left| \sum_s a_s^* a_{s+j} a_{s-n} a_{s-n+j}^* \right|^2 \tag{47}$$

and the quantity will achieve its lower bound of $2d^3/(d+1)$ if and only if the following d^2 equations are satisfied:

$$\sum_s a_s^* a_{s+j} a_{s-n} a_{s-n+j}^* = \frac{1}{d+1}(\delta_{n0} + \delta_{j0}) \,. \tag{48}$$

Defining the (unnormalized) vectors $|\psi_j\rangle$ by

$$|\psi_j\rangle = \sum_s a_s^* a_{s+j} |s\rangle \tag{49}$$

another way to write Eq. (48) is as

$$\langle\psi_j|X^n|\psi_j\rangle = \frac{1}{d+1}(\delta_{n0}+\delta_{j0}) \; . \tag{50}$$

(I'm only going to the trouble of introducing this notation so that one can identify the pieces of the little Mathematica routine I'm about to record. It's not essential for what is about to be said.)

Reducing the Number of Equations Drastically

OK, with this set-up, here's the exciting thing. Numerical work—at least from $d=4$ to 9 (I've only checked this little bit because I'm hoping Marcus will see this note before he goes to sleep, and so I'm rushed for time)—seems to indicate that we can effectively get rid of the n-index in the equations all together, being left with a little over $3d$ equations.

That is, it seems we can trim the full set of equations to (at least) only the following. 1) $n=j=0$,

$$\sum_s |a_s|^4 = \frac{2}{d+1} \; . \tag{51}$$

2) $n=0$, $j\neq 0$, (and similarly the case $j=0$, $n\neq 0$),

$$\sum_s |a_s|^2|a_{s+j}|^2 = \frac{1}{d+1} \; . \tag{52}$$

3) $n=j$, $j\neq 0$,

$$\sum_s (a_s^*)^2 a_{s+j}a_{s-j} = 0 \; . \tag{53}$$

And 4) $n=j+1$, $j\neq 0$

$$\sum_s a_s^* a_{s+j}a_{s-1-j}a_{s-1}^* = 0 \; . \tag{54}$$

There may be further simplification possible, but I haven't had a chance to look into it yet. My first instinct was to hope that condition 3) could be taken away too—the roots of this were in one of Hoan's early hopes (one equation per diagonal in the outer product matrix, remember Hoan?) but at the moment this doesn't appear to be the case. (Or it may simply be that Mathematica's numerics are just having trouble settling down when I throw that constraint away. I'm just not sure at the moment.)

Anyway, you should probably check this independently as you have a chance. Below is the Mathematica instruction set I used:

```
a[i_] := b[i]+ I c[i]

NN = Sum[Abs[a[Mod[s,d]]]^2,{s,0,d-1}]

NN2 = Sum[Abs[a[Mod[s,d]]]^4,{s,0,d-1}]

CC[j_,n_] := Abs[Sum[Conjugate[a[Mod[s,d]]]*a[Mod[s+j,d]]*
             a[Mod[s-n,d]]*Conjugate[a[Mod[s-n+j,d]]],{s,0,d-1}]]

EC := Abs[CC[0,0]-2/(d+1)] + Sum[Abs[CC[j,0]-1/(d+1)],{j,1,d-1}] +
```

```
    Sum[Abs[CC[0,n]-1/(d+1)],{n,1,d-1}] +
    Sum[CC[j,j],{j,1,d-1}] + Sum[CC[j,j+1],{j,1,d-2}]

d = 7

nn = NMinimize[{EC, NN == 1, NN2 == 2/(d+1)},
     Join[Table[b[i], {i, 0, d-1}],Table[c[i], {i, 0, d-1}]],
     Method -> {"DifferentialEvolution", "RandomSeed" -> 3}]

bb = Table[b[i] /. nn[[2, i + 1]], {i, 0, d-1}]

cc = Table[c[i] /. nn[[2, i + d + 1]], {i, 0, d-1}]

aa = bb + I cc

psi[j_] := Conjugate[aa] RotateRight[aa, j]

Table[Conjugate[psi[j]].RotateRight[psi[j], n], {j,1,d},{n, 1, d}]

MatrixForm[%]
```

To look at other dimensions, simply change the value of d in there. Also you have to jiggle a bit with the random seeds in each case, to get a correct answer. Here are the random seeds that worked best for me (at least on my machine):

dimension	random seed
4	2
5	3
6	0
7	3
8	5
9	11

The last line of the code above generates a view of how Eq. (50) is satisfied. *EC* is minimized to zero as it should be with the constraints advertised above. But what is nice is then that *all of* Eq. (50) is satisfied automatically.

I am very excited by this.

28-09-06 *Simple, Getting Simpler* (to D. M. Appleby & H. B. Dang)

Notation

Recall that the frame potential in the Weyl-Heisenberg case is given by

$$F = d^3 \sum_{jn} \left| \sum_s a_s^* a_{s+j} a_{s-n} a_{s-n+j}^* \right|^2 \tag{55}$$

and the quantity will achieve its lower bound of $2d^3/(d+1)$ if and only if the following d^2 equations are satisfied:

$$G_{jn} \equiv \sum_s a_s^* a_{s+j} a_{s+n} a_{s+n+j}^* = \frac{1}{d+1}(\delta_{n0} + \delta_{j0}) \ . \tag{56}$$

Defining the unnormalized vectors $|\psi_j\rangle$ by

$$|\psi_j\rangle = \sum_s a_s^* a_{s+j} |s\rangle \tag{57}$$

we can also express the matrix elements G_{jn} by

$$G_{jn} = \langle\psi_j|X^n|\psi_j\rangle \ . \tag{58}$$

Understanding the Problem Better

What it seems we were finding yesterday is this: That the full set of d^2 equations

$$G_{jn} = \frac{1}{d+1}(\delta_{n0} + \delta_{j0}) \tag{59}$$

is actually implied by the smaller set of $3(d-1)$ equations

$$G_{00} = \frac{2}{d+1} \tag{60}$$

$$G_{j0} = \frac{1}{d+1} \qquad j = 1, ..., d-1 \tag{61}$$

$$G_{jj} = 0 \qquad j = 1, ..., d-1 \tag{62}$$

$$G_{j,j+1} = 0 \qquad j = 1, ..., d-2 \tag{63}$$

I still don't know how to prove this implication, but it is starting to seem much less surprising than when I first stumbled across it a couple days ago. It might well be semi-trivial to prove it, if we just think about the problem in the right way.

The reason has to do with the thing Marcus pointed out about how the frame function has roughly a factor of 8 redundancy in it. He worked with a more symmetric matrix H_{jk} in the case of odd d than the matrix G_{jn} here, but the conclusion is surely almost exactly the same in both even and odd d and can be seen directly in terms of the G_{jn}. I think it must simply come from careful index play/redefinition in the definition (56) above—i.e., I haven't checked it directly yet, but I have loads of faith. For, one can clearly see this kind of structure by taking a random $|\psi\rangle$ and looking at the magnitudes $|G_{jn}|$ numerically. They have a pretty and simple layout even without any special conditions on $|\psi\rangle$. For instance, in $d = 8$ one obtains a structure that looks like this

```
Z | Y X W V W X Y
-   - - - - - - -
Y | A B C D C B A
X | B E F G F E B
W | C F H I H F C
V | D G I J I G D
W | C F H I H F C
X | B E F G F E B
Y | A B C D C B A
```

And in $d = 9$, this

```
Z | Y X W V V W X Y
-   - - - - - - - -
Y | A B C D D C B A
X | B E F G G F E B
W | C F H I I H F C
V | D G I J J I G D
V | D G I J J I G D
W | C F H I I H F C
X | B E F G G F E B
Y | A B C D D C B A
```

Anyway, in general one must have:

$$|G_{j,n}| = |G_{-j,n}| = |G_{j,-n}| = |G_{-j,-n}| = |G_{n,j}| = |G_{n,-j}| = |G_{-n,j}| = |G_{-n,-j}| \ .$$

Whenever $j = -j$ or $n = -n$ or $n = j$, etc., some of the distinctions collapse.

What can be seen from this is that specifying the diagonal term to zero for $|G_{jn}|$, and similarly for the first off-diagonal, wipes out a whole lot of the terms! For instance, in the examples above, only C, D, and G remain *ostensibly* free. But of course, we know they they are not completely free. And it really shouldn't be that hard to see that they must actually vanish.

But how to show it, I don't know. I tried several sorts of things with expansions of some vectors in terms of others, and with Schwarz inequalities, but so far I've failed.

In any case, looking at these structures promotes an even simpler looking conjecture. And I propose this conjecture get the bigger proportion of study anyway.

A Prettier Conjecture

One can note that if one specifies the first three columns of these matrices, one is specifying just as many variables as if one specified according to the earlier scheme. Thus, it seems that an even better conjecture would be: That the following $3(d-1)$ equations imply the full set of d^2

$$G_{00} = \langle\psi_0|X^0|\psi_0\rangle \;=\; \frac{2}{d+1} \tag{64}$$

$$G_{j0} = \langle\psi_j|X^0|\psi_j\rangle \;=\; \frac{1}{d+1} \qquad j = 1, ..., d-1 \tag{65}$$

$$G_{j1} = \langle\psi_j|X^1|\psi_j\rangle \;=\; 0 \qquad j = 1, ..., d-1 \tag{66}$$

$$G_{j2} = \langle\psi_j|X^2|\psi_j\rangle \;=\; 0 \qquad j = 1, ..., d-1 \tag{67}$$

(In fact, by looking at the general structure of $|G_{jn}|$, one would really only need to specify about $3(d-1)/2$ equations.)

This is starting to strike me as looking extremely clean. And I think it is as likely to be true as the previous conjecture. I have checked it numerically for various dimensions here and there up to $d = 13$—not as thoroughly and for as many seeds as previously, but enough to give me a sense that it must be true.

Supposing that it is relatively easy to show the equivalence: Can it really be so hard to satisfy the remaining equations? Surely it is not even remotely on the same playing field with Fermat's last theorem or the Poincaré conjecture.

28-09-06 *Simple, Getting Simpler, 2* (to H. B. Dang & D. M. Appleby)

Dangism 1: *By the way, I'm curious how you found out about that set of* $3(d-1)$ *equations. It's so amazing that it's true numerically! And do you know that if you don't have all those* $3(d-1)$ *equations then it won't work, i.e. can we further eliminate some of them?*

Well, I can definitely see that they can be reduced to (roughly, i.e., plus or minus 1 or 2) a total of $3(d-1)/2$ equations. That comes from the automatic symmetry of the G_{jn} matrix. But can they be reduced still further? I don't know. Possibly. If you have a concrete proposal, I can test it out with my newfound Mathematica skills. I had tried simply the equations for the main diagonal and the edges and that didn't work. And I think I've tried other variations on this, but no great success.

How did I find the first set? Well, I was enamored with the $n = j$ equations and had played with them for a day, trying to take their Fourier transform and such. (I was hoping the magnitude equations—the ones on the edge—supplemented by a one-parameter set of equations that said something about the phases would do the trick.) Then, once I got up and running numerically, I thought I would see if they (along with the edge equations) implied anything numerically. The thing that surprised me was that they came pretty close to specifying the full set. So, I thought, maybe if I take one of the off diagonals too, that would add enough. And nicely, it did. That's the basic story.

Now that you've got me thinking about this, I think I was able to successfully drop the $(0,0)$ equation in one of my earlier trials. Let me see if I can still do that. I don't know why I didn't think of this again this morning.

... [time goes by]

Wow! I quickly checked $d = 7$ and $d = 8$, and it seems indeed that that normalization equation—the $(0,0)$ one—can be dropped. So, we're down to $3(d-1) - 1$ equations! (Or half that, as your taste may take you.) That is a little more symmetric and prettier set.

Dangism 2: *My feeling is that it is some inequality (probably no longer the Schwarz) that would do the proof, but I still can't prove anything yet.*

Yes, it would be good to use those known zeroes as upper bounds on the remaining terms. That's why I was trying to use Schwarz yesterday, but no luck. Maybe something to do with concavity? Jensen's inequality? Arithmetic – geometric mean inequality? It sure would be nice to get some sleep tonight!

Let me shuttle this note off to you and Marcus before checking further on dimensions.

28-09-06 *Simpler, Simpler, Simplest?* (to H. B. Dang & D. M. Appleby)

Furthering on what I wrote below. I have now further checked that the conjecture is numerically so in $d = 9$, 10, 11, and 12. So, I think we're good to go on the new conjecture of $3d - 4$ equations. I also checked that some further deletions would not help. For instance, keeping the $(0,0)$ normalization, but getting rid of the 0-column equations otherwise, is no good. Nor does it help to reinstate one of the 0-column terms.

This may indeed be the minimal set. Or if you really want to be picky in the accounting (eliminating all known redundancies):

If d is odd. The unadorned total comes to:

$(d-1)/2$	from the 0-column
$(d-1)/2$	from the 1-column
$(d-1)/2-1$	from the 2-column

for a grand total of $3(d-1)/2-1$.

If d is even. The unadorned total comes to:

$d/2$	from the 0-column
$d/2$	from the 1-column
$(d-2)/2$	from the 2-column

for a grand total of $3d/2-1$.

If you have Mathematica 5.0 (Marcus I know you don't), and you want to do your own experimentation, here is the code I used:

```
a[i_] := b[i]+ I c[i]

NN := Sum[Abs[a[Mod[s,d]]]^2,{s,0,d-1}]

CC[j_,n_] := Abs[Sum[Conjugate[a[Mod[s,d]]]*a[Mod[s+j,d]]*
             a[Mod[s-n,d]]*Conjugate[a[Mod[s-n+j,d]]],{s,0,d-1}]]

EC := Abs[NN-1] + Sum[Abs[CC[j,0]-1/(d+1)],{j,1,d-1}] +
      Sum[CC[j,1],{j,1,d-1}] + Sum[CC[j,2],{j,1,d-1}]

d = 7

Do[Print[k] && Print[NMinimize[EC,
   Join[Table[b[i], {i, 0, d-1}],Table[c[i], {i, 0, d-1}]],
   Method -> {"DifferentialEvolution", "RandomSeed" -> k}]],{k,0,24}]

nn = NMinimize[EC,
     Join[Table[b[i], {i, 0, d-1}],Table[c[i], {i, 0, d-1}]],
     Method -> {"DifferentialEvolution", "RandomSeed" -> 3}]

bb = Table[b[i] /. nn[[2, i + 1]], {i, 0, d-1}]

cc = Table[c[i] /. nn[[2, i + d + 1]], {i, 0, d-1}]

aa = bb + I cc

psi[j_] := Conjugate[aa] RotateRight[aa, j]

Table[Conjugate[psi[j]].RotateRight[psi[j], n], {j,1,d},{n, 1, d}]

MatrixForm[%]
```

The "DifferentialEvolution" method works pretty well up to about $d = 11$, then it's better to use "RandomSearch" as the method. Do the preliminary part first to find an adequate random seed, then do the rest if you want to check that you're getting a full set of equations. Or if you want to test properties of the $|\psi_j\rangle$, etc.

05-10-06 *So Whiskey Tango Foxtrot?* (to M. D. Sanders)

Sandersism 1:

`http://web.archive.org/web/20061005192320/`
`http://www.cnn.com/2006/TECH/science/10/04/teleportation.reut/index.html`

Is this really going on? This is kind of freaking me out.......but it is way cool.....

Yes, it's real. But it's not nearly as exciting as the newspaper makes it sound. "Teleportation" in the quantum information sense isn't so very much like the Star Trek version as the press always wants to portray it. It's not about getting things from here to there without going in between, but about making my information stop being about this and start being about that without being about anything else in between.

Let me tell you a funny story about Polzik. He's a guy who sought asylum in the US after escaping from Russia during the Cold War. In 1998 we were roommates at a conference at Northwestern University (Evanston, IL). We stayed in a dorm room. The last night of the meeting around bed time—I had an early flight the next morning—Polzik said, "I'm gonna go have a swim in the lake," while putting on his swim suit. "Do you want to come with me?" I told him about my early flight and declined. He grabbed a bottle of vodka and went out the door. I got in bed, turned out the lights, etc. About a half hour later, Polzik was back in the room pulling pants over his still dry swimming suit and muttering, "No policeman is going to tell me I can't have a swim." I said, "What's up?" He said, "I'm gonna get to the lake one way or other." I have no idea what he meant by that or what his plan was. But I do know the next morning I found a wet swimsuit in the bathroom and the room reeked of vodka.

That was the same year we had the teleportation paper at Caltech, teleporting from light field to light field; Polzik was one of the authors with us. (He had leant us a student who did much of the actual work.)

05-10-06 *How I Sold Us* (to D. M. Appleby & H. B. Dang)

FYI, here are the words I used to try to sell our project with my superiors. Here's the section on the subject I wrote for this year's performance report. ... I deposit it here, just in case you too would like to know why you're working on this blasted problem!

> The main portion of my research this year has been on using new techniques to tackle a 33-year-old open mathematical problem, and collaborators and I have made significant headway toward its solution—so much so that we think we are far ahead of the game with respect to anyone else thinking about it. Most importantly, by way of this work, I believe I have gained my deepest understanding yet of the structure of quantum information. The final goal is still a little out of reach (and we have felt compelled to hold back on publication of intermediate results), but it is a very exciting time.

The motivation for this particular problem is to find a useful way of formulating finite-dimensional quantum mechanics so that density operators are at the center of its considerations, rather than state vectors. A technical reason for this is for efficiency in quantum information calculations, where density operators always play a prominent role in noisy, real-world situations; a fundamental reason for it has to do with its easier connection to the idea that quantum states represent information, rather than intrinsic properties of quantum systems—a prime component in my research for many years now. For a d-level system (with a d-dimensional Hilbert space, a so-called *qudit*), its density operators live in a d^2-dimensional vector space of Hermitian operators. In fact, they live in the positive cone of that vector space, i.e., the set of operators with non-negative eigenvalues. An example of what I mean by bringing density operators to the center of considerations, is, for instance, that one might like to know how to formulate a superposition principle using elements solely within the cone. For such a project, one should have an analog of an orthonormal basis of state vectors within the cone.

