is in conflict too: For one would have to be careful that the probabilities being spoken of here are distinctly not conditional probabilities, or at the very least, when they are conditional probabilities, a further analysis of their subjective status is required.

Now, that said, *I do not advocate changing statements* 1 *to* 6. All I'm trying to do in my snideness is give you a feel for how *ugly* a formulation the paper would take on if you were consistent with yourselves. For instance,

1'. "We first review the main arguments for the general claim that probabilities sometimes represent degrees of belief."

2'. "The updated probabilities mostly depend on the agent's prior probabilities as well as on the data and thus can be different for agents in possession of the same data."

[115] This was the footnote (it did not ultimately appear in print): "One of the authors—CAF—strongly dislikes exceptions on matters of principle, and the present exception is no exception. The problem, *as he sees it*, with the formulation that there is a case whereupon a fact strictly determines a probability is that it puts the horse before the cart: It acts as if abstract 'logical implication'—a statement of the form "$d \Rightarrow h_0$"—has a meaning independent of the *subjective* judgment "$\Pr(d|h) = 0$ for $h \neq h_0$." (See for instance, F. C. S. Schiller, *Formal Logic: A Scientific and Social Problem*, (Macmillan, London, 1912), and F. C. S. Schiller, *Logic for Use: An Introduction to the Voluntarist Theory of Knowledge*, (G. Bell, London, 1929), for a development of this point.) Therefore the reader should associate neither the sentence of text cited by this endnote, nor the three sentences following it, with the views of CAF. Since it is CAF's belief that these sentences undermine the very consistency of the quantum Bayesian point, it is a lucky thing that, *from his point of view*, they are not actually used anywhere in the paper's argumentation. Instead, they should be treated as dangling appendages that will be surgically removed in any subsequent CAF publications."

[116] B. de Finetti, "Probabilismo," Logos **14**, 163 (1931); translation: "Probabilism," Erkenntnis **31**, 169–223 (1989).

3'. "We argue, following de Finetti, that in the last analysis probability assignments are fairly often but not always subjective in the sense defined earlier."

4'. "We emphasize that certainty is *always* an agent's certainty ... except in those cases when it is not"

5'. "Probability assignments are not arbitrary, but here and there they have an irreducibly subjective component."

Remind me: Just what "possible misunderstanding" is this *exception* supposed to be saving the reader from? I've never seen that it leads anywhere other than to weakening our argument.

- Fourth par. from last. I instated a parenthesis around the 'nontrivial'. I figured if you allowed the parenthesis once a few paragraphs above, you'd allow it again.

- Par. where state preparation is given an equation. Deleted "essentially," because it struck me as apt to confuse—implying that there are exceptions. Also took out "thus the posterior state is independent of the prior state" for reasons of repetitiveness.

- Par. starting with "The quantum operation depends, at least partly ... " I have changed the logic of this argument because I feel that Referee 4 is right—it's just the problem of trying to say all this crap about the "Copenhagen interpretation." It is dangerous business. For instance, it's really hard—probably impossible—to reconcile these things we say with a passage like this one (drawn from Plotnitsky's book *Complementarity*):

  > Bohr insists that indeterminacy affects the interaction, and thus the possibility of sharp distinction, between the measured object and the measuring instrument, since both must be treated as quantum systems (PWNB 1:11; PWNB 2:25-26, 72-74).

  And anyway, I have always felt uncomfortable putting so much weight on a "church of the larger Hilbert space" view of state preparation. As far as I am concerned, the really only conclusive argument (for the subjectivity of operations) is the one we present in the two paragraphs preceding this one:

  > It is tempting to conclude that objective facts, consisting of the measurement outcome d and a classical description of the preparation device, determine the prepared quantum state σ. This would violate the category distinction by allowing facts to fully determine (nontrivial) probabilities derived from σ. What this can only mean for a thoroughgoing Bayesian interpretation of quantum probabilities is that the posterior quantum state σ *must* depend on prior beliefs through the quantum operation.

  It was fine to have the church argument lying around as a heuristic to help convince people (like Carl) if needed, but when it is touted as 1) the ultimate reason for the subjectivity of operations and 2) an explicit contradiction to Bohr and the like, then it gets dangerous. Because then every amateur reader of Bohr out there can be in a position to pounce.

  We say in the last draft,

  > Classical facts cannot suffice to specify a preparation device completely because, among other things, a complete description must ascribe to the device an initial quantum state, which inevitably represents prior beliefs of the agent who is attempting to describe the device.

Now, it was I who inserted the phrase "among other things," but that really didn't go nearly far enough to save my conscience from agony. Delete it, as almost surely no readers will take note of it anyway, being such a slight deviation from the rest of the flow, and what do you get?

> Classical facts cannot suffice to specify a preparation device completely because a complete description must ascribe to the device an initial quantum state, which inevitably represents prior beliefs of the agent who is attempting to describe the device.

Would Bohr himself buy that? (Carl will be quick to say that he doesn't give a damn what Bohr would say. But without some firm foundation for this great enemy that we're supposed to be fighting, 'the Copenhagen interpretation', we're just erecting a straw man that we're taking pleasure in kicking down. Mermin alluded to this, and so did Referee 4, and, honestly, in my own head I've always thought it.)

Here's a nice passage from Asher Peres's paper "Karl Popper and the Copenhagen Interpretation":

> Quantum mechanics provides statistical predictions for the results of measurements performed on physical systems that have been prepared in specified ways (Peres, 1995). (I hope that everyone agrees at least with that statement. The only question here is whether there is more than that to say about quantum mechanics.) The preparation of quantum systems and their measurement are performed by using laboratory hardware which is described in classical terms. If you have doubts about that, just have a look at any paper on experimental physics. The necessity of using a classical terminology was emphasized by Bohr (1949) whose insistence on this point was very strict:
>
>> However far the [quantum] phenomena transcend the scope of classical physical explanation, the account of all evidence must be expressed in classical terms. The argument is simply that by the word 'experiment' we refer to a situation where we can tell others what we have done and what we have learned and that, therefore, the account of the experimental arrangement and the results of the observations must be expressed in unambiguous language with suitable application of the terminology of classical physics.
>
> The keywords in that excerpt are: classical terms . . . unambiguous language . . . terminology of classical physics. Bohr did not say that there are in nature classical systems and quantum systems. There are physical systems for which we may use a classical description or a quantum description, according to circumstances, and with various degrees of approximation. It is according to our assessment of the physical circumstances that we decide whether the q-language or the c-language is appropriate. Physics is not an exact science, it is a science of approximations. Unfortunately, Bohr was misunderstood by some (perhaps most) physicists who were unable to make the distinction between language and substance, and he was also misunderstood by philosophers who disliked his positivism.
>
> It is remarkable that Bohr never considered the measuring process as a dynamical interaction between an apparatus and the system under observation. Measurement had to be understood as a primitive notion. Bohr thereby eluded questions which caused considerable controversy among other authors (Wheeler and Zurek,

1983). Bohr willingly admitted that any intermediate systems used in the measuring process could be treated quantum mechanically, but the final instrument always had a purely classical description (Bohr, 1939):

> In the system to which the quantum mechanical formalism is applied, it is of course possible to include any intermediate auxiliary agency employed in the measuring process [but] some ultimate measuring instruments must always be described entirely on classical lines, and consequently kept outside the system subject to quantum mechanical treatment.

So, I think, Bohr would reject our very starting point. How can we really argue that he'd be wrong in rejecting it? We'd say, "But you're not really giving a complete description of the ultimate measuring device because a complete description must ascribe to the device an initial quantum state." He'd say, "Young men, you just don't understand the practice and scope of quantum mechanics."

OR, if I wanted to play like Bohr anticipated us all along, I think I could actually pull that off too. For I can think of a completely different reading of Bohr where he might have been in essential agreement with us and even gone on to refine the point. For instance, he might say,

> Right you are young men that there is an essential subjective character in state preparation—that's what Plotnitsky was reporting on my behalf—but what do you think I meant by saying, "The argument is simply that by the word 'experiment' we refer to a situation where we can tell others what we have done and what we have learned and that, therefore, the account of the experimental arrangement and the results of the observations must be expressed in unambiguous language with suitable application of the terminology of classical physics."? I meant that two agents have to have common enough priors that they can actually speak to each other—there has to be enough intersubjective agreement that they're in the same 'language game.' Didn't you read Bernardo and Smith, who say:
>
> > There is an interesting sense, even from our standpoint, in which the parametric model and the prior can be seen as having different roles. Instead of viewing these roles as corresponding to an objective/subjective dichotomy, we view them in terms of an intersubjective/subjective dichotomy. To this end, consider a *group* of Bayesians, all concerned with their belief distributions for the same sequence of observables. In the absence of any general agreement over assumptions of symmetry, invariance or sufficiency, the individuals are each simply left with their own subjective assessments. However, given some set of common assumptions, the results of this chapter imply that the entire group will structure their beliefs using some common form of mixture representation. Within the mixture, the parametric forms adopted will be the same (the *intersubjective* component), while the priors for the parameter will differ from individual to individual (the *subjective* component). Such intersubjective agreement clearly facilitates communication within the group and reduces areas of potential disagreement to just that of different prior judgements for the parameter. As we shall see in Chapter 5, judgements about the parameter will tend more towards a consensus as more data are acquired, so that

> such a group of Bayesians may eventually come to share very similar beliefs, even if their initial judgements about the parameter were markedly different. We emphasize again, however, that the key element here is intersubjective agreement or consensus. We can find no real role for the idea of objectivity except, perhaps, as a possibly convenient, but potentially misleading, "shorthand" for intersubjective communality of beliefs.
>
> When I am talking about the ultimate measuring instrument, I am talking about precisely the situation where there is intersubjective agreement between agents. So, you can purify the description of measurement if you wish (i.e., ascribe a quantum state to the preparation device), but then there is no further subjective freedom in those quantum states, for those hypothetical agents would be so in disagreement that they will not be able to communicate with each other. That is to say, I say it's time for a classical description of a measurement device just at the moment where your argument about the subjectivity of states no longer holds for two disparate agents.
>
> A complete description of a preparation device is a fact? Who said anything about facts? I didn't.

This is why I think we have really worked ourselves into a corner—and done our relatively clear initial thoughts a disservice—by making the phrase 'the Copenhagen interpretation' such a focal point.

But there's not much that can be done about this now, without scrapping the whole project. Thus rather than attempting to delete the argument (which I'm sure would create an outcry like never heard before), what I propose is that we change the logic of the argument (and then only slightly ... enough to get us through the night). The flow used to be "a complete description of a preparation device *requires* that a quantum state be ascribed to the device." To at least stave off the Bohrians-in-the-know a little bit at this point, and to frame the argument more in terms that I can agree with, here's what I changed it to. 1) Take any purported agent-independent, complete classical description of the preparation device. 2) That description can always be 'quantized' into one in the church of the larger Hilbert space, i.e., one of the variety we discuss. But then, 3) the latter description of the process clearly has a subjective element in it in the form of a prior quantum state for the device. 4) Since there is no operational distinction between the descriptions, either the initial quantum state in the latter description is in fact objective (contrary to our assumption), or the initial purported classical description had a subjective element in it that was unacknowledged previously.

By the way, let me just put it down for the record why I'm not all that attracted to going to the church of the larger Hilbert space to justify the subjectivity of preparation operations. The reason is that it is effectively like saying that to prove the subjectivity of conditional probabilities you have to start from the subjectivities of the joints and the marginals. But the conditional should not require the existence of a joint distribution before its own existence—it is a stand-alone entity, as Rüdiger emphasizes in his classes. And so, its subjectivity is stand-alone too. Similarly, I would say, for quantum operations.

Changes in Section 4

- par. 2. Changed tense in this paragraph. Deleted the use of "with certainty" that confused Referee 2.

- par. 3. Changed 'incomprehensible' to 'inconsistent' for Referee 4.

- last par. Deleted 'the quantum state of' because 1) my previous railing on church-of-the-larger-Hilbert-space justifications, and 2) because it gives the impression one can have beliefs about the (true) quantum state, rather than admitting forthrightly that quantum states are beliefs. Also added "that is true or false of the system" to "The statement that the measurement outcome is 1 with certainty is thus not a proposition, but an agent's belief—and another agent might make a different prediction." for the purposes of Referee 2.

Changes in Section 5

- par. 3. Added "external to the agent" to guard against those who would ask, "What, the agent is not part of the world?" I think that's as far as we want to go anyway.

- last par. "slippery slope" ⟶ "path" The former seemed too alliterative for the Rüdigerian style we had settled on. Also, it seemed too judgmental to be stated without back-up.

Changes in Section 6

- par. 6. Added reference to Garrett.

- par. starting "It might still be ..." Add "if he is bound by a classical worldview" to the last sentence.

- par. starting "For instance, take a complete ..." Changed "raw" to "bare"—seemed less harsh that way (I'm sensitive because of Carl's "meaty" jokes). Also added "law-of-thought" as an adjective to help emphasize the point. "shows its head" ⟶ "shows itself"

- Last paragraph. Deleted "of the world"—didn't seem needed in that context. "dogged" ⟶ "plagued" (I had gotten carried away previously). "finally" ⟶ "most importantly" (didn't want an overuse of finals). Changed "what features of the quantum formalism" to "what features of the quantum formalism beyond the ones discussed here" just to make it clear that we had already discussed some.

07-12-06 *(Select) Replies to Referees* (to R. Schack & C. M. Caves)

Replies to Referee 1

> **Referee:** In fairness to Copenhagen shouldn't you add that though Copenhagen holds the quantum state to be objective in the sense you describe, this (by itself) does not imply that the state is an objective property of the system to which it is assigned. Surely Bohr would never have said such a thing. It is an objective property of the "whole experimental setup" which includes both the system and the preparation device. You do indeed say this a little further down the page, but only reluctantly ("perhaps supplemented by..."). You seem to be trying to make Copenhagen sound worse than it is.

Agreed. We softened the language and made the enemy more specific throughout the paper. You are correct that Bohr would have likely called the quantum state (though he rarely spoke of quantum states) as an objective property of the "whole experimental setup". What he failed to realize though—in CAF's reading of Bohr—was the dependence of the phrase "whole experimental setup" upon an agent's judgment. (An interesting exchange between Bohr and Pauli from 1955 bears this out to some extent.)

> **Referee:** "The main issue here is whether there is any difficulty with the idea of an utterly certain belief about an admittedly contingent fact." Yes indeed. And this is the issue that underlies most of my concerns about your not paying enough attention to what constitutes a fact, and not giving any example of the certain beliefs of two agents that underly different state assignments. This is central to your argument. Is a reference to de Finetti all you're going to give the reader? (This reminds me of a friend who was receiving Catholicism lessons from a priest so he could be married in a church. He kept asking the priest why he should believe in the immaculate conception, and then why he should believe that an angel had announced it, etc., until he got to a point where the priest said triumphantly, because German scholarship has established it.) Surely you owe your readers some gloss on de Finetti, or an explanation of why he is not central to your case.

You are quite right about this, and initially we tried to fill in the gap here. But then we realized it was too large a task to try to bite off in a "committee report" and, we backed off. So we removed the paragraph completely. Further elucidation will have to await another publication.

> **Referee:** I once read somewhere in Jaynes that no Bayesian would take $p(h) = 1$ for any h other than a logical tautology, because no acquired data whatever could then permit updating the probability to anything less than 1. I assume that what he meant was that since $p(d)$ in (2) is the sum on h of $p(d|h)p(h)$, then $p(d)$ is necessarily equal to $p(d|h)$ when $p(h) = 1$.
>
> Given this, why isn't your entire paper about a situation (certainty) that no self-respecting Bayesian would ever find himself in? Presumably the reason it interests you is that quantum theory does assign $p = 1$ to certain data given certain state assignments, and this requires some interpretation. But then shouldn't the position of the Bayesian be that pure state assignments are ideal limiting cases that one can never encounter in practice? Analogous to initial conditions specified to infinite precision in chaotic classical dynamical systems. (You have seduced me into making dubious classical analogies.) All physically achievable states are mixed states. A pure-state assignment should not be viewed as subjective, but as impossible. A quantum operation may well be subjective but this has nothing to do with pure states being subjective, because there is no physical quantum operation that prepares a pure state. The best you can ever do is prepare a mixed state of very low entropy.

One of us—CAF—has never seen the relevance of this point (which the referee has made previously in other contexts) for what is at issue here. CMC, on the other hand, says, "This is an interesting point that we are well aware of, but it is not a point we agree with, nor is it one we wish to deal with in this paper."

But, back to CAF. Your concern seems to be this. If one should, methodologically, never assign a pure state, then there are no handles by which to address pure states' subjectivity or objectivity. (In fact it seems, one should just write them out of the theory.) But that's not true. The Born rule tells us how to calculate probabilities from pure states—so the issue has to be adressed, and in fact there's something to be learned from it. If one has accepted all the arguments for (or simply the beauty and simplicity of) interpreting ***all*** probabilities as subjective, Bayesian degrees of belief, then one must conclude that the pure state has a subjective element or the measurement description has a subjective element or both have a subjective element.

Replies to Referee 2

> **Referee:** The category distinction between facts and probabilities is explained quite nicely. Nonetheless, the authors might wish to emphasize this point further. The confusion I have in mind (which might be my own) is the following one. It is typical to assert that assignments of probabilities 0 and 1 to a proposition are equivalent to assignments of truth and falsity to that proposition. If this is so, then one cannot say that "the truth value of a proposition is a fact" and simultaneously that no probability assignment is a fact. Presumably, the mistake is in identifying probability 0 and 1 with truth and falsity. Or, perhaps there is a more subtle distinction to be made between the actual truth value of a proposition and the truth value that an agent assigns to it (which might be different from the actual value). In any case, treating propositional logic as a special case of probability theory is sufficiently ubiquitous that more explanation seems in order here.

Indeed we all agreed with the referee on this point, but we could never come to great agreement among ourselves on how to handle the issue in the context of this paper—where much of the groundwork required to address it properly had not been laid. Thus, we added a small—perhaps confusing—footnote to nonetheless mildly address the issue. We will try to do your point better in further publications.

> **Referee:** It should be emphasized by the authors that they are making the strong claim that the Bayesian approach allows one to hold on to the assumption of locality. This is likely to be a very controversial claim and consequently should not be left implicit. Wiseman and others have argued that maintaining locality is only possible if one is willing to deny the reality of distant observers, that is, it is only possible if one is willing to adopt a solipsist view. The authors may choose not to address such issues in detail in this paper, but should certainly say more than has been said about locality in the Bayesian approach.

Wiseman (personal conversations with CAF) has never understood the category distinction we are making—and that is the root of his further misunderstandings. Since we have laid out the category distinction fairly carefully in this paper, we think we have said enough for the time being. There's only so much that can be done in one paper.

Replies to Referee 3

> **Referee:** The authors attempt to defend the following general thesis. There are no facts about probabilities in the world (see e.g. Section II). Attempts (e.g. Lewis's PP) to connect between probabilities and facts are highly problematic. Moreover, in principle the gap between probabilities and facts is unbridgeable. Probability assignments always have an irreducibly subjective component, essentially because they involve priors. This holds for both deterministic (e.g. classical statistical mechanics) and indeterministic theories (where the probabilities are given by dynamical laws, e.g. some versions of quantum mechanics).

This captures part of our paper relatively accurately.

> **Referee:** I agree that PP-style and similar approaches have problems. But this does not mean that probabilities are not grounded by facts. Here is a counter-argument to the above. Under quite general circumstances, it is provable that if an agent updates probabilities in accordance with Bayes' rule the probabilities will converge to the long term relative frequencies (for large enough samples), no matter what the prior probabilities are (except for priors equal to 0 and 1). The dependence on the priors (for large enough samples) washes out in the long run, and so the priors, however subjective, don't matter. The authors seem to be aware of this point (see p. 4, last paragraph), but they don't directly address it. The same argument applies also to the quantum mechanical probabilities and state assignments (Section III).

The counter-argument holds no water for a subjective Bayesian. 'Quite general circumstances'? For whom? For sufficiently distinct priors, there need be no convergence. What you point out is only true if two agents for whatever reason—perhaps simply because of their common genome—happen to adopt 'compatible' priors of one variety or other. We explore this issue in detail (particularly in the quantum case) in C. M. Caves, C. A. Fuchs, and R. Schack, "Conditions for Compatibility of Quantum-State Assignments," Phys. Rev. A **66**, 062111 (2002)—so, yes, we are aware of it.

The book by Bernardo and Smith that we cite in the present paper puts the issue very nicely:

> [T]here is an interesting sense, even from our standpoint, in which the parametric model and the prior can be seen as having different roles. Instead of viewing these roles as corresponding to an objective/subjective dichotomy, we view them in terms of an intersubjective/subjective dichotomy. To this end, consider a *group* of Bayesians, all concerned with their belief distributions for the same sequence of observables. In the absence of any general agreement over assumptions of symmetry, invariance or sufficiency, the individuals are each simply left with their own subjective assessments. However, given some set of common assumptions, the results of this chapter imply that the entire group will structure their beliefs using some common form of mixture representation. Within the mixture, the parametric forms adopted will be the same (the *intersubjective* component), while the priors for the parameter will differ from individual to individual (the *subjective* component). Such intersubjective agreement clearly facilitates communication within the group and reduces areas of potential disagreement to just that of different prior judgements for the parameter. As we shall see in Chapter 5, judgements about the parameter will tend more towards a consensus as more data are acquired, so that such a group of Bayesians may eventually come to share very similar beliefs, even if their initial judgements about the parameter were markedly different. We emphasize again, however, that the key element here is intersubjective agreement or consensus. We can find no real role for the idea of objectivity except, perhaps, as a possibly convenient, but potentially misleading, "shorthand" for intersubjective communality of beliefs.

Particularly, there is no requirement of nature that there must be intersubjective agreement of the type discussed. If it happens, it is often nice—it leads to less violent worlds for instance—but nature cannot decree it.

> **Referee:** p. 4, last par – I think that the authors don't address the real problem faced by any purely subjectivist interpretation of probabilities. Take for example classical statistical mechanics. The problem isn't about whether the uniform probability measure brings about the melting of the ice cube. Of course it doesn't.