This summer, with my intern Hoan Dang, we were able to formulate this question in a more interesting way than had been done previously, and the answer was surprising. Since there cannot be an orthonormal basis of d^2 operators in the cone, one might ask for a set of operators that, on average, are as close to being orthonormal as possible. We found a rigorous bound on the average orthonormality and also the necessary and sufficient conditions for achieving that bound. To my great pleasure, the conditions were ones I had seen before, but in fairly disparate work—particularly, my work on optimal alphabets of quantum states for sensitivity to eavesdropping in quantum cryptography. This connection is something I had suspected, or more accurately hoped for, for some time, but I did not know how to formulate it very well or make it rigorous. (In fact, I mentioned a preliminary result along these lines in last year's Form 1, but it was significantly weaker than the present one. In the older version, the symmetry was built in by hand, rather than a result of the calculation.) In the usual formulation of the superposition principle, the one at the state-vector level, basis vectors represent the *most classical* properties—ones that can, for instance, be cloned or eavesdropped upon without disturbance. But in the density-operator formulation of a superposition principle, we are led to using bases of states that are as *quantum* as they can be—the ones that are most easily perturbed by their environment. The reason I am very pleased about this is that it gives me a tool for exploring my pet idea of what powers quantum information and computing: It is nothing to do with parallel universes or action-at-a-distance, or anything as science-fictiony as that, but simply quantum systems' greater sensitivity to external stimulus than classical systems.

The condition that must be satisfied for such a beautiful symmetry to be true is that one must be able to find a set of d^2 pure density operators $\Pi_i = |\psi_i\rangle\langle\psi_i|$ such that $|\langle\psi_i|\psi_i\rangle|^2 = 1/(d+1)$ when $i \neq j$. But does such a set of states exist? It is not obvious, and in fact the question is equivalent to the 33-year-old mathematical problem alluded to above—the problem of the "maximal number of equiangular lines"—which had its origin in classical coding theory. Furthermore, independently of the things reported here, the question of the existence of these states had already captured the interest of the quantum information community because of the set's intrinsic symmetry. The working conjecture of several groups, and the one we are on the tail of, is that the operators Π_i can always be generated by taking certain orbits of the standard set of unitary operators used in quantum error correction, the generalized Pauli operators. One thing that is remarkable about representing quantum states in terms of the Π_i is that then a general quantum error would be nothing more than an unknown permutation of indices—there are no longer any distinctions to be drawn between phase-flip vs. bit-flip errors, etc. Thus, viewing quantum errors in this way may open a further book of ways in which powerful classical error correction techniques can be adapted to the quantum domain. For all these reasons, proving the existence of these operators and giving a technique for actually constructing them would be a great achievement.

What has made my collaboration with Hoan Dang (now at Princeton) and Marcus Appleby (at Queen Mary) special in comparison to the rest of the pack considering the existence problem, is that we have opted for a basic—but steady—linear algebraic approach, rather than invoking abstract group theory and abstract number theory, as has been the fashion in most of the literature so far. We are banking that the problem does not really call for all that, and that these high-level approaches have clouded more than they revealed. For instance, until our work, the best numerical technique for checking for the existence of such a symmetric set scaled as a sum of d^{12} terms; we have been able to reduce that to a sum that scales as d^2. Concomitant with this, and more interesting actually, we have been able to reduce the exact problem to finding a single state vector, whose components must satisfy (roughly) $3d/2$ simultaneous quartic equations (of a very particular structure). We feel that we are not all that far from a complete solution to this problem. Personally, I feel this is some of my best work yet in quantum information theory.

What will come next is to ask in much greater detail what insight this kind of representation can give to quantum computing. On two fronts I hope to tackle this directly; one through a collaboration with Lov Grover in our own department, and one through a collaboration with Al Aho, a Bell Labs alumnus who continues to come into the lab often. Both of these collaborations are just starting up.

10-10-06 *Phone Tag* (to J. E. Sipe)

PS. Carl Caves is visiting me for a couple of days at the moment, and we're being forced to confront all our sins and indiscretions in this quantum Bayesian business. Not a pleasant way to spend one's time.

13-10-06 *Rabid Pragmatists (but in the sense of W. James, J. Dewey, and C. Fuchs)* (to R. D. Gill)

Thanks for calling my attention to your updates. I am impressed by how much we both seem to be attracted to the same ideas. (Of course, at this level of description—like the one found in your presentation—it is always easy to agree or to disagree. But I genuinely think there are similarities in our ontologies.)

Gillism 3: *Detector clicks in the past are real.*

Yes.

Gillism 4: *The future is a wave of possibilities.*

Yes.

Gillism 5: *As now moves relentlessly forward the past crystallizes out of it randomly.*

Yes.

Gillism 6: *There is no nonlocality problem, no Schrödinger cat problem, no measurement problem (time is measurement).*

Yes.

The only place where we significantly disagree is on the issue of probability in quantum mechanics. I too—i.e., like you—believe that quantum mechanics gives every indication of an *ontic* indeterminism or randomness in our world. I just part company with you in thinking that the concept of an *ontic probability function* sheds any light on this wonderful feature/fact of nature. In fact, I think it does just the opposite: Holding onto the idea of ontic probabilities—i.e., trying to make it make sense—only clouds our vision and gets in the way of proper description of this feature of nature.

In the note below (which I had originally written to a Princeton physics professor in one of my own more rabid moments), there are a few more details about what I actually mean when I speak of *ontic indeterminism* and *subjective quantum probabilities* in the same breath. The two ideas can coexist. (By the way, that guy really pissed me off. You never piss me off, so I wouldn't write you a rude note like that. But I forward the note to you because I do like the formulation I gave to the issue you and I happen to be talking about now.)

Tell me ultimately (i.e., as you get a chance), what you thought of the details of G. H. Mead's ideas.

14-10-06 *Pragmatism and the Weather, 1* (to R. D. Gill)

Gillism 7: *or do you mean pragmaticist?* `http://en.wikipedia.org/wiki/Pragmaticism`

No, I really meant the strain of pragmatism from William James and John Dewey (and an admixture of F. C. S. Schiller). Peirce's pragmaticism is quite a different thing, and not to my taste.

Talk about striking deep chords, I really liked this remark of yours:

Gillism 8: *I have this idea that if intelligent life would arise on Jupiter and develop mathematics then the most fundamental and deep mathematics would be probability theory (since Jupiter is basically weather and nothing else). The pure mathematicians would do statistics. The applied mathematicians would do number theory. It is just a cultural accident that probability is an embarrassingly tricky add-on to mathematics. It could have been the other way round.*

That is a beautiful idea! Danny Greenberger once wrote me an eloquent little passage about how it might have been the case that the real numbers would have been taken as mathematically primary (over the integers) if evolutionary pressures had been different—I'll include that passage below [see note to Greenberger, dated 06-12-02]—but I like your idea even better! And, in any case, you might not need Jupiter to pull it off. It may already be the case with us here on earth; we've just strayed a little from the natural progression of ideas in the last few centuries.

I'll be back in a couple of minutes after I dig up another passage.

14-10-06 *Pragmatism and the Weather, 2* (to R. D. Gill)

The other thing I had wanted to send you was a passage in my computer about the philosopher Chauncey Wright. He was a friend of James and Peirce and had been deeply influential on them (before ending his life early). The reason I send you this is because of your remark that "Jupiter is basically weather and nothing else." Wright was famous for saying on many opportunities, "The universe is only weather." The passage below gives some flavor of that.

> [Chauncey] Wright did not consider himself an evolutionist. To him the term denoted a belief that the world was getting, on some definition, "better." His loyalty was only to the theory of natural selection, which he thought corresponded perfectly to his notion of life as weather. "[T]he principle of the theory of Natural Selection is taught in the discourse of Jesus with Nicodemus the Pharisee," he explained in a letter to Charles Norton's sister Grace. The allusion may be a little gnomic today. The discourse with Nicodemus is in the Gospel of John, and the words of Jesus Wright was referring to are these: "The wind bloweth where it listeth, and thou hearest the sound thereof, but canst not tell whence it cometh, and whither it goeth: so is every one that is born of the Spirit." Wright was, in short, one of the few nineteenth-century Darwinians who thought like Darwin—one of the few evolutionists who did not associate evolutionary change with progress. "Never use the word[s] higher & lower," Darwin scribbled in the margins of his copy of the *Vestiges of the Natural History of Creation* in 1847. The advice proved almost impossible to follow to the letter, even for Darwin, but if anyone respected its spirit, it was Chauncey Wright.
>
> Wright's particular bête noire was the evolutionist Herbert Spencer, whose work seemed to him a flagrant violation of the separation of science and metaphysics. "Mr. Spencer," as he declared, "is not a positivist." Spencer's mistake was to treat the concepts of science, which are merely tools of inquiry, as though they were realities of nature. The theory of natural selection, for example, posits continuity in the sequence of natural phenomena (evolution does not proceed by leaps). But "continuity" is simply a verbal handle we attach to a bundle of empirical observations. It is not something that actually exists in nature. Spencer failed to understand this, and he therefore imputed cosmic reality to what are just conceptual inferences—just words. He did with the word "evolution" what Agassiz did with the word "creation": he erected an idol.
>
> "Mr. Spencer's philosophy contemplates the universe in its totality as having an intelligible order, a relation of beginning and end—a development," Wright said. But the universe is only weather.
>
> > Everything out of the mind is a product, the result of some process. Nothing is exempt from change. Worlds are formed and dissipated. Races of organic beings grow up like their constituent individual members, and disappear like these. Nothing shows a trace of an original, immutable nature, except the unchangeable laws of change. These point to no beginning and to no end in time, nor to any bounds in space. All indications to the contrary in the results of physical research are clearly traceable to imperfections in our present knowledge of all the laws of change, and to that disposition to cosmological speculations which still prevails even in science.
>
> "No *real* fate or necessity is indeed manifested anywhere in the universe," he wrote to a friend, "—only a phenomenal regularity."

16-10-06 *Paper* (to C. M. Caves)

Cavesism 80: *Chris, I have changed "prompting" to "eliciting". I think it captures much better what you have in mind, but won't mind going back to "prompting".*

Just noticed this PS, which I hadn't noticed before. Neither word, I think, in the end is completely adequate, but I don't know what's better at the moment. Elicit is fine. And you're probably right, it is closer to the mark at the moment.

16-10-06 *Our Professor* (to R. Schack)

Cavesism 81: *I think we ought to be thinking about a paper that lays out our entire approach, particularly, the idea Chris and I discussed of a three-pronged approach to subjectivity and objectivity: (i) quantum states and probabilities are wholly subjective; (ii) system attributes are wholly objective; and (iii) measurement outcomes are where the rubber meets the road, i.e., where subjective and objective meet to produce something that is not under the control of the agent, but is also not out there in the world.*

This paragraph of Carl's is one that took me absolutely by shock. I wish you could have been here for our first day of interaction, when Carl was still in his mode of saying how I've been "muddying things beyond belief." In fact, it all started with him going into a soliloquy his first day at the office. "I want to get one thing straight: With this business about 'fact for the agent', I'm not going there. Even if my position is not consistent and that one is, *I'm not going there*." That, I'm fairly sure, is an almost verbatim record of what was said. Then he outlined his story of "facts" being those things that are out there for all to see, and that *that's* what we've been talking about in this paper all along . . . yada, yada, yada.

It was hard to get past it, but I held my ground. I told him that you and I had both moved beyond that kind of understanding of "a fact." (I used some of your emails to bolster the point.) I explained how he would always be forced into a corner by Finkelstein with his present view, and similarly be absolutely stuck by the time he ever got to Wigner's friend.

It was a priceless scene actually, him rubbing his temples, going silent, looking extremely annoyed, rubbing his forehead, and then cutting off all conversation. The next day he woke up a fairly different man, saying, "We're going to make some progress on this paper today." I said, "Oh no," with complete dread. He said, "No, you'll be pleased." So, all of that was pretty cool. But then to see the proposal above was a complete shock.

I hope these new duties at your university aren't killing you too much: We need you man!

17-10-06 *The Book Proposal* (to D. M. Appleby)

I've finally read your book proposal. The words in it are nice, but I'm not sure that I got any insight toward answering these questions of yours: [. . .]

With regard to the content, there were a couple of parts that I marked to look at a second time.

1) I enjoyed the two mid paragraphs on page 8, the ones about how "It may seem . . . as though the epistemic interpretation must lead . . . to a depressingly positivistic view in which physics begins and ends with the task of predicting detector clicks. For a long time I had the same fear." That is a point, as you know, that is near and dear to my heart. It is a perception that I try to fend off at every point, and at every talk I give, to only small success. I'm out of inspiration for how to make

the point better, but it looks like you're not. Therefore, I think it'd be great if you were to expand those paragraphs even further. Find a way to really drive the point home.

2) The lines on page 9 that read, "Calling the statement epistemic only means that there is not, in addition to such features as the fact that one of the wings is on the verge of falling off, an additional mind-independent physical property called 'propensity for crashing'." This is because it reminded me of a conversation I had with Jos Uffink at our Konstanz meeting. I remember saying something like, "Why is it not good enough that the realm of the real world is already clearly marked out in a subjectivistic conception of probability? It is marked out in the facts, the clicks, the outcomes, which are distinct from the probabilities. The facts do not depend upon the agent. Someone once said, the world is everything that is the case—and there it is; it's in the form of the facts that the subjective degrees of belief happen to be about. But it seems that you, and all objectivists for probability, want more than that. It's as if you want a soul that lives behind the facts. The facts as they occur in nature are too secular, they're not good enough; they would be nothing if they didn't have a spiritual aspect that gives rise to them. It's as if you want a soul to be responsible for them." Jos simply replied, "That's right."

18-10-06 *Real Possibility* (to A. Shimony)

I was thinking about you the other day as I was writing Richard Gill for another purpose. I'll include that note below, which daisy chains to still another one (written to Kirk McDonald). [See 13-10-06 note "Rabid Pragmatists (but in the sense of W. James, J. Dewey, and C. Fuchs)" to R. D. Gill and 30-01-06 note "Island of Misfit Toys" to K. T. McDonald.] The subject matter is, in essence, the idea of "real possibility" and quantum mechanics' indication of it as a feature of our universe. I found myself thinking back on things you've said on the subject over the years and, in particular, during the Perimeter Institute meeting this summer.

In some ways, I feel there's really not that large a gap in our opinions about this pretty idea that "the universe is on the make" and in the directions we think physics should turn to to get a better grasp on it. We are both intrigued by the category of potentia. I know that I think (some flavor of) the conception is the greatest discovery in physics, certainly in the last 90 years, and maybe ever. But there is this one thing that keeps getting in our way of effectively communicating to each other and sharing our reverence for it—it is our feeling about quantum mechanical probabilities. Bayesian of a stripe though we both are, we certainly have different feelings for the meaning of probabilities that come from quantum mechanical pure states.

Thus I started to think that writing a careful statement of my view, and the arguments I use to support it, might be a worthy contribution to the festschrift Wayne Myrvold is organizing for you. In fact, the more I think about the idea, the more I am excited about it.

How can one have "chance" without "objective probabilities"? That's what the note to Gill (actually much more so the note to McDonald) starts to address. For me, chance is the primary ontic category and, as far as I can tell, it cannot be quantified. Quantum mechanics, and the probability relations it suggests, from my view, is a tool—a wonderful tool—for helping *physical* agents swim in this world of chance. The statement that we live in a world of chance or real possibility is indeed represented in the very structure of the quantum formalism, but as a kind empirical addition to de Finettian / Ramseyan coherence. Not in the specification of some kind of objective probabilities.

That's the idea, anyway, that I think I would like to expand upon. The groundwork has already been laid in some other things I've written—1) the note below, 2) a paper with Caves and Schack that I'll be able to send you a draft of in a couple of days, and 3) a sort of pseudo-paper (samizdat actually) that I'll attach to the present email. Particularly the last item goes into much more detail about what I mean by "objective indeterminism."

I thought it might be fun to start to get some feedback from you before I draw up the plans for the new paper in too great of detail. Your objections and queries could be part of the very structure and help me tailor my contribution to the things you find confusing or untenable. Anyway, that's my thought and I'd dearly love to get some feedback from you.

It was great seeing you again this year, and for me, the Perimeter Meeting was quite the most interesting conference I went to in some time. I'm very happy it happened (as it might not have in this world of real possibility).

18-10-06 *Back From My Long Silence* (to W. C. Myrvold and W. L. Harper)

This note is way, way, way overdue, but I have not forgotten about your kindness to me, and I wanted to thank you both for giving me feedback when I was stressed over my presentations and presentation style just after the AbnerFest. Both of your comments were very useful and helped me "make it through the night," so to speak, during that tough time. The reason this note is coming to you so late is that I got another comment from the fellow who had taken me aside at Perimeter, just after Wayne's writing and a little before Bill's leaving a message on my answering machine. Basically it was just an email version of what he had already said, but it caused me to feel even worse than I had before, and I decided to simply shut down for a while on the issue. (He is a physicist whose opinion I respect more than about anyone else's, and I got very confused about myself for a while.) Thus my philosophizing, my usual samizdating, and my emailing fell by the wayside for the summer, as I became a hermit and plunged myself deep into calculation like I had not done in quite some time. It was a form of crisis management. Anyway the fruits of the tactic were definitely good—I'll present them at the QCMC meeting Tokyo this Fall (in a different style! . . . I say facetiously)—and it allowed me to distance myself from the hurt. But it's time now for me to face the issues I left behind, and more importantly, to become a little more balanced in my research and thought again.