Of course it doesn't? Like you, we would have said so. But you should not mock. To quote the reference [35] you bring up in your Point (8) below (i.e., J. North's paper) at length:

> There are two main, and to my mind fatal, problems with the epistemic view [of probabilities in statistical mechanics]. The first stems from the role the uniform probability distribution plays in explanations of thermodynamic phenomena. Consider the explanation of an ice cube's melting towards the future. If we take an epistemic view of the uniform distribution that is placed over its current macrostate, then part of the reason for the ice's melting will be our ignorance of its initial microstate. On the assumption that explanations of physical phenomena ought to be objective—and in any case not rely on our epistemic state—we should not maintain that part of the explanation that entropy increases (that ice melts, that coffee cools, that gases expand) is the extent of our knowledge. How could our epistemic state have anything to do with the ice cube's melting? This would be like saying that if we happened to be the kinds of beings who did have epistemic access to the initial microstate of the ice cube, then it might have behaved differently. It is also a consequence of this view that no matter what kind of world we live in, we must assume that the ice is most likely to melt towards the future. All of that seems crazy: we are after an objective, scientific explanation of thermodynamics.

We have added a more explicit reference to this paper, so that perhaps a reader will be led to it.

> **Referee:** The authors seem to imply (Sections V and VI) that the Bayesian approach to QM is local, since it doesn't assign determinate instruction sets (even in eigenstates). This, however, is completely mistaken. Assuming that measurements have outcomes, any local theory is committed to Bell's inequality. So any theory that produces the statistical predictions of quantum mechanics must be nonlocal, no matter whether or not it admits instruction sets.

'Completely mistaken' is a rather strong expression for a referee who hasn't shown many indications of having understood much of the point of view of the paper.

> **Referee:** The authors claim that there is no fact of the matter about probability assignment (including quantum states; Section VI). But they accept the Dutch-book argument (Section I). This is a contradiction. The Dutch-book argument presupposes that there are factual constraints (sure loss) on probability assignments.

It is not a contradiction. We view the Dutch-book argument as a normative principle—not a statement of fact or a property of the physical world. Our view is along the lines of these words from our Bernardo and Smith reference:

> What is the nature and scope of Bayesian Statistics ...?
>
> Bayesian Statistics offers a rationalist theory of personalistic beliefs in contexts of uncertainty, with the central aim of characterising how an individual should act in order to avoid certain kinds of undesirable behavioural inconsistencies. The theory establishes that expected utility maximization provides the basis for rational decision making and that Bayes' theorem provides the key to the ways in which beliefs should fit together in the light of changing evidence. The goal, in effect, is to establish rules and procedures for individuals concerned with disciplined uncertainty accounting. The theory is not

> descriptive, in the sense of claiming to model actual behaviour. Rather, it is prescriptive, in the sense of saying "if you wish to avoid the possibility of these undesirable consequences you must act in the following way."

Dutch-book coherence is something to strive for. For if not satisfied, an agent with any logical powers will see that his gambling commitments could lead, in the appropriate circumstances, to sure destruction.

To help abate misunderstandings like yours, we have changed the sentence in our Introduction reading

> The Dutch-book argument shows that, to avoid sure loss, an agent's probabilities must obey the usual probability axioms.

to

> The Dutch-book argument shows that, to avoid sure loss, an agent's gambling commitments should obey the usual probability axioms.

> **Referee:** Some items in the references list don't appear in the text, e.g. [10], [35].

We thank the referee for pointing out his likely identity.

Replies to Referee 4

> **Referee:** A final point about this passage: you write
>
> > The occurrence or nonoccurrence of an event is a fact for the agent. Similarly, the truth or falsehood of a proposition is a fact. Facts are objective; they are not functions of the agent's beliefs.
>
> What work, precisely, is the modifier 'for the agent' supposed to be doing here? It comes across as slightly odd to say that occurrence is a fact 'for the agent' and then go on to emphasize the non-dependence of these fact[s] on the agent. (Of course, there is no inconsistency here: apparently, facts are *facts for everybody* on your view, and so *a fortiori* they are facts 'for the agent'. But still [the] way you put things here strikes me as misleading somehow.)

This paper does not emphasize it, but no, we do not mean "the facts we are talking about here are facts for everybody." We mean that the facts too are personal, though in a very careful sense. There is only so much work one can put into a paper as a view is evolving (and as the authors are *slowly*, ever so very *slowly*, coming to agreement), without scrapping the whole project and starting over.

We have tried to meld the phrase "fact for the agent" a little better than previously into its surrounding text—so that it is there at least as some shadow of our presently agreed upon view—but it will have to remain somewhat awkward in the present context.

A better exposition would have emphasized the full setting of our view, including some discussion of the ontological—i.e., noninstrumental—pieces of it. 1) There are two physical systems in the story of this paper. One takes the role of the agent—the possessor of subjective degrees of belief and the activator of the measurement process. The other takes the role of the object system. 2) What is being discussed when one speaks of gathering data in the quantum context is an interaction or transaction between the agent and the object. 3) Without the agent, there would be no quantum "measurement" to speak of, but without the object, there would be no means for the agent to obtain the data, the spikes upon which he pivots his probabilities (his subjective degrees of belief). 4) There are no other agents in this story. 5) We do not go any further than points 1-5 warrant by giving the data obtained in a quantum measurement an autonomous existence—for instance, as something beyond the agent's sensations. That would run into inconsistencies in a "Wigner's friend" scenario. Nonetheless, quantum measurement outcomes are beyond the control of the agent—they are only born in the interaction—and thus are not functions of the agent in the way that his degrees of belief are. The degrees of belief find their source in the agent (the subject); the outcomes find their source in the external quantum system (the object). But the outcomes lead back to the agent in that they are personal to him.

This does not mean that the agent-object interaction and its fuller consequences are not autonomous events in spacetime, but it does mean that if there are any such things, quantum theory is not directly concerned with them. In CAF's view, quantum theory takes its whole definition as a normative theory for organizing an agent's *personal* probabilities for the *personal* consequences of his interactions with external physical systems. The structure of the agent-independent world that lies behind quantum mechanics is, in the end, still codified by the theory, but only in a higher-order, more sophisticated fashion than had been explored previously—it is through the normative rules, rather than quantum states and Hamiltonians.

Unfortunately a more detailed account like this will have to wait for another paper.

Referee: You write:

> The Copenhagen assumption that a preparation device can be given a complete classical description neglects that any such device is quantum mechanical and thus cannot be specified completely in terms of classical facts.

I said above that I wouldn't quibble about what the 'Copenhagen Interpretation' says, and I won't but I will argue that Bohr, at least, is not fairly described in this way. For one thing, Bohr does not deny that the physical instruments that play the role of measuring devices can be described quantum-mechanically. (Bohr says this in several places. I was quickly able to locate one (1949 Schilpp volume): "… of course, the existence of the quantum of action is ultimately responsible for the properties of the materials of which the measuring instruments are built and on which the functioning of the recording devices depends".) Indeed, it must be possible to do so, on Bohr's view, since they could themselves become the object of measurement. (The quotation just above even indicates that Bohr will agree that in order to analyze the functioning of the measuring device, one must use quantum theory.) What Bohr will insist on is: (1) that the only 'facts' about the physical world to which we ultimately have access are 'phenomena', by which he means "observations obtained under specified circumstances, including an account of the whole experimental arrangement" (also from the Schilpp volume); and (2) the 'specification of circumstances' must be given in terms of concepts from classical physics. Now, one could well dispute either of these claims, but if we accept them for the moment, then Bohr has an easy reply to the point that you are making here: for the purposes of describing the phenomena that a given measuring device is capable of eliciting, the device must be described classically, but if we are to investigate how or why it functions as it does, we describe it quantum-mechanically. (Of course, an *empirical* investigation of the device will itself involve observations of the device, and these observations will be made by means of yet other devices, which will be described classically, for the purposes of revealing phenomena that involve the original device.) Given Bohr's (highly debatable) assumptions, it seems to me that he has a reasonable response to the point that you make here.

Actually we take explicit issue with the point you make near the end of this paragraph:

> Bohr has an easy reply to the point that you are making here: for the purposes of describing the phenomena that a given measuring device is capable of eliciting, the device must be described classically, but if we are to investigate how or why it functions as it does, we describe it quantum-mechanically.

The logic goes like this. 1) Take any purported agent-independent, complete classical description of the preparation device. 2) That description can always be 'quantized' into a quantum mechanical one on a larger Hilbert space, i.e., one of the variety we discuss, where there is only unitary evolution. But then, 3) the latter description of the process clearly has a subjective element in it in the form of a prior quantum state for the device. 4) Since there is no operational distinction between the descriptions, either the initial quantum state in the latter description is in fact objective (contrary to our assumption), or the initial purported classical description has a subjective element in it that was unacknowledged previously.

We have tried to emphasize the logic of this argument by rewriting this section somewhat. We have also bolstered the point by quoting Bohr directly, where he says things similar to your summary above, and saying a little on how we differ.

> **Referee:** It is important not to give the impression that in 'the Copenhagen' view, there is *no room* for subjective probabilities.

That is probably true, and we hope that we have taken this into account by being more careful to say that our concern in this paper are "realist readings" of Copenhagen. Finally, to defuse the issue of what is or what is not "the Copenhagen interpretation" a little, we have replaced most instances of that phrase with "the objective-preparations view" which better identifies the issue at hand in any case.

> **Referee:** After all, a Copenhagen-ist can still agree that there is some measure of uncertainty about whether a device really prepares the state that we generally think it prepares. (Perhaps it is true for them that the *true* classical description of the device fixes the state, but they are not committed to the claim that we know what the true description is.)

But we would never say something like this. Remember, for us, a "preparation" is a synonym for an initial quantum state (pure or mixed). There is never a question about whether a device *really* prepares the state that we generally think it prepares—such a statement ontologizes states in a way that we're trying to get away from.

> **Referee:** I'm more concerned about the presumption that there must be facts that guarantee the outcome in the first place, *even* for the Copenhagen view. Indeed, in at least one common form, the Copenhagen view is more or less an anti-realist, more specifically instrumentalist, view. Now, anti-realists will exactly *deny* that there must be 'facts' that underwrite the accuracy of the predictions made by theory. Copenhagen-ists of this stripe will not have any problem with your conclusion that "we must abandon explanations in terms of pre-existing properties" – they couldn't agree more! See, for

example, van Fraassen's and Fine's essays in the volume "Philosophical Consequences of Quantum Theory" (ed. Cushing and McMullin). Both of them argue explicitly for the view that even predictions with certainty do not have to be 'underwritten' by facts about the world, of whatever sort. As van Fraassen puts it, succinctly, "There does not have to be a reason for everything."

This is a good point. We have tried to take into account your concern by defining a little better what we are calling the "Copenhagen-like interpretations."

On the other hand, we wonder whether you have van Fraassen right, at least in this particular context. We say this because one of us—CAF—had the following email exchange with him on 14 November 2005.

> **CAF:** [With regard to van Fraassen's sentence]
>
>> Writers on the subject have emphasized that the main form of measurement in quantum mechanics has as result the value of the observable at the end of the measurement – and that this observable may not even have had a definite value, let alone the same one, before.
>
> your phrase "MAY NOT even have a definite value" floated to my attention. I guess this floated to my attention because I had recently read the following in one of the Brukner/Zeilinger papers,
>
>> Only in the exceptional case of the qubit in an eigenstate of the measurement apparatus the bit value observed reveals a property already carried by the qubit. Yet in general the value obtained by the measurement has an element of irreducible randomness and therefore cannot be assumed to reveal the bit value or even a hidden property of the system existing before the measurement is performed.
>
> I wondered if your "may not" referred to effectively the same thing as their disclaimer at the beginning of this quote. Maybe it doesn't. Anyway, the Brukner/Zeilinger disclaimer is a point that Caves, Schack, and I now definitely reject: From our view all measurements are generative of a NON-preexisting property regardless of the quantum state. I.e., measurements never reveal "a property already carried by the qubit." For this, of course, we have to adopt a Richard Jeffrey-like analysis of the notion of "certainty"—i.e., that it too, like any probability assignment, is a state of mind—or one along (my reading of) Wittgenstein's—i.e., that "certainty is a tone of voice"—to make it all make sense, but so be it.
>
> To which he responded:
>
> **van Fraassenism 11:** *Suppose that an observer assigns eigenstate $|a\rangle$ of A to a system on the basis of a measurement, then predicts with certainty that an immediate further measurement of A will yield value a, and then makes that second measurement and finds a. Don't you even want to say that the second measurement just showed to this observer, as was expected, the value that A already had?*

Thus at least on a surface reading of this, it seems we are saying something in this paper on quantum certainty that even takes van Fraassen by surprise.

> **Referee:** There is of course nothing wrong with the proof in section V, but at this point in the history of the philosophy of quantum theory, I confess that I don't see why it is there. Isn't a quick reference to the 10,000 other proofs of nonlocality sufficient? If not, can you say what is special or new about this one? I would personally rather see that space used for a more subtle discussion of the newer issues, perhaps addressing some of the points that I've made above.

There is a folklore in the physics community that a paper without equations will not get read. We wanted physicists to read our paper too. More seriously, though, the context of this use of KS is quite different from previous uses of it. You yourself call it a "proof of nonlocality." That's not what it is to us: It is a proof that, under the assumption of locality, probability-1 predictions in quantum mechanics correspond to subjective certainty rather than objective certainty.

07-12-06 *Getting It Right* (to S. J. van Enk)

Attached is a draft of a revised version of my "certainty" paper with Caves and Schack. I remember you thinking I didn't capture your point about the Tsirelson bound correctly at the end of it. Could you give me a recommendation for a better more accurate statement?

Steven's Reply

> What I meant was this: a Bayesian is not surprised as much as a realist is by violations of the Bell inequality because he considers the correlations are (at least partly) in his head, not really in the quantum systems (oversimplifying it a bit). That's good, you solved part of the mystery. But what I say then is why are the correlations in your head still restricted by Tsirelson's inequalities? That should be much harder to explain.

07-12-06 *Catching Up on a Southbound Train* (to D. M. Appleby)

I'm sorry I've been silent. Things have just been a little overwhelming, and since I didn't have much to tell you, I didn't write. At the moment, I'm on a train making my way to Washington, DC. I've got to work for the APS tomorrow to get the quantum information topical group sessions organized. (At last count, there were 214 abstracts.)

The talk in Tskuba went fine. I checked the essential part of your minimum-uncertainty state derivation, and I found no mistakes. So, it was part of the overall presentation. [...]

Going back to science a little, the discussions last week with Bennett were the most fruitful I've ever had with him (foundation-wise, that is). Lately he's been worried about information erasure again, and what quantum mechanics adds to the idea. Taking a strong many-worlds kind of stance as his starting point, he asks, if "facts" are just correlations between branches, what happens when those correlations move away from the original systems to which they were concerned? Are the facts as "real" as they used to seem to be? Well, of course this gets him into all kinds of trouble—the sort of trouble he's not used to since he normally shuns all discussions of foundations. So it was an absolute surprise to me one morning when he calls down to say that our discussions had caused him to think a lot, and, quote, "... it almost pains me to say this ... but I can see why you might use the language of calling a quantum state a state of knowledge." OK, he's coming up a little toward the Chris of about 10 years ago (not the radical Bayesian), but given what I know of him, it was almost a miracle to hear this! It was an essentially infinite step really! Here's what I wrote Kiki that night:

> But over all, it was a good day. Probably one of my proudest moments ever: Charlie took me aside early this morning and said that because of our discussions yesterday, he was starting to adopt a view of quantum mechanics that comes closer to mine—he wouldn't go so far as me, mind you, or at least he said so—but it was "closer." [. . .] I was proud and humbled at the same time.

Now, to nurture this seed!

11-12-06 *Chris's House from Space* (to J. Racette)

Thanks for the holiday letter. I enjoyed it, and it was great to learn where you guys are at in your lives now. Please give Kim a big Merry Christmas from Kiki and me. (Include yourself too.)

Of course, you were always more literary than me: In all these years I've never put together a holiday letter. Maybe the closest I can come at the moment, is to forward you a letter (with the associated photos attached) that I had written to an Irish friend recently. [See 01-12-06 note "Chris's House from Space" to K. R. Duffy.] (It was spurred by him telling another colleague in a pub that the orange of my house could be seen from space.)

Our two kids are growing too. Emma is setting herself to conquer the world. She reads like a scanner, and works out like a gymnast. And Katie's coming along quite nicely too, though her enjoyments are pulling weeds with the old man and cooking. Kiki is constructing and reconstructing the house constantly—partially restoring it to 1896 and partially just Kikifying it. Me, I'm just trying to understand quantum mechanics as usual, and traveling the world while I do it. This year I went to Portugal, Sweden, Italy, Canada and Japan. (Last year was busier; I went to Australia, Poland, Austria, Sweden, Ireland, Canada, and Germany (twice).)

Sadly I don't have satellite TV yet (still with trudgy old cable): Too bad I'm not in central New Mexico!

11-12-06 *Quantum Brunch* (to P. Grangier)

Grangierisme 21: *Following our "quantum breakfast" in Tsukuba, here is the talk which includes the arguments with Gleason and Wigner theorems, given at ENS in Paris in November 2004 (see* `http://www.spectro.jussieu.fr/Seminaires/Resumes_2004/Resu041116.html`*).*

I have various improvements as drafts in my files, but I did not find time to write them down.

I enjoyed the quantum breakfast indeed. Thanks for sending your presentation. I shall study it, and maybe we can get together for a quantum brunch in February.

I'm just back from the APS sorters meeting, preparing for the March meeting. That was a lot of hard work. But it was also a lot of hard work in the many fights Carlton Caves and I had about our own interpretive stuff. I wonder why I get involved in these things sometimes.

As I say, I will study your presentation. It would be nice if it turned out that there is more common ground between us than was initially apparent.

12-12-06 *More Stable Version of Manuscript on Operational Axiomatization of QM* (to G. M. D'Ariano)

Thanks for the note. I too much enjoyed our discussion. I'm sorry about the notes; when I saw you at breakfast, I was in such a hurry everything spilt out of my mind. Anyway, I am working on the paper with Appleby now, and hope to get it posted early next week.

Thanks for the coordinates of your latest posting. You are right that there is probably much latitude for joining our ideas. I admire your axiomatic system—of all that I have seen, it is the one that smells the most right for leading to a deeper understanding of the essence of quantum phenomena. On the other hand, my Bureau-of-Standards measurement idea is only a small piece of the puzzle, and I certainly need to wed it to a larger structure.

I will inform you of the coordinates of the thing with Appleby just as soon as I can.

12-12-06 *Small Changes* (to R. Schack)

Since we haven't heard from you, I went ahead and made some small changes to Carl's last draft. I'm guessing that they won't interfere with anything that you may be doing to it.

1) I modified the last paragraph to better capture van Enk's point (he had remarked that I didn't quite get the point across that he thought was important). On top of that, with this modification, the flow of the logic is a better than it was before anyway.

2) I wimped out on a longer exposition of the Principal Principle troubles again, which I was going to put in a footnote. So, I just deleted the flagged footnote.

I'd probably like to do a few more *small* (literally) changes, but I'll go ahead and send you this much in case you do happen to be working on the draft.

The biggest issue probably—the one that will require the most work—is about de Finetti's previous statements on certainty. As it stands, we say this:

> The main issue here is whether there is any difficulty with the idea of an utterly certain belief about an admittedly contingent fact. This issue arises in the classical setting, where it has been dealt with masterfully in Bruno de Finetti's "Probabilismo" (Sect. 18-19). Nothing of de Finetti's argument loses force when we come to quantum mechanics; indeed, the quantum denial of instruction sets seems to give it yet more force.

I don't think that quite frames it right. (Plus—but this is slightly an aside—Bruno de Finetti's world was neither 'classical' nor 'quantum' in the usual physics sense.) I think the real issue is closer to the one that Timpson brings up: The agent is certain of the outcome, even though he is also certain that the system *cannot* be (objectively) 'certain'. That is the apparent conundrum. I'm not now sure that de Finetti considered such a stronger situation. Or is my memory/understanding now failing? (You can read what I had written previously on the issue—when I thought de Finetti had indeed done the job—at [now defunct pages].) So the question is what to write. Do you want to tackle this one?

My present feeling is that the solution—or at least one solution—is implicit in our ontology (though I'm not all that happy with what I had written Timpson previously). All that's being recognized with a Bell-KS argument is that quantum outcomes cannot be a function of the world external to the agent alone. They come about, in part, by the participation of the agent himself.

On the previous point of contention—this phrase "Bayesian updating is, as it should be, consistent with logical deduction of facts from other facts"—I'm now willing to leave Carl's draft alone with regard to it. But I don't think it is nearly as meaningful as you two think it is. In fact, I still think our disagreement is more than linguistic. I'll explain in more detail in a later note.

13-12-06 *Seeking an Objective Substructure, Yes; Theory of Fundamental Events, Maybe No* (to J. Barrett)

<u>NOTE</u>: This letter was apparently never finished or sent off. I suspect it was composed roughly on the date listed here.

I've finally gotten back to reading your note again and thinking about it for a day. I'm sorry for the delay. I have enjoyed your questions and your thoughts. Let me reply to a few of them, though I don't think I have as much to say as I had originally thought I would.

First let's go back to the issue of "fundamental events," since I've already referred you to some of my ruminations on the subject. You wrote this in your note:

Barrettism 2 : *at present we have only a provisional, half-baked theory in which these events are "outcomes of interventions". But a fundamental formulation of a complete theory must not use such vague terminology, and will eventually supply an ontology of primitive events that agents can in principle bet on.*

And let me recall the thing I wrote for the referee of our "certainty" paper:

> [Q]uantum measurement outcomes are beyond the control of the agent—they are only born in the interaction—and thus are not functions of the agent in the way that his degrees of belief are. The degrees of belief find their source in the agent (the subject); the outcomes find their source in the external quantum system (the object). But the outcomes lead back to the agent in that they are personal to him.
>
> This does not mean that the agent-object interaction and its fuller consequences are not autonomous events in spacetime, but it does mean that if there are any such things, quantum theory is not directly concerned with them. In CAF's view, quantum theory takes its whole definition as a normative theory for organizing an agent's *personal* probabilities for the *personal* consequences of his interactions with external physical systems. The structure of the agent-independent world that lies behind quantum mechanics is, in the end, still codified by the theory, but only in a higher-order, more sophisticated fashion than had been explored previously—it is through the normative rules, rather than quantum states and Hamiltonians.