You two helped me see that my work and the choices I've made for trying to convey it were not made in vain, even though at the same time there is probably a lot of wisdom in what my old friend said . . . at least for particular audiences. All I can do is keep trying, making sure to try to take into account each datum that comes my way.

Concerning the points where we left off:

Myrvoldism 4: *I think that there is less disagreement between my view and yours than might appear. (I can explain this more if you'd like).*

Yes, I would like you to explain this more as you get a chance. I am curious (now that I've come back to being thoughtful again!). Surely, I know that we agree on some things. For instance, I think we would both say that quantum mechanics is a story of a world with inherent chance. But certainly there are two sticking points that always get in the way of our communication: 1) objective, *quantified* chance (i.e., the Lewisian stuff), and 2) nonlocality. As I understand you, you accept both. As I understand myself, I reject both. So there is some nontrivial distance between our views. But if an open universe is the more basic of the things we are both hoping to get a real handle on—i.e., the bigger goal—it is certainly worth the attempt to open up a dialogue, and I'd welcome better understanding what you mean.

It's probably not a coincidence that I happened to write all the stuff below to Abner this morning: These particular issues are on my mind again. [See 11-08-06 note titled "Real Possibility," to Abner Shimony.] And, actually, all this concerns you in two ways. As you'll see from my proposal to Abner, I think this subject will be the topic of my contribution to the festschrift you're editing.

Bill said,

Harperism 1: *At our discussions I suggested that you might find my introduction to and many of the papers in the volume Stalnaker, Pearce and I edited. Here is the reference: Harper, Stalnaker, Pearce, eds.* IFS: conditionals, belief, decision, chance and time*, D. Reidell Publishing Company, 1980. I think we have many informative things to talk about.*

As luck would have it, I just found a copy at Barnes and Noble online for only $42.00! The receipt says I should have it in my mailbox in 3 to 6 days.

Best wishes to both of you, and I apologize again for my long silence.

20-10-06 *Slammed by the Closet Door* (to N. D. Mermin)

Merminition 154: *My point was simply that you badly undersell yourself and what you're doing in your talks ... But jokes and cartoons and metaphors and lack of focus on specific controversial points (is "quantum nonlocality" nonsense? is there a "measurement problem"?) won't convey this to anybody. I mean you knew Leggett and Pearle, both of whom think the measurement problem is the most important unsolved problem in physics, would be there.*

I knew that Abner would be there.

And more than anything I wanted to make a talk that somehow touched base with Jamesian pragmatism for him. In the end, I failed my own standards (and I was aware of that). But I tried in the off hours of that interesting meeting to get it all into a self-contained package. You can't see it, but I actually worked very hard at that talk—much more than I have for any talk in quite a while. You had seen everything before? I should burn the transparencies and start completely over? Maybe. But, in fact there were 26 transparencies in there that were new; I just counted them again. You had never seen them before.

Leggett and Pearle? They don't mean as much to me as they mean to you. I know the protest you will surely give me over what I am about to say, but they are ideologues. They will carry the prejudice against epistemic quantum states with them to the grave. Bill Clinton said it very nicely in a speech a couple of days ago, "If you've got an ideology, you've already got your mind made up. You know all the answers and that makes evidence irrelevant and arguments a waste of time." They may be great scientists when it comes to other subjects, but with regard to this one subject, they are ideologues. The evidence is overwhelming that quantum states live in the mind rather than in the physical world (leaving aside, for the moment, the *detail* of whether they are knowledge, credence, information, belief, or whatever variation of such a kind of thing). The *only* thing those guys have motivating their research in the other direction—the direction that gives rise to a "measurement problem" and "nonlocality"—is the religion that a fundamental physical theory should not be IN PART about things to do with minds in the sense above. That is their one motivator. But the scale is completely imbalanced toward the other direction: It screams out in almost every piece of the phenomena of quantum information—the no-cloning theorem, teleportation, the "go ask Alice" point, and so on. And yet they don't see it. (And while I'm here, you, with all your admirable open-mindedness and nonprejudice, don't see it either.) The only thing that is really an open issue is getting a better answer to your question, "Information about what?" This was not the first time Leggett or Pearle were at one of my talks, or instead, one of Peres's, or one of Schack's, or Pitowsky's, or probably in the long past, one of John Wheeler's. Tony has been to at least five or six of my talks, and in particular was at the Seven Pines meeting in Minnesota for a week where the epistemic view of quantum states got the vast majority of the discussion. These guys are not ones that can be reached out to on this issue, my involvement or not. Where I can hope to make an impact is, as Zeilinger said, with the young ones. I may not be doing it successfully, but that's the only place I can hope to do it.

That aside, though, I did *try* to address directly those very questions you raise, and I did it with concrete examples too—think of the classical no-cloning theorem example I gave and the example of teleporting a probability distribution for the outcomes of a coin-toss. Even YOU don't see the force of those examples (I could hear it in your question that day), and because of that, they don't seem like concrete examples to you at all. But they carry the whole story. There is absolutely nothing inherently quantum mechanical about quantum teleportation. The only thing that is quantum mechanical is the answer to the question, "Information about what?" And that question is well-posed without anything to do quantum teleportation. That was the point.

It was that IF one can just get one's head around the idea that quantum states are epistemic, then there is no measurement problem and there is no need to talk of nonlocality. Peirce wrote this to James in 1904, "[P]ragmatism solves no real problem. It only shows that supposed problems are not real problems." And so too, this is the reason for adopting an epistemic conception of quantum states AS A STARTING POINT. It is to say, there never was a measurement problem.

You tell me I should have addressed these things. But I tried. I used the wrong language for some of you, but I tried.

22-10-06 *Wishful Thinking* (to C. M. Caves)

Well it was wishful thinking on my part. It's Sunday now, and I haven't done any tinkering on the paper; just looked at the draft and the comments. Birthday and NY City took more of my attention away than I thought it would. And now Appleby is arriving today. So, let me unlock the paper, so that you can return to tinkering on it if you wish. I much more liked our method of working on it together; too bad we didn't have just one or two more days of that.

I had a very thoughtful day in NY (they don't come very often to me any more), and I drew up all kinds of grand plans for how best to present the program ... to philosophers at least. I think the way I'll tackle it now is to start the presentation with all ontological sounding stuff—objects, events, indeterminism—get that established, and then throw in agents and subjective probabilities. Traditionally I always started with subjective quantum states first, how that alleviates the measurement problem, etc., and then worked backward toward an ontology. I sketched out a few pages of notes on the train and in coffee shops. At least right now, I'm decently excited about this, *dreaming* that maybe it will stave off the usual sorts of fears and confusions, like Finkelstein's and everyone else's. One thing I might try to do before Christmas with this is give a seminar at Princeton and see how it flies; another thing is I might try is to make it the format of my AbnerFest contribution. If it looks after those two preliminaries to be on the right track, I may lobby for that with you and Rüdiger as the right way to go for our next joint venture (where surely all the language will be toned down from my preliminaries).

Thinking how 42 is supposed to be the answer to life, the universe, and everything, I've decided I want to try to have a different kind of 42nd year than Lewis Carroll and Rüdiger Schack. That's probably the most important result of my last three days of thought.

25-10-06 *Maximum Uncertainty States* (to H. B. Dang)

It seems the price of SICs just went up again today! (Remember how you would say that every time we find a new question for which SICs are the answer, their price goes up.) Well, remember how I had speculated how the SICs shared some features with coherent states, and therefore might in some sense be "minimal uncertainty states" for measurements with respect to a complete set of mutually unbiased bases? Marcus and I finally drudged through the calculation today, and we found that I was just about right: They're not the minimal-uncertainty but the maximal-uncertainty states![112] (At least when $d =$ prime, this is true.) It's been a very exciting day. At the moment, we're trying to see if the SICs are the *only* maximal uncertainty states; for that we don't have an answer yet.

We still have not been able to figure out why the d^2 equations can apparently be reduced to only $\sim 3d/2$. That would probably be our main topic of conversation, to see if we can make any progress there.

28-10-06 *Please Email Abstract* (to K. H. Knuth)

This is a minor modification of the abstract I used for the Applied Maths colloquium at Princeton—making it look a little less mathematical and a little more physicsy, but I hope it will do.

> Title: Math Problems from the Far Side of Quantum Information
>
> Abstract: The field of Quantum Information has recently attracted great interest for the technological fruits it may bear. But there is a sect of its practitioners who think it stands a chance to have an even greater legacy than that—namely, that its theoretical tools will give us a means for exploring what quantum mechanics is really all about and for settling some of the deepest problems in physics. The roots of this optimism come from a very old thought: that quantum states have more to do with representing their users' information than any inherent physical properties of the systems they describe. What is new and nice is that quantum information teaches us how to formulate this idea precisely and even check its consistency. Nicer still is the number of juicy mathematical problems the consistency-checking process poses. In this talk, I will review some of the history of this and then quickly settle on a sample problem that has been annoying me a lot lately (the existence of a very symmetric, informative quantum measurement) and discuss the insights its existence would give for the structure of quantum mechanics as a whole.

01-11-06 *Plunging Ahead* (to W. C. Myrvold)

I never heard back from you concerning my proposal for an Abnerfest contribution. Anyway, I'm plunging ahead. Please let me know the last date you will be willing to accept the manuscript.

You know I always start my thinking with a slogan. Here's the slogan for this paper (which I'll also send to Bill H. in another note; I want to let him know I just got a copy of "Ifs"). The flavor

[112] Ha! We soon learned from Bill Wootters that we had made a minus sign mistake! They were minimal uncertainty states after all. See D. M. Appleby, H. B. Dang, and C. A. Fuchs, "Symmetric Informationally-Complete Quantum States as Analogues to Orthonormal Bases and Minimum-Uncertainty States," `arXiv:0707.2071v2`.

of quantum Bayesianism that Caves, Schack and I are trying to establish concerns in great part the following thought:

> The *formal structure* of quantum mechanics represents an empirical addition to Ramsey / de Finetti coherence, not an empirical addition to the setting of priors.

That, in a single sentence, is an attempt to capture the technical part of what I sent you last time.

I hope you're having fun at the PSA meeting. I really regret having to miss it this year.

01-11-06 *SBT, the Reprise* (to H. C. von Baeyer)

von Baeyerism 24: *So, to cover up my guilt, I'll go on the attack. I'm reading Caves, Fuchs, and Schack on quantum certainty, and thinking that I'm getting the drift, when I come up to an example – which is my way of understanding – and whammo, on page 10 you hit me with 33 states, which are (the cute little "of course" rubs salt in the wound) connected by 96 rotations and one shoulder separation. I can't envision that. Can't you use a simpler manifestation of KS like Mermin's very cogent* 3×3 *matrix, or maybe it was* 4×4*? As popularizer I'm always on the lookout for simpler versions. (I remember that when GHZ first came out in about 1991 it was such an improvement over EPR that I wrote an article about it which came out so well that even Anton requested a reprint just this Fall.)*

Well, that's just the tip of the iceberg of my own troubles with that paper. Rüdiger and Carl had convinced me that we should try to write it in a "metaphysically neutral" manner—saying the things the authors could all agree on, without too greatly exploring the meaning of the words "fact" and "truth" in the quantum domain (a place where we ourselves we had significant differences). But that was definitely the wrong thing to do: For it is precisely the place where the *four* referees picked on us the most. Clearly some clarity and commitment was called for! (By the way, of the reports, two thought it was an outstanding paper (though needing plenty of revisions), one was somewhat neutral but generally positive and also asked for revisions, and one thought it was so hopeless we should simply scrap it at the outset. The thing that tickled me most about the last report is that I had never before imagined that I could be wrong in so distinctly many ways.)

Anyway, I say this to warn you that I think a much better version of the paper is coming together now, and you shouldn't think too deeply about the present version. We intend to have the new version posted before December.

About the section you mention, one of our referees even said this:

> There is of course nothing wrong with the proof in section V, but at this point in the history of the philosophy of quantum theory, I confess that I don't see why it is there. Isn't a quick reference to the 10,000 other proofs of nonlocality sufficient? If not, can you say what is special or new about this one? I would personally rather see that space used for a more subtle discussion of the newer issues, perhaps addressing some of the points that I've made above.

In a way, he has a point; that section may bring us more trouble than it's worth. Its main point was really to say only that neither 1) Kochen-Specker, nor 2) Bell inequalities alone, lead to conclusive results with regard to the question of the pre-existence of "with-certainty" measurement outcomes. However, the conjunction of locality + KS (in the way of Stairs) does. To make that point, not all (or almost any) of the construction needed to be shown. References alone might well have done the trick. In any case, I'll share your concerns with my coauthors and treat your remark as a fifth referee report.

08-11-06 *November 8th* (to N. D. Mermin)

I apologize for my long delay in replying to you; this time it was not intentional. First I had Appleby here and we were completely single-minded on our simultaneous-quartic-equations problem to the exclusion of all else. Then I had the misfortune of getting a very bad case of food poisoning (cold left-overs from Taco Bell) which sent me to Emergency Care and knocked me out for several days. And, finally, yesterday was Election Day and I could not tear myself away from the television!

But like America as a whole on this glorious November 8th, I am recovering.

Merminition 155: *Don't be so quick to dismiss Leggett as an ideologue, just because he takes quantum states to be objective. It's hard to spend decades worrying about the phase diagram of helium-3 without believing that quantum states are objective. It's hard to spend a decade thinking about information theory without believing that quantum states are states of knowledge. Does that make you an ideologue? It seems to me (probably too superficial a thought) that neither of you has enough to say about the background that underlies the other's ideology.*

Your last sentence is fair enough: There is such a divide between me and the nuts-and-bolts, roll-up-your-sleaves-and-actually-do-something-with-quantum-mechanics physicists that there is certainly a communication barrier. (By the way, Tony happened to be visiting UBC in Vancouver during my interview there two and a half years ago. And just coincidental with that and the remark above, I remember after the interview Philip Stamp telling me that someone on the committee said, "Well, if he loves quantum mechanics so much, why doesn't he do anything with it!" I doubt it could have been Tony (not being on any UBC committees), but these separate strands bring it all together in my mind.) I don't know how to cross the divide; it's been a problem that has plagued me all of my career. I am just a very narrow specialist in physics (who, like Ringo Starr, was always just lucky to be there), and to bridge the divide would require a real generalist … one like you or David DiVincenzo. Particularly someone far more capable than me.

With regard to your phase-diagram remark in particular, I think it's got to be instructive to try to imagine what a turn-of-the-century physical chemist (trained in the worldview of classical physics) should have thought of the tables of heat capacities and whatnot that he had spent much of his life compiling. What can those numbers represent in the classical worldview? Why would two distinct chemists compile the same tables of numbers if those numbers didn't signify something objective and intrinsic to the chemicals themselves? Well, a Maxwell demon wouldn't compile the same tables. And there is surely a continuum of positions between us and him. What those tables represent is something about the relation between us, the coarseness of our senses, our inabilities to manipulate bulk materials, all kinds of things like that, and the materials themselves. Those numbers are just as much about us ("anyman") as about "it."

Anyway, forgetting about Leggett, how would I convince the classical physical chemist of such a point of view? It would be damned hard (as history has already shown). Instead of skirting so close to such an anti-Copernican idea—that knowledge gained in science is as much about "us" as about "it"—he'd probably spend his life trying to poke holes in the conceptually simple Maxwell demon idea and try to return his beloved thermodynamical quantities to their pristine objectivity (a place where they'll last forever).

I just think it'd be instructive to carry that out in more detail before tackling anything more specific to quantum mechanics.

On your other point, no I don't consider myself an ideologue (clearly). The reason is, I came to this position kicking and screaming … as Carl and Rüdiger, for instance, can attest to you. It has been a very slow transition and has really only gained momentum in the years that I've happened to know you. After the kicking and screaming phase—after Caves and Peres had laid the seed—"consistency" kicked in and carried me the rest of the way to the "radically subjective Bayesian" where I am now. And that's all that's happened. (Can you really imagine that Tony went in the reverse direction, kicking and screaming all the way himself?) In the years before I knew you, I had all kinds of crazy ideas about objective wave functions and objective probabilities and passion-at-a-distance and giving up on the notion of spacetime and .... And they all only expressed *one* thing: Fear of taking the observer seriously as a component of what quantum theory is about.

To let that "fear" or its equivalent be the one over-riding piece of "evidence" for shaping one's foundational program, I call an ideology. I've always liked the way Spekkens put it in his toy-theory paper:

> We shall argue for the superiority of the epistemic view over the ontic view by demonstrating how a great number of quantum phenomena that are mysterious from the ontic viewpoint, appear natural from the epistemic viewpoint. These phenomena include [about a million things]. ... The greater the number of phenomena that appear mysterious from an ontic perspective but natural from an epistemic perspective, the more convincing the latter viewpoint becomes. ...
>
> Of course, a proponent of the ontic view might argue that the phenomena in question are not mysterious *if* one abandons certain preconceived notions about physical reality. The challenge we offer to such a person is to present a few simple *physical* principles by the light of which all of these phenomena become conceptually intuitive (and not merely mathematical consequences of the formalism) within a framework wherein the quantum state is an ontic state. Our impression is that this challenge cannot be met. By contrast, a single information-theoretic principle, which imposes a constraint on the amount of knowledge one can have about any system, is sufficient to derive all of these phenomena in the context of a simple toy theory, as we shall demonstrate.

So, my statement is one about the mass of evidence. It's one about good scientific practice ... even in the context of quantum interpretations. To ignore a mass of evidence (in some context) and stick with one's gut is to be an ideologue (in that context).

Merminition 156: *Like my referee's report? You're right. I still don't get it. But I want to get it. The tension between what is known and what is a matter of judgment is somehow crucial to the whole business (and as far as I'm concerned, is what the "measurement problem" translates into in your way of looking at things. It's still there.) I guess there was also tension among the three coauthors which did not promote complete clarity of expression.*

Your referee report was fabulous. And much needed. It was by far the best of the lot (there were four of them, along with detailed comments from Jerry Finkelstein and Chris Timpson). Actually they were all needed. I blame the paper's lack of clarity on myself—it came about because I lost soul and didn't want to fight. The real sin of the presentation is that we tried to write the discussion in a "metaphysically neutral" way, if you will, without making too much commitment about these hard words like "fact" and "truth" (in the quantum context or out of it). In my gut, I didn't feel that was the right way, but I lost soul. And also Rüdiger assured me that in all the "unsaid things" we three really didn't differ. Well, the referee reports called us out on that: We had set ourselves up to confuse everybody. And when push came to shove I found out that Mr. Caves hadn't agreed with Rüdiger and me at all in the fine metaphysical details. So, no wonder the paper was confusing at a very deep level.

In fact, I actually had made a feeble attempt to say things a little more clearly when Jerry first commented. (I'll place the note below that I had written to Jerry at the time; it is relevant to some of your own points.) Carl responded with an angry, "I admit that my initial responses were too curt to be very useful, but now the waters are muddied beyond belief." At which point, I just curled up into a ball and went into hibernation.

Your report and the others at least helped dispel Carl's overwhelming obstinacy that nothing more needed saying. And that in turn—like a good marriage counselor—led us to start speaking to each other again. I think you will find a significant improvement in the paper when I can finally show it to you. At least I think it reached much better clarity when we were working on it last ... even though it is still written in the sparse style my two coauthors prefer. And I even gained ground: 1) it is not written in such a very "metaphysically neutral" way as it had been before (it attempts to make some statements of substance), and 2) Rüdiger and I even shockingly got this remark from Carl soon after our meeting:

> I think we ought to be thinking about a paper that lays out our entire approach, particularly, the idea Chris and I discussed of a three-pronged approach to subjectivity and objectivity: (i) quantum states and probabilities are wholly subjective; (ii) system attributes are wholly objective; and (iii) measurement outcomes are where the rubber meets the road, i.e., where subjective and objective meet to produce something that is not under the control of the agent, but is also not out there in the world.

Point (iii) represents a very deep shift in Carl's thinking indeed—I honestly thought I had long since pounded the opposite conception out of him—and I really don't think we would have gotten there if your referee report hadn't forced him to confront these issues that I've been babbling about for the last couple years.

... I just read that Donald Rumsfeld resigned while I was writing this note to you. I didn't know that a third of a president could resign? Quite a shock to me. Anyway, more evidence that it is a glorious day!

So let me leave you with one remark on my favorite line in your report. You say, "your real point, which you then expand on nicely, is that you have a rather nice, somewhat off-beat interpretation of the Born rule." Thank you. Because this really is the essence of where this research effort is now going. I tried to put it in a slogan the other day and this is what came out:

> The *formal structure* of quantum mechanics represents an EMPIRICAL ADDITION to Ramsey / de Finetti coherence, not an empirical addition to the setting of priors.

What survival in the quantum world is imposing on us agents is not some kind of "principal principle" (i.e., that we should adopt this or that objective probability), but rather an addition to "coherence" (in de Finetti's sense). When I am gambling on the sensations I will receive from interacting with a quantum system, my gambles should not only be coherent in de Finetti's sense, but more. For, considering all the ways I can imagine interacting with the system, all my gambles for each of those individual ways should also be related to each other. The precise way in which they should be related is an empirical statement: And in our contingent world it happens to be via the Born rule. (I.e., it could have been different if our universe were different.) And that is where we have our clearest window on quantum reality.

But I tried to say all that in my Waterloo talk (never to be mentioned again!); maybe I said it more clearly this time.

09-11-06 *Quantum Foundations at the APS March Meeting* (to a large distribution list)

Dear quantum foundations friends,

Please note that there will be a "special focus session" on Foundations of Quantum Theory at the APS March Meeting in Denver, Colorado, March 5–9, 2007. This session is organized by the TGQI—the Topical Group on Quantum Information, Concepts, and Computation—which hopes to promote the field of quantum foundations within the American Physical Society and the broader physics community.

We hope you will help make this session successful by submitting abstracts (to sorting category 23.8.1 "Foundations of Quantum Theory (GQI)"). The deadline for submissions is Monday, November 20. More information can be found at the very bottom of the page at

`http://www.aps.org/meet/MAR07/abs.cfm`.

Please spread the word to others you may know who are interested in quantum foundations.

The meeting announcement is at `http://meetings.aps.org/Meeting/MAR07/`. You can join the TGQI at `http://www.aps.org/units/gqi/`.

Best wishes,

Chris Fuchs
for the TGQI Program Committee

> 23.8.1 GQI Foundations of Quantum Theory
>
> Advances in both theory and experimental technique have made possible a golden age of investigations in the foundations of quantum mechanics. This session encourages both theoretical contributions that illuminate our understanding of foundational aspects of quantum physics and reports on the sophisticated new experiments that are probing the foundations of quantum theory.

13-11-06 *Zing! Went the Strings of My Heart* (to H. J. Bernstein)

Bernsteinism 3: *I had some thoughts about the last (co-authored) paper of yours that you shared; in fact I thought you were letting the pressure of admitting to a classical world get you a bit far over from what we really know we can say. Which is the beauty of Bayesian approaches: sure there is "zing" out there but updating our tables of probabilities and conditionals is about all we know if it.*

Rather than dig it out and try to get a recollection about the point I'd make, I know you must have at least almost finished the paper if not the negotiations with Carl & whomever, so could you send a newer version to me and my student Zac?

I'm not sure what you're saying, but it's always good to hear from you!

Actually, I'm working all this week to re-edit our paper once again. So any input you might have would be really good. Attached is the version of the paper that arose after David Mermin's detailed comments. Next, I've got to tackle the other three(!) referee reports, and maybe take into account Jerry Finkelstein's and Chris Timpson's comments. Why not join the club! It'd be great to hear which parts you think could be made clearer.

13-11-06 *'Many Worlds at 50' Invitation* (to A. Kent)

Thank you for the invitation to the Many Worlds meeting. I've marked my calendar in all worlds (i.e., one). Please put me down for a talk titled, "13 Direct Quotes from Everettian Papers and Why I Find Them Unsettling." I'm looking forward to this.

13-11-06 *Quantum Foundations at the APS March Meeting* (to F. E. Schroeck)

Schroeckism 2: *I got your message about the Q Foundations focus group of the APS to be held HERE, in Denver. I didn't know you had started this group. Anyway, congratulations; I hope it gets off the ground.*

I'm just a worker bee; the thanks for starting the group go to Danny Greenberger and Anton Zeilinger, and a big petition signed by over 400 people. You should join the group; we definitely need larger representation from the quantum foundations community.

Schroeckism 3: *I don't know what I could say that is new at this stage, but I'll think about it. Maybe something about informational completeness in measuring by placing holes in a "screen" at points in phase space in the mean. I have talked about q.m. on phase space until I'm blue in the face in Europe, but it still is mostly unknown here in the U.S.*

That sounds good.

Schroeckism 4: *What are you doing, researchwise now?*

Well, there's the things I have to do for Bell Labs and (dreaming of) building quantum computers.

But I'm also taken with informationally complete observables, particularly very symmetric ones. I'm writing a new paper on that at the moment, and I'll send you a copy when it is done in early December.

13-11-06 *Dove & Hudson Old Books* (to A. Caticha & K. H. Knuth)

By the way, Ariel, Kevin, I should have told you about the outcome of my book-buying excursion. I found this place called Dove & Hudson Old Books (on the corner of Dove and Hudson). It was a wonderful place, and I walked away with about 15 new books (on pragmatism and Heidegger). Anyway, on the small chance that you didn't know about it, I thought I should bring the place to your attention.

14-11-06 *No Stand-Alone Event Space at All* (to V. Palge & W. G. Demopoulos)

I'm going to cc this note to Bill Demopoulos since my reply to your technical question somewhat involves him. I don't think the papers of his that I refer to are posted on the web; so he would probably have to send them to you if you want to dig into this more deeply.

Palge-ism 1: *In the classical probability theory one assumes that the event space has the structure of a sigma-algebra. In their quest to formulate the probability theory for the quantum realm in an analogous manner, various approaches in the quantum logic tradition postulate non-commutative structures, e.g., partial boolean algebras and the like.*

The question then arises: what is the structure of the quantum event space according to your subjective Bayesian approach? Is it a sigma-algebra, like in classical probability theory, or is it perhaps some non-commutative structure? If the latter, perhaps you can specify in more detail what it is?

The best answer I can give you, I think, is that neither of these kinds of structures map onto what I'm thinking. The main reason for this is that I think it is incorrect to think of the process of "quantum measurement" either 1) as the *revelation* of a property inherent in the system under observation, or 2) as the *production* of such a property in the system. And without that, I don't think there is enough glue to bind the events occurring in quantum measurements together into an algebraic structure (say, a lattice or a Boolean algebra, or even a partial Boolean algebra, where there are Boolean algebras tied together at the edges)—at least not in any useful sense that intrigues me as a physicist.

Unfortunately, the only reading recommendations I can give you at the moment (where I try to make this kind of idea of measurement clear) are in the form of little personal essays. I am hoping to put this all together into a paper before the end of January (for the Abnerfest), but it is not there yet. So, let me recommend the following pieces:

1. "'Action' instead of 'Measurement'" (to van Fraassen)
2. "Snowflakes" (to Bub and others)
3. "Me, Me, Me" (to Mermin and Schack)
4. "Questions, Actions, Answers, and Consequences" (to van Fraassen)
5. "Canned Answers" (to van Fraassen)
6. "Incompletely Knowable vs 'Truth in the Making'" (to Bill Demopoulos)

Maybe it is best to read the pieces in that order.

Particularly in light of your question, maybe it is important for you to understand the type of point of view that Bill Demopoulos is trying to develop. (I give my report of it in Item 6 above, but you should probably get Bill's original papers.) I think there is a fruitful similarity between what he and I are seeking, even if we ultimately diverge. It is this: In both our views—and they are the only places I've ever seen this style of idea—even when two measurements share a common element (say a given projector P_i), there is no implication of a common truth value being imposed on P_i across the measurements. The reason for this for Bill is that the system's properties are bound up with the whole orthogonal family of projectors the individual P_i happens to be embedded within. In contrast, the reason for this for me is that I don't think of quantum measurement outcomes as signifying properties intrinsic to the system—they are simply consequences of actions for me. What makes the element P_i identified across measurements—for both of us—is not truth value, but that the *probabilities* for P_i are identical in both cases. What this means particularly from my Bayesian way of thinking is that a judgment is being made: I, the agent, am identifying *this* potential outcome of this measurement with *that* potential outcome of that measurement because I judge their probabilities equal under all imaginable circumstances. (See Section 4.1 of my `quant-ph/0205039`.) It is not that they are identified in Nature itself. Thus, for me, I think, there is no good sense in which they lie in the same event space at all.

I hope all of that helps. That's the best I can do at the moment.

14-11-06 *Visit?* (to A. Wilce)

Wilce-ism 3: *Any chance we can lure you out here to give a talk this spring? (The schedule's pretty open so far.)*

As a matter of fact, I had just started to accumulate my meeting schedule into a centralized view so I could contemplate the upcoming year. When I put it all together, it started to look pretty frightening! But I still owe you! And it would be very nice to see you again.

Not listed in there is that my in-laws will probably be in and out of our house from Jan 1–13.

Thus, what would you think of sometime in the week of Jan 17? Or maybe better, sometime in the week of Feb 7 or the week of Feb 14?

- "Quantum Communication, Measurement, and Computing," Tokyo, Japan, 27 November – 4 December 2006.
- "APS Sorters Meeting," Washington, DC, 7–9 December 2007.
- "Visit to Geraldine," Cuero, TX, circa 21–30 January 2007.
- "Pragmatism and Quantum Mechanics," Paris, France, 22–23 February 2007.
- "APS March Meeting," Denver, CO, 5–9 March 2007.
- "15th UK and European Meeting on the Foundations of Physics," Leeds, UK, 29–31 March 2007.
- "6th annual New Directions in the Foundations of Physics Conference," College Park, MD, 13–15 April 2007.
- "William James and Josiah Royce a Century Later," Harvard U., Cambridge, MA, 25–27 May 2007.
- "Vienna Symposium on the Foundations of Modern Physics," Vienna, Austria, 7–10 June 2007.
- "Workshop on Operational Probabilistic Theories as Foils to Quantum Theory," Cambridge, UK, 1–13 July 2007.
- "Many Worlds at 50," Perimeter Institute, Waterloo, Canada, 21–24 September 2007.

15-11-06 *Rethinking and Rethinking* (to W. G. Demopoulos)

This line of yours intrigues me:

Demopoulosism 7: *I've been slowly rethinking things of mutual interest to us but am not quite where I want to be about them; but maybe I'm getting close. I'll write soon in any case*

For some reason, "rethinking" always has a positive connotation with me. I myself am hoping to rethink a lot as I put together this Abnerfest contribution. Particularly, I want to get straight the extent to which I want to ascribe any ontological statements to the "quantum Bayesian" view—I think I may end up with several (or at least events and objects, all that Donald Davidson says I need anyway).

16-11-06 *Quantum Foundations at the APS March Meeting* (to J.-Å Larsson)

Larssony 1: *Will you be very angry with me if I submit to Quantum Cryptography instead?* ☺

That's funny; I just got a note this morning from Rob Spekkens that said, "Have you got a sense of whether many good foundations types will be submitting abstracts?" You would have counted as a "good foundation type"!

(You see a big worry of ours is that we get a sufficient number of serious people submitting ... since we want foundations to start looking legitimate in the APS's eyes. Last year we were lucky enough to have one of the two sessions completely full of interesting people, with only one filled with fringe people. If we can at least continue that kind of trend, we'll probably be OK.)

16-11-06 *Challenges to the Kierkegaardian Bayesian* (to A. Shimony)

Thank you for the continued kind words. [...]

Anyway, on to more fun things:

Shimonyism 5: *I can't possibly say in one letter all that I have to say in response to your ideas, just as you haven't said all you have to say. But I'll start, and in due time we shall carry the discussion further.*

Let me try to do that (at least a little) now.

Shimonyism 6: *Top of p. 3, point 4 of your list of similarities and differences with Gill: You don't give arguments that there is no measurement problem and no nonlocality problem. As to the first, if the entire dynamics of qm is linear, including the dynamics of macroscopic systems, then it is hard to see how definite events occur at the conclusion of a measurement – hence a problem. As to the second, I think quantum non-locality is a fact, and it is also a fact that it cannot be used to send signals superluminally. Does this show that there is tension between qm and relativity theory and nevertheless "peaceful coexistence"? I used to think so, but Bell convinced me otherwise – hence there seems to be a problem.*

It is true that I don't give any arguments there, but they have been peppered throughout my writings. The key to much of it is to realize just how *thoroughgoing* an epistemic view my closest collaborators and I take on QUANTUM STATES. Take for instance, your point that "if the dynamics of qm is linear, including the dynamics of macroscopic systems, then it is hard to see how definite events occur at the conclusion of measurement."

My reply to that is that the dynamics of quantum mechanics has nothing to do with how definite events occur. It is silent on the matter. It is silent on the matter in the same way that the formal structure of Bayesian probability theory is silent on the matter of where a datum d comes from by which a gambling agent updates from a prior probability $P(h)$ to a posterior probability $P(h|d)$.

It is simply not within the power of the formal structure of probability theory itself to say either 1) how a truth value for d comes about or from where it finds its origin, or 2) how the agent has become aware of d so that he may conditionalize.

Similarly, I will say of quantum states. For this clique of friends that I call "the quantum Bayesians" a quantum state represents a catalogue of Bayesian probabilities and has no independent existence beyond that. A quantum state is nothing other than the complete catalogue of probabilities. Probabilities for what? States of the world? No. They are probabilities for things concerning the very agent himself who has ascribed those probabilities. They are probabilities for something interactive: Namely, the agent interacts with a piece of the world external to himself and there are consequences of that interaction for him—at the very least there are various sensations that may come about. What the probabilities derived from a quantum state signify are the agent's expectations for the consequences of his actions.

What about the dichotomy of linear evolution and collapse? For the quantum Bayesians it is no conceptual problem—they are simply two modes of the same thing, namely updating probabilities for whatever reason. In the case of collapse it is of the cloth of conditionalizing. In the case of linear evolution it is more of the flavor of Jeffrey conditionalization (and some of the updating processes van Fraassen has described). But these are distinctions of detail, rather than conceptual distinctions.

I expand on some of this in the essays "Raining Down in Cambridge," "The Evolution of Thought," and "More Linearity," between pages 222 and 239 of my book *Notes on a Paulian Idea* (which I sent you a copy of). You might find some of that amusing, if not instructive.

Similarly, I could go on about your statement, "I think quantum non-locality is a fact." I would say it is a confusion that takes its origin in not properly appreciating the disconnection between quantum states (epistemic) and quantum events (ontic, but partial consequences of the agent himself). I tried to say this as best I could in Section 3 of "Quantum Mechanics as Quantum Information (and only a little more)" (`quant-ph/0205039`). I would be honored if you'd read that section.