Also a piece of the Preamble section of "Delirium Quantum"

> I think the greatest lesson quantum theory holds for us is that when two pieces of the world come together, they give birth. [Bring two fists together and then open them to imply an explosion.] They give birth to FACTS in a way not so unlike the romantic notion of parenthood: that a child is more than the sum total of her parents, an entity unto herself with untold potential for reshaping the world. Add a new piece to a puzzle—not to its beginning or end or edges, but somewhere deep in its middle—and all the extant pieces must be rejiggled or recut to make a new, but different, whole. That is the great lesson.
>
> But quantum mechanics is only a glimpse into this profound feature of nature; it is only a part of the story. For its focus is exclusively upon a very special case of this phenomenon: The case where one piece of the world is a highly-developed decision-making agent—an experimentalist—and the other piece is some fraction of the world that captures his attention or interest.

So, clearly, I have sympathy for *something* that goes beyond quantum theory. But what is that something? The idea behind the Preamble passage has its origin in a kind of Copernican principle.

13-12-06 *Offline Discussion* (to R. Schack)

Here are the passages you and Carl wrote:

Schackcosm 95: *I am, however, totally puzzled by your problem with what you call the "exception". I have said over and over again that from our perspective this is a trivial issue. I think you have some kind of mental block here. All probabilities are degrees of belief. All probabilities reside in the agent, not in the world. But the agent has to be coherent. The agent's probabilities generally depend on facts (these are facts for the agent) and his prior. Given a prior and some facts, the agent is forced by coherence to a particular probability assignment. There are trivial cases, however, where the prior doesn't come in. If $x = 5$ is a fact for the agent, then the agent is forced to the probability assignment $P(x = 5) = 1$ by coherence alone. There is nothing deep here at all.*

and

Cavesism 82: *The point of the exception is to make clear that we are not saying that probability theory is inconsistent with logic. It is consistent with logic. Now in logic, you could say that some facts imply other facts. When thinking in terms of probabilities, you would say the same thing as some unit probabilities imply other unit probabilities via Bayes's rule. Now you can always maintain a distinction—and we would want to maintain one—between the facts themselves and certainty about facts, and I personally would be happy to change things so that we're saying the right thing.*

The main point is that sometimes in the case of certainties, facts do imply some other unit probabilities by logic, and there is no escaping that. For example, suppose we observe that one thing has the value two and another thing has the value three. These are now facts (for the agents), but the agent cannot escape assigning unit probability to the sum of the two having value five. That's the only thing I want to guard against.

And here's what I had written in the now deleted footnote:

> The problem, *as [Fuchs] sees it*, with the formulation that there is a case whereupon a fact strictly determines a probability is that it puts the horse before the cart: It acts as if abstract 'logical implication'—a statement of the form "$d \Rightarrow h_0$"—has a meaning independent of the *subjective* judgment "$\Pr(d|h) = 0$ for $h \neq h_0$." (See for instance, F. C. S. Schiller, *Formal Logic: A Scientific and Social Problem*, (Macmillan, London, 1912), and F. C. S. Schiller, *Logic for Use: An Introduction to the Voluntarist Theory of Knowledge*, (G. Bell, London, 1929), for a development of this point.)

Let me try to say the same thing, but in a little more detail.

In my weakest criticism of this exception business, I would point out that you two seem to be drawing no distinction between analytic and synthetic truths (facts). It seems you're wanting to apply a blanket rule to both, and that's partially what's getting under my skin:

> We may … adopt the unsophisticated definition that a synthetic statement has meaning only in terms of matter of fact, whereas an analytic statement has meaning independently of matter of fact (roughly, the Leibnizian distinction between *vérités de fait* and *vérités de raison*). An analytic statement, as has been charged, may still be considered as relative to the language or symbolism in which it is stated … However, these considerations should not affect the essence of the distinction, which is that, in theory, an analytic statement, since it is concerned only with the relations of meanings, cannot

be verified or falsified by any conceivable human experience, whereas a synthetic statement, regardless of its "certainty," may always, in theory, be upset by experience. A typical analytic statement is, "two plus two equals four." If the meaning of the words "two," "plus," "equals," and "four" is made clear, it is impossible for this statement not to be valid. Synthetic statements are the material of science, and their degree of certainty may approach any assignable limit, with the qualification that they are always subject to verification in experience, i.e., may conceivably be falsified.

Propositions corresponding to quantum measurement outcomes are not analytic statements (nor are classical measurement outcomes for that matter). And so, so-called "logical implication" between any two such statements can be nothing other than a subjective judgment of certainty, $\Pr(d|h) = 1$. Logical implication in this kind of situation has no independent definition.

As previously written in the paper, Carl's choice of words seemed to indicate a contradiction to this point. (Actually, it went further than that—and may still in Carl's mind—as evidenced by all the earlier attempts of Carl to draw a distinction between classical and quantum based on such ideas.)

My heels dug in when I looked at the passage on Bayes' rule as it had been written:

Classically, Bayes's rule,

$$\Pr(h|d) = \frac{\Pr(d|h)\Pr(h)}{\Pr(d)}\,, \tag{68}$$

is used to update probabilities for hypotheses h after acquiring facts in the form of data d. The posterior probability, $\Pr(h|d)$, depends on the observed data d and on prior beliefs through the prior probabilities $\Pr(h)$ and the conditional probabilities $\Pr(d|h)$. The only exception to the dependence on prior probabilities occurs when the observed data d logically imply a particular hypothesis h_0, i.e., when $\Pr(d|h) = 0$ for $h \neq h_0$, thus making $\Pr(h_0|d) = 1$.

and saw nothing but subjective judgments in every slot on the right-hand side, yet talk of *exceptions*. To me, it sent the wrong message about our whole enterprise. Once one exception, why not two? Particularly if some subjective judgments are forced by facts (without prior judgment), why not others? Why not, in fact, allow that some nontrivial probabilities—quantum probabilities—can even be forced by facts (without prior judgment)?

Since the real subject matter of our paper was for h and d that are measurement outcomes, I saw no reason to sew a seed of doubt.

But—you might say—"That was just a little trouble in the way Carl wrote up the point. What we really meant to convey is that $\Pr(h|h) = 1$, and that holds true without subjective judgment even for synthetic statements. It's just coherence."

And I say, "NO, even that is wrong—or at least irrelevant—as long as h is synthetic."

It is Aristotle's logic which is usually taken as the archetype of formal logic. However, the 'logical analysis of judgment' in anyone's hands is bound to come to failure if it discounts the personal intention and circumstances of the maker of the judgment. Thus Hegel's formula of judgment as identity in difference disregards the fact that identities are always made or postulated by us through conscious disregard of those differences which we take for the moment to be irrelevant to the purpose of judgment.

If the right-hand entry and the left-hand entry of $\Pr(h|h)$ are meant to be two distinct empirical instances of "h" (the quotes important), then it is a subjective judgment. If the right-hand entry is synthetic, while the left-hand is treated as (now) analytic, I don't know what the very expression $\Pr(h|h)$ means.

Take your particular point:

Schackcosm 96: *If $x = 5$ is a fact for the agent, then the agent is forced to the probability assignment $P(x = 5) = 1$ by coherence alone.*

Why would the agent write down $P(x = 5) = 1$ unless he were contemplating gambling on whether $x = 5$ (and is quite certain of the outcome)? The only sense I can make of that situation is that what is really happening is that the agent is contemplating gambling on a NEW instance of $x = 5$, and because of the previous observation he is certain he will find it again. But that is a subjective judgment. If you take away my right to think of it as a new instance, then I will say he cannot be gambling on it at all—the statement $x = 5$ is a dead fact; it has passed away. And what you must mean by $P(x = 5) = 1$ is something other than a gambling commitment.

The same can be said for Carl's example above (though he does slip in a little "2+2=4" issue on the side, which as far as I can see is irrelevant for the observation he really wants to make ... which is the same as the one you made, or at least he told me so).

So, now we get to the point. My present opinion is that probability statements are really only ever meant to be made about "live options" (to use a phrase of William James, though I may not be using it exactly the same way as he did). One can indeed write $P(x = 5) = 1$, but then $x = 5$ had better a live option, rather than a "fact for the agent." If it is a fact for the agent, then we are reinstating the category error. The only role for the "facts for the agent"—despite their very real consequences, like 'life' or 'death'—are in pivoting the agent's subjective probabilities. They are never used for the setting of probabilities unconditionally.

Could I make the criticism stronger? Yeah, I think so, if I were to argue along the lines of Schiller that there simply are no such things as analytic judgments anyway. But that's probably further than I need to go.

Do you see my concern any more clearly now?

Rüdiger's Reply

> Let me try to tell you what I understand about facts and certainty. You say that once A is a fact for the agent, the agent can't be certain of it in the sense of assigning probability 1 to it. When something is a fact for the agent, it doesn't normally make sense for him to ask "Am I certain of the fact?". This is one of Wittgenstein's points. And I fully appreciate it. In the quantum context, this has to do with the status of "clicks", which are directly given to the agent. Facts are facts for the agent and don't have an independent existence out there. This is why the agent should not assign probabilities, not even 0 or 1, to facts.
>
> But where does leave the analytic/synthetic distinction? Isn't that a pre-Wittgensteinian distinction? I think the analytic/synthetic distinction moves the whole discussion in the wrong direction.

13-12-06 *More on Identity* (to R. Schack)

Let me supplement what I just sent you with a little email conversation I had with Charlie Bennett on the very point of 'identity'. [See 28-11-06 note "Funes + Borges" to C. H. Bennett.] The messages below are in reverse time order. What Charlie is referring to is Matt Leifer's paper, `quant-ph/0611233`; and CFS refers to you, Carl, and me.

There's a funny anecdote that goes with it too. One evening while walking back from dinner in Tsukuba, Charlie said to Daniel Gottesman while pointing up to a traffic light, "For instance, Chris wants to say that that traffic light right now is not the same the traffic light as ..." And, by wonderful fate, just as Charlie gestured up to it, the light changed color! We all had a very good laugh, and it's clearly already become one of Charlie's palette of stories: I heard it at least three times over again at the meeting.

13-12-06 *Analytic/Synthetic* (to R. Schack)

Schackcosm 97: *But where does leave the analytic/synthetic distinction? Isn't that a pre-Wittgensteinian distinction? I think the analytic/synthetic distinction moves the whole discussion in the wrong direction.*

And a pre-Jamesian and pre-Schillerian distinction too. Yes, it does move the discussion in the wrong direction. But I left my exposition couched in terms of it because I thought it might strike a chord more quickly in you that way. (It was a first assault.) That's why I said, "In my weakest criticism of this exception business, I would point out ..." Later I hinted at the corrective with this:

> Could I make the criticism stronger? Yeah, I think so, if I were to argue along the lines of Schiller that there simply are no such things as analytic judgments anyway. But that's probably further than I need to go.

Schiller, too, rejects the distinction.

Blending that point into the mix, the simplest solution to the dilemma caused by the "exception" was to have never imagined it to exist in the first place. No mention of analytic/synthetic, but no mention of exceptions either. (We had tried that solution once in an earlier draft, but it only made Prof. Caves that much more bitter.)

14-12-06 *What a Friend!* (to J. A. Smolin)

I just sent these words off to Mr. Khrennikov for part of the Preface to his latest volume. Now, read that and tell me I'm not a good friend! At some stage relatively soon, we've got to get back to working that out. ... At the moment though SIC-existence is more important.

> **Swedish Bayesian Team.** Eight of the meeting's participants came to Växjö as a task group to further develop an understanding of quantum probabilities as Bayesian degrees of belief and to examine various technical issues surrounding the idea. These were D. Marcus Appleby, Hans C. von Baeyer, Ariel Caticha, G. Mauro D'Ariano, C. A. Fuchs, Matthew S. Leifer, Rüdiger Schack, and John A. Smolin. Quantum Bayesianism is a view of quantum mechanics that has been making much progress and is becoming widely recognized; it was thus good to be able to come back to Växjö, which played a pivotal role in its development already with the "Shannon meets Bohr" session of the 2001 meeting. As concerns the talks, D. M. Appleby gave a nice introduction to the Bayesian conception of quantum-state tomography and explored the extent to which complete sets of mutually unbiased bases (so-called MUBs) and symmetric informationally complete measurements (so-called SICs) are optimal measurements for tomography. A. Caticha gave a potential derivation of the quantum formalism along lines inspired

by R. T. Cox's derivation of the axioms of probability theory. G. M. D'Ariano presented some very fresh work on an axiomatic system for quantum mechanics inspired by the practice of quantum tomography and many of the work-a-day features of quantum information theory. C. A. Fuchs gave a presentation aiming to clarify some the ontological aspects of the quantum Bayesian position, arguing that, though quantum states are subjective from this conception, the Born rule for transforming probabilities from one measurement context to another represents an objective feature of the world. M. S. Leifer presented a new and very useful isomorphism between bipartite quantum states and quantum operations and discussed its implications: Particularly, he argued that from a Bayesian conception, to be consistent, quantum operations should be interpreted as of the same subjective character as quantum states. R. Schack discussed the issue of what it could possibly mean for a quantum random number generator to be better than a classical one and gave a rather deep answer: When an observer writes down a pure state for a quantum system, he is not only expressing his certainty for the outcome of some measurement, but he is also expressing his certainty that no one else can have what he would deem as "inside information." Finally J. A. Smolin posed what was perhaps the deepest question of the conference (for the Bayesians at least!): Forget about better and better Bell inequality violations; to what extent has the basic Born rule for calculating probabilities ever been independently tested, and indeed, can it be experimentally tested?

We might add that three other participants of the meeting count as *honorary* members of the Swedish Bayesian Team (whether they would like such an association or not!). First, there is Arkady Plotnitsky, whose riveting talk on Bohr's reply to EPR, helped make clear the single-case conception of all quantum phenomena (thus seemingly requiring a Bayesian notion of probability). Then there is Ingemar Bengtsson, who discussed the still-open (for >30 years!) problem of the existence or nonexistence of MUBs for non-prime-power dimensional Hilbert spaces. This kind of work and related constructions are likely to be crucial for better Bayesian reconstructions of the quantum formalism. And finally Jan-Åke Larsson, for his role as the conscience for Bell-violation experimentalists; we fear that one day he will be the conscience of the quantum Bayesians!

15-12-06 *Background Independent Bayesians* (to L. Smolin)

I know he's already in your neighborhood, and you probably know him better than I do, but I just thought I'd tell you that you guys have an excellent postdoc in Matt Leifer. I've been editing the volume for the Växjö proceedings and discovered I really like Matt's submission: `quant-ph/0611233`. (Well, of course I would like it—and you'll easily catch why if you read the Introduction.) But because of the closing remarks in the paper it struck me that you might have some interest in the paper too. I think it is a good point, and if this quantum Bayesian—i.e., me—were to try to dabble in quantum gravity, it might be the first observation I'd try to get some traction from.

Also, in spite of the motivation for the formalism (i.e., if you can't stomach those Bayesians), you might find the formalism independently useful.

15-12-06 *Swedish Delirium* (to D. Gottesman)

I don't know if you could see it in my face, but I was taken quite aback when you said at the Tsukuba banquet (something like), "The trouble with *all* the interpretations is that, by hook or crook, they always try to describe quantum mechanics in some classical way." Well ... ahem ... of course I thought that about every *other* interpretation, but I had never imagined such a criticism being leveled at me!

Anyway, I thought of you again last night as I was hurriedly annotating the attached "pseudo-paper" for the wacky Swedish proceedings. And I wondered whether after reading it you'd still drop me in the same pot with all the rest. (Maybe I just want to think I'm "more anti-classical" than the rest so that some one will call me MAC-daddy some day.) But seriously ... You probably will (drop me in the same pot, that is). But I'd like to better understand why, particularly in light of the peculiarities of the attached document.

On a different subject, might I ask you to send me a copy of your Tsukuba presentation? I gave your paper a perusal, but didn't find your nice little example in it with the transition matrices written explicitly. I think I'll need that kind of gentle leading to absorb your point.

18-12-06 *I and It* (to N. D. Mermin & C. G. Timpson)

I'm going to cc this note to Chris Timpson, since it is directly relevant to him. (I.e., I will treat it as out of the context of my other notes to you today.)

Merminition 158: *Footnote 25. I can't imagine how a successful gambler can be certain that red will turn up next without also feeling that it is certain that red will turn up next. So this footnote just confuses me.*

I think your confusion here comes from not parsing the sentence the right way. (We probably need to add something more to the text to make sure no one else has the same trouble as you.)

It comes from some things that Chris Timpson brought to our attention. Let me paste in Timpson's explanation.

Or maybe that's not the trouble at all—as I keep staring and staring at your sentence, I start to wonder. Maybe it is actually the same trouble that Timpson expressed below?

Here's a far-fetched example of how it could possibly be. Schrödinger knew—nay, was certain—that with a fresh lover he would be able to make a great scientific discovery. The lover is the catalyst for the discovery. No lover, no discovery. Yet, ask the lover, and she will have no clue about what her presence does for his science. He is certain, but she is not.

From our view—let me be careful, from my view—a quantum system is a catalyst. It brings about a transformation in the agent who interacts with it. Sometimes the agent is certain (in the subjective sense) about the transformation that will be the result; sometimes he is not. But even in those times in which he is certain, there is nothing in the system itself that is informative of his certainty.

Buy it?

18-12-06 *Bennett's Hoffa Talk and Certainty* (to R. E. Slusher)

By the way, here's a copy of Bennett's painful (to him) Tsukuba talk.

Also attached is a much better version of our certainty paper than you had seen before. [C. M. Caves, C. A. Fuchs, and R. Schack, "Subjective Probability and Quantum Certainty," Stud. Hist. Phil. Mod. Phys. **38**, 255–274 (2007).] It's what gave rise to the Schrödinger story below.

> Here's a far-fetched example of how it could possibly be. Schrödinger knew—nay, was certain—that with a fresh lover he would be able to make a great scientific discovery. The lover is the catalyst for the discovery. No lover, no discovery. Yet, ask the lover, and she will have no clue about what her presence does for his science. He is certain, but she is not.
>
> From our view—let me be careful, from my view—a quantum system is a catalyst. It brings about a transformation in the agent who interacts with it. Sometimes the agent is certain (in the subjective sense) about the transformation that will be the result; sometimes he is not. But even in those times in which he is certain, there is nothing in the system itself that is informative of his certainty.

20-12-06 *All Unambiguous Account* (to C. M. Caves)

Cavesism 83: *One thing I discovered as I was doing this. Shouldn't that quote from Bohr to Pauli start with "In all unambiguous accounts" instead of "account"?*

Nope, that is just as Bohr said it. I was very careful in entering those words into my computer, which come from a fascinating set of letters between Bohr and Pauli (written in English!) that Henry Folse supplied me with.

Bohr's letters can be found on pages 14–16 of the attached document. (And a quote of Folse quoting the phrase "in all unambiguous account" too can be found on page 39.) Pauli's more interesting (by my estimate) replies can be found on pages 132–135.

We could add an "[sic]" to the Bohr quote.

20-12-06 *New Jersey Atoms* (to D. Gottesman)

Thanks for sending me your talk.

Gottesmanism 2: *When you talk about an "event", that is a classical concept. Less obviously, "information", "knowledge", "belief" are also all classical concepts. Of course, the actual classical concepts don't quite fit the quantum objects you'd like to assign them to, so you have to start to modify them, to give them more quantum properties.*

I pretty much expected you'd say that, at least with "event"—you said about as much in Tsukuba (though I think you used the word "data"). But I guess I was hoping you'd expand on what you mean by all this. For instance, I don't know what you mean when you say "belief is a classical concept." Classical in the sense of classical physics? For myself, I would think terms like "belief" have essentially nothing to do with any particular conception of the world. For instance, one could speak of beliefs (and even rudimentary probability theory) at a time when the world was thought to be animated with little spirits or when rocks were thought to fall according to Aristotelian rules. Or in Hinduism where the world is but the dream of four brothers dreaming Vishnu dreaming the world containing four brothers dreaming Vishnu dreaming . . .

If I see you in early February, maybe I can get you to tighten up what you mean.

Gottesmanism 3: *This, I think, is not at its root different from the way most interpretations work: They take some classical concept and try to modify it to allow it to describe quantum mechanics. I don't know that there's anything* wrong *with that, but I also don't know why one would expect there to be a uniquely "best" way of doing it.*

True enough. I understand your point on this. But I do think the quantum formalism is trying to tell us something unique about the world, and despite our using the formalism every day, we don't yet have a good grasp of what "it" is trying to get at. Whatever it takes to move forward on that project is, in the end, the important thing. (And so: I'm ready to be Darwin'd out if it so happens, but at the moment the Bayesian way strikes me as the best way to proceed.)

Gottesmanism 4: *While there are certainly many ways in which atoms can be distinct, they also can, in fact, be exactly the same. The very notion of "separateness" of atoms breaks down in a BEC.*

There's something in the way you pose this that makes me think you don't quite get what I was shooting for in that rumination. (And it's no wonder, because I don't like the way I wrote it now either.) From my *toyed-with* conception, atoms (and events) are not something larger bodies (and histories) are built up from. But rather atoms are residues of in-common judgments about the bodies. So, even from this point of view atoms can be exactly the same (as you would have them). But now the statement almost turns into a tautology, rather than being empirical. That is to say, if one has adopted an epistemic view of quantum states as a working hypothesis (as Caves, Schack, and I have), a symmetrized or anti-symmetrized quantum state is still an epistemic state, rather than a state of the world.

In connection with that point, I'll attach the latest Caves-Fuchs-Schackism in case there's an evening when you find you can't fall asleep. (This version is significantly different from the one we put on the web earlier under duress.)

20-12-06 *Paper* (to R. Schack)

Schackcosm 98: *Not that I disagreed with what it says, but I thought it would disturb some readers unnecessarily. So I have some sympathy with the idea of dropping it.*

Disturb some reader unnecessarily in what sense?

The whole point of our paper is that we say that quantum mechanics leads us to think that there can (validly) be subjective certainty without an underlying objective certainty. What is wrong with citing[117] someone who backs up a similar idea—or at least an idea that moves in a similar direction—and, in a clearer way than we do, in another context?