Anyway, to sum up, none of these things are PROOF that a purely epistemic view of quantum states is the way to go, but instead it is a question of the mass of evidence. And you know that I am a pragmatist. I would think that any good Kierkegaardian Bayesian, too, would only adopt priors flexible enough that they could eventually be swayed by the mass of evidence if there is such. In that regard, I think one of the most outstanding arguments (which you should be aware of) is Rob Spekkens' paper "In Defense of the Epistemic View of Quantum States: A Toy Theory," which can be found at `quant-ph/0401052`. I've always thought Rob put the main point so nicely with these words:

> We shall argue for the superiority of the epistemic view over the ontic view by demonstrating how a great number of quantum phenomena that are mysterious from the ontic viewpoint, appear natural from the epistemic viewpoint. These phenomena include [about a million things]. ... The greater the number of phenomena that appear mysterious from an ontic perspective but natural from an epistemic perspective, the more convincing the latter viewpoint becomes. ...
>
> Of course, a proponent of the ontic view might argue that the phenomena in question are not mysterious *if* one abandons certain preconceived notions about physical reality. The challenge we offer to such a person is to present a few simple *physical* principles by the light of which all of these phenomena become conceptually intuitive (and not merely mathematical consequences of the formalism) within a framework wherein the quantum state is an ontic state. Our impression is that this challenge cannot be met.

> By contrast, a single information-theoretic principle, which imposes a constraint on the amount of knowledge one can have about any system, is sufficient to derive all of these phenomena in the context of a simple toy theory, as we shall demonstrate.

That's the way I see it in our own debate—the one between you and me. From my point of view, you are stuck with all these mysteries—the dichotomy of linear and nonlinear evolutions (when does one kick in and the other leave off?), passion-at-a-distance but no action-at-a-distance, and so on and so on. Whereas I would say a thoroughgoing epistemic view of quantum states alleviates so many of these difficulties automatically that it is already worth exploring for that reason alone. Here's the way Rob put it more eloquently in an earlier version of the paper already mentioned:

> Because the [toy] theory is, by construction, local and non-contextual, it does not reproduce quantum theory. Nonetheless, a wide variety of quantum phenomena have analogues within the toy theory that admit simple and intuitive explanations. ... The diversity and quality of these analogies provides compelling evidence for the view that quantum states are states of knowledge rather than states of reality, and that maximal knowledge is incomplete knowledge. A consideration of the phenomena that the toy theory fails to reproduce, notably, violations of Bell inequalities and the existence of a Kochen-Specker theorem, provides clues for how to proceed with a research program wherein the quantum state being a state of knowledge is the idea upon which one never compromises.

Here's what I would love to get a better sense of from you: Does an argument like Rob's particular one (the paper is very easy reading, so I encourage you to give it a shot) ... does an argument like Rob's put any dent in your armor? And if not, why not?

Shimonyism 7: *I agree, of course, that there is ontic indeterminism, for that is at the heart of quantum potentiality, but I don't agree that "ontic probability function" throws no light on this indeterminism.*

Well, certainly my point is that it hinders our progress by presenting a false god—one that stands in our way of seeing a purer, more direct path to salvation! More seriously, in toned down language: That is my trouble. The examples I pointed you to above give I think overwhelming technical evidence that quantum states should be viewed epistemically. And that then has to trickle into my view of quantum indeterminism. There is something about this world that keeps me, the agent, from having too much certainty about too many things (particularly the consequences of the various actions I might take on a given physical system). This is expressed through the quantum probability rule—the Born rule (via Gleason's theorem). The more subjectively certain I am about the outcome of spin-x measurement, the less subjectively certain I should be about the outcome of spin-y measurement, say. This something—the thing that bars me from too much certainty about too many things—is, I would say, a direct handle on "quantum potentiality." But I don't need to go so far as to assume that particular quantum-probability values are ontic to express this idea. My very actions have uncertain consequences (this is undeniable under the assumption of quantum mechanics); no matter what I do I cannot gain a god-like foresight. That seems to be a property of the world, but it is a property that finds its expression in epistemic terms.

Here's one of the ways I put it in the past (in my `quant-ph/0205039`). The language is not quite as refined as what I would use now, but it carries a good piece of the point:

> The last seventeen years have given confirmation after confirmation that the Bell inequality (and several variations of it) are indeed violated by the physical world. The

Kochen-Specker no-go theorems have been meticulously clarified to the point where simple textbook pictures can be drawn of them. Incompleteness, it seems, is here to stay: The theory prescribes that no matter how much we know about a quantum system—even when we have *maximal* information about it—there will always be a statistical residue. There will always be questions that we can ask of a system for which we cannot predict the outcomes. In quantum theory, maximal information is simply not complete information. But neither can it be completed. As Wolfgang Pauli once wrote to Markus Fierz, "The well-known 'incompleteness' of quantum mechanics (Einstein) is certainly an existent fact somehow-somewhere, but certainly cannot be removed by reverting to classical field physics." Nor, I would add, will the mystery of that "existent fact" be removed by attempting to give the quantum state anything resembling an ontological status.

The complete disconnectedness of the quantum-state change rule from anything to do with spacetime considerations is telling us something deep: The quantum state is information. Subjective, incomplete information. Put in the right mindset, this is *not* so intolerable. It is a statement about our world. There is something about the world that keeps us from ever getting more information than can be captured through the formal structure of quantum mechanics. Einstein had wanted us to look further—to find out how the incomplete information could be completed—but perhaps the real question is, "Why can it *not* be completed?"

Shimonyism 8 : *Certainly when one has systems simple enough to be characterized by pure quantum states, and those states govern the transition probabilities into other states – as in emissions and absorptions – then a quantitative character has been added to merely qualitative indeterminism. Doesn't that throw light on the character of quantum potentiality? And even more light is shed when one considers how these quantitative transition probabilities are related to the geometric structure of the Hilbert space of states, particularly to the inner product of vectors in the Hilbert space.*

Again there is a divergence between us because you are, at the outset, thinking of quantum states in ontic terms. For me, if a system has a pure state, it is because I have a very strong, particular belief about what might arise as a consequence from my interactions with it. If I could imaginatively ask the quantum system what its quantum state is, it would say, "I don't know; I don't have a quantum state. It's up to you to answer that question yourself—you're the only one who has a quantum state for me."

Still, I think there is much to be gleaned about the actual structure of our world from the Hilbert-space structure of the quantum probability rule—that's predominantly what my research program is about. It seems to me that the content of the Born rule is a statement about how to be "coherent" (in something like a Ramsey / de Finetti sense) when gambling on the consequences of our physical interactions. The Born rule, as I see it, is an empirical addition to probabilistic coherence . . . and that's where we stand a chance of learning something lasting about the precise nature of quantum indeterminism.

This idea is fleshed out in greater detail in the closing section of the attached paper (which Caves, Schack, and I are presently in the process of revising, so it is not ready for wide distribution yet). But I figure I will give you a copy now as this point will be the core of my planned festschrift contribution for you. If you have any particular criticism to this concept, I would welcome it.

Shimonyism 9 : *There remains a difficult question of whether the world view of qm accommodates indeterminisms that are not quantitative, such as the outcome of a war.*

Now, this point definitely intrigues me. For, as you may have already gathered of me, I would say ALL indeterminisms are of this variety *including* the quantum ones. In this regard I was deeply influenced by Pauli and Markus Fierz. If you go to pages 577–582 of my book *Notes on a Paulian Idea*, you'll find an essay of Fierz's on the subject, reprinted in full. I'd be curious to know what you think of it?

Shimonyism 10: *But there are many varieties of Bayesianism, including logical probability theory, personalism, tempered personalism, and a peculiar variety that I call "Kierkegaardian Bayesianism." I.J. Good has a taxonomy of Bayesianisms somewhere that is very diverse and still not complete. The important point is that some of the strategies for being rational are not prior to empirical science but depend upon the structure of the world and human adaptations to that structure: we not only learn by experience (using probability as a tool) but we learn how to learn by experience (and therefore how to use probability). As you see, I am not radically in disagreement with you, but I think there are nuances.*

And you are right. On this point, I think we have an issue of potential convergence, rather than divergence. I hope you'll see everything above in the light of this very point!

17-11-06 *Certain Comments* (to C. G. Timpson)

Like I said yesterday, thanks so much for the comments. Don't you mind sending me "excessively long emails." When long emails are thoughtful like yours, I love them!

Timpsonism 3: *I enjoyed reading your certainty paper. I'm glad I'll now be able to direct people to that now rather than encouraging them to read through all of 'Quantum States: WHAT'! I had a few comments, mainly about presentation really.*

Yes, it is long since overdue that Caves, Schack, and I have an official statement on this subject. I'm not very pleased with the paper because we made too much of an attempt to stay "metaphysically neutral" on what the h's in a probability assignment $P(h)$ stand for in the case of the quantum context. But still the paper has improved significantly since the first posted version: We had extremely detailed referee reports from two of our four(!) referees, and taking their points into account has improved the paper significantly … and helped me win back a little territory of what I would have liked to have seen emphasized more in the paper.

However, now that we will soon have a stabilized triumvirate statement out, I plan to start embellishing it into something more to my taste for the Abnerfestschrift (where I'll be going it alone). I plan to have that finished by end of January.

Timpsonism 4: *On the distinction between probability assignments and propositions. It seems to me that, while pedagogically useful, this distinction cannot be the whole story. To make a probability assignment may not be to express a proposition (or at least not one concerning objective facts in the world), but one can have truths concerning probability assignments: "He thinks that the probability is p", for example, could express a truth. De Finetti allows this, I notice (having just checked the sections of Probabilisimo you refer to towards the end): "That a fact is or is not a practically certain is an opinion, not a fact; that I judge it practically certain is a fact, not an opinion" (end section 19). Thus one does need to add a claim to the effect that judgements of probability aren't responsive to any facts about chances in the world, as there are no such facts as the latter, on this view.*

Yes, you are correct about that, and it probably should be reflected in better wording on our part. I'll try to do the point better justice in the revised paper.

Timpsonism 5: *On that reading it would be ok to say that stating that the measurement outcome is 1 with certainty does not express a proposition. But one could question whether it is necessary to go so far anyway; all that is required for the position is that any proposition expressed when making a probability assignment doesn't concern how things are in the world external to the agent.*

That, of course, is what we were shooting to express. So, ditto my last remark above: I'll work harder to make our language a little less clumsy.

Timpsonism 6: *p.2 "Certainty is a function of the agent, not of the system." That puts it nicely. The philosopher Alan White distinguishes between the certainty of people and the certainty of things, arguing that these are quite distinct things. Subjective probability concerns certainty or otherwise of people. (Did I send you a copy of his paper 'Certainty'? I have a vague feeling that I might have done, but I'm not sure.)*

No, I don't believe you ever told me about Alan White. I think I would have remembered that. What of his should I read? I didn't find anything in quick look on the web.

Timpsonism 7: *Against objective chance (Section 2). A quibble: I'm not sure I was 100% persuaded by the argument you give in the final few paragraphs here. Some accounts of objective chance – I am thinking particularly of Mellor's in* The Matter of Chance *– can deal with the problem of specifying initial conditions precisely. Mellor argues that a propensity is a dispositional property of a chance set-up, so that if the conditions allow the disposition to be manifest, then a certain probability distribution will be displayed. There would presumably be a range of detailed initial conditions that would allow the display of this disposition, and other ranges which would not.*

I think that is the weakest part of the whole paper. In fact, so weak, as to be almost irrelevant . . . or actually damaging. What you read was the residue that remained after we scrapped our attempt at a direct blow to the principal principle . . . one that was going to expand on Richard Jeffrey's against it. But we got lazy and gave up on the project, particularly because Carl kept saying, "We're writing this paper for physicists," and it started to look too hard to get any consensus between us.

Maybe I'll try to do this better for the Abnerfest thing. I think Jeffrey is right: The principal principle simply cannot be properly formalized, and to the extent that it can be, it just captures judgmental probabilities after all.

Timpsonism 8: *But there's another challenge close by – Howard's – which is: can one be certain that q when one knows that it is not certain that q (when one knows that there is no fact of the matter whether q)? It seems not; yet this is apparently the situation that a self-conscious Bayesian must admit. (There's a scope distinction in the negation here: one can still be certain that q when it's not the case that one knows that it is certain that q: here the form is "not (Knows(Certain q))"; but one can't be certain when one knows it's not certain that q: "knows (not (Certain q)".)*

So looking at the clause (p. 12 third para from bottom) 'an agent could not be certain about the outcome "Yes" without an objectively real state of affairs guaranteeing this outcome . . . , I think you are right to maintain that this is false. The assertion that there is such a state of affairs isn't needed for one to be certain. However, it seems we do require, in order to be certain, the absence of the assertion that there is no fact guaranteeing the outcome.

This discussion of yours is very helpful, and it helps emphasize the pitfalls of our sparse representation. I think it's more evidence that, despite Caves' objections, we really did need to get more metaphysical.

Here's something relevant that I wrote to David Mermin the other day:

> With regard to your phase-diagram remark in particular [I.e. "Don't be so quick to dismiss Leggett as an ideologue, just because he takes quantum states to be objective. It's hard to spend decades worrying about the phase diagram of helium-3 without believing that quantum states are objective."], I think it's got to be instructive to try to imagine what a turn-of-the-century physical chemist (trained in the worldview of classical physics) should have thought of the tables of heat capacities and whatnot that he had spent much of his life compiling. What can those numbers represent in the classical worldview? Why would two distinct chemists compile the same tables of numbers if those numbers didn't signify something objective and intrinsic to the chemicals themselves? Well, a Maxwell demon wouldn't compile the same tables. And there is surely a continuum of positions between us and him. What those tables represent is something about the relation between us, the coarseness of our senses, our inabilities to manipulate bulk materials, all kinds of things like that, and the materials themselves. Those numbers are just as much about us ("anyman") as about "it."
>
> Anyway, forgetting about Leggett, how would I convince the classical physical chemist of such a point of view? It would be damned hard (as history has already shown). Instead of skirting so close to such an anti-Copernican idea—that knowledge gained in science is as much about "us" as about "it"—he'd probably spend his life trying to poke holes in the conceptually simple Maxwell demon idea and trying to return his beloved thermodynamical quantities to their pristine objectivity (a place where they'll last forever).

and something more particular to our paper that I had written to Jerry Finkelstein a good while back:

> In our scenario there is only the agent and the external world. The way one should think of the measurement device is the same way one should think of a prosthetic hand—it is an extension of the agent.
>
> "Detector click" is shorthand for *sensation* in the agent, and in my personal view, that is all it is. The value of the "detector click" is beyond the control of the agent; it is not a function of his beliefs or his desires. His interaction with the external world gives the class of potential sensations, but it does not set the value.
>
> Thus, the value of the detector click—call it d—is objective for the agent. (There is one sentence in the paper where adopted almost that phraseology "an event is a fact for the agent," and it might have been wise to adopt it more consistently.) What is subjective from our view—i.e., a function of the agent and not the data or external world alone—is the POVM associated with those potential values. That is, the set of operators E_d. [...]
>
> There is an agent, there is an external world, there is an interaction between the two—the agent acts on the external world, it causes a reaction back in him (sensation). As far as he is concerned that reaction is not subjective; it's as real as anything he's ever seen.

I think the solution to your conundrum lies in extending these points. Particularly this. The reason the two statements

1. <u>One</u> is certain
2. <u>One</u> knows that “<u>It</u> cannot be certain”

are not inconsistent is because of the “metaphysical piece” that’s missing from most of our language in our paper. The outcome of a quantum measurement is a joint product of the agent and the quantum system. [I remember once writing on my notepad that the idea of quantum measurement—even in our conception of measurement (or, should I say, *particularly* in our conception!)—without a system to measure upon is as much of a koan as the sound of one hand clapping.]

When an agent expresses certainty about the outcome of some measurement, he is judging that, in effect, the quantum system’s contribution to the outcome will be negligible. (See the note titled “Philosopher’s Stone” for an expansion on this conception of measurement. Also, in a separate email, I’ll supplement this with a note I wrote to Veiko Palge recently; there are several references in it that still further expand on this point.) So the agent can self-consciously say “<u>I</u> am certain which will occur” at the same time as saying “<u>it</u> is not certain,” because “neither <u>it</u> nor <u>I</u> is the whole story.” The outcome comes out of a marriage of the two of us. “When <u>I</u> interact with <u>it</u> I am quite certain which sensation that interaction will lead to; <u>it</u> won’t surprise me.”

If I were to kick the cat after a hard day at the office, I am certain that it will lead to my satisfaction. (For whatever crazy reason, I am also certain that it cannot react quickly enough to spoil the moment by scratching me.) On the other hand, because of my fundamentalist Baptist upbringing, I might also believe that the cat cannot foresee how it will react to my kick, by running or fighting—“it’s just a soulless dumb animal.” Even more relevantly, it cannot foresee whether I will be satisfied or not. In other words, performing a quantum measurement on a system for which I am certain of the outcome is like kicking a cat.

Does that make any sense to you?

Going back to the last point of yours quoted above,

Timpsonism 9: *However, it seems we do require, in order to be certain, the absence of the assertion that there is <u>no fact</u> guaranteeing the outcome.*

what I said above, I think, may not contradict this. It just means that we should be a little more careful to say, “there is no fact *in the object* guaranteeing the outcome.” Of course, there is no fact in the agent guaranteeing the outcome either; otherwise his certainty wouldn’t be subjective certainty.

Timpsonism 10: *On a quite different matter: have you ever come across Diederik and Sven Aerts’ work?*

I’ve seen a very little bit of it, but even that I haven’t absorbed all that well.

Timpsonism 11: *They want to explain the appearance of quantum probabilities as arising from what they call a hidden measurement model, involving ignorance of some processes going on in measurements, rather than ignorance of some underlying properties of the object systems. [...] This seems to be close to what I think you have on occasion said might be one way – one of the less interesting ways – your and Rüdiger and Carl’s programme might turn out.*

I think you’re probably right in this assessment. “Hidden variables in the agent,” (maybe a more honest way of saying “contextual hidden variable theory”) is something that has crossed my mind from time to time as *possibly* consistent with my forming point of view of quantum mechanics. But as you say, it seems for me that it would be “one of the less interesting” potential endings to our research program. I clearly am immensely attracted to the idea that a quantum system and an agent, when put in conjunction with each other give rise to something that was in neither physical system alone. That a quantum measurement outcome is a birth of sorts. Even a "relational" viewpoint on measurements (say like Mermin or Rovelli, or what Spekkens desires) doesn't seem to be enough for me. There's something in my gut that says that anything weaker than the radical, Paulian direction (the thing that in a bar room I call "the sexual interpretation of QM") is ultimately inconsistent. But indeed I don't have a good argument for that right now.

On the other hand, I do think there is a pearl of wisdom in this quote you sent me:

> If one wants to interpret our hidden measurements as hidden variables, then they are hidden variables of the measuring apparatus and not of the entity under study. In this sense they are highly contextual, since each experiment introduces a different set of hidden variables. They differ from the variables of a classical hidden variable theory because they do not provide an 'additional deeper' description of the reality of the physical entity. Their presence as variables of the experimental apparatus has a well-defined philosophical meaning, and expresses the fact that we, human beings, want to construct a model of reality independent of our experience of this reality. The reason is that we look for 'properties' or 'relations between properties', and these are defined by our ability to make predictions independent of our experience. We want to model the structure of the world independently of our observing and experimenting with this world. Since we do not control these variables in the experimental apparatus, we do not allow them in our model of reality, and the probability introduced by them cannot be eliminated from a predictive theoretical model.

so maybe I should look at these guys more carefully.

Timpsonism 12: *My aim in the next couple of months is finally to write something more substantial about your approach (which will end up as the final chapter of my book), so I shall be sitting down to try and think hard about it. I'll try not to pepper you with emails, but you may get one or two. I see that there is a new collection of emails on your webpage which I imagine I ought to take a look at to see how your thoughts have been progressing.*

It would be very useful for us to have your commentary. So, please do pepper me any time you'd like. If I don't answer right away, it'll only mean that I'm busy or traveling or on holiday; it won't mean at all that I'm bothered by your queries or objections. I get more out of your emails than I've probably ever adequately expressed to you. I want to understand quantum mechanics before I die; that is first and foremost the goal ... and whatever tension will lead me there is precisely what I need.

I hope Rüdiger's inaugural lecture goes well. I wish I could be there too. I think what he's talking about (a quantum Bayesian definition of randomness) is very deep stuff, and it will be a while before it is appreciated. I myself have yet to incorporate it into my metaphysics, but I think it will be a crucial piece of it ultimately. Have a good time.

17-11-06 *March Meeting* (to R. W. Spekkens)

Spekkensism 32: *I was about to submit my abstract for the focus session on foundations, and then I reread the email I received from APS. It says: "the proposed title of your talk is 'Interpretations of Quantum Mechanics'." My best guess is that this wasn't meant to be a real proposal for my title,* *and that I should speak on a topic of my choice (I'm thinking of speaking on the toy theory), but I just wanted to make sure that this was the case.*

I think you should definitely talk on the toy model. Put it in the wider context of the interpretation debate of course, and I would hope that you *not* spend much time on the latest and greatest variant or new achievements. Instead, I hope you spend plenty of time getting the basic points across.

Was the paper ever published, by the way?

It's funny, I was just advertising the paper to Abner yesterday and rethinking that lovely closing line in the abstract of an earlier draft:

> A consideration of the phenomena that the toy theory fails to reproduce, notably, violations of Bell inequalities and the existence of a Kochen-Specker theorem, provides clues for how to proceed with a research program wherein the quantum state being a state of knowledge is the idea upon which one never compromises.

Yes, Bell and Bell-Kochen-Specker are clues—the most important ones. But not clues toward the epistemic nature of quantum states. They are clues about the event space, and that is a much deeper issue.

17-11-06 *Birds and Stones* (to S. L. Braunstein)

Braunsteinism 4: *I must be getting old. I no longer believe in mixed states — except as a convenient language/tool.*

Well, you know you shouldn't believe in pure states either. It's funny, just yesterday I wrote this to Abner Shimony:

> Again there is a divergence between us because you are, at the outset, thinking of quantum states in ontic terms. For me, if a system has a pure state, it is because I have a very strong, particular belief about what might arise as a consequence from my interactions with it. If I could imaginatively ask the quantum system what its quantum state is, it would say, "I don't know; I don't have a quantum state. It's up to you to answer that question yourself—you're the only one who has a quantum state for me."

21-11-06 *The Self-Preservation Society* (to M. S. Leifer)

I read a good bit of your paper last night, and I really, really enjoyed it. It's no-nonsense like your talks, and the whole thing is put together in a very compelling way. This pretty construction of yours makes my mouth water again for a kind of Gleason theorem behind trace-preserving completely positive (TPCP) maps—it's got to be there ultimately. We really ought to get together and think about this. (There is some chance I'll be visiting PI in late Jan or early Feb; will you be around?)

I checked with Andrei and he says it's OK to post things on `quant-ph`. So there you go.

But before posting, let me bring up one political point. I thought it was a bit unfair to me how you introduce the motivation for the paper:

> The situation is less clear when considering a unitary operation on the system of interest alone, since in this case the environmental state is irrelevant to the action of

> the operation on the system, and unitary operations do not cause convergence of distinct states. Thus, unlike the previously discussed cases, the subjectivity of unitary operations cannot be argued directly from the subjectivity of quantum states.

particularly

> This offers the opportunity for CFS to hold onto the objectivity of unitary operations, which might be tempting, since the specification of a Hamiltonian seems to encode the objective content of our most successful physical laws.

To be sure, your technical contribution is great and was needed, and I'll be advertising it to everybody as the best little piece of quantum foundations in a while. But your wording gives no indication that the subjectivity of unitaries had ever crossed my mind or the preliminary and very public arguments I've given for it. See, for instance,

- Section 7 in `http://www.arxiv.org/abs/quant-ph/0205039`,
- or Section 6 in `http://www.arxiv.org/abs/quant-ph/0404156` where particularly footnote 9 makes it clear,
- or Section 4 in `http://www.arxiv.org/abs/quant-ph/0307198` where I consciously did not single out unitaries as anything special among TPCPs,
- and there are certainly significant pieces in "Quantum States: W.H.A.T.?" that I could pinpoint where I think the point is strictly argued.

The arguments may not have been conclusive, or even, you might think, right (though I think they are), but they started the whole subject. The idea of the subjectivity of operations I consider my best work ever in physics—it was no easy wall to climb over. Your work is a nice turning point, giving us something far more solid and productive to work with, but don't forget the old hint-giver who is still himself struggling for a stable career. If that's my only role—and it's not too bad of a role—I still need to get credit for it, like the rest of you, to survive.

Matt's Reply

> You are right. Originally, I had wanted to say that this gives the C of CFS an opportunity to hold onto the objectivity of unitaries, since he's clearly the one who wants to, but I thought that was unfair because C has not yet written any paper to that effect. I didn't mean to imply that $C \cup F \cup S$ actually wanted to take this option, only that it would not be a logical contradiction for any of them to do so. Obviously, I am aware of your earlier discussions of the subjectivity of unitaries and these inspired my argument, but in my haste to finish the paper in time I may not have emphasized this.
>
> If you can give me a couple of extra days I should be able to fix this. It's not a big job, but unfortunately I have more than one deadline to deal with at the moment.
>
> As regards visiting PI, I should be there in Jan and Feb, apart from the week of the 11th Feb. I can see that a Gleason's theorem for TPP maps potentially follows from your tensor product argument, but I am still not completely sure what the motivation for studying it is. I mean, any conceivable dynamics must map density operators to density operators, so the only real question is linearity. For an operationalist, this would be argued from the possibility of forming mixtures. I am guessing you don't like this

> because it uses a notion that is analogous to a "probability of a probability". The more general issue of how to argue for convexity in the Bayesian approach without making use of the mixing argument is also worth discussing. I know you have an email to Lucien on this in your Samizdat, and Rüdiger also discusses it in his response to Lucien's papers, but I still think there is something more to be fleshed out here.

21-11-06 *The Self-Preservation Society, 2* (to M. S. Leifer)

Leiferism 4: *I can see that a Gleason's theorem for* TPCP *maps potentially follows from your tensor product argument, but I am still not completely sure what the motivation for studying it is.*

The motivation is the usual one: The search for a direct argument for something, rather than a roundabout or secondary one for it. It would just be nice to get a straight-out argument for CPMs without *first* invoking the idea of a single-time density operator. Moreover, it would be like a development of probability theory that defines conditional probabilities at the outset, without reliance on marginals and joints—it would be more radical probabilist at its core.

Leiferism 5: *The more general issue of how to argue for convexity in the Bayesian approach without making use of the mixing argument is also worth discussing.*

That would be good too.

22-11-06 *The Self-Preservation Society, 3* (to M. S. Leifer)

You made the old man happy! I think the paper's great. And you really do "significantly strengthen the case for the subjectivity of all TPCP," so we should uncork a bottle of bubbles when we're together.

My PI visit is now settled. I should be there roughly Jan 29 to Feb 11. It'll be good to see you.

This morning I dug up the notes I had written on trying to find a dynamical Gleason theorem. Almost to my shock, I saw that they were dated "1 December 2000, Vienna" ... but it's not really to my shock: I'm pathetic about ever completing anything. (My biggest character flaw is that I seem to need ridiculous amounts of interaction to get anything done ... and Bell Labs can be a lonely place.) At least I was pleased to see the way the notes start off:

> Let us take the following idea as fundamental: Hilbert spaces need not be associated with systems per se, but with measurements. Thus if I make a measurement on a 'single system' at two distinct times, I should consider that a POVM on $H \otimes H$. If, later, I might wish to consider H as the only relevant Hilbert space, I might do that — but that is a derivative step, at least from this conception.

If you give me a fax number where you can be reached, I'll fax you the notes (there's about 20 pages). Maybe you can start thinking about all my wrong turns—and how to fix them—in the background of your mind before we meet up.

Tell me as soon as your paper is complete to the point of posting. I want to bug Charlie Bennett about it before seeing him in person Monday. Have you discussed the closing idea in your paper with Lee Smolin? I should think if nothing else interested him about it (and all this subjectivity gobbledygook actually turned him off), he might still be intrigued by the formalism.

22-11-06 *A Place in the World, 1* (to C. H. Bennett)

I just read these words of yours:

Bennettism 28: *Fortunately public interest is now such that lay people are overcoming their fears and asking us questions like "What is a quantum computer?", "How can a particle be in two places at once?", or "How can observing one particle affect another particle?" By coming up with intelligible and respectful answers to these questions, we will be doing our profession, and our fellow humans, a great service.*

Made me feel like maybe I have a place in the world, after all.

Really looking forward to joking around with you in Japan next week. I hope you'll be there the whole time.

22-11-06 *A Place in the World, 2* (to C. H. Bennett)

Bennettism 29: *I'll be at QCMC there starting the late afternoon or evening of 28 November. I look forward to joking around with you and trying on some ideas about quantum Darwinism and the ontological status of Jimmy Hoffa, a little further developed from the ones you heard before.*

Then here's a good way to start preparing for the joust. I just got this paper from Matt Leifer [see `quant-ph/0611233`], which he'll be posting today. I think it's really very good. (And, of course, completely relevant to the ontological status of Jimmy Hoffa.)

See you the 28th. I'll be waiting for you in the hotel lobby!

22-11-06 *CFS Philosophy, Ontic and Epistemic States and Evolutions, Funes the Memorious* (to C. H. Bennett)

Bennettism 30: *Matt's paper deliciously deduces from your execrably anthropocentric CFS philosophy that if quantum states have no ontic existence, merely epistemic, then so do quantum evolutions. This would include the identity "evolution" which leaves all "states" the same. So even the process of staying the same is not a process, but a correlation between states of knowledge at two timelike separated events. To thus problematize the process of merely existing, of remaining the same, is to begin to think like Borges' character Funes in* Funes the Memorious*, who "was disturbed by the fact that a dog at three-fourteen (seen in profile) should have the same name as the dog at three-fifteen (seen from the front). His own face in the mirror, his own hands, surprised him on every occasion."*

I'm glad to hear you liked Matt's paper!!

Hey, tell Theo Happy Thanksgiving from all of us in Cranford. (I'm trying to get a big roaring fire going for tonight.)

22-1l-06 *The Usual Behavior of Chris* (to C. M. Caves & R. Schack)

Let me give you a progress report as of 2:00 PM Wednesday, Nov 22, just before I take off until Friday morning (for Thanksgiving), whereupon I will start up on the project again.

Truth is, I've been mulling over and working on our paper since late last week, and corresponding privately with some of our critics. Over the weekend I hit an extreme low point, and contemplated writing both of you that I would simply drop out of the project. Upon carefully reading the reports and carefully reading again the paper as a whole, I just started to feel icky about the whole thing. It dawned on me that the whole paper wasn't nearly as clear as I had pipe-dreamed it was and I didn't really feel like it represented my view on anything. So why propagate the trouble I'm going to have to try to dig myself out of? 1) The paper doesn't convey any sense of the *privacy* of the single agent's description of his beliefs and the outcomes of his measurements, yet to be consistent requires it. 2) The paper is not consistent about the complete disconnect between the epistemic and the ontic. ("Logical implication" should be viewed is simply an instance of "subjective certainty" again—to talk of "exceptions" kills our whole point.) 3) It bandies about this term—this enemy—"the Copenhagen interpretation" to complete distraction, when I myself think there are so many subtleties here that it would be best to never mention Copenhagen.

Anyway, that was my low point. Since then I've started to climb the hill of optimism again, and at the moment at least, I am feeling like with enough *subtle* editing work I can pull it into a convincing package that has everything that *each* and *every one* of us wants. I am trying.

Mermin wrote me this:

Merminition 157 : *Eager to see your revised version. Your problems confirm my long-time practice of never having any collaborators if I can possibly help it. Particularly on the kind of paper you guys are trying to write. Reporting calculations is one thing, but what you're doing is just too subtle for a committee to get right.*

He's right, you know. I think we should think much harder about this in the future.

Below is a sample of some the changes made in Section 1. Through them I am thinking that I am addressing the issues of three of the referees, but also Timpson, Finkelstein, and von Baeyer. I think I only have two days more work now that I'm on a positive, can-do note again. (And my attitude really is positive again, even if the above does not convey it.)

I have every intention of shipping the thing to you before leaving for Japan Monday morning.

25-11-06 *Your Bravery* (to M. S. Leifer)

It dawned on me yesterday when I saw your posting that you are a brave man! What a brave thing to get involved in any way with these loons, the subjectivist Bayesians! I commend you.

By the way, I already got a little feedback from Charlie Bennett on your paper. (Very dangerous to put "deliciously" and "execrably" in the same sentence.) [See Bennettism in 22-11-06 note "CFS Philosophy, Ontic and Epistemic States and Evolutions, Funes the Memorious" to C. H. Bennett.]

Guard your flank.

25-11-06 *Hoffa and the Bayesians* (to C. H. Bennett)

I had a lovely email exchange with Matt Leifer this morning. Below is Matt's reply, of which I asked him if I could forward it to you—I knew you'd enjoy the story at the end. (When I see you, I'll tell you the one about the Jewish mystic I met on a plane.) The ontological status of Jimmy Hoffa and subjective unitaries — what is Osamu going to think of us now? (I just hope he won't slap me on the rear this time around.)

Leifer Excerpt

Finally, I think I should relate the story of what happened to me last night. Around 7pm I decided to go to a little Italian café for dinner. I had been writing an application for a faculty position (which I should be finishing now), and was thinking about what I should write about Bayesian stuff in my research statement. Now, in this café the tables are quite close together and you often meet "interesting" characters. It turns out that the guy on the table next to me had some weird variant of Tourettes that caused him to mumble incoherently to himself the whole time. At one stage, the conversation became coherent for just a few moments and went as follows:

Him: Are you studying here?
Me: I'm a postdoc.
Him: What subject?
Me: Maths.
Him: Do you like your......Bayesian.........Analysis?
Me: Yes, I like it very much thanks.

Of course, I tried to ascertain how he had known to say that, given that I had not been talking out loud about this stuff anywhere nearby, but the responses were all incoherent, mainly involving "Bayesian arseholes", "lesbians" and comments to the effect that he was more handsome than me. In some ways this reminds me of your story about the guy you sat next to on the airplane. Is there some sort of curse associated with writing papers on quantum Bayesianism? Perhaps the savants of the world are trying to tell us something.

25-11-06 *The Subjectivity of Convincing* (to R. W. Spekkens)

Spekkensism 33: *I also wanted to mention that I am finally convinced that, within a Bayesian approach, even unitary maps must be considered to be subjective. (Of course, I myself am not so sure that the Bayesian approach is the correct one, but that's irrelevant to the question.) I remained unconvinced by your original argument, the recent CFS paper on certainty (actually it wasn't clear that it was arguing for this conclusion), and Matt's first draft of* `quant-ph/0611233` *(which he gave me a copy of). But, after discussing it with Matt, he finally came up with an argument that did convince me (well, I haven't made a concerted effort to find fault with the argument, but intuitively, it seems right). This is the one that is now found in sec. 5 of* `quant-ph/0611233`*. Perhaps this argument was implicit in a previous argument made by one of you, but if so, it wasn't spelled out in enough detail for me to really get it until now. If you haven't had a look at Matt's paper, you really should.*

Yeah, I'm very proud of Matt's paper. That's very nice work, and I am very impressed by him.

The CFS certainty paper made no mention of the issue. 1) It didn't need to for the point at hand (that objective facts don't determine quantum states), but 2) because Caves is still an obstinate hold out on the issue of unitaries. I'm hoping Matt's paper will finally make some dent in his armor.