[117] The citation in question was this one: More philosophical, quantum independent, precedents for this notion of 'certainty' can be found in A. White, "Certainty," Proc. Aristotelian Soc. **46**, 1 (1972). For example, White puts it this way,

> The certainty of persons and the certainty of things are logically independent of each other. Somebody can be (or feel) certain of something which is not itself certain, while something can be certain without anybody's being (or feeling) certain of it. 'He is certain that p' neither implies nor is implied by the impersonal 'It is certain that p'. The same thing cannot be both certain and not certain, though one person can be certain of it and another of its opposite ... People can become more or less certain of something which itself has not become any more or less certain. ... A gambler need not feel that *it* [our italics] is certain that red will turn up next in order to feel certain that it will.

See also, L. Wittgenstein, *On Certainty*, (Blackwell, Malden, MA, 1975).

Timpson may be wrong that this is relevant, but he is not dismissive and is thinking hard about the issue. We need people like him, and if it helps to put our thoughts a little into the context of his world (and people's like his), I don't see the harm. Saying the truth—as we understand it at any moment—is the only thing that's ever going to make us free (almost a JC quote).

Carl says this paper is "written for physicists." What physicist is going to look at a journal like SHPMP? The only people who will look are the ones who really want some clarity, or have a philosophical bone to pick. Either way, it seems to me, we ought to be providing them with as much material as we can, when we can.

It strikes me that you guys always work from a starting point of the "the less said the better". But I think we're tearing a huge whole in these guys' (our reader's) worldview and if we don't put something in its place—some kind of metaphysics, some kind of world picture—we're just asking for trouble after trouble upon ourselves. Wisemans calling us solipsists; Bubs calling us instrumentalists; Stamps calling us behaviorists; Pereses calling us positivists. Everyone thinking we're making the world smaller, rather than bigger. It is true that we may never get rid of all those biting, deaf dogs, but if we don't try, we've really only got ourselves to blame.

That said, I am willing to remove the quote of White (rather than adding a little more to it to help set the context) and leave only a citation of he and Wittgenstein if you really wish. But I'd hope you'd do it out of a reason deeper than fear. (Fear, that is, that some jerk out there who says, "This is not physics; I know what physics is. This is philosophy with no impact on physics, and I am therefore warranted to close my mind." It is that kind of arrogance that keeps such people from making the really big discoveries, and I want a community around us that will make big, really big, discoveries, even if we never do.)

20-12-06 *I and It, 1* (to R. Schack)

Mermin's replies on I and It. The first was to my note (about Schrödinger and his lovers). The second was to Timpson's long linguistic analysis on the Moore-type sentences. (Which—I disagree with you—are relevant if one thinks of quantum measurement in the common "question-answer" motif, *rather than* in the alchemical motif I keep trying to refine. In fact, the questions he raises give extra impetus, give extra reason for the alchemical/Paulian motif. For that view, I think, sidesteps the issue he fears. Timpson's distrust, I believe, has its source in what I railed about earlier: Our tearing too much out of his worldview without replacing it with a new image.)

23-12-06 *Real Data!* (to G. L. Comer)

Comerism 14: *If you take a look at* `astro-ph/0605007` *you'll find a paper of Nils, Reinhard Prix, and me referenced. This is quite unique for me, because our model for neutron star glitches is being put to the test via real data analysis. And ... we're still in the hunt! It turns out that glitch data and our model share a certain linearity.*

That's exciting! What a way to go into the Christmas season.

I've never had anything comparable in my life—to the extent I have made any positive predictions at all, they've always been of use for engineering, never explaining any naturally occurring phenomenon. I can tell you one funny story in that regard that happened recently. A couple of weeks ago in Japan I was walking through the poster session at QCMC, and ran across two guys from MIT with a very professional looking poster titled, "Experimental Realization of the Fuchs-Peres-Brandt Probe." I thought, "what's that?" and stopped to talk. Well, they tell me all about my original paper with Asher—or so I thought that's what they were telling me at first—and about how they used the calculations there to design a real-world optimal eavesdropping setup. I ask them how much it cost to perform the experiment and that kind of stuff—about $10K in parts plus a very, very expensive laser that was already in the lab, etc., they tell me. Then, at some point, it all starts to sink in: Whatever they've done, they've used it for eavesdropping on BB84. Whereas my paper with Asher had solely to do with B92! So, I explain this, and they say, "No, there's a part on BB84." I say, "No, no, there's nothing on BB84 in it." They say, "Yes there is, Professor Shapiro told us so!" Well, like a big Emily Litella, I think the whole experiment—or at least the title of it!—was a big "Never mind."

To think, there's a neutron star out there that knows the name of Greg Comer. (Newton's Third Law ultimately says knowledge is reciprocal, you know.)

24-12-06 *Spekkens and Kant* (to R. W. Spekkens)

Happy holidays!

Rob Spekkens on wave functions:

> We shall argue for the superiority of the epistemic view over the ontic view by demonstrating how a great number of quantum phenomena that are mysterious from the ontic viewpoint, appear natural from the epistemic viewpoint. These phenomena include [about a million things]. ... The greater the number of phenomena that appear mysterious from an ontic perspective but natural from an epistemic perspective, the more convincing the latter viewpoint becomes. ...
>
> Of course, a proponent of the ontic view might argue that the phenomena in question are not mysterious *if* one abandons certain preconceived notions about physical reality. The challenge we offer to such a person is to present a few simple *physical* principles by the light of which all of these phenomena become conceptually intuitive (and not merely mathematical consequences of the formalism) within a framework wherein the quantum state is an ontic state. Our impression is that this challenge cannot be met.

Immanuel Kant on ghosts:

> I do not dare wholly to deny all truth to the various ghost stories, but with the curious reservation that I doubt each of them singly, but have some belief in them all taken together.

24-12-06 *Christmas Conversations in My Head* (to C. H. Bennett)

I read the lines below (which I'd like stored in my computer anyway, from Reuben Abel's book *The Pragmatic Humanism of F. C. S. Schiller*), and I thought again of our conversations over the years. Particularly I wondered whether the quote of Schiller (the very last sentence in the paragraph below) might characterize our relationship.

> This amount of indeterminism does not upset the structure of science. Alternative modes of conduct are, at least partially, calculable. Continuity of character is a limitation on complete freedom. But this is not equivalent to saying that, since character and habits affect choice, choice is therefore not free. It is commonplace that people

> frequently do things on impulse, or without reason, or "unexpected of them." Moreover, character is not a fixed entity, but a growing, evolving, changing concept. Is it ever completely formed? And besides, there exist situations in which the motives to contrary actions balance each other. A choice can frequently be shown to have, in retrospect, rational connections with the antecedent circumstances. But this does not imply that another choice in the same circumstances would not also have, in retrospect, such rational connections. Alternative courses may be equally free, yet they need not be haphazard. Determinists have argued that if the course of events were not completely and rigidly determined, it must be indeterminable. This, Schiller shows, is not necessary. The two postulates do not clash. There is a certain amount of indeterminism in the world which is determinable in alternative ways. The choice between these is a real freedom which does not involve the dire consequences of either complete determinism or complete indeterminism. Scientific calculability and moral freedom are not in conflict. Determinism as a scientific postulate is not endangered; as an ontological dogma, like all other statements of metaphysics, one may freely take it or leave it. "As we cannot vindicate our freedom unless we are determined to be free, so we cannot compel those to be free who are free to be determined, and prefer to think it so."

Just my weird way of saying: Merry Christmas; you're never far from my thoughts.

27-12-06 *My Christmas Present?* (to G. L. Comer, S. J. van Enk, and J. W. Nicholson)

To my three most open-minded friends,

I've just got to share this thing I discovered with someone. Go to Google and do a search on the three terms: "Chris Fuchs", "crazy", and "quantum". On the results page, click on the link at the bottom that'll take you to page 3(!) of the results, and look at the very last hit. It's to something titled, "Captain Stabbin – Captain Stabbin Interpretation of Quantum Mechanics." If you're not on a company machine, and you're feeling brave, click on the link. You'll be quite surprised!

Happy holidays!

27-12-06 *New Year's Delirium* (to H. J. Bernstein)

Hey Herb, you old reality maker,

I hope you're having a nice holiday, despite the meanness Charlie and I heaped on you the other day. I'm having a nice time, thinking a lot about what quantum mechanics is trying to tell us, and reading up on F. C. S. Schiller's flavor of pragmatism. (I'm giving a talk in Paris, Feb 23 at a meeting *Pragmatism and Quantum Meeting*, titled "William James, F. C. S. Schiller, and the Quantum Bayesians".) Schiller's ideas are fascinating and I think, perhaps, deeper than James's even.

Anyway, I was thinking I should send you a holiday letter and I came across a quote today that's giving me an opportunity. Ultimately, it's about the "big bang" being right here, right now, all around us. I'll give you the idea in three flavors, first in the form of a transcribed conversation between John Wheeler and R. Q. Elvee, second in an excerpt from my pseudo-paper "Delirium Quantum" (which is attached in its final form, just sent to the publisher), and third in my newfound quote from Schiller. It comes from his 1924 book, *Problems of Belief*.

Wishing the best to you and your family for the coming year. It sure would be nice to see you again sometime soon. (Will you be going to the Zeilinger foundations meeting in Vienna in June?)

Flavor 1:

ELVEE: Dr. Wheeler, who was there to observe the universe when it started? Were we there? Or does it only start with our observation? Is the big bang here?

WHEELER: A lovely way to put it—"Is the big bang here?" I can imagine that we will someday have to answer your question with a "yes." If there is any conclusion that follows more strongly than another about the nature of time from the study of the quantum nature of space and time, it is the circumstance that the very idea of "before" and "after" is in some sense transcended.

There are two aspects of this idea. First, Einstein's theory of space and time tells us that in order to predict all of space and time for time to come, we have to know what the conditions of space are now and how fast they're changing. Only then do we have enough information to predict all the future. The uncertainty principle of quantum theory tells us that if we know the condition of space now, we cannot know how fast it's changing. Or if we know how fast it's changing now, we cannot know what the geometry is now. Nature is so built with this complementary feature that we cannot have the information we need to give a deterministic account of space geometry evolving with time.

That deterministic account of space evolving in time is what we mean by spacetime. Everything that we say in everyday language, about time is directly built on that concept. And with determinism out, the very ideas of before and after are also out. For practical everyday matters, this indeterminism, this indefinability of spacetime is of no concern. The uncertainties only show up effectively at distances of the order of 10^{-33} cm. Nobody at present has equipment fine enough to reach down to a distance so small.

What does all this have to do with the big bang? At the very beginning of time we know that—according to Einstein's account—the universe was indefinitely small. Things were indefinitely compact. When we talk about time when the universe itself is so fantastically small, we deal with a state of affairs where the very words "before" and "after" lose all meaning. This circumstance puts one heavy restriction on the usefulness of the word "time." There is another.

When we do our observations in the here and the now on photons, quanta of light, hunks of energy coming from distant astrophysical sources, we ourselves have an irretrievable part in bringing about that which appears to be happening. We can put it this way: that reality is, in a certain sense, made up of a few iron posts of definite observation between which we fill in, by an elaborate work of imagination and theory, all the rest of the construction that we call reality. In other words, we are wrong to think of the past as having a definite existence "out there." The past only exists insofar as it is present in the records of today. And what those records are is determined by what questions we ask. There is no other history than that. This is the sense in which we ourselves are involved in defining the conditions of individual elementary quantum phenomena way back at the beginning of the big bang.

Each elementary quantum phenomenon is an elementary act of "fact creation." That is incontestable. But is that the only mechanism needed to create all that is? Is what took place at the big bang the consequence of billions upon billions of these elementary processes, these elementary "acts of observer-participancy," these quantum phenomena?

Have we had the mechanism of creation before our eyes all this time without recognizing the truth? That is the larger question implicit in your comment. Of all the deep questions of our time, I do not know one that is deeper, more exciting, more clearly pregnant with a great advance in our understanding.

Flavor 2:

The way I see it, quantum measurement outcomes are ultimate facts without specific call for further explanation. And indeed the quantum formalism supplies none. Thus there is more to the world than the quantum formalism can supply. Nothing to do with hidden variables. ...

How does the theory tell us that there is much more to the world than it can say? It tells us that *facts* can be made to come into existence, and not just at some time in the remote past called the "big bang" but here and now, all the time, whenever an observer sets out to perform (in antiquated language) a quantum measurement. I find that fantastic! And it hints that facts are being created all the time all around us. But that now steps out of the domain of what the quantum formalism is about, and so is the subject of future research. At the present—as a first step—I want rather to make the interpretation of the quantum formalism along these lines absolutely airtight. And then from there we'll better know how to go further.

Doesn't that just make you tingle? That (metaphorically, or maybe not so metaphorically) the big bang is, in part, right here all around us? And that the actions we take are *part* of that creation! At least for me, it makes my life count in a way that I didn't dare dream before I stumbled upon Wheeler, Pauli, and Bell-Kochen-Specker.

Flavor 3:

On a very minute scale, but in a very real sense, our preferences and our acts are contributing to the shaping of the world, and sharing in the unceasing process of creation, which did not come to an end 5,928 years ago, but is continuously manifested in the all-pervasive creativeness which engenders ... novelties in every region of the universe.

If Humanism then is right, human agency is *not* the illusion it is so tempting to make it. Truth may be, like the other values, like our moral and aesthetic ideals, a real contribution to reality, which the real might not possess unless we had made it.

27-12-06 *Bayes, Born, and Everett* (to F. J. Tipler)

Tiplerism 1: *You probably have never heard of me, but I was a post-doc of John Wheeler's from 1979 to 1981.*

Of course I've heard of you. I read your book with Barrow on anthropic principles about 20 years ago and enjoyed it immensely. (My copy burned up in the Cerro Grande fire that came through Los Alamos six years ago, but I used to keep one of Sam Hurt's Eyebeam cartoons in it as a bookmark. It was a scene of Eyebeam explaining anthropism to Ratliff; when each would turn his back on the other, the other would disappear from the scene.)

Your sentence indicates though, that you thought John Wheeler might be a hook for my interest. Indeed I have the greatest respect for some of John's more outlandish ideas on quantum mechanics. (You might enjoy the Wheeler story on page 149 of my `quant-ph/0105039`. And you can find more

Wheeler stories by looking in the index; there's a better indexed version on my website.) I wish I had known you were one of John's postdocs; I would have invited you to the little meeting Marlan Scully and I organized at Princeton last year for John on quantum information and quantum foundations. Schumacher, Wootters, Unruh, and various of John's other quantum-interested associates came. John even made an appearance for about 30 minutes. It was quite nice to see him even at this stage in his life. You could tell he was understanding the emotion of the occasion, even if not much else. His smile and the thrusting of his fist into the air made it all worth it.

Tiplerism 2: *In reference to your "Being Bayesian in a Quantum World," conference last year, I've just put a paper on the* `arXiv` *(*`quant-ph/0611245`*), wherein I derive the Born interpretation using the Bayesian approach to probability, namely that probabilities are precise quantitative measures of human ignorance.*

I have downloaded your paper and will study it carefully. As it turns out, I'll be speaking at the "Many Worlds at 50" conference in Waterloo in September, and the title I gave the organizers for my talk is, "13 Direct Quotes from Everettian Papers and Why I Find Them Unsettling." Not a lie. I hope your paper doesn't make my list!

You certainly have a different use of the Bayesian idea of probability in mind with regard to quantum mechanics, than my closest colleagues and I do. For fun, I'll attach two pieces of writing that aren't posted on the web yet—one's a paper, and one's a pseudo-paper—so you might see what I mean by this remark. However, I might also send you to `quant-ph/0205039` which is the paper I'm most pleased with at the moment. (It is not a mistake that the number above is `0105039`, while this one is `0205039`; it's just an interesting coincidence.) Anyway, of the two papers attached, the pseudo-one tries to express what I don't like about block-universe (in the sense of William James, say) conceptions of the universe—the Everettian idea is a species of this. I'd rather think the universe is not complete in any sense, and I think quantum mechanics gives us plenty reason for exploring this turn of thought. The other paper, particularly in its concluding section, tries to express what my colleagues and I see as the import of the Born rule: The idea we are trying to develop is that it is not a rule for *setting* probabilities, but rather a rule for *transforming* Bayesian/personal/subjective probabilities.

27-12-06 *Residue of the Category Error* (to S. J. van Enk)

van Enkism 8: *Do I get this right, at least with high probability?*

So, it's a live option for you?! Not a fact?

Anyway, indeed you are on the right track (probably just using mildly different language than I use). h cannot both be a fact for the agent and a live option. One makes the category error (i.e., thinking a probability assignment can be implied by a fact alone, and therefore itself is a fact) if one thinks $h \rightarrow h$ (a statement about a fact) enforces $P(h|h) = 1$. The latter is a judgment because, in order for $P(h|h)$ to be meaningful at all, the left-hand h must be a live option. That is, one judges that the live option will be the same as the dead fact.

Steven's Preply

What you say here sounds right to me:

> So, now we get to the point. My present opinion is that probability statements are really only ever meant to be made about "live options" (to use

a phrase of William James, though I may not be using it exactly the same way as he did). One can indeed write $P(x=5)=1$, but then $x=5$ had better a live option, rather than a "fact for the agent." If it is a fact for the agent, then we are reinstating the category error. The only role for the "facts for the agent"—despite their very real consequences, like 'life' or 'death'—are in pivoting the agent's subjective probabilities. They are never used for the setting of probabilities unconditionally.

In particular, I needed the part about "reinstating the category error" to be convinced.

"$x=5$" could be either in the part labeled "d", or in the part labeled "h" in probabilities like $P(h|d)$, but they have different meanings then, one is a fact, the other is a live option. So, writing $P(h|h)$ or $P(d|d)$ are both category errors.

Do I get this right, at least with high probability?

28-12-06 *I and It, 2* (to R. Schack)

Schackcosm 99: *I am just not sure what the problem is with simultaneously (a) knowing there is nothing objective in the world guaranteeing an outcome and (b) being certain of the outcome.*

I'm finally replying to this. Though, not much to say actually. It is just that I think analyses of the Timpson type are valuable for showing how twisted things can become under the "question-answer" motif for quantum measurement—that is, viewing a quantum measurement as asking a question of a system, and the system coughing up an answer. With that imagery, how could the agent be certain of the outcome if he acknowledges that the system is not certain? I can see his quandary. But if one takes the alchemical view, as far as I can tell, it doesn't seem to be any big deal at all—it is not a great quandary. The quantum system's role is that of a catalyst, not an answerer of questions—there is no reason for it to be "certain" of the outcome, i.e., there is no reason to have a fact residing in the system that indicates the outcome of the measurement. And so my desire for Timpson to run through a pretty thorough analysis of the opposing conception is a bit self-serving. It's a useful exercise and someone should do it.

28-12-06 *The Scandal of Bayesianism* (to A. Hájek)

Once upon a time, you showed me a draft of a paper that contained these words:

> The scandal of Bayesianism is that no rational constraints on subjective probabilities beyond probabilistic coherence have been widely accepted. ... Bayesians maintain and even celebrate a remarkably anarchistic attitude to priors, (and derivatively to posteriors): as long as they are coherent (or appropriately derived from a coherent prior), anything goes.
>
> ... Just as our beliefs aim for more than consistency, our probabilistic judgments surely aim for more than coherence. What, then, do they aim for? What does such a judgment's 'fitting' the world amount to? What plays the role for subjective probability analogous to the role that truth plays for all-or-nothing belief? Presumably something plays this role, for probabilistic judgments seem also to be governed by a norm of veracity. How else can we explain the fact that we regard some weather forecasters as better than others, even when they couch their predictions probabilistically? And when different people assign different probabilities to the same event—as the managers and

> engineers did the day before the ill-fated space shuttle launch in 1986—we think that they are *disagreeing* about something. There is surely some fact about the world that a subjective probability assignment strives to track. Beliefs strive for truth; probabilistic judgments strive for <u>(fill in the blank)</u>?

Could I ask you to email me a copy of that paper if you still have it around?
Thanks!

Alan's Reply

> [CAF said:] "Thanks for the paper. Was it never published?"

> Not yet. I did send it to a journal. The referee's report wrote that I "didn't even discuss the obvious objection that nothing fills in the blank". Not only DID I discuss this objection, but it got a section to itself, with an italicized heading. Maybe next time I should put it in bold face as well. When I complained to the editors, they were very good about it — apologetic, and they invited me to resubmit the paper. I eventually will, when I've revised it further.

28-12-06 *Prepare Yourself* (to N. D. Mermin)

Sorry for my holiday absence (not that you probably minded!). I started gearing up this morning to reply to your 12/18 note, particularly what I deem to be your main trouble expressed in it:

Merminition 159: *All I'm saying is that this is rotten pedagogy, because it gives the student no basis whatever for getting the whole process started. Part (b) of the figure makes this dramatically clear. All the circuit does is transfer the state from the ancilla to the Qbit. It doesn't begin to answer the student's question of how you make an initial state assignment independent of any prior state assignment. Whether the initial state assignment is objective or subjective, the grounds for making one remain utterly obscure.*

and

Merminition 160: *With reference to what you say below, the prior, as I understand Figure 1 is that the damned ancilla on the left has the state assignment* $|0\rangle$*, so you haven't told the [poor] student anything about what it means to make such a state assignment, either objectively or subjectively. It's all circular.*

So, I did a few Google searches. For instance, I did one on "Bayesian" and "prior come from." Well, there's some tasty quotes out there:

> Bayes' Rule is central to modern economics and modern psychology. According to Bayes' Rule, a rational person starts with some beliefs about probabilities (his "priors") and changes them in a particular way as new information arrives, in order to reach new beliefs (his "posteriors"). Psychologists usually emphasize that people should use Bayes' Rule; economists are more likely to assume that people do use Bayes' Rule.
>
> The main problem with Bayes' Rule is that it doesn't say where priors come from, or which ones you should have. It is tempting to say that every prior is just your last posterior. But where did your first prior come from? If you picked the wrong one, then everything based on it could be wrong as well.