Regarding your "unconvinced" point, that's fine. But you shouldn't forget that "being convinced" depends upon a prior. All argument of this variety is a function of 1) one's prior, and 2) the mass of evidence in comparison to the prior. It is, just as you argue in your toy theory paper. I became "convinced" a long time ago, not through one killer argument, but through several inconclusive arguments—programmable quantum circuits, teleportation of unitaries, the non-uniqueness of ancilla representations of quantum operations, the Choi-Jamiołkowski isomorphism (though without a strong operational interpretation), various analogies to stochastic evolution equations (not as strong as Matt's), and so on. But then the real cap was beauty and a sense of adventure. The Bayesian edifice just looked sturdier and simpler without the Cavesian cycles and epicycles (i.e., that "true, there are some subjective, 'effective' unitaries, but there are also the objective ones too"). I understood that a conceptual leap might need to be made—i.e., that maybe we would never be able to make a strict logical argument *from* the subjectivity of states *to* the subjectivity of unitaries, i.e., that maybe it was an independent assumption. But if anything, that thrilled me a little.

It gave me a small chance to play pretend to be William James, and I could let W. K. Clifford be the proxy for my Carl Caves:

> The talk of believing by our volition seems, then, from one point of view, simply silly. From another point of view it is worse than silly, it is vile. [[As that]] delicious enfant terrible Clifford writes: "Belief is desecrated when given to unproved and unquestioned statements for the solace and private pleasure of the believer. . . . Whoso would deserve well of his fellows in this matter will guard the purity of his belief with a very fanaticism of jealous care, lest at any time it should rest on an unworthy object, and catch a stain which can never be wiped away. . . . If [a] belief has been accepted on insufficient evidence [even though the belief be true, as Clifford on the same page explains] the pleasure is a stolen one. . . . It is sinful because it is stolen in defiance of our duty to mankind. That duty is to guard ourselves from such beliefs as from a pestilence which may shortly master our own body and then spread to the rest of the town. . . . It is wrong always, everywhere, and for every one, to believe anything upon insufficient evidence."

Whereupon I could clench that, by his fears and lack of foresight, he was giving up the chance to make real progress in quantum foundations: A REAL leap is needed to understand quantum mechanics—not just for us, but for any foundational direction in QM. Pure logic won't do it; not for any of us (not for me, not for David Deutsch). And to the extent that we quantum Bayesians really believe we smell the right direction, we should be willing to take a leap in it:

> Believe truth! Shun error! — these, we see, are two materially different laws; and by choosing between them we may end by coloring differently our whole intellectual life. We may regard the chase for truth as paramount, and the avoidance of error as secondary; or we may, on the other hand, treat the avoidance of error as more imperative, and let truth take its chance. Clifford, in the instructive passage which I have quoted, exhorts us to the latter course. Believe nothing, he tells us, keep your mind in suspense forever, rather than by closing it on insufficient evidence incur the awful risk of believing lies. You, on the other hand, may think that the risk of being in error is a very small matter when compared with the blessings of real knowledge, and be ready to be duped many times in your investigation rather than postpone indefinitely the chance of guessing true. I myself find it impossible to go with Clifford. We must remember that these feelings of our duty about either truth or error are in any case only expressions of our passional life. Biologically considered, our minds are as ready to grind out falsehood as veracity, and he who says, "Better go without belief forever than believe a lie!" merely shows his own preponderant private horror of becoming a dupe. He may be critical of many of his desires and fears, but this fear he slavishly obeys. He cannot imagine any one questioning its binding force. For my own part, I have also a horror of being duped; but I can believe that worse things than being duped may happen to a man in this

> world: so Clifford's exhortation has to my ears a thoroughly fantastic sound. It is like a general informing his soldiers that it is better to keep out of battle forever than to risk a single wound. Not so are victories either over enemies or over nature gained. Our errors are surely not such awfully solemn things. In a world where we are so certain to incur them in spite of all our caution, a certain lightness of heart seems healthier than this excessive nervousness on their behalf. At any rate, it seems the fittest thing for the empiricist philosopher.

Anyway, that was my little sense of adventure. And Matt's work is a great cushion at the bottom of the leap. Actually it's much more than that: For it gives us a proper formal structure to start building upon.

By the way, with regard to this whole method of reasoning—i.e., beating down the opponent with a BIG mass of inconclusive evidence—I was reminded of your example (i.e., the toy theory paper) by a passage in Marcus Appleby's submission for the Växjö proceedings with regard to interpreting probability. Let me dig that up and paste it in for you.

> The complaint of the Bayesians about the orthodox statistical methodology has always been that it is (in the words of de Finetti) "ad hoc" and "arbitrary". Jeffreys makes the point with characteristic irony when he says of Fisher (one of the founding fathers of the orthodox methodology)
>
>> I have in fact been struck repeatedly in my own work, after being led on general principles to the solution of a problem, to find that Fisher had already grasped the essentials by some brilliant piece of common sense. [Jeffreys, p. 393]
>
> This is, in a way, a compliment. However, the compliment is distinctly back-handed: for what Jeffreys is really saying is that Fisher, notwithstanding his confusions and inconsistencies, often contrives to get the right answer owing to the power of his intuition. It is rather as if a physicist were to congratulate a snooker player on his ability to pot a ball notwithstanding his ignorance of Newtonian mechanics; or to congratulate a fish on its ability to swim notwithstanding its ignorance of the principles of hydrodynamics. I have argued elsewhere that that criticism is amply justified. Generally speaking what drives the Bayesian school of thought is a desire for clarity and logical cogency. By contrast the orthodox statistical methodology is driven by what Jaynes describes as an ideological conviction that, if statistics is to be scientific, then probability distributions must be conceived as objectively real entities. To attain that ideological end orthodox statisticians are willing to make whatever sacrifice of logical coherence seems necessary.

Happy Thanksgiving.

26-11-06 *Jimmy Hoffa's Bones* (to C. H. Bennett)

> "The hypothesis that there is an external world, not dependent on human minds, made of *something*, is so obviously useful and so strongly confirmed by experience down through the ages that we can say without exaggerating that it is better confirmed than any other empirical hypothesis."
>
> — Martin Gardner [and Chris Fuchs]

Just packing up and saw this on one of my transparencies, and thought of you.

26-11-06 *Sample Talk* (to R. E. Slusher)

By the way, here's a sample of my present talks, just in case you would need it for anything.

> Quasi-Orthonormal Bases for the Space of Density Operators
>
> Recently there has been much interest in the quantum information community to prove (or find a counterexample to) the existence of so-called symmetric informationally complete measurements (SICs). In this talk we show that there should be even more interest. For, under a robust measure of orthonormality for operator bases (one that does not build in any symmetry at the outset), one can show that SICs, if they exist, come as close as possible to being orthonormal bases for the space of density operators. Moreover, in contrast to the usual expression of the superposition principle (where bases are taken to be orthogonal sets of state vectors), writing a superposition principle in terms of SICs leads to a more intrinsically-quantum representation for quantum states. This is because the basis states, rather than being the easiest to eavesdrop upon (as the usual ones are), are actually the hardest. Furthermore, such states fulfill a few other extreme non-classical properties that make them very interesting. Because of all this, writing the quantum-state space in these terms gives hope for a direct derivation of it from a plausible information-theoretic constraint principle. Various aspects of this problem will be discussed.

28-11-06 *Funes + Borges* (to C. H. Bennett)

On the flight over, I read the Borges story you sent me. It was great and much more meaningful than I had expected it to be. That guy really builds atmosphere. Anyway, you were right: there is certainly a sympathy between my thoughts and Funes's. But in another aspect of it, there is also a significant sympathy with Borges's. Particularly the line "To think is to forget a difference, to generalize, to abstract. In the overly replete world of Funes there were nothing but details, almost contiguous details," struck me. Though, for me, the importance is not quite in "forgetting a difference" but rather in paying no attention to it.

You'll see the similarity between what I think of quantum measurements and this point of Borges's if you dare enter the attached file [my paper "Delirium Quantum"]. The appropriate part is Section 3, titled "Snowflakes."

28-11-06 *Whose Lagrangian?* (to M. A. Nielsen)

I'm shamefully ignoring a talk at QCMC in Japan at the moment. I'm writing because I just looked at the scheduled and discovered that you're not here. I don't know why, but I had it in my head that you were going to be here (maybe you were on an earlier schedule?).

Anyway, I was looking forward to talking to you. I had wanted to discuss a paper with you posted by Matt Leifer last week—its number is `quant-ph/0611233`. Particularly, I guess I wanted to know whether it alleviates any of your troubles about this whole Bayesian quantum state and operation business that Carl, Rüdiger and I are trying to develop. I remember your asking in Konstanz what good is the 'search' for a fundamental Lagrangian if they're subjective (in the Bayesian sense) anyway. And I remember your not looking too pleased with my answer (I also talked to Menicucci about this later)—fair enough, it wasn't a very good answer. But now we've got a little more to work with, so it seemed like a good time for me to *try* to develop some answers.

(Hideo's sitting beside me doing his email too. Two times shameful between the two of us.)

Michael's Reply

I haven't seen Matt's paper. I'll be curious to have a look, although it may take a while [...]

On the general issue: as I recall, I essentially asked whether or not the people who'd been searching for a single universal Lagrangian had been in search of a chimera. Your answer was, I think it's fair to say, rather equivocal — you didn't say "yes", but you didn't give a clearcut "no", either. Given the astounding success the program of searching for a Lagrangian has had, I think any answer short of a resounding "No" spells big trouble for the Bayesian program.

29-11-06 *Whose Lagrangian?, 2* (to M. A. Nielsen)

Quick question, upon which I'll then chew on the answer more slowly ... being careful to write you again only after you have some time to breathe. Suppose a classical world, as was supposed, for instance in the days of Gibbs and Boltzmann. Given the astounding success (at that time) of the canonical distribution for a wide range of statistical mechanical and thermodynamical calculations and predictions, would that have spelt big trouble for a Bayesian view of statistical mechanics?

Michael's Reply

I don't think the situation is at all analogous, for at least two reasons.

First, much of the importance of the "quest for a Lagrangian" is as a guide to how we as physicists should work, and not so much as a theory of how the world is (unlike stat mech). The Lagrangian viewpoint might be quite wrong, yet that wouldn't change the fact that it's been hugely useful as a guide to making progress. Indeed, even if it does turn out to be wrong, it's reasonably likely to be replaced by some similar guiding principle. If the Bayesian point of view says we shouldn't look for a Lagrangian, I therefore view that primarily as a strike against Bayesianism, not Lagrangians.

Second, the Bayesian point of view explicitly addresses some shortcomings of the old stat mech formalism. I doubt very much that you're claiming that this point of view is a serious contender for explaining some shortcoming in the modern approach to quantum field theory.

29-11-06 *The Funesian Path* (to C. H. Bennett)

Now that you've got me thinking about this issue more than I had been before, it seems I keep running across things that bring it back to the top of my attention. Reading the book *The Pragmatic Humanism of F. C. S. Schiller* in this lovely Japanese bath tub, I came across this passage:

> It is Aristotle's logic which is usually taken as the archetype of formal logic. However, the 'logical analysis of judgment' in anyone's hands is bound to come to failure if it discounts the personal intention and circumstances of the maker of the judgment. Thus Hegel's formula of judgment as identity in difference disregards the fact that identities

are always made or postulated by us through conscious disregard of those differences which we take for the moment to be irrelevant to the purpose of judgment.

29-11-06 *Thinking of Brad* (to S. J. Lentz)

Hi from Japan. I'm so glad to hear that Brad seems to have made it through the operation OK; I told so many people about it here yesterday, it became a topic of conversation. Tell Brad that there were a load of quantum information physicists in Japan worried about his health!

Thinking of Brad's interest with the *Eats Shoots And Leaves* thing, as I was lying here with jet lag, it dawned on me that you might take him this class of examples to think about. (It was one of the topics of the dinner conversation last night.)

- "Buffalo buffalo buffalo buffalo."

If you parse it right, you'll see that it's a proper English sentence! Not a lie. (Don't tell him right away, but one reading of it can go like this: "The buffaloes from the city Buffalo bamboozle their fellow buffaloes everywhere." The reason this can be made to work is because one spelling of the plural of the noun "buffalo" is "buffalo". When buffalo is used as a verb, it means bamboozle or baffle.)

But it gets worse, buffalo can also be an adjective. My Webster dictionary gives it this definition as an adjective, "of the kind of style prevalent in Buffalo, NY." So,

- "Buffalo buffalo buffalo buffalo buffalo."

is also a proper English sentence. (Those "Buffalo buffalo" are a very self-deceptive lot.) And it can actually be made still worse, with even more repetitions of buffalo, if you work at it.

And now here's a different kind of example—this one invented by Charlie Bennett many years ago. If you cycle through the words "toll, house, cookie, delivery, and truck" you can make an infinite number of meaningful, distinct concepts.[113] For instance,

- Toll (that's meaningful enough)
- Toll House (meaningful too)
- Toll House Cookie (you know what those are)
- Toll House Cookie Delivery (if we only had a company like that in Cranford!)
- Toll House Cookie Delivery Truck (a truck that delivers those delicious cookies)

Now here's where it starts to get fun.

- Toll House Cookie Delivery Truck Toll
  (it's silly but it's meaningful; it's a special charge required for toll house cookie delivery trucks to use the road)
- Toll House Cookie Delivery Truck Toll House
  (ok, those trucks have to take a special lane when they pay their tolls)

[113] Charlie also has a method of modifying this example so as to produce a *continuous infinity* of meaningful, distinct concepts!

- Toll House Cookie Delivery Truck Toll House Cookie
(a toll house cookie that happens to be in the toll house cookie delivery truck)
- Toll House Cookie Delivery Truck Toll House Cookie Delivery
(not much market for it, but a very specialized company that delivers toll house cookies from the original toll house cookie delivery truck)
- Toll House Cookie Delivery Truck Toll House Cookie Delivery Truck
(and that's the truck employed by that weird delivery service)

You get the pattern now. And it can be made to go on forever, if you think about it. For instance, those weird delivery trucks from the last example could also be tolled. And there must be a place from where that toll is taken. And so on, and so on, and so on.

When Brad's ready to think a little, see if he enjoys these.

30-11-06 *Early Morning Rabbits* (to D. Gottesman)

It's not very conclusive evidence, but it is along the lines of what I thought I remembered hearing:

> There is another myth that says that there are rabbits on the moon making mochi, pounding away with their mochi maker, since there is a rabbit shaped series of dark areas on the moon, according to Japanese myth ... then there is another myth that Tsuyoiko's rabbit is descendant from the rabbit on the moon ...

The more important outcome of this, though, is that I learned that the rabbit I have been "seeing" all these years is quite different from the "official" image: See:

`http://en.wikipedia.org/wiki/Moon_rabbit`.

01-12-06 *Chris's House from Space* (to K. R. Duffy)

Ahh Ken, I miss you! I myself wouldn't say it's burnt Lamborghini orange—a little more subtle than that—but if having Lamborghini in the name will help me sell the place when the time (eventually, surely) comes, I'll use it liberally. Attached is a colorful picture for your further pub stories.

And while I'm here, let me advertise the opening of the Orange House Quantum Information-Foundations Seminar Center. That's what's in the second picture. My girls have agreed to rent the space out from time to time, as the needs of science require. Since that picture was taken, the two front columns have been rigged with fasteners for holding a large (green) chalkboard across the front, when meetings are in session. (If you look carefully, you'll notice that the main walls are constructed completely of doors; there are 12 in total. Kiki ripped them out of a nearby 1890's house. And bless her soul, she built the whole place by herself, from floor to roof, without an ounce of help from her worthless husband or anyone else.)

I should send you a picture of the newest member of the family too, but I won't clog the airwaves. Kiki decided that our retriever Murphy shouldn't be alone. So, he now has a spry little border collie companion, Beamish. Now, don't you think Ireland made some impression on us?

Finally to answer your question: Yes, the house can be seen on Google Earth ... but not because of the color! It's an old photo, most likely from a time before we purchased the house (the old roof can still be seen, and that is one of the first pieces of construction we had done). Here are the coordinates, which I had written up for a relative some time ago: [...]

Too bad you can't see the orange.

Greetings from Tsukuba Science City! Wish you guys were here. I'll try to get Charlie Bennett to send you pictures of the (before-cooked) menu selections he, Bill Wootters, and Lev Levitin had the other night. I don't recall the animal, but three of the items were "womb", "rectum", and "kidneys"—I nearly fainted at the sight.

03-12-06 *Our Stuff* (to M. Sasaki)

I found the Bartlett paper on the web, i.e., the one he presented to me at the poster session. You might enjoy it too; it is: `http://www.arxiv.org/abs/quant-ph/0608037`.

As you find some free time, let us develop this theory of ours more!

Thank you again for providing me with a wonderful week. I truly enjoyed this meeting. I think it was a great success.

05-12-06 *The Future of Quantum Information* (to O. Hirota)

I just wanted to write you a short note of thanks for making it possible for me to come to Japan. The meeting was wonderful; I learned so much from it. Particularly I was happy for the venue it gave me to continue my debate with Charlie and the progress I made therein. The issue is not just one of philosophy, I think, but rather something that will give rise to deep technical issues, and through them, a new means to move quantum information forward. So, I should thank you too in proxy for "the future of quantum information"!

In that regard, let me point you to two excellent papers that demonstrate the more technical side of the debate:

- `http://www.arxiv.org/abs/quant-ph/0401052`
- `http://www.arxiv.org/abs/quant-ph/0611233`

If you have any students interested in such matters, I hope you will put them in the service of this army! More seriously, not everything between Charlie and me is a joke. Some of it leads to good equations!

06-12-06 *Fourth and Fifth* (to J. Barrett)

I'll address your points "Fourth" and "Fifth" right away, and I'll come back with a longer, more specific reply to your note as a whole maybe by the end of next week. (I'm just in the middle of significantly revising `quant-ph/0608190`, and that has to be done before I go to the APS sorter's session, which will block out my time through the end of this week.)

Funny that you bring these things up, because I've provisionally titled my Shimony festschrift contribution, "Even Quantum Bayesians Like a Little Ontology from Time to Time." Anyway, for a provisional (though overly poetic) answer, see

1. Sections 6 and 7 of my paper "Delirium Quantum"
2. Maybe also Section 4 in it, picking up at the paragraph that starts with "Why is this not solipsism?", and

3. the paragraphs below that were written in response to one of the points of one of the 4(!) referees for the present paper.

If these passages provoke any other thoughts or other questions in you, feel free to write me with them, and I'll try to incorporate the issues into my larger response next week. (I.e., feel free to mail me any further thoughts, just be prepared for my not replying for a little while.)

Remarks to a Referee of `quant-ph/0608190`

This paper does not emphasize it, but no, we do not mean "the facts we are talking about here are facts for everybody." We mean that the facts too are personal, though in a very careful sense.

We have tried to meld the phrase "fact for the agent" a little better than previously into its surrounding text—so that it is there at least as some shadow of our presently agreed upon view—but it will have to remain somewhat awkward in the present context.

A better exposition would have emphasized the full setting of our view, including some discussion of the ontological—i.e., noninstrumental—pieces of it. 1) There are two physical systems in the story of this paper. One takes the role of the agent—the possessor of subjective degrees of belief and the activator of the measurement process. The other takes the role of the object system. 2) What is being discussed when one speaks of gathering data in the quantum context is an interaction or transaction between the agent and the object. 3) Without the agent, there would be no quantum "measurement" to speak of, but without the object, there would be no means for the agent to obtain the data, the spikes upon which he pivots his probabilities (his subjective degrees of belief). 4) There are no other agents in this story. 5) We do not go any further than points 1-5 warrant by giving the data obtained in a quantum measurement an autonomous existence—for instance, as something beyond the agent's sensations. That would run into inconsistencies in a "Wigner's friend" scenario. Nonetheless, quantum measurement outcomes are beyond the control of the agent—they are only born in the interaction—and thus are not functions of the agent in the way that his degrees of belief are. The degrees of belief find their source in the agent (the subject); the outcomes find their source in the external quantum system (the object). But the outcomes lead back to the agent in that they are personal to him.

This does not mean that the agent-object interaction and its fuller consequences are not autonomous events in spacetime, but it does mean that if there are any such things, quantum theory is not directly concerned with them. In CAF's view, quantum theory takes its whole definition as a normative theory for organizing an agent's *personal* probabilities for the *personal* consequences of his interactions with external physical systems. The structure of the agent-independent world that lies behind quantum mechanics is, in the end, still codified by the theory, but only in a higher-order, more sophisticated fashion than had been explored previously—it is through the normative rules, rather than quantum states and Hamiltonians.

Unfortunately a more detailed account like this will have to wait for another paper.

Jon's Preply

Here's my own take. Parts at least are different from yours, so you might not like it.

First, both probabilities and quantum states are descriptions of degrees of belief and are thus subjective.

Second, quantum theory doesn't need to specify what these beliefs are about, or What is a measurement? any more than classical probability theory needs to specify a sample set, or What is a measurement? Classical probability theory has such broad application just because it does not specify the sample set, it can be applied to any betting scenario. Classical probability theory may be derived with Dutch book arguments. The hope is that quantum theory can be derived from similar arguments supplemented with a small number of physical postulates, which get us to Hilbert space, whence Gleason's theorem can take over. Quantum theory could then be applied in any betting scenario in which those postulates are true.

Third, classical probability theory on its own is not a theory of physics, it is a tool that can be applied in physics. A theory of physics needs to specify an ontology of events that agents can, at least in principle, bet on. Thus Newtonian mechanics gives an ontology of events (system at particular point in phase space at time t) that one could in principle bet on. Newtonian mechanics plus classical probability theory gives Liouville mechanics. By the same lights, quantum probability theory needs to be supplemented with a theory of physics that provides an ontology of events to bet on.

Fourth, at present we have only a provisional, half-baked theory in which these events are "outcomes of interventions". But a fundamental formulation of a complete theory must not use such vague terminology, and will eventually supply an ontology of primitive events that agents can in principle bet on.

Fifth, the relationship between this fundamental theory and current theory need not be anything so simple minded as a hidden variable interpretation of quantum theory, in which the fundamental theory supplies instruction sets, and quantum states are distributions over instruction sets. In this light, worries along the lines of, "but hidden variables must be contextual" are too shallow. In a fundamental theory, space and time themselves may well be emergent, in which case worries along the lines of "but hidden variables must be nonlocal" are also too shallow.

As I understand you would resist the fourth and fifth here, insisting that quantum theory is complete and fundamental, that the objective events I speak of are not supplied by further physical theory, but are simply "outcomes of interventions", and that pace Bell, "Against Measurement" etc, there is nothing wrong with this. But might I ask why? The view I outlined seems supported by many of your arguments, in so far as quantum states are subjective. It is relatively humble (physics is not there yet, it's not even close). It also avoids mysticism (we will never understand the universe, it's too ineffable, thus don't aim for a god's eye view, just predict measurement outcomes).

06-12-06 *Made Wrong* (to J. Barrett)

Another quick point before I fade out of contact. With regard to:

Barrettism 1: *What is my point? Just that beliefs, described by quantum states, can be objectively right or wrong, and we are forced to this point by the need for objective outcomes of bets. This need not imply a complete instruction set for every quantum system. But it does imply that a theory must specify an ontology of events that give objective wrong status to (at least some) quantum states.*

Go to the file titled "Cerro Grande II" at the very bottom of my webpage, and in it do a search on the phrase "made wrong". The essays surrounding that phrase may go a little way toward explaining my take on what you just said. This very point is why I keep stressing the resemblance between quantum mechanics and pragmatic theories of truth—James, Schiller, Dewey—rather than correspondence theories, which, I think, lies in the background of your remark.

07-12-06 *0611283* (to C. H. Bennett)

Bennettism 31: *I never liked GRW much, but this paper, rather rudely refuting the infamous "Free Will" paper, mentions our differences in its introduction, e.g. my seeking for a quantum theory in which the observer plays no role.*

Well, I'm all for getting rid of the observer. But my strategy has always been to try to isolate which parts of quantum theory are explicitly about observers, and which parts aren't. I don't believe the latter is an empty set. But I don't believe the former is an empty set either—thus it needs to be carefully excised, and that is what I've been shooting for for a long time now. Perhaps I'm wrong, but I view it as a very careful approach, whereas things like GRW strike me as sheer speculation, based on rather fantastic ideas.

I'll look at the paper you recommend later tonight (I'm in DC, gonna go see some monuments before it gets dark).

In the meantime, do send me a copy of your Tsukuba talk. I want to think about it again.

07-12-06 *Adding and Subtracting* (to C. H. Bennett)

Here's another way to put what I wrote to you in the last note that strikes me as a possibly useful formulation. Traditionally the tack that's been taken in trying to recover an observer-free quantum mechanics (i.e., the thing you say you're seeking) has been in trying to *add* something to the raw formulation:

Bohm $\longrightarrow$ hidden variables
GRW $\longrightarrow$ a collapse mechanism
Everett $\longrightarrow$ a plethora of unseen worlds

What I say of myself is that I too am seeking an observer-free formulation of the content of quantum theory. But where I differ from the pack above is that, rather than adding anything to it to get the job done, I think it's just the opposite: Some elements need to be taken away. There's too much stuff in quantum theory as it stands—for, some of it is explicitly about observers. (Otherwise there wouldn't be such a resemblance to good Spekkens' toy theory ... which is, by construction, about states of knowledge.)

07-12-06 *The Cantankerous Colleague* (to R. Schack & C. M. Caves)

It's a little after 12:30 AM, December 7, and I think I'm going to call it quits for now. I'll ship you all the changes I've made, along with replies to the referees, and a list of most changes (with explanations for why I made them). It's my hope that Carl will be able to download these things and read them before we meet this afternoon. (Be careful to take your blood pressure pills first.)

I think I have pretty much covered everything, except:

1. Referee 2's point about extending the discussion of the distinction between "truth" and "probability 1". That's probably an important point, but given the contention between us, I didn't feel like going into this now. And maybe we shouldn't touch it at all ... ever.

2. The needed extension of text around the sentence, “The main issue here is whether there is any difficulty with the idea of an utterly certain belief about an admittedly contingent fact.” I think we can profitably build something based on a reply to Timpson’s criticism (pasted in the referee replies document for your convenience). It’s quite an important point I think, but I’ve just lost steam now.

Finally, I think it would be useful to give Mermin some more extended replies. Particularly we should say something about why this point he keeps bringing up—the one about how we should simply focus on never making probability-1 statements—is irrelevant, and just plain off the point.

In total, at this late stage, I don’t like the paper very much. Mermin’s report, but maybe more so Referee 4’s, made a big impression on me. I became ashamed of myself, knowing that I knew better and that if I had just been more engaged this year, maybe everything would have been OK. Rüdiger is right:

Schackcosm 94: *But without the joint effort it would not have been written at all. And are you really confident that any of us would have written a better paper by himself?*

It likely would not have been written, but I don’t know—the main delay on it, I think, was the issue of consensus. Certainly, I am not confident that I would have written a better paper by myself, but it would have been a very different paper. I’ve come to detest this business about the Copenhagen interpretation that runs throughout it. I’ve tried my best to cover us against the community, but in my heart I know it’s basically a lie (there’s plenty of stuff out there on Bohr and Pauli that slaps us right in the face). I don’t like that we never got “metaphysical” in the paper anywhere—without the imagery in the background, most readers will think that there’s little but another version of positivism in it (the world is sense impressions) and/or they’ll bring in their prejudices about what “facts” and “truth” are (correspondence and coherence theories), ones that I certainly don’t share and I know that I could guard myself against in a paper that didn’t demand consensus. You think you guard against those misimpressions by being quiet about them; I think it’s just the opposite. Mermin’s frustration was acute. And the issue of the exception to the subjectivity of probability—I find it so dangerous and so distasteful.

The trouble is my mother didn’t raise a very self-confident son. For some reason, on this project—this now 5-year-old project—I urgently felt the need for consensus between the three of us. Consensus was never reached in any but a superficial way. We would have been better off to all write our own papers on our own thoughts. The papers would have been finished long ago, and we could think in a civilized way how we agree or disagree with each other and maybe make some progress that way.

07-12-06 *Changes I Made To Certainty* (to R. Schack & C. M. Caves)

Changes in Section 1

- Abstract. Why did I change the abstract? Predominantly because I was bothered by this sentence: “In this paper we investigate the concept of certainty in quantum mechanics, *because* it is the with-certainty predictions of quantum mechanics that highlight the fundamental differences between our Bayesian approach on the one hand and Copenhagen . . . ” This paper has slowly been morphing into a referendum on us against Copenhagen and I don’t like that. For one thing, I don’t know what the hell the Copenhagen interpretation is and no one else does either, and that is just setting ourselves up for years of pain (as effectively Referee

4's report attests to). I wish I hadn't allowed it to get this far, but I did and I can't back out now. All I can try to do now is temper the damage, and then run for the hills as soon as I'm finished with this project. In Rüdiger's very first draft the word Copenhagen appeared 17 times; by the time we submitted to `quant-ph`, the paper contained 28 instances. Now, with Carl's latest modifications, we have 33. We would have been better to never mention it once.

- Abstract and throughout paper. I replaced all instances of "with-certainty" with "probability-1". I'm not adamant about this, but the new phrase did strike me as unneeded, and that the reader would more easily have a sense of what "probability-1" means and where the paper is going than taking a time to ponder over what we might mean with this never-before-seen adjective "with-certainty." There were only four instances of "with-certainty" in the whole paper anyway.

- Abstract. Left Stairs reference, but took out phrase "originally due to" and replaced it with "of." Don't want our abstract to seed a priority battle (even though Stairs says that there is a version of the argument in his 1978 thesis, predating Heywood-Redhead significantly). Anyway, in this way, our statement is certainly true: I don't understand the Heywood-Redhead paper (so we can't be giving a version "of" their argument).

- par. 2. Too repetitive, so I trimmed it down. Also made the logic flow a little better, and tried to tone down the "fact for an agent" which sticks out like a sore thumb. See discussion with Referee 4 for this point. Got rid of the parenthetical "(or results)" because we just don't use that terminology so much—doesn't need to be introduced. Modified footnote on "eliciting"—I don't like power-packed long sentences.

- par. 3. Got rid of the "generally." Didn't see any need for it, as we make no admission to other kinds of conditionalizing, like Jeffrey, etc., in this paper. Changed "probabilistic argument" to make Referee 4 happy. Also changed "functions of" to "depend upon" because Referee 4 raised a flag.

- par. 3. Also changed "probabilities must obey" to "gambling commitments should obey" to make my Darwinian side feel better, also to head off the reading of the statement as a tautology.

- par. 5, 6. "theory" $\longrightarrow$ "world". Added "purview" and all kinds of stuff like that. I took out the parenthetical "(the Born rule)" because people are not always so specific—they just like to flippantly throw out the phrase "specified by physical law" and act as if that means something obvious. I know that you added that, Carl, to help introduce the next paragraph and to help it not seem so out of place (which it indeed is). In general, I tried to round a lot of edges, connect things better, and build up to the next paragraph.

- par. 7. Fundamentally reworked.

- par. 8, 9. In line with what I said above in the abstract, I changed descriptions to "our main aim" and "along with this." The reason I added "more carefully address" is because previously we had already said, "We have shown in a series of previous publications that ... all probabilities in quantum mechanics can be interpreted as Bayesian degrees of belief .... A consequence of the Bayesian approach is that all quantum states, even pure states, must be regarded as subjective." I also got rid of a little bit of repetition. Also I backed off some instances of "the Copenhagen interpretation", and in places where the phrase "and similar interpretations" were invoked, I replaced it with the more compact "Copenhagen-like interpretations." Note also that here and there (this paragraph and others) I peppered the phrase "agent-independent" to get across the idea of what is different in the Copenhagen-like interpretations.

- (what had been) par. 10. I've always thought this comment about not commenting on other interpretations had no natural place. So, I've decided to place it in a footnote. I think it much less breaks the flow this way.
- 4th par. from last. Added, "even when derived from the "ultimate measuring instruments" of Ref. [114]," again to address Referee 4's concerns.
- Sect. 1, 3rd and 2nd par. from last. Tightened up greatly to reduce repetition of previous paragraphs and also modified some language to try to alleviate confusion (of the sorts Timpson had). Changed "originally due to Stairs" to "of Stairs" and also gave credit to Heywood-Redhead and Brown-Svetlichny as "independent" variations on the theme. Also inserted "noncolorability" to better set apart the KS result from itself being a full no-preexisting-property proof.

Changes in Section 2

- par. 1, last sentence. Changed to "we shall say that that facts are objective in the sense that ..." to make it a little clearer that this is our definition of objective, rather than a categorical statement (potentially carrying the reader's own connotations, rather than ours).
- par. 2, last sentence. Removed 'in probability theory' because a) we don't elaborate on what that means, and b) because it created too many questions in Ref. 2.
- par. 3. 'takes this category distinction seriously' $\longrightarrow$ 'takes this category distinction as its foundation'.
- par. 4. Added "predominantly" because I modified (extended) the quantum discussion at the end of the section.
- 2nd par. of PP discussion. Changed 'typical' to 'exchangeable' because typical conveys the sense the there is a correct class of priors. Why not be specific? Stripped away the closing sentence, "The whole idea, however, is plagued with a fundamental conceptual difficulty" because it is not at all justified by our nonquantum, coin toss example. It can't be a "fundamental conceptual difficulty" if it potentially works in the quantum world. So, I played up the point that instead that chance simply serves no useful role.
- 3rd par. of PP discussion. Built a new transition into this paragraph.
- Last par. Drastically reconstructed to take into account Referee 4's point about how we have the logic of the issue backward. Also humbled the presentation somewhat.

Changes in Section 3

- par. 4. I removed the parenthetical phrase "(often called the *model*)" (and the single further instance of "model" later in the paper), because I saw no use for the terminology. No need to introduce an essentially unused term. I also italicized "exception" and introduced an endnote

[114]Letter from Niels Bohr to Wolfgang Pauli, 2 March 1955 (provided to us by H. J. Folse).

to distance myself from the "exception pack"[115]. By the way, I think the paper would be distinctly better if we could turn off this annoying feature of the REVTEX 4 style file that turns footnotes into endnotes. Independent of my definitely wanting this note of mine to be seen, it would help ensure that *all* notes aren't simply overlooked as references, and the reading would flow easier. Is there anything in the paper that distinctly depends on the REVTEX 4 style? We are almost surely going to have to change style for submission to SHPMP anyway.

Just to be snide, by the way, I will point out that the following sentences of Carl's latest draft (i.e., the one just before my present modifications)

1. "We first review the main arguments for the general claim that probabilities always represent degrees of belief." [in the abstract]
2. "The updated probabilities always depend on the agent's prior probabilities as well as on the data and thus can be different for agents in possession of the same data." [in the introduction]
3. "We argue, following de Finetti [116], that in the last analysis probability assignments are always subjective in the sense defined earlier." [again in the introduction]
4. "We emphasize that certainty is always an agent's certainty . . . " [once more in the introduction]
5. "Probability assignments are not arbitrary, but they always have an irreducibly subjective component." [in section 2]

are in direct conflict with the *exception*. Similarly, without a more careful statement, this

6. "Probabilities for outcomes or data are not facts." [back in the introduction again]