Maybe more relevantly I dug into my personal archives and found, for instance, this nice thing by Alan Hájek (from a 1998 draft of something):

> The scandal of Bayesianism is that no rational constraints on subjective probabilities beyond probabilistic coherence have been widely accepted. Bayesians maintain and even celebrate a remarkably anarchistic attitude to priors, (and derivatively to posteriors): as long as they are coherent (or appropriately derived from a coherent prior), anything goes.
>
> … Just as our beliefs aim for more than consistency, our probabilistic judgments surely aim for more than coherence. What, then, do they aim for? What does such a judgment's 'fitting' the world amount to? What plays the role for subjective probability analogous to the role that truth plays for all-or-nothing belief? Presumably something plays this role, for probabilistic judgments seem also to be governed by a norm of veracity. How else can we explain the fact that we regard some weather forecasters as better than others, even when they couch their predictions probabilistically? And when different people assign different probabilities to the same event—as the managers and engineers did the day before the ill-fated space shuttle launch in 1986—we think that they are *disagreeing* about something. There is surely some fact about the world that a subjective probability assignment strives to track. Beliefs strive for truth; probabilistic judgments strive for ___(fill in the blank)___?

But then I went back to bed … and so now this is a restart. (I hate it when I do that, for it forces me to change the planned titles of my notes. The present title was meant to be the second title in the series. But I've decided that maybe I'll just go for broke and put my complete reply in the present note.)

What I read into your note is simply a species of this general worry about Bayesianism. "Where does the prior come from? Without telling me where a prior comes from, how can you have given me a complete solution to the meaning of probability?"

Compare: Where does the initial quantum state come from? Without telling me where the initial quantum state for a quantum computer comes from, how can you have given me a solution to the meaning of quantum states? Particularly, how can you make any sense of what a quantum computer is doing if you don't give an answer for where its initial quantum state comes from other than saying that it's conditioned from (effectively) a previous quantum state?

Remember, for me, a quantum state is *nothing but* a single probability distribution (for the outcomes of a singled-out informationally complete observable). Thus, to the extent that a subjective Bayesian leaves the ultimate origin of *any* probability assignment unanalyzed, precisely the same point holds for quantum states.

You call that circular. The subjective Bayesian calls it necessary: It is the cutting of a Gordian knot. Without the stark recognition that all (ultimate) priors are personal to the agent, one would have an infinite regress. Not circularity, but an infinite regress. So, one says, "There's a starting point, I can't get past that."

For myself, I think, "Why is that admission any more mysterious than what one finds in Newtonian mechanics?" A pendulum, for instance, has an equation of motion and an initial condition. Why doesn't anyone in a classical physics class complain, "But where does the initial condition come from? Without telling me the origin of the initial condition, you have not told me the complete story of the pendulum!" Or why don't the instructors complain to the textbook writers, "You think this is good pedagogy? How am I going to explain to the students that they must just take initial conditions for granted … and that it is beyond the bounds of the problem to ask where the initial conditions come from?"

As far as I can tell, in the two classes of problems the *only* difference of any note is in what the initial conditions are about. There's no great conceptual or philosophical difference between the two. The ordered pair (x_0, p_0) is the initial condition of the pendulum. The prior $P(h)$ is the initial condition of the agent. Dynamics leads to (x_1, p_1); conditioning leads to $P(h|d)$. Why does the initial condition of the agent call for any more explanation or justification than the initial condition of the pendulum?

Or maybe let's put the two examples together. (x_0, p_0) is the initial condition of the pendulum, but $P_0(x, p)$ is the initial condition of the classical observer using Liouvillian mechanics (the agent). Both systems, the pendulum and the agent, have unexplained initial conditions — what's wrong with that?

Above I said "only difference of any note," but of course there is a difference of detail here and there. When we come to the quantum case particularly, there is this difference between the classical Liouvillian observer and the quantum observer. When the classical observer writes down $P_0(x, p)$, it is his initial uncertainty of a preexistent reality for the pendulum; when the quantum observer writes down a quantum state $|\psi_0\rangle$, it is his initial uncertainty for *what will come about for him* in the case that he takes a certain fiducial action upon the system (i.e., makes a certain measurement)—it is not an uncertainty for a preexistent value.

Is that difference of detail enough to require that $|\psi_0\rangle$ be given more explanation or justification than $P_0(x, p)$? We say (over and over), no. What I should better understand about you is why you think it needs more. My guess at this point is that it is nothing other than the usual fear of Bayesianism (even in the classical context of $P_0(x, p)$): "Surely there is a 'right' prior, and whatever makes it 'right' is what should be delineated." That's what you are asking for.

Now, before moving on to another point, let me come back to part of your second quote above:

Merminition 161: *With reference to what you say below, the prior, as I understand Figure 1 is that the damned ancilla on the left has the state assignment $|0\rangle$, so you haven't told the [poor] student anything about what it means to make such a state assignment, either objectively or subjectively.*

That is just incorrect. We have told the poor student over and over what it means to make the state assignment $|0\rangle$. It means that for his subjective assignment that IS the measurement gate (that particular quantum operation), he is quite certain what the consequence of its action upon the quantum system will be for him—he will get the datum 0. He can predict the outcome with (subjective) certainty. That is the *meaning* of $|0\rangle$: It is the statement of certainty. It is the statement that the student is prepared to gamble his life on the outcome.

You don't have to like our answer, but that is the answer we give. It is clearly a meaning for the state $|0\rangle$—a very personal one, with operational consequences. What we don't do is give a larger story that explains the origin of the agent's state of mind, $|0\rangle$. Where did he get that from? I don't know. It might be a good question to ask, but it is not one that the calculus of probability can answer. For, the calculus of probability requires as its very input a probability assignment—just like the calculus of Newtonian mechanics requires as its very input an initial state for the system under discussion.

So, why did I title this note "Prepare Yourself" (other than for its expected length)?

Just what is happening, you ask, for the quantum computer scientist with the initial preparation gate in your depiction of a quantum computer? What is he doing when we *say* he is preparing the qubit? From the Bayesian point of view, he is preparing himself. He is tightening his state of belief for what will come about in future interactions with the qubit.

I guess that's why I showed such dismay at your talk in Konstanz:

Merminition 162: *As I understand you it is unacceptable because that would give the state an objective character. (The basis for the remark I made early in my talk in Konstanz that made* *you say I still hadn't understood a goddam thing. Probably I still don't. If the reading of the measurement gate is a fact, then the only room for subjectivity is whether the measurement gate is indeed a measurement gate — e.g. is it properly aligned, or, in Figure 1, the subjectivity of making the state assignment $|0\rangle$ for the ancilla.)*

I remember you had a big question mark as the output of the preparation gate—seemingly implying that the quantum computer scientist would not know what the output of the gate was. But he knows exactly what it will be. The "preparation gate" is an action whose consequence will prepare his state of mind to something he wants it to be. The subjectivity of the measurement gate (or preparation gate, I can't remember your exact terminology) means that it is *his* description of his action upon the qubit. Making it *his* description—rather than a fact about ultimately remote parts of the universe external to him, as the conception you are shooting for does (see my previous note)—makes it no less useful to him. (Maybe it makes it more so.)

At the moment, I fail to see how this would be so very mysterious to a computer scientist. To perform a (quantum) computation, you build your confidence about some things to do with a machine (what you will see if you press this button). Then you bank on that to let the machine help you build up various inverse probabilities for something you are not very sure about (say the factors of some large number).

Does any of this answer anything for you?

P.S. In return for all this labor this morning, I would love a reply from you on what I'm getting wrong with my critique of your "disembodied facts" account of quantum states.

28-12-06 *Goose and Gander* (to R. W. Spekkens)

Spekkensism 34: *On the subject of the ontic/epistemic status of the quantum state, at the end of a talk to the history and philosophy of physics group at Leeds, Ian Lawrie (a physicist) had a comment which, after I had finally understood it, impressed upon me (more strongly than before) that there's a sense in which the distinction breaks down when one tries to treat agents as physical systems. I'm curious what you think about the following argument. Suppose one devises a physical theory for the ontic states of the world – no external observer is required for the theory to be well-defined; it is a "god's eye view" type of theory. And suppose that this theory does in fact provide a useful model of known physics and, in particular, of observers and the process of observation. In other words, all observers are treated internally to the theory. Assuming a materialist position on the mind-body problem, everything that is known to any observer is encoded in the ontic state of the world according to this theory (either in the intrinsic properties of their brains, or, more likely, in the relational properties of their brains and the rest of the world). According to the epistemic view of quantum states, different quantum states represent different beliefs. However, in such a physical theory, different beliefs correspond to different ontic states of the world, and so different quantum states correspond to different ontic states of the world.*

Personally, I don't see much of a problem with granting that quantum states are ontic in this sense. They are simply not ontic in the traditional sense of describing the reality of the system to which the state is assigned. Furthermore, even though they may be ontic in this sense, they certainly will not correspond to a complete description of reality in such a theory. In other words, quantum theory can't be this "über"-theory. What's your take on it?

Well, I don't think much of such hoped-for god's-eye-view theories, because I doubt the concept is even consistent at all. They don't have enough fire in the loins, so to speak, to power a real universe. (That's part of what I think quantum theory is trying to tell us.) But I'll grant you the possibility, for the purpose of getting this discussion off the ground.

If you limit me to that context, then I'd say I probably pretty much agree with your second paragraph above. In my presentations, I know that I often use language like this (the presentational Chris Fuchs is usually not as radical as the Chris Fuchs of correspondence—I tend to think it's better to be a little less than true-to-myself in such a forum for the purpose of more progress and less confrontation; Lord knows I already have enough confrontation). I find myself saying things like I said to Greg Comer in a 4 July 2003 note:

> A wave function and its evolution are not properties intrinsic to the system for which they are about. Rather, if they are properties of anything at all, they are properties of their user's head—for they capture all his judgments about what might occur if he were to interact with the system of interest.

Indeed, that's not so very different from calling a quantum state an ontic state of the agent (when treated as an agent per se). [Just for completeness sake, let me point out the difference between that and a situation where *I* treat *you* as a physical system (rather than an agent) of which I can contemplate performing measurements on. For instance, I might ask you what you believe of that electron for all measurements you could perform on it. Your answer to me will be in the form of a density operator—that is to say, the outcome of my quantum measurement will be something that symbolizes a quantum state in your possession. Since I generally won't know what your answer to me will be—treating you as a physical system—I encode my uncertainty about the answer you'll give my questions in a density operator. That density operator—which is an epistemic state for me—has nothing to do with the ontic state we are talking about above. Nor is the outcome of my quantum measurement directly so either—for the outcomes of quantum measurements are not revelational of properties intrinsic to the system (they are a joint product of the observer and the system). This, I think, is another way of saying what you said above, that quantum theory will not be its own über-theory.]

Or to give a more recent example of my using this kind of imagery, I might paste in the note I composed for David Mermin this morning. Throughout it, I lean on the idea that a quantum state is effectively an ontic state for the agent (along the lines of how x and p are ontic states for a pendulum). I think the note is relatively self-contained and you'll see its relevance for the present issue. The figure Mermin refers to is in the attached paper—a revised version of the CFS paper "Subj Prob and Q Certainty". The issue that seems to bother Mermin is that Bayesians give no account of the origin of a prior; I say that is no deeper a problem than Newtonian mechanics giving no account for the origin of any initial condition. What's good enough for the goose, should be good enough for the gander.

Spekkensism 35: *On a different topic, I recently finished a paper on pooling quantum states. The central result is something that I worked out during the BBQW workshop after Todd Brun's talk and have since developed with Howard Wiseman. It appeared on the* `arxiv` *on Christmas day (I'm attaching a copy). I'm sure that you will be unhappy with it for the same reasons that you're unhappy with the Brun-Finklestein-Mermin compatibility criterion. Still, as someone who likes to think about quantum analogues of features of classical probability theory, you might be interested in the problem.*

Thanks for sending the paper. I'm quite OK with exercises like this—I think they're essential—as long as they are advertised for what they are: Examples of conditions under which disparate agents will move closer to agreement. One would like to identify those cases! If Agent X believes this, and Agent Y believes that, then they will be willing to pool their beliefs for a sharper belief. But to demand that beliefs always be poolable—I say—effectively transforms them back into ontic states (defeating the purpose of trying to draw an ontic/epistemic distinction in the first place)—they become incomplete perspectives on the "true" ontic state and regain an ontic character in that way. BFM could just never get that into their heads (it's really hard to give up the idea of an ontic quantum state).

I'll certainly study your paper. I hope you advertise the result the right way!!

Spekkensism 36: *Matt Leifer and I are writing a follow-up paper which makes extensive use of Matt's "conditional density operators", and goes much further on the problem than my paper with Howard does.*

Glad to hear about that. Reflecting on Bayesianism, one knows that the foundation is really in the idea of conditional probability $Pr(h|d)$ rather than unconditioned probabilities $Pr(h)$. Similarly I'm starting to think perhaps quantum mechanics is focusing on the wrong mathematical object for a smooth development along Bayesian lines. It is not the quantum state, but something *like* (if not exactly) Matt's conditional density operators. So, it'll be good to get a better feel for these objects in as many ways as possible.

Happy New Year to you too!

29-12-06 *Your Amazing Efficacity* (to A. Plotnitsky)

I came into Bell Labs today and found to my great surprise the package containing your new book! You really are quite amazing. Prolific. I wish I had a fraction of your productivity! I'll certainly study your new material.

When will you be in New York again? I'd love to get together with you one day for a long lunch.

Attached you will find my own latest, with Caves and Schack: `quant-ph/0608190`. [...]

For the moment though, I hope you will hang on the words "fact for the agent" which I introduced into this article. I think it is the key for much of what I want to say in the next paper. Here's a little discussion I had with one of the referees of the present paper.

> This paper does not emphasize it, but no, we do not mean "the facts we are talking about here are facts for everybody." We mean that the facts too are personal, though in a very careful sense.
>
> We have tried to meld the phrase "fact for the agent" a little better than previously into its surrounding text, but a better exposition would have emphasized the full setting of our view, including some discussion of the ontological—i.e., noninstrumental—pieces of it. 1) There are two physical systems in the story of this paper. One takes the role of the agent—the possessor of subjective degrees of belief and the activator of the measurement process. The other takes the role of the object system. 2) What is being discussed when one speaks of gathering data in the quantum context is an interaction or transaction between the agent and the object. 3) Without the agent, there would be no quantum "measurement" to speak of, but without the object, there would be no means for the agent to obtain the data, the spikes upon which he pivots his probabilities (his subjective degrees of belief). 4) There are no other agents in this story. 5) We do not go any further than points 1-5 warrant by giving the data obtained in a quantum measurement an autonomous existence—for instance, as something beyond

the agent's sensations. That would run into inconsistencies in a "Wigner's friend" scenario. Nonetheless, quantum measurement outcomes are beyond the control of the agent—they are only born in the interaction—and thus are not functions of the agent in the way that his degrees of belief are. The degrees of belief find their source in the agent (the subject); the outcomes find their source in the external quantum system (the object). But the outcomes lead back to the agent in that they are personal to him.

> This does not mean that the agent-object interaction and its fuller consequences are not autonomous events in spacetime, but it does mean that if there are any such things, quantum theory is not directly concerned with them. In CAF's view, quantum theory takes its whole definition as a normative theory for organizing an agent's *personal* probabilities for the *personal* consequences of his interactions with external physical systems. The structure of the agent-independent world that lies behind quantum mechanics is, in the end, still codified by the theory, but only in a higher-order, more sophisticated fashion than had been explored previously—it is through the normative rules, rather than quantum states and Hamiltonians.

When we get together, I'd like to come back to your old 'efficacity' concept. Ever more I feel it's relevant to what I want to say ... but I wonder if that is one of the things you have changed your views on (as I don't see the word appearing in your index).

29-12-06 *The Finish Line* (to S. Hartmann)

Hartmannism 2: *Could you send me the final version by the end of December? This would be great.*

OK, we just barely made your deadline! Attached, please find our paper (both in LaTeX form and PDF) and our replies to the referees (they are all in one single PDF file).

I can tell you, you have no idea how much (and how deeply) we fought in constructing this paper. The whole thing was built out of negotiation—and you'll get some sense of that if you read our replies to the referees (particularly our remarks to Ref 1—i.e., Mermin—and Ref. 4). And every single word was pained over. Thus, we pretty much beg of you not to ask for any further changes to the text. Very seriously. My word processor shows our word count to be 10,582—it is over the 10,200 word limit you and Roman set, but only by a little.

I hope you enjoy the new version of the article. I think you got much more than you bargained for: You asked for a review, but we gave you a new research article. Thanks for giving us this opportunity.

By the way, I found Referee 4's comments excellent (as I hope my replies to him show). If he is amenable, I would like to further the conversation with him, as I think I would get much out of the exercise and because I have many points to add to what I already said to him (that I couldn't express when speaking for Carl and Rüdiger). Thus, if you will, please give him my card (i.e., this paragraph), and tell him to contact me if he has any further interest.

Best wishes to you and your wife for the coming year!

31-12-06 *Tipler Speaks* (to R. Schack)

I don't think I'm going to reply to Tipler's reply to my reply to Tipler, but I am curious in what pithy way you would answer his sentence, "Anyone with the same information would assign exactly the same probabilities." I'm afraid we have Ed Jaynes to blame for this one, and so we'll keep hearing it. It might be good to develop a good canned answer.

> **Chris:** The other paper, particularly in its concluding section, tries to express what my colleagues and I see as the import of the Born rule: The idea we are trying to develop is that it is not a rule for *setting* probabilities, but rather a rule for *transforming* Bayesian/personal/subjective probabilities.

> **Tipler:** Here I think you are indeed taking the wrong approach to probability theory. There is nothing personal or subjective about assigning probabilities. Anyone with the same information would assign exactly the same probabilities. This was also Laplace's view, and he was a determinist like me. Probabilities are not in nature, they are only precise measures of human ignorance. Which is why I prefer to call my approach "Laplacean probability" rather than "Bayesian probability." And I think that you will have difficulty improving the priors that come from quantum indistinguishability.

03-01-07 *David Signals* (to N. D. Mermin)

Judging from your present note, it doesn't look like you'll like the latest incarnation of the footnote. (I'm sorry; I just realized that I had not sent you the finalized manuscript. It is attached.) In this version we had said:

> N. D. Mermin (private communications, 2003 and 2006) characterizes as "dangerously misleading" the idea that the post-measurement quantum state $|\psi\rangle$ of B is an objective property of system B alone. He "reject(s) the notion that objective properties (must) reside in objects or have physical locations." Yet the quantum state of B, if objective, is a property of the world, external to the agent, and since it changes as the world changes, it is hard to see how it can have only the disembodied objectivity Mermin is describing. If the objectivity of $|\psi\rangle$ *does* reside somewhere, say, in the entire experimental setup, including the device that prepares A and B and the measurement on A and its outcome, then consider a measurement of an observable of B for which $|\psi\rangle$ is an eigenstate with eigenvalue λ. If λ is an objective property, how can it fail to reside in B (under the assumption of locality), thus making $|\psi\rangle$ a property of B after all?

For, clearly here we use that bad word "property" again.

But, while we're on this subject, you say:

Merminition 163: *The naughty things I'm searching for are facts — in this case the facts of the "preparation procedure". There's nothing wrong with some of the facts being facts about us. (Can't have "correlations between the manifold aspects of our experience" without invoking us.)*

In what way do you distinguish the phrase "facts about us" from "properties of us"? I would normally think of these two phrases, "facts about" and "properties of," as synonyms, and I think everything I have written can be interpreted that way. But you seem to reject that usage.

However, there's a still more worrisome issue here. Previously I would have *never* thought you would allow the facts for which you take quantum states to be short-hand of to refer to the agent in any way (or the preparer, if you will). But now it seems that is part of your very formulation. Has it always been so?

Because the quantum state—from our view—depends on the AGENT as well as the data, we have insisted on calling it subjective. As I understood you, you wanted to think that quantum states could be made to refer to facts alone—agent-independent facts particularly—and you therefore wanted to call (pure) quantum states objective. If you are willing to explicitly renounce the requirement of agent-independentness (which I had thought you had always been making), in what substantial way does your view differ from ours?

Well, I would guess it still differs deeply in that you say:

Merminition 164: *I would say that the "something in the world ... that guarantees the outcome YES" has to be the whole state preparation — all the relevant history of the system prior to the measurement.*

For even if you were to substitute into that:

> I would say that the "something in the world ... that guarantees the outcome YES" has to be the whole state preparation — all the relevant history of the system AND THE AGENT prior to the measurement.

CFS would still get hung up on your idea of "guarantees."

Let me paste in a note that I wrote to Rob Spekkens (just after writing you last) [dated 28-12-06, titled "Goose and Gander"] that I think is directly relevant to the issue. In that note to Rob I say one might validly call a quantum state an ontic state of the agent (though maybe I should have called it 'ontic aspect'). Is that all that your way of phrasing things is trying to capture?

If it is, then in a later note I'll try to argue that our way of phrasing things in better, but first I've got to understand this NEW (I think) twist I'm hearing from you.

03-01-07 *New Year's Alchemy* (to H. C. von Baeyer)

Thank you for the sweet New Year's note. Though I've only known you for a short while now, I've learned that when I need some reassurance that I'm not wasting my life away, I can at least look to your emails. That's more resources than I had before! The idea of the Republica Literaria sounds charming.

So what should I call my upcoming lump of collected emails if not samizdat? Your description was inspiring, but I need to distill the idea into a name that won't make me appear to be self-aggrandizing. At the moment, I run dry.

Have you had a chance to read through (or translate) any more of the Pauli-Fierz correspondence? I've been thinking about modern alchemy again—aka quantum measurement—as I've been thinking about how to put together my Shimonyfest contribution and also reading F. C. S. Schiller in preparation for my lecture in Paris. (Will you still be in Paris Feb 22 and 23? If so, you should come; the meeting is titled "Pragmatism and Quantum Mechanics," and my talk is titled "William James, F. C. S. Schiller, and the Quantum Bayesians." Schack will be there too.) Maybe I'll be able to get a quote of Schiller into my computer in the next few days and send it to you; it'll help reveal a little of what I see as the connection between Schiller's metaphysics (of a plastic reality) and Pauli's alchemy.

Attached is a copy of the finalized version of my recent paper with Caves and Schack on certainty. (We haven't re-posted it yet; that'll have to wait until Rüdiger is back from vacation.) It is much changed since the version you last saw; though not too much with regard to the particular point you made. Sorry about that. Still I hope the paper makes a little more sense this round. I'm not all that pleased with the paper, but it'll have to do. Particularly, the next stage of development really has to be an explicit and open discussion of the ontology that underlies our view of quantum mechanics. That is what my Shimonyfest contribution will attempt to be about; I want it to be a much more detailed development of the point I made to one of our referees, which I'll paste in below. Measurement involves *two* systems, so it is not solipsism (or positivism) even if the outcomes make reference only to the observer's sensations. The quantum system is the philosopher's stone that transforms the agent. (In that way, there is a bit of Pauli in me; but the passage also shows where I differ from Pauli—his and Bohr's 'outcomes' were automatically public, for the quantum Bayesians, they remain private … at least till communicated.)

Hans Christian's Preply, "Happy New Year," 30 December 2006

Dear Chris, for the New Year I wish you new insights, renewed certainty in your employment, and much joy. Also good wine.

I am in gray, cold, wet Paris, which is nevertheless brightly illuminated, snug, and exhilarating indoors. In the course of reviewing two new biographies of Emilie du Châtelet, Voltaire's lover and Newton's translator, I am reading a book that reminds me of you. In *The Republic of Letters* the historian Dena Goodman describes the 18th century forerunner of today's "scientific community", which is distinct from both the university world and the international system of professional societies. Both of the latter already existed during the Enlightenment, but the Republic of Letters was broader in both subject matter and membership.

The Republic of Letters was a network (you see where this is going?) of people interested in the arts, humanities, and sciences. As early as 1699 it was described as follows: "The Republic of Letters is of very ancient origin. It embraces the whole world and is composed of all nationalities, all social classes, all ages, and both sexes [!]."

Goodman singles out three features: In the 18th century the RoL depended on two fundamental inventions of the modern world – the printing press and the postal system – which together made possible the cosmopolitan polity of the RoL. Further on she quotes another historian: "… it was the strict duty of each citizen of the Republica Literaria to establish, maintain, and encourage communication, primarily by personal correspondence or contact." Citizens considered it their duty to bring others into the republic through the expansion of their correspondence. And finally: "Reciprocity is the distinctive feature of correspondence as a mode of communication …. Reciprocity was the fundamental virtue of the republic."

It was this last sentence that struck me – the difference between your style of research and the conventional style of publication. The RoL was a social construct that co-existed but contrasted with the monarchy, and, according to Goodman, eventually helped to bring about the revolution. This is certainly a more cogent reading of history than the fairy tale of the masses rising up spontaneously against the evil king, but it's not what interests me here.

I once told you that I didn't think samizdat was a good description of your work, but I didn't have a better suggestion. Now I realize that you are restoring the Republic of Letters by means of the latest technology, which replaces both the printing press and the postal system. This insight puts your work into historical context and, in my mind at least, enhances its value and importance. I doubt that you intend to or will start a revolution, but I do think that your style will flourish.

06-01-07 *Free Will, William James, NY Times* (to me)

From Maureen Dowd, "Monkey on a Tiger," *New York Times*, 6 January 2007:

> There was a touch of parody to the giddy Democrat takeover this week: Nancy Pelosi indulging her inner Haight-Ashbury and dipping the Capitol in tie-dye, sashaying around with the Grateful Dead, Wyclef Jean, Carole King, Richard Gere, feminists and a swarm of well-connected urchins.
>
> The first act of House Democrats who promised to govern with bipartisan comity was imperiously banishing Republicans from participating in the initial round of lawmaking. Even if Republicans were brutes during their reign, Democrats should have shown more class, letting the whiny minority party offer some stupid amendments that would lose.
>
> Perhaps the Democrats' power-shift into overdrive is a neurological disorder, or neuropolitical disorder.
>
> If free will is an illusion – if we are, as one philosopher put it, "nothing more than sophisticated meat machines," doomed to repeat the same mistakes over and over – that would explain a lot about the latest trend in which everyone is reverting to type.
>
> William James wrote in 1890 that the whole "sting and excitement" of life comes from "our sense that in it things are really being decided from one moment to another, and that it is not the dull rattling off of a chain that was forged innumerable ages ago."
>
> But in Science Times this week, Dennis Overbye advised Dr. James to "get over it," observing that "a bevy of experiments in recent years suggest that the conscious mind is like a monkey riding a tiger of subconscious decisions and actions in progress, frantically making up stories about being in control."
>
> As Mark Hallett of the National Institute of Neurological Disorders and Stroke told Mr. Overbye, "Free will does exist, but it's a perception, not a power or a driving force. … The more you scrutinize it, the more you realize you don't have it."
>
> That would explain why, after voters insisted that the president wrap it up in Iraq, he made a big show of pretending to listen, then decided to do a war do-over.
>
> Is this just the baked-in stubbornness of one man, or is W.'s behavior evidence that he has no free will? Is the Decider freely choosing another huge blunder or is he taking instructions from his genetic and political coding, fearing that if he admits what a foul hash he's made of Iraq, he'll be labeled a wimp, as his dad was?

09-01-07 *Harsanyi Principle* (to P. Grangier)

Thank you for your note; let me think about how I will reply. In the meantime, you can read one of my mumbles on the principle Jaynes is pushing here: `http://netlib.bell-labs.com/who/cafuchs/nSamizdat-2.pdf`. See pages 251 (note to David Poulin) to 253.

Philippe's Preply

> I stepped down on Jaynes's book on (strongly Bayesian, actually he tells Laplacian!) probabilities, and it does contain a lot of funny and interesting things (plus a few weird ones). Here is one (up to you to decide in which category it fits):
>
> > "Subjective" vs. "Objective"
> >
> > These words are abused so much in probability theory that we try to clarify

> our use of them. In the theory we are developing, any probability assignment is necessarily "subjective" in the sense that it describes only a state of knowledge, and not anything that could be measured in a physical experiment. Inevitably, someone will demand to know: "Whose state of knowledge?" The answer is always: "The robot - or anyone else who is given the same information and reasons according to the desiderata used in our derivations in this Chapter." Anyone who has the same information but comes to a different conclusion than our robot, is necessarily violating one of those desiderata. While nobody has the authority to forbid such violations, it appears to us that a rational person, should he discover that he was violating one of them, would wish to revise his thinking (in any event, he would surely have difficulty in persuading anyone else, who was aware of that violation, to accept his conclusions). Now it was just the function of our interface desiderata (IIIb), (IIIc) to make these probability assignments completely "objective" in the sense that they are independent of the personality of the user. They are a means of describing (or what is the same thing, of encoding) the information given in the statement of a problem, independently of whatever personal feelings (hopes, fears, value judgments, etc.) you or I might have about the propositions involved. It is "objectivity" in this sense that is needed for a scientifically respectable theory of inference.

So: a pure quantum state (my "modality") is "subjective" in the sense that you certainly have to know something (and in particular the "context") to speak about it. But it is "objective" in the sense that every "robot" (or whatever "thinking observer") which has that information can predict results with certainty, repeatedly, and without changing the system.

So is that Jaynes enough to convince a Bayesian that a pure quantum state is "contextually objective"?

With Best Wishes for 2007

09-01-07 *Harsanyi Principle, 2* (to P. Grangier)

Grangierisme 22: *Here the mumbles do not shake me too much. You write:*

> I will agree to your definition of "state of knowledge." But, backtracking from that, an initial state upon which everyone agrees? If one is taking a subjectivist approach (or what I had been calling a "Bayesian approach") to interpreting the quantum state, there is nothing in nature to enforce an initial prior agreement. God does not come down from on high and say to all the agents (i.e., all the observers), "Your starting point shall be the quantum state $|\psi\rangle$." Everyone is left to fend for himself.

But for QM, don't you think that there IS something to "enforce an initial prior agreement", it is simply what I call the "context", which is more or less what most people would call "reality"? (in the classical sense = if you don't believe in the wall, try to kick in it . . .)

So again I am tempted to think that your "extreme subjectivism" denies ALL KINDS of "realities", quantum as much as classical.

Actually, I start liking this idea of "prior knowledge", but in Jaynes' sense, which apparently is not exactly yours (I hoped so!), but is closer to this "Harsanyi doctrine", which has the infamous goal of trying to be "objective" . . .

So we have to try again!

Maybe not, we shall see.

Also let me send you the latest version of my paper with Caves and Schack. (It's quite different than the posted version; can't update it until Schack is back from vacation.) The closing section of it again comes back to the issue of what—in our view—is objective in the quantum world. It is more than nothing, but it is probably less than you are hoping for with your contextual objectivity.

But that's only a short reply. If one will allow "levels of objectivity" maybe the differences between us will disappear after all.

09-01-07 *Talk about Anthropocentric!* (to D. Bacon)

I just enjoyed your anti-Wolfram [`http://dabacon.org/pontiff/?p=1402`] and "Why I'm Not a Bohmist" [`http://dabacon.org/pontiff/?p=1339`] columns with my lunch. Nice. I agree with both points. Particularly your "I do not believe in computers" put a big smile on my face. It has some of the flavor of the de Finetti phrase I co-opted for our quantum Bayesian program. De Finetti said, "Probability does not exist," and I keep advertising "Quantum states do not exist." The point is, for Caves, Schack, a few others, and me, (all) probabilities and quantum states are anthropocentric constructions. To say that is not to give up on the project of figuring out what physics is telling us about the world in itself (i.e., the world without us), but simply to recognize those *particular* mathematical objects for what they are (and what they are has something intrinsically to do with us). Thus, when we say something like that, we're simply saying, "Don't look here" if your question is "What is the universe made of?" Look somewhere else.

Similarly I would say of a computer: It's as anthropocentric of a concept as a hammer or screw driver. A computer is a tool that satisfies a need; it is a *piece* of nature that has been harnessed for an external purpose. There is no more indication that computers are any more likely to be parts of the fundamental constituents of the world than are hammers. You didn't emphasize the anthropocentric aspect of it, but I think your point is pretty much the same.

Let me paste in a couple of pieces of my own writing that I hope will similarly put a smile on your face. The first is a nasty referee report that I wrote on a Bohmian funding proposal. I think the last paragraph of it gets at what really bugs me about what they're doing, and I think it makes much the same point as you were shooting for. The other is a letter I wrote to a professor at Princeton when he pissed me off by saying that what Caves, Schack and I am up to is trying to turn physics into a branch of psychology. I came out swinging! Anyway, he too is one of those people who says "the universe is a computer" and thinks that's saying something significant. Since I view that contrarily as an attempt to anthropocentrize the universe, I was doubly offended when he made the remark about psychology!

09-01-07 *Politically Correct* (to D. Bacon)

Baconism 3: *So every few months I try to come up with some new way of phrasing foundational problems, so that I have something to write about on my blog :) Today I've decided my next one will be "why is a qubit so much like a probabilistic bit?"*

Sounds like a good blog. When you write it send me an announcement, as I don't visit your blog on a regular basis. (Today's visit occurred because I wanted to see what your website name is; I'm thinking I need to get one for myself ... for when Bell Labs eventually lays me off.)

On a technical point, maybe your question should be "why is a qubit so much like two probabilistic bits?" For, if one wanted to think of a qubit's quantum state as a simple probability distribution (for the outcomes of an informationally complete measurement), the minimal event space has to have four outcomes. Similarly, a qudit requires an event space worth $2 \log d$ classical bits. It's probable that you've seen the paper, but in case not, have a look at Rob Spekkens' "toy theory" `http://www.arxiv.org/abs/quant-ph/0401052`. It's just a nice list of similarities between qubits and partially known cbits (maybe I'll call them pcbits). And he, like you, suggests that the place where we're really going to learn something about quantum mechanics is in its deviation, not from cbits (i.e., the event space), but from pcbits (the space of allowed probability distributions over the event space). So there: quantum theory's real value comes in precisely where it is not pc! (Those bad boys of quantum mechanics.) Who would have expected anything else?

09-01-07 *Facts-in-Themselves* (to H. C. von Baeyer)

von Baeyerism 25: *My Fierz translation is on hold. When I planned it, I thought that in retirement I would have nothing else to do. Then retirement turned into an avalanche of other things to do, and besides, Fierz died (though that should really spur me on all the more).*

That is too bad; I hope your conscience will send you back to the project eventually. That's because it's not Fierz, the man, that is important (and so the project should have nothing to do with his death, one way or other), but the set of ideas he and Pauli were exploring. The issue is getting those ideas into the consideration of a wider audience. I'm always about building workforce; what can I do to get you to think that way too?

Thanks for the Russian analysis:

von Baeyerism 26: *The big difference between samizdat and your technique, besides the issue of secrecy, is that the former obliges you to copy, whereas letters oblige you to reply. This principle of reciprocity is really fundamental, and should be reflected in the name of your work. But I have not coined a sexy slogan yet.*

You have me intrigued. I hope one of us can dream up a term.

You're right that reciprocity is really fundamental. It is in letter writing and in the world. Below is the F. C. S. Schiller quote I had promised you (originally from a 1903 Int. J. Ethics paper). I don't agree with it completely, but I like it much for the things I do agree with—particularly the part about reciprocity.

In fact I think I can localize the precise transition in the words that I don't like. He writes, "The simple fact is that we know the Real *as it is when we know it*; we know nothing whatever about what it is apart from that process. It is meaningless therefore to inquire into its nature as it is in itself." Particularly, I agree with the first sentence, while disagreeing with the second. I will agree that quantum measurements reveal nothing of the thing-in-itself, nor do they even generate facts-in-themselves—they are "facts for the agent." I think Schiller's description is quite nice in getting that kind of idea across. It's another take on the Paulian alchemical idea. But what of the Born rule for transforming probabilities from measurement to measurement? Of that, I would say, when we postulate it, we are taking a guess about some property of the world—a property of the world as it is in itself. It's an indirect statement, but it's a statement nonetheless. What's left is figuring out the precise nature of that guess (and its rather tight connection to some of the other things in Schiller's paragraphs!).

That the Real has a determinate nature which the knowing reveals but does not affect, so that our knowing makes no difference to it, is one of those sheer assumptions which are incapable, not only of proof, but even of rational defence. It is a survival of a crude realism which can be defended only, *in a pragmatist manner*, on the score of its practical convenience, as an avowed fiction. In this sense and as a mode of speech, we need not quarrel with it. But as an ultimate analysis of the fact of knowing it is an utterly gratuitous interpretation. The plain fact is that we can come into contact with any sort of reality only in the act of 'knowing' or experiencing it. As *unknowable*, therefore, the Real is *nil*, as *unknown*, it is only potentially real. What is there in this situation to sanction the assumption that what the Real *is* in the act of knowing, it is also outside that relation? One might as well argue that because an orator is eloquent in the presence of an audience, he is no less voluble in addressing himself. The simple fact is that we know the Real *as it is when we know it*; we know nothing whatever about what it is apart from that process. It is meaningless therefore to inquire into its nature as it is in itself. And I can see no reason why the view that reality exhibits a rigid nature unaffected by our treatment should be deemed theoretically more justifiable than its converse, that it is utterly plastic to our every demand—a travesty of Pragmatism which has attained much popularity with its critics. The actual situation is of course a case of interaction, a process of cognition in which the 'subject' and the 'object' determine each other, and both 'we' and 'reality' are involved, and, we might add, *evolved*. There is no warrant therefore for the assumption that either of the poles between which the current passes could be suppressed without detriment. What we ought to say is that when the mind 'knows' reality both are affected, just as we say that when a stone falls to the ground both it and the earth are attracted.

We are driven, then, to the conviction that the 'determinate nature of reality' does *not* subsist 'outside' or 'beyond' the process of knowing it. It is merely a half-understood lesson of experience that we have enshrined in the belief that it does so subsist. Things behave in similar ways in their reaction to modes of treatment, the differences between which seem to us important. From this we have chosen to infer that things have a rigid and unalterable nature. It might have been better to infer that therefore the differences between our various manipulations must seem unimportant to the things.

The truth is rather that the nature of things is not *determinate* but *determinable*, like that of our fellow-men. Previous to trial it is indeterminate, not merely for our ignorance, but really and from every point of view, within limits which it is our business to discover. It grows determinate by our experiments, like human character. We all know that in our social relations we frequently put questions which are potent in determining their own answers and without the putting would leave their subjects undetermined. 'Will you love me, hate me, trust me, help me?' are conspicuous examples, and we should consider it absurd to argue that because a man had begun social intercourse with another by knocking him down, the hatred he had thus provoked must have been a pre-existent reality which the blow had merely elicited. All that the result entitles us to assume is a capacity for social feeling variously responsive to various modes of stimulation. Why, then, should we not transfer this conception of a determinable indetermination to nature at large, why should we antedate the results of our manipulation and regard as unalterable facts the reactions which our ignorance and blundering provoke? To the objection that even in our social dealings not all the responses are indeterminate, the reply is that it is easy to regard them as having been determined by earlier experiments.

10-01-07 *Hyle* (to A. Shimony)

I'm very happy to hear that you are OK. I did start to get worried because the silence seemed a little unlike you.

Shimonyism 11: *I suggest that you read certain of my epistemological papers which are relevant but perhaps not familiar to you: In my collection* Search for a Naturalistic World View *vol. 1 (Cambridge U. Press 1993), papers 1, 2, 3, 9 (sections 3, 4, 5), and 10; and "Some Intellectual Obligations of Epistemological Naturalism" in* Reading Natural Philosophy*, ed. by David Malament.*

I will do. In fact, I just ordered your book from Amazon.com. They say it will ship by tomorrow.

The last two weeks I've been reading F. C. S. Schiller in preparation for the talk I'm giving at the "Pragmatism and Quantum Mechanics" meeting in Paris Feb 22–23. (I hope I do much better than I did in my talk in Waterloo for you this year.) Now he is an obscure philosopher!—I wonder if you've ever read him at all—but I find that I'm even more attuned to him than James or Dewey ... probably why he is a forgotten philosopher. He too was a fan of Aristotle's hyle, but in a much different way than Peirce.

10-01-07 *Anti-Algebra, the Reprise* (to V. Palge)

I'm sorry to take so very long to reply to your email. I'm behind on everybody's email.

Palge-ism 2: *It seems that one of the main reasons you reject a well-structured event space is that it assumes a realistic interpretation: its elements would correspond to intrinsic properties of quantum systems (either possessed by systems before a measurement or being generated by a measurement). However, I wonder if one is forced to such realistic commitment. Can't one understand the e.g. partial Boolean event space in an instrumentalistic and hence more Bayesian spirit? Can't one just take the elements as corresponding to clicks and blips in the measurement apparatus? What I have in mind is Pitowsky's 2003 ("Betting on the outcomes of measurements: a Bayesian theory of quantum probability," SHPMP,* **34***). As you probably know, he assumes that quantum event space is a partial Boolean algebra and then lays down the rules a Bayesian must follow in a world whose event space ultimately has this structure.*

In short, I am wondering if your argument applies to the Pitowskian Bayesian picture which is free from a realistic understanding of properties?

The reason this issue seems important to me is that I believe eventually a Bayesian should say something about the structure of the event space—this seems like a minimal condition for calculating probabilities. And what this structure is has interesting implications on further issues in QM.

Let me start with your first sentence: "It seems that one of the main reasons you reject a well-structured event space is that it assumes a realistic interpretation: its elements would correspond to intrinsic properties of quantum systems." That is the wrong direction of reasoning—though I am probably the cause of this misimpression through the restrictive choices of readings I recommended to you. It is not that I reject a well-structured event space because it *assumes* its elements would correspond to intrinsic properties of quantum systems, but rather this is the *result* of a thoroughgoing subjective interpretation of probabilities within the quantum context. What cannot be forgotten is that quantum-measurement outcomes, by the usual rules, *determine* posterior quantum states. And those posterior quantum states in turn determine further probabilities.

Thus, if one takes the timid, partial move that Itamar and Jeff Bub, say, advocate—i.e., simply substituting one or another nonBoolean algebra for the space of events, and leaving the rest of

Bayesian probability theory seemingly intact—then one ultimately ends up re-objectifying what had been initially supposed to be subjective probabilities. That is: When I look at the click, and note that it is value i, and value i is rigidly—or I should say, *factually*—associated with the projector Π_i in some nonBoolean algebra, then I have no choice (through Lüders rule) but to assign the posterior quantum state Π_i to the system. This means the new quantum state Π_i will be as factual as the click. And any new probabilities (for the outcomes of further measurements) determined from this new quantum state Π_i will also be factual.

So, the starting point of the reasoning is to *assume* that there is a category distinction between probabilities and facts (this is the subjectivist move of de Finetti and Ramsey). Adding the ingredient of the usual rules of quantum mechanics, one derives a dilemma: If there is a rigid, factual connection between the clicks i and elements Π_i of an algebraic structure, then probabilities are factual after all. Holding tight to my assumption of a category distinction between facts and probabilities, I end up rejecting the idea that there is a unique, factual mapping between i and Π_i.

Let me point you to two papers of mine that emphasize (and make a little more formal) this kind of reasoning. The first is `quant-ph/0404156`, and the particular place to look in it is Section VI, starting on page 22. The second is attached to this note. It is a fairly drastic revision of `quant-ph/0608190` that we haven't posted yet (can't re-post it until Rüdiger gets back from vacation with the passwords). In large part, this paper is on the very point we are discussing here. Finally, let me recommend an excellent recent paper by Matt Leifer that extends these points: `quant-ph/0611233`.

But let me return to your paragraph before signing off. If I read this question of yours in isolation: "Can't one just take the elements as corresponding to clicks and blips in the measurement apparatus?" Then at one level my answer is, "Of course; I've never said otherwise." What is at issue here is whether the events—the clicks and blips themselves—fall within the kind of algebraic structure you speak of, or whether it is something else (something a conceptual layer above the events) that falls within it. From the CFS point of view, for a single device with clicks i, one agent might associate the clicks with a set of orthogonal projectors Π_i, and another agent might associate them with a set of noncommuting effects (i.e., POVM elements) E_i. This was the sense in which I meant there is no stand-alone event space at all: For us, the algebraic structure of the events (the clicks and blips), their level of commutivity or noncommutivity and whatnot, is just as subjective as the quantum state. The clicks i themselves are objective (in the sense of not being functions of the subject's beliefs or degrees of belief), but their association with a particular set of operators E_i is a subjective judgment.

I hope this completely answers your question now.

But let me extend the discussion a little to try to give you a more positive vision of what we're up to. The starting point is the category distinction between facts and probabilities applied to the quantum measurement context. From this we glean that quantum operations and quantum states are of the same level of subjectivity. But that is not our ending point. Because, implicit in everything we have said there are these autonomous, realistically-interpreted quantum systems: The agent has to interact with the quantum system to receive his quantum measurement outcome. No quantum system, no measurement outcome. Thus the CFS position is more than a kind of positivism or operationalism. The objects of the external world with which we interact have a certain kind of active power, and we become aware of the presence of that active power particularly in the course of quantum measurement. When we kick on a quantum system it surprises us with a kick back.

Can we say anything more explicit about the active power? Can we give it some mathematical shape? Yes, I think we can, but that is a research project. Still, I think the hints for it are already in place ... and indeed they are in the quantum formalism, as we would expect them to be. One of the hints is this: The Born transformation rule. When we make probability assignments in quantum mechanics, we are assuming more than de Finettian / Ramseyian coherence. We assume that if we set the probabilities for the outcomes of this measurement this way, then we should set the probabilities for the outcomes of that measurement that way and the rule of transformation is a linear one. This, from the CFS view, is the content of the Born rule (see the last section in the attached paper). And it is empirical, contingent: A different world than the one we live in might have had a different transformation rule. So, if we're looking for something beyond personal probabilities in quantum mechanics, that is a point to take seriously. It hints of some deep property of our world, and I'd like to know what that property is.

10-01-07 *Anti-Algebra, the Moral* (to V. Palge)

I walked into the hall to get a glass of water, and immediately felt that I had not properly clenched off the last two paragraphs of my last note. There were several points made there, but among them is this, and I just want to be explicit about it:

Though CFS banish the algebraic structure of Hilbert space from having anything to do with a fundamental event space (and in this way their quantum Bayesianism differs from the cluster of ideas Pitowsky and Bub are playing with), they do not banish the algebraic structure from playing any role whatsoever in quantum mechanics. It is just that the algebraic structure rears its head at the conceptual level of coherence rather than in a fundamental event space. It is not that potential events are objectively tied to together in an algebraic way, but that our gambling commitments (normatively) *should be*. This is another point of contact between my view and Bill's.

10-01-07 *Mulling* (to N. D. Mermin)

I've been mulling over your letters "State Preparation" and "The Grangier Letter" from 1/2/07 for several days now, but the more I think about it, I don't know how to respond in any detail until I hear your thoughts on my note "David Signals" from 1/3/07. Particularly, much will hinge on you respond to the part that starts off, "However, there's a still more worrisome issue here."

I know it's getting very close to your leaving for vacation; so I am not betting strongly to hear back from you on the subject for quite a while (probably not till you're visiting Princeton). Basically, you just give me the signal when you're ready (by answering those questions), and we'll pick back up where we left off.

At the moment I'll only observe this much, with regard to these two things you said:

Merminition 165: *You have to understand that much of my attitude towards quantum foundations these days really does grow out of the past six years of teaching the subject to computer scientists. From this narrow perspective quantum mechanics is a set of rules enabling us to describe important aspects of the operation of a particular bounded, isolated, piece of machinery.*

and

Merminition 166: *And it wipes out the beautiful symmetry between measurement gates being crucial at both the start and the end of the computation, which I can't help think is telling us something (about correlations between aspects of our experience.)*

In some ways, you seem to be roughly where I was when I started writing that ill-fated piece for Physics Today with Asher in 1999—basically the position of Asher in his 1980s paper, "What

Is a State Vector?" (Does this mean I've devolved since then?) Anyway, I paste in a bit of the correspondence I had with Asher at the point when I started to turn away from the master.

Best wishes, and stay clear of the lava,

Excerpt of: 15-11-1999, to A. Peres, "Have a Good Trip"

One point that we may need some private side discussion on before we set it in stone, is captured among other places in your sentence:

Asherism 68: *The notion "state" refers to a method of preparation, it is not an intrinsic property of a physical system.*

In general I have noticed in this manuscript that you lean more heavily on the word "preparation" than we did in our letter to Benka. (In fact, I can't find any mention at all of the word "preparation" in that letter.) Unless I misunderstand your usage of the word, it may actually be a little too anthropocentric even for my tastes. The problem is this: consider what you wrote in the paragraph about the wave function of the universe. It seems hard to me to imagine the wave function of those degrees of freedom which we describe quantum mechanically as corresponding to a "preparation." Who was the preparer?

It is for this reason that Carl Caves and I prefer to associate a quantum state (either pure or mixed) solely with the compendium of probabilities it generates, via the Born rule, for the outcomes of all potential measurements. And then we leave it at that. Knowing the preparation of a system (or the equivalence class to which it belongs) is one way of getting at a set of such probabilities. But there are other ways which surely have almost nothing to do with a preparation. An example comes about in quantum statistical mechanics: when the expected energy of a system is the only thing known, the principle of maximum entropy is invoked in order to assign a density operator to the system. There may be someone beside me in the background who knows the precise preparation of the system, but that does not matter as far as I am concerned—my compendium of probabilities for the outcomes of all measurements are still calculated from the MaxEnt density operator.

To help ensure that I was not jumping to conclusions on your usage of the term, I reread today your paper "What is a state vector?" [AJP **52** (1984) 644–650]. There was a time when I agreed with everything you wrote there (in fact, I think it was the first paper with which I got to know you). But as of today at least, I think a more neutral language as in our letter to Benka is more appropriate. [...]

Excerpt of: 20-10-2000, to P. Benioff, "Not Instructions, but Information"

Benioffism 2: *If I recall correctly you wrote a paper with Peres on QM without interpretation but stated that a quantum state corresponds to an algorithm for preparing it.*

In this, though, you're confusing two things. Asher wrote a paper in the early 1980s for AJP titled "What is a State Vector?" and in that paper he took the point of view you mention. That is, that a quantum state corresponds to nothing more than the (equivalence class of) instructions for preparing a system one way or the other. I've never felt completely comfortable with that point of view, so in the paper that Asher and I co-wrote for *Physics Today* last year we worked around that. I think also that I may have even swayed Asher's opinion on this issue, but you would have to check with him directly. (Perhaps I'll just carbon copy this letter to Asher.) Here's how I put it in a note to Asher 15 November 1999: [...]

I believe this point of view is adequately expressed in the article Asher and I wrote for *Physics Today*: a quantum state is nothing more and nothing less than one's best (probabilistic) information on how a system will react to our experimental interactions with it. How we may have come by that information—be it through a preparation, through a sheer guess based on all available evidence, or the principle of maximum entropy—is something I view as largely outside quantum theory proper. The structure of quantum theory instead codifies how we should manipulate our information (this is what time evolution and the collapse rule is about) and enumerates the varied ways with which we may gather new information (this is what the structure of observables or POVMs is about).

In this sense, I would call what we are talking about an "information interpretation" or "Bayesian interpretation" of quantum theory, rather than an "algorithmic interpretation." For the most part, however, I would like to avoid the wording of an interpretation.

I will go further—and this is one point where I may diverge from Asher—and say that I do suspect that we will one day be able to point to some ontological content within quantum theory. But that ontological statement will have more to do with our interface with the world—namely that in learning about it, we change it—than with the world itself (whatever that might mean).

10-01-07 *Pragmatism in Paris* (to A. Grinbaum)

Grinbaumism 2: *First, all the best wishes for 2007! It's been long time since we talked–hope all is well. I was told that you'll be in Paris around February 22 for a seminar: what are the exact dates? It would be wonderful if you had time to talk and perhaps visit our new foundations of physics lab at the CEA, LARSIM, where I now work.*

Good to hear from you. That's quite interesting: A nuclear physics research center investing in quantum foundations?! That's very nice. And congratulations on your new position. Is it permanent? Or is it a limited appointment? I hope it is the former and affords you much leisure to do good work.

I will arrive in Paris just in time to make it to the start of the meeting, Feb 22. I'll be coming from London with Schack on a Eurostar. Then I fly directly out of Paris on the 25th. Thank you on your kind invitation to visit your lab, but I think I will take a rain check on it this time. It is true that I'll be in Paris an extra day beyond the meeting, but I had already drawn up grand plans for the day: To walk around the city all alone and use its lonely sounds to try to think deeply and possibly provoke some new thoughts in my head.

Happy new year to you too, and see you in February.

11-01-07 *Pyroclastic Surge* (to N. D. Mermin)

Merminition 167: *The hope is that quantum foundations will be clarified by a spectacular sunset and not by a pyroclastic surge. But my main reading project is* Origin of Species*, which I somehow missed growing up.*

Worthy book. Read it, and then take all those ideas to physics. Might I recommend as supplementary material:

11-01-07 *Matter, Money, and Change* (to A. Shimony)

Shimonyism 12 : *I am pleased that you have ordered my papers. I felt frustrated engaging in a written debate with you when my full position cannot be presented briefly, and when I have already spent years trying to present it adequately. After you have read the papers you may be convinced by me, or you may have cogent criticisms which will persuade me.*

Yes, you are probably right that that is a more efficient method. By the way, your book only cost me $13.29 (and is supposed to be in "essentially new" condition). Since my Mom sent me $20 for Christmas, I still have almost $7 left! Thanks for providing the form to the hyle, and thanks for the change!

12-01-07 *Out of the Blue* (to H. Halvorson)

I wonder: 1) if I can ask a favor of you that is surely beneath a professor, and 2) if I might have a conversation of deeper value with you as I pick up on favor 1 (if indeed you take up that task)? (I'll explain below.)

First the favor to ask: I'm giving a talk at the "Pragmatism and Quantum Mechanics" meeting in Paris, Feb 22–23, titled, "William James, F. C. S. Schiller, and the Quantum Bayesians," and partly because of that I'm doing everything I can to strengthen my knowledge of Schiller. It's not easy, as he's a pretty obscure philosopher—though you can guess he stirs me like no one else!—and particularly I haven't been able to get my hands on one of his most important papers: "Axioms as Postulates." This is the favor that's beneath a professor, but I wonder if I can ask it of you anyway (for a friend)? The Princeton Library has a copy of the volume that contains the paper, but it's archived at some off-site facility. Could I ask you to recall the volume from there?

If you wouldn't mind doing that, I could drop by and copy the paper one day next week.

13-01-07 *Conference "Pragmatisme et Mécanique Quantique"* (to M. Bächtold)

Thanks for making the reservation for me. I'll forward your note to Schack; I'm sure the accommodation will be fine with him.

One thing about the program: The title of my talk should be "William James, F. C. S. Schiller, and the Quantum Bayesians" rather than the original title you have listed. (I sent you a note earlier changing the title, but maybe you didn't get it.) The talk will be on an updated, quantum mechanical rendering of this quote of Schiller:

> That the Real has a determinate nature which the knowing reveals but does not affect, so that our knowing makes no difference to it, is one of those sheer assumptions which are incapable, not only of proof, but even of rational defence. It is a survival of a crude realism which can be defended only, *in a pragmatist manner*, on the score of its practical convenience, as an avowed fiction. In this sense and as a mode of speech, we need not quarrel with it. But as an ultimate analysis of the fact of knowing it is an utterly gratuitous interpretation. The plain fact is that we can come into contact with any sort of reality only in the act of 'knowing' or experiencing it. As *unknowable*, therefore, the Real is *nil*, as *unknown*, it is only potentially real. What is there in this situation to sanction the assumption that what the Real *is* in the act of knowing, it is also outside that relation? One might as well argue that because an orator is eloquent in the presence of an audience, he is no less voluble in addressing himself. The simple fact is that we know the Real *as it is when we know it*; we know nothing whatever about what it is apart from that process. It is meaningless therefore to inquire into its nature as it is in itself. And I can see no reason why the view that reality exhibits a rigid nature unaffected by our treatment should be deemed theoretically more justifiable than its converse, that it is utterly plastic to our every demand—a travesty of Pragmatism which has attained much popularity with its critics. The actual situation is of course a case of interaction, a process of cognition in which the 'subject' and the 'object' determine each other, and both 'we' and 'reality' are involved, and, we might add, *evolved*. There is no warrant therefore for the assumption that either of the poles between which the current passes could be suppressed without detriment. What we ought to say is that when the mind 'knows' reality both are affected, just as we say that when a stone falls to the ground both it and the earth are attracted.
>
> We are driven, then, to the conviction that the 'determinate nature of reality' does *not* subsist 'outside' or 'beyond' the process of knowing it. It is merely a half-understood lesson of experience that we have enshrined in the belief that it does so subsist. Things behave in similar ways in their reaction to modes of treatment, the differences between which seem to us important. From this we have chosen to infer that things have a rigid and unalterable nature. It might have been better to infer that therefore the differences between our various manipulations must seem unimportant to the things.
>
> The truth is rather that the nature of things is not *determinate* but *determinable*, like that of our fellow-men. Previous to trial it is indeterminate, not merely for our ignorance, but really and from every point of view, within limits which it is our business to discover. It grows determinate by our experiments, like human character. We all know that in our social relations we frequently put questions which are potent in determining their own answers and without the putting would leave their subjects undetermined. 'Will you love me, hate me, trust me, help me?' are conspicuous examples, and we should consider it absurd to argue that because a man had begun social intercourse with another by knocking him down, the hatred he had thus provoked must have been a pre-existent reality which the blow had merely elicited. All that the result entitles us to assume is a capacity for social feeling variously responsive to various modes of stimulation. Why, then, should we not transfer this conception of a determinable indetermination to nature at large, why should we antedate the results of our manipulation and regard as unalterable facts the reactions which our ignorance and blundering

> provoke? To the objection that even in our social dealings not all the responses are indeterminate, the reply is that it is easy to regard them as having been determined by earlier experiments.
>
> In this way, then, the notion of a 'fact-in-itself' might become as much of a philosophic anachronism as that of a 'thing-in-itself,' and we should conceive the process of knowledge as extending from absolute chaos at the one end (before a determinate response had been established) to absolute satisfaction at the other, which would have no motive to question the absolutely factual nature of its objects. But in the intermediate condition of our present experience all recognition of 'fact' would be provisional and relative to our purposes and inquiries.

It captures a good piece of what we quantum Bayesians are up to. But it also contrasts some—for we would say that the quantum formalism is telling us *something* of the world in itself. Below is how I wrote Veiko Palge on the subject recently. [See 10-01-07 note "Anti-Algebra, the Reprise," to V. Palge.] Anyway, that's what the talk will be about, and I'll tie it all in with a) the quantum formalism, and b) with William James too.

16-01-07 *Axioms as Postulates* (to H. Halvorson)

I don't know if you looked any at the document you copied, but already in the outline, Section 1, I love it! Matter is the resisting medium. That is just the right conception, I think, for a quantum system.

Read it as a novel (not for literal truth, but for inspiration) as you get a chance!

16-01-07 *Don't Forget Schiller!* (to H. Price)

I've only read the first page of your Federation Fellow proposal, but in that little bit I already like it much. And said to myself, "I've got to print this out." In the meantime, I'll fly this note off to you.

When I read your listing of Peirce, James, and Dewey, I thought, "Don't forget Schiller!" My recent fascination with his thinking is the partial source of the title of my last note. I'm now starting to surmise that his take on pragmatism perhaps better tacks with what I'm aiming for in quantum mechanics than even James. We shall see.

Anyway, two notes below on my plans with Schiller that you may enjoy. Particularly the long Schiller quote itself at the bottom. [See 03-01-07 note "New Year's Alchemy" and 09-01-07 note "Facts-in-Themselves" to H. C. von Baeyer.]

I'll head toward the printer now.

16-01-07 *The Information *Was* in the Warning* (to H. Price)

I just finished the "Aims" section, and I'm still with you. Very nice. Now, I'm off to the "Background" section.

I must have shown you this montage I put together once, playing on the words of Tilgher (some early Italian pragmatist, I think):

> A quantum state is not a mirror in which a reality external to us is faithfully reflected; it is simply a biological function, a means of orientation in life, of preserving and enriching it, of enabling and facilitating action, of taking account of reality and dominating it.

17-01-07 *Ego* (to A. R. Calderbank)

It's of no consequence now, but let me just record this for my own satisfaction. As I was driving home this evening, reviewing the day in my head, I thought: "Wow did I ever undersell myself with that line about how 'my main interest in a cross appointment arose because I'm neither a great mathematician, nor a great philosopher, but a little good at each'." Rest assured, I think much more of myself than that! Particularly, I'm quite confident that the school of thought in quantum foundations I am building up around the world is deeply significant and paving the way for the next big step in physics. All I really meant to imply is that I fit no department per se, and these are the closest fits. But I don't doubt for a minute that I would inspire the students around me to do some dazzling work in these fields (by those departments' own standards).

Thanks, by the way, for talking to me. Your clarity was much appreciated. As we can schedule it (with my fairly full travel schedule this Spring), I'd be more than happy to give a seminar for you guys.

18-01-07 *Pragmatism Old and New* (to R. E. Slusher)

Keeping with the idea of 'something old, something new . . . ', I thought you might like to take this old book with you down to Georgia. Certainly you'll need pragmatism (with a little p) to make big things happen in your lab. But perhaps the book will also give you a chance to reflect on how *Pragmatism* (with a big P) finds its best argument in our quantum world.

Good luck, and many more years of good science from you.

29-01-07 *Toy Model, 1* (to S. J. van Enk)

Well, I've finally gotten your paper printed out. I'll be taking it to Toy Model Central (i.e., PI) with me on my flight tomorrow. I want to understand this. . . . [some days]

Now, I've started putting work into understanding your paper. I still think it's nice (very nice actually), but I'm not sure to what extent it has a claim to being called a toy model for epistemic states. Once the "probabilities" come out of the "information theoretic principle" (both quotes have to be taken seriously now, because those words cannot be interpreted literally any more) as having to be negative, they lose their epistemic meaning. They're something else now.

I'm thinking, though . . .

30-01-07 *Polchinski Story* (to L. Smolin)

As it turns out, I just finished reading your new book as I landed in Toronto today. (Literally so! I was reading the last paragraph of the last page as the airplane wheels hit the pavement.) I enjoyed it and got a lot out of it, particularly the chapters on "the anthropic solution" and "what is science." I also thought your last chapters made a powerful argument for the place and style of foundational work—nice.

Let me tell you a story about Joe Polchinski that one of your pages brought back to mind. On page 137, you write:

> . . . from 1984 to 1995, we were like amateurs . . . [missing] most of what was necessary to make the system work until Polchinski discovered the missing essentials. . . . In the fall of 1995, Polchinski showed that a string theory, to be consistent, must include not

> only strings but surfaces of higher dimensions moving in the background space. ... If a string, which is a one-dimensional object, can be fundamental, why can't a two-dimensional surface, be fundamental? In higher dimensions, where there is a lot of room, why not a three-, four-, or even five-dimensional surface?

Well, sometime around 1985 or 1986 ('87 at the latest), I was at a physics colloquium at the University of Texas and Joe Polchinski was the speaker. Steven Weinberg was in the first or second row of the auditorium in his usual seat. Polchinski talked about strings. What was funny was that early in the talk, Weinberg interrupted to ask, why stop with strings? Why not two- or higher dimensionsal objects? And, in particular, he ended, "Once you move away from the particle concept, why not just entertain a universe filled with gummy bears?" Polchinski at first just paced back and forth on the stage, looking down ... a bit of a silence. Then Weinberg said, "I'm not being facetious! Why not gummy bears? What in the theory constrains you to strings?" The audience, of course, laughed. And I remember Polchinski saying, "I know you're not being facetious." However, I don't remember his answer beyond that. Just a cute story you might like (and I might record).

31-01-07 *Nature Giving a Flip* (to me)

> "Perhaps nature doesn't give a flip about such questions, because c is finite."

Good point. John Wheeler used to say of counterfactual games like this (at least with quantum mechanics): "Why talk of them? They're worlds that never were and never could be."

01-02-07 *Metaphysics of the Time Process* (to L. Smolin)

Here's some words from the paper I was telling you about, F. C. S. Schiller, "The Metaphysics of the Time-Process," originally published in Mind, 1895.

The abstract to the paper reads:

> Significance of Dr. McTaggart's admission that the Hegelian Dialectic cannot explain the reality of succession 'in Time.' The reason of its failure, viz. that Time, Change, and Individuality are features of Reality we abstract from in our formation of Concepts. Hence abstract metaphysics always fail to account for Reality. Must we then either accept scepticism or reject a procedure on which all science rests? No; for to admit the defects of our thought-symbols for reality need merely stimulate us to improve them. As for science, it uses abstractions in a radically different way, to test and to predict experience. Thus 'law' is a methodological device for practical purposes. Science practical both in its origin and in its criterion, and ethics as the science of ends conditions metaphysics. Such an ethical metaphysic accepts and implies the reality of the Time-process. And *therefore* it has a right to look forward to the realization of its ends in time, and forms the true Evolutionism.

More to the point with regard to yesterday's considerations after Tegmark's talk are these. (In the long quote Schiller says about the same thing five times over, but I think I'll record it all in case there are some subtle distinctions I'm missing at the moment.)

> [T]he incompatibility between the assertion of the reality of the Time-process and its comprehension by any system of 'eternal' logical truth (whether Hegel's or any one else's) has its origin in very simple and obvious considerations.

Dr. McTaggart cannot find room for the reality of the Time-process, i.e. of the world's changes in time and space, within the limits of Hegel's Dialectic. But is this an exclusive peculiarity or difficulty of Hegel's position? Is the Time-process any more intelligible on the assumptions of any other purely logical[118] system, as, for instance, on those of Plato or Spinoza? I think the difficulty will be found to recur in all these systems. And this shows that it is not accidental, but intrinsic to the *modus operandi* of all systems of abstract metaphysics.

They cannot account for the time-factor in Reality, because they have *ab initio incapacitated* themselves from accounting for Time as for change, imperfection and particularity—for all indeed that differentiates the realities of our experience from the ideals of our thought. And their whole method of procedure rendered this result inevitable. They were systems of abstract truth, and based on the assumption on which the truth of abstraction rests. They aimed at emancipating philosophy from the flux to which all human experience is subject, at interpreting the world in terms of conceptions, which should be true not here and now, but 'eternally' and independently of Time and Change. Such conceptions, naturally, could not be based upon probable inferences from the actual condition of the world at, or during, any time, but had to be derived from logical necessities arising out of the eternal nature of the human mind as such. Hence those conceptions were necessarily *abstract*, and *among the things they abstracted from was the time-aspect of Reality.*

Once abstracted from, the reference to Time could not, of course, be recovered, any more than the individuality of Reality can be deduced, when once ignored. The assumption is made that, in order to express the 'truth' about Reality, its 'thisness,' individuality, change and its immersion in a certain temporal and spatial environment may be neglected, and the timeless validity of a conception is thus substituted for the living, changing and perishing existence we contemplate. ...

The true reason, then, why Hegelism can give no reason for the Time-process, i.e. for the fact that the world is 'in time,' and changes continuously, is that it was constructed to give an account of the world irrespective of Time and Change. If you insist on having a system of eternal and immutable 'truth,' you can get it only by abstracting from those characteristics of Reality, which we try to express by the terms individuality, time, and change. But you must pay the price for a formula that will enable you to make assertions that hold good far beyond the limits of your experience. And it is part of the price that you will in the end be unable to give a rational explanation of those very characteristics, which you dismissed at the outset as irrelevant to a rational explanation. Thus the whole contradiction arises from a desperate attempt to eat one's cake and yet have it, to secure the eternal possession of absolute truth and yet to profit by its development in time! ...

If these considerations are valid, the idea of accounting for the time-process of the world on any system of abstract metaphysics is a conceptual jugglery foredoomed to failure, and must be declared mistaken in principle.

02-02-07 *Something Fun* (to C. H. Bennett)

I wonder if you'd do something fun for me. I'm visiting the Perimeter Institute, and I've been bragging about how their cafeteria could take some lessons from IBM Research's cafeteria.

[118]I.e. intellectualist.

Particularly the little paper and pencil boxes you have sitting on the tables. (It came to me as I was having great difficulty writing on a napkin.) Would you take a nice picture of one of them, or show how they're situated on the tables, so I can make a case to the people here that they should do the same thing.

Wish you were up here; I'm having a great time, just hanging out and being the old Chris again.

03-02-07 *Bill's Thoughts on QL and QI Frameworks* (to W. G. Demopoulos)

Demopoulosism 8: *I've had an idea which I would like to run by you. It was prompted by several things: your exchange with Veiko Palge, a re-reading of some of our previous correspondence, and some more general reflections suggested by work of Lucien and others. (Among "others," I ran across two very suggestive papers of Colin Howson on Ramsey on probability and logic which I can send you the details of if you're interested.)*

Yes, I would like to know what you're talking about here. I remember being extremely disappointed when I first met Howson at the LSE a couple of years ago. For despite his Bayesian credentials—I had cut my eyeteeth on his book with Urbach—he seemed to hold fast to the idea that subjective probability *had to be* supplemented with objective chance … and for the silliest of reasons: To explain how predictable frequencies could come about. I was taken aback! In case, just in case, you harbor your own reservations about this issue, let me recommend Marcus Appleby's papers "Facts, Values and Quanta," and "Probabilities Are Single-Case, or Nothing," `quant-ph/0402015` and `quant-ph/0408058`, respectively. He makes the argument there about as decisive as I've ever seen it.

Demopoulosism 9: *What I have to say is pretty abstract and at the level of the "framework" which I believe is implicit in your approach, and I think that for just this reason it may clarify a little further the connection between us.*

You definitely get several of the elements right, I would say. Though I do have some quibbles, as you'll see below. Of course, these may just correspond to parts of the framework you reject. We'll see.

Demopoulosism 10: *I want to contrast what I'll call the quantum logical (QL) and quantum informational frameworks (QI), where by a framework I mean something very general, having to do with the language or conceptual structure within which one seeks to formulate things, rather than any particular thesis. One thing that I think emerges from looking at things in this way is that it makes it clear that realism vs. anti-realism is not an issue, and I think it also shows that some of the classical foundational issues, like whether values of observables are created on measurement, are also not to the point.*

Well, I certainly agree with the first part of this sentence, i.e., "that realism vs. anti-realism is not an issue," but the jury for me remains out on the second issue … at least until I better understand precisely what you mean by "values of observables are created on measurement."

Demopoulosism 11: *It may raise the question of instrumentalism, but it does so in a sense that doesn't contrast with realism.*

I've always been impressed by this passage of Richard Rorty's (from the introduction to his volume, *Objectivity, Relativism, and Truth: Philosophical Papers Volume 1*):

> The six papers that form Part I of this volume offer an antirepresentationalist account of the relation between natural science and the rest of culture. By an antirepresentationalist account I mean one which does not view knowledge as a matter of getting reality right, but rather as a matter of acquiring habits of action for coping with reality.
>
> Philosophers in the English-speaking world seem fated to end the century discussing the same topic—realism—which they were discussing in 1900. In that year, the opposite of realism was still idealism. But by now language has replaced mind as that which, supposedly, stands over and against "reality." So discussion has shifted from whether material reality is "mind-dependent" to questions about which sorts of true statements, if any, stand in representational relations to nonlinguistic items. Discussion of realism now revolves around whether only the statements of physics can correspond to "facts of the matter" or whether those of mathematics and ethics might also. Nowadays the opposite of realism is called, simply, "antirealism."
>
> This term, however, is ambiguous. It is standardly used to mean the claim about some particular true statements, that there is no "matter of fact" which they represent. But, more recently, it has been used to mean the claim that *no* linguistic items represent *any* nonlinguistic items. In the former sense it refers to an issue within the community of representationalists—those philosophers who find it fruitful to think of mind or language as containing representations of reality. In the latter sense, it refers to antirepresentationalism—to the attempt to eschew discussion of realism by denying that the notion of "representation," or that of "fact of the matter," has any useful role in philosophy. Representationalists typically think that controversies between idealists and realists were, and controversies between skeptics and antiskeptics are, fruitful and interesting. Antirepresentationalists typically think both sets of controversies pointless. They diagnose both as the results of being held captive by a picture, a picture from which we should by now have wriggled free.

At least when it comes to quantum states, I know that I am thinking of them in an antirepresentationalist way. Thus, the issue of realism vs. antirealism with regard to the quantum-Bayesian view (which asserts outright that quantum states are subjective) is just off the mark.

Demopoulosism 12: *I'm imposing this on you as a way of getting my head around some part of what I will say in Maryland in April, so I hope I'm catching you at a time when you are able to send me your reactions.*

The idea of QI that I want to focus on is its rejection of the QL framework of propositions and their structure in favor of an emphasis on what I'll call "effects," a term whose significance will I hope become clear.

I include with QI's rejection of the propositional framework all related and to my mind equivalent ideas. I know that you sometimes distinguish between propositions which are true or false vs. events which happen or not, just as one also distinguishes both of these categories from properties which hold or fail to hold, but I can't really see any basis for marking such distinctions and see them all as of one piece.

I don't know if this will help, but let me at this point include something I wrote to Rüdiger Schack, when we were having a fiery debate on what to include in our "certainty" paper, `quant-ph/0608190`. [See 12-12-06 note to Schack titled "Offline Discussion".] The distinction I keep drawing and that you don't like—I think—has to do with all that.

Demopoulosism 13 : *QI rejects them all. By contrast, the QL tradition takes as its starting point the classical Kolmogorov theory of probability which is naturally regarded as formulated within a framework based on an algebraic structure of propositions, events or properties; these latter notions are respectively about, associated with, or belong to the objects whose probabilistic behavior is described in a classical probability framework. QI doesn't deny that elementary particles sustain relations to propositions, events and properties, it simply does not take the propositions, events or properties associated with them to be the proper objects of quantum probability assignments.*

I like this last sentence very much.

Demopoulosism 14 : *What is conventionally described as a property of a particle is, for the purposes of the probability theory, replaced by the notion of an effect which the particle produces at the observable level of experimental results; and what is conventionally understood as the probability that a particle has a particular property is re-conceived as the probability that a particular effect will be produced under certain experimental conditions. The particle contributes to this effect and is not equated with the totality of its effects, but it is effects—rather than properties of particles—that are the proper subject-matter of quantum probability assignments.*

Yes.

Demopoulosism 15 : *Effects are all describable at the macroscopic level of experimental results; they are not properties of the particles that produce them, although their occurrence is a function of particle behavior. Hence, in one sense, there is no question of realism, since the framework of QI assumes the reality of the micro-level. I think QI can even assume the observer-independent reality of the micro level without in any way compromising what is novel and important about its framework, but I'll leave this to another letter.*

Yes, I agree with all this too. But I would put it differently. I don't like drawing the distinction between the micro and macro levels. It sends one on the goose chase (like Zurek's decoherence program) of thinking that the distinction is a physical one, rather than a categorical one. The distinction to be drawn—as far as I am concerned—is only between the *object* and the *agent*.

Demopoulosism 16 : *One reason why Bayesianism is so attractive as an approach to probability within the QI framework is because of the naturalness of the idea of a fair betting quotient as an account of the meaning of probability and the fact that this is readily paired with the primacy which QI gives to the notion of an effect which is conditional on the performance of an experiment: probabilities are regarded as the fair odds associated with conditional bets, in the present case with bets which are conditional on an effect occurring should a particular experiment be performed.*

You're right about it being *one* reason. As a matter of history, I came across it from the other end. I started out as a strong objectivist about quantum probabilities, thinking that that conception could eventually be made well-defined. But in reading everything I could on objective chances and propensities (from '91 to '96), I slowly came to the belief that those notions were contentless. Eventually the Ramseyan notion struck me as the only one with any operational content.

Demopoulosism 17 : *As with conditional bets in general, if the experiment is not performed, the bet is off. This is the basis for the claim, often made by some proponents of the QI framework, that unperformed experiments have no outcomes. So understood, the claim is neither contentious nor surprising, and has no obvious implications for anti-realism about the micro level. It does suggest an element of instrumentalism, however.*

Instrumentalism for the quantum state, indeed. But such is true for *all* Bayesian probabilities: they are never representational of "matters of fact" about their objects. Thus, along the lines of Rorty, it seems to me the wrong distinction to make. Bayesian probabilities never had a chance to represent anything about their objects.

Demopoulosism 18: *A useful way of putting the difference between the two frameworks is the centrality which one gives to* <u>*conditional probability*</u> *and the other to* <u>*conditional bets*</u>*. Within the QL framework of propositions or events we can show that the [Lüders] rule generalizes the notion of conditionalization from a classical or Boolean algebraic context. This is a formally elegant aspect of the QL framework, but its interpretation is elusive for reasons connected with the Kochen and Specker theorem. (Part of what I am thinking is that perhaps this theorem should make us re-evaluate the QL framework. I'm unsure whether the QI framework relieves the tensions that the theorem poses for QL.) We can perhaps retain some of the formal elegance of the QL account of conditionalization without incurring its interpretational difficulties by focusing on the probabilities of effects. The idea is that conditional bets have this advantage: whenever a conditional bet takes place, there is no question of the determinacy of the effects bet upon; their determinacy raises no puzzles and is beyond question.*

I think I need you to explain what you mean by "determinacy." I've heard you say this word many times, but I've never pushed on you to explain what you mean. What do you mean?

And does what you mean have anything to do with Rorty's use of the word in the same Introduction that I already quoted. (I don't know what Rorty means either.) Here's his usage of it:

> The later Wittgenstein, Heidegger, and Dewey, for example, would all be as dubious about the notion of "truth-makers"—nonlinguistic items which "render" statements determinately true or false—as they are about that of "representation." For representationalists, "making true" and "representing" are reciprocal relations: the nonlinguistic item which makes S true is the one represented by S. But antirepresentationalists see both notions as equally unfortunate and dispensable—not just in regard to statement of some disputed class, but in regard to all statements.
>
> Representationalists often think of antirepresentationalism as simply transcendental idealism in linguistic disguise—as one more version of the Kantian attempt to derive the object's determinacy and structure from that of the subject. This suspicion is well stated in Bernard Williams's essay "Wittgenstein and Idealism." Williams says there that a Wittgensteinian view of language seems committed to the following chain of inference:
>
> > (i) 'S' has the meaning we give it.
> > (ii) A necessary condition of our giving 'S' a meaning is Q.
> >
> > *Ergo*
> >
> > (iii) Unless Q, 'S' would not have a meaning.
> > (iv) If 'S' did not have a meaning, 'S' would not be true.
> >
> > *Ergo*
> >
> > (v) Unless Q, 'S' would not be true.
>
> Since the values of Q will typically include human social practices, the conclusion of this set of inferences is, indeed, reminiscent of transcendental idealism. But the

antirepresentationalist will reply that (v) merely says that unless certain social practices are engaged in, there will be no statements to call "true" or "false." [*Though, this part starts to sound a little bit like what you are saying.—CAF*] Williams, however, rejoins that "it is not obvious that for the later Wittgensteinian view … we can so easily drive a line between the sentence 'S' expressing the truth, and what is the case if S." His point is that antirepresentationalists typically do not think that, behind the true sentence S, there is a sentence-shaped piece of nonlinguistic reality called "the fact that S"—a set of relations between objects which hold independently of language—which makes 'S' true. So, Williams concludes, antirepresentationalists, and in particular the later Wittgenstein, are committed to the idea that "the determinacy of reality comes from what we have decided or are prepared to count as determinate."

The trouble with this conclusion is that "comes from" suggests causal dependence. The picture called up by Williams's terminology is some mighty immaterial force called "mind" or "language" or "social practice"—a force which shapes facts out of indeterminate goo, constructs reality out of something not yet determinate enough to count as real. The problem for antirepresentationalists is to find a way of putting their point which carries no such suggestion. Antirepresentationalists need to insist that "determinacy" is not what is in question—that neither does thought determine reality nor, in the sense intended by the realist, does reality determine the thought. More precisely, it is no truer that "atoms are what they are because we use 'atom' as we do" than that "we use 'atom' as we do because atoms are as they are." *Both* of these claims, the antirepresentationalist says, are entirely empty.

Demopoulosism 19 : *A principal difference between QI and QL is that QL seeks to explain the quantum probability assignments by appealing to the algebraic or logical structure of quantum propositions. (Here I'm thinking of Jeff and Itamar; my recent work is different in just this respect, since I don't credit the logical structure (i.e., the "basic" rather than the "derived structure" of my incompletely knowable domain paper) with that kind of explanatory power.) This idea is a reasonable one in view of Gleason's theorem. For it to be wholly successful, it would be necessary to show how the structure of Hilbert space can be recovered from logical or algebraic constraints on the family of physical propositions, which is the central goal of the quantum logical axiomatic program. It would also be necessary to show that this is the correct direction of explanation—i.e. we should go from logic to probability, rather than in the opposite direction or in neither.*

By contrast, I take it that QI envisages no such explanation of the probabilities. For QI, the situation is the same as with classical probability theory: classical logic is insufficient for explaining the coherence of classical probabilistic reasoning. Its explanation may plausibly be said to depend on the interpretation of probabilities as fair betting quotients and the theorem of de Finetti. So also in the context of quantum probability theory, where one also seeks a general strategy for all possible gambles—but where significantly, not all gambles can be taken simultaneously—if one's betting quotients do not obey the quantum probabilities, one is sure to lose.

That is the idea. Now, Itamar claims to prove just this. But he takes the quantum logical structure of propositions as given. The quantum Bayesians of the CFS variety, however, do not want to take that as given. And in that regard, what you say—"if one's betting quotients do not obey the quantum probabilities, one is sure to lose"—is only an idea for an idea: It is a research program.

Demopoulosism 20 : *The remarkable and striking fact here is not the suggestion that logical relations explain probability assignments, but that an empirical theory of the probability of outcomes* *of experiments should inform the consistent distribution of probabilities over a family of hypothetical gambles,* [. . .]

I agree to this point.

Demopoulosism 21 : [. . .] *a distribution which contravenes the classical constraints on their distribution.*

But I disagree here. I don't think there's any sense in which the Born rule specifying probabilities for all measurements contravenes the usual Ramsey / de Finetti coherence. As I see it, the extra quantum restrictions are an addition on top of usual coherence. (Remember, as I see it, quantum measurement outcomes for distinct measurements are not within a single algebra of any interesting variety.)

Demopoulosism 22 : *Following tradition, I call the puzzling phenomena which comprise the first grouping, quantum paradoxes, and the second, the measurement problem. I depart from tradition by calling the problem of hidden variables the theorem which is often invoked as a solution to what usually passes for this problem; by the problem of hidden variables I mean the problem of understanding the significance of this result in the formulation which has become canonical since the work of Kochen and Specker.* [. . .]

I claim that the classification is nevertheless a useful one because it isolates a conceptual issue that is more purely philosophical from those that are peculiar to quantum theory, and which are therefore more properly regarded as foundational issues specific to that theory; the more purely philosophical issue is the problem of hidden variables. Even though the theorem of Kochen and Specker might never have suggested itself were it not for the development of quantum mechanics and the presumption that it might bear on the foundational problems mentioned earlier, the conceptual issues the theorem poses are rightly distinguished as philosophical rather than foundational because the notions on which their formulation depends are of such generality that they are held in common by virtually every theory.

Aha! You may not agree with me in detail, but you seem to agree with me in sentiment. Recall what I wrote in the old Caltech proposals:

> **Quantum Mechanics as a Powerful Hint.** In my opinion, the most profound statement yet to come out of quantum theory is the Kochen-Specker theorem. For it licenses the slogan, "Unperformed measurements have no outcomes." This is just a beginning. If one canvasses the philosophic traditions for one that has significantly developed this slogan, one will find the now mostly-forgotten tradition of pragmatism fathered by William James and John Dewey. As a source of ideas for what quantum mechanics can more rigorously justify, no block of literature is more relevant: The connections between the two fields cry out for systematic study. Quantum mechanics holds the promise of drastically changing our worldview on the wide scale. It is time to let that happen.

and

> **Quantum Mechanics and Anti-representationalist Philosophies.** There are various threads connecting the quantum research program proposed here to a wider philosophical tradition, which to my knowledge has never been greatly examined in

> this context. The tradition comes under the rubric of what Richard Rorty calls 'anti-representationalist philosophies.' This tradition, spearheaded by the pragmatism of William James and John Dewey, also includes thoughts of (the later) Ludwig Wittgenstein, Martin Heidegger, Donald Davidson, Hilary Putnam, Rorty himself, and several others. How else can one understand the implications of the Kochen-Specker theorem than by realizing it hints at something like James' analysis of the concept of 'truth'? How else can one make sense of a Bayesian take on pure quantum states than to explore the same paths as Wittgenstein in his book *On Certainty*?
>
> Since becoming immersed in the subject, I have found nothing more exciting than these trains of thought. For they indicate the extent to which quantum foundations research may be the tip of an iceberg—indeed, something with the potential to drastically change our worldview, even outside the realm of physical practice.

You may become a pragmatist yet!

Demopoulosism 23: *The idea I propose to develop is based on the assumption that no satisfactory interpretation of quantum probabilities is possible so long as the probabilities are understood to be defined over propositions "belonging to" a particle. I say that a proposition belongs to a particle if its constituent property is a possible property of the particle. I claim that such an interpretation is compelling only when the propositions form a Boolean algebra.*

That sounds good.

Demopoulosism 24: *The essential idea of my positive proposal is that the probabilities of "quantum probability theory" are not defined over the totality—or even a sub-totality—of the propositions belonging to a particle, but over the totality of effects which are induced by an interaction with an experimental set-up and that are registered in the experimental apparatus.*

I hope you'll give some credit to old Asher Peres here, "Quantum Theory Needs No Interpretation." This is a formulation he would have accepted:

> Our purpose here is to explain the internal consistency of an "interpretation without interpretation" for quantum mechanics. Nothing more is needed for using the theory and understanding its nature. To begin, let us examine the role of experiment in science. An experiment is an active intervention into the course of Nature: We set up this or that experiment to see how Nature reacts. ... What [quantum theory] does is provide an algorithm for computing *probabilities* for the macroscopic events ("detector clicks") that are the consequences of our experimental interventions. This strict definition of the scope of quantum theory is the only interpretation ever needed, whether by experimenters or theorists.

and

> We surely agree with Brun and Griffiths that "in science, one cannot rule out alternatives by fiat; one must evaluate them on their merits." We do not find any merit in the various alternatives that were proposed to the straightforward interpretation of quantum theory: It is a set of rules for calculating probabilities for macroscopic detection events, upon taking into account any previous experimental information. Brun and Griffiths may think this a "straitjacket," but it prevents the endless conundrums that arise solely from shunning quantum theory's greatest lesson—that the notion of experiment plays an irreducible role in the world we are trying to describe.

Demopoulosism 25: *Effects, which comprise the macroscopic historical record of such interactions, are the proper objects of quantum probability assignments. My claim is that it is this shift in conception that is mandated by the classical hidden variable theorems. Because these theorems are formulated in a propositional framework, they possess a kind of "dialectical" significance by showing the necessity of replacing the propositional framework on which they are based. As a point about the conceptual framework of quantum theory, the claim lends itself to the following formulation: The logical form of the representation of an elementary particle is not that of a class of propositions whose constituent properties are possible properties of the particle, but that of a function which, when subjected to a specified class of operational procedures, produces a family of effects.*

I tentatively like the sound of this formulation, but I'm not completely sure yet that I know what you mean.

Demopoulosism 26: *The representation as a function implicates the particle in an essential way in the production of the effects associated with its interactions with a class of experimental procedures. But it is not committed to the idea that an effect would have been the same had the particle been presented with a different experimental set-up than the one with which it was in fact presented. By contrast, the view of the particle as a class of propositions is committal on this counterfactual claim in just the way that the functional representation is not.*

Within this framework the problem of determinism is posed as follows: Given a class of experimental procedures, to predict their effects with perfect knowledge, i.e. to predict uniformly, and without foreknowledge of the experimental procedure to which the system will be subjected, the answer to every question regarding the occurrence of a possible effect. The no hidden variable theorems show that the quantum probabilities of such effects are not compatible with the existence of a function which predicts every possible effect with probability 0 or 1; hence, neither is it possible to construct a reconstruction of the state of a particle on which to base such predictions: the probabilities of the effects are logically inconsistent with the existence of such a state. The representation of an elementary particle as a function which, when presented with an experimental configuration, yields an effect, is interchangeable with its representation as a class of propositions only when the effects are predictable with 0-1 probability. The fact that the particle-effects described by quantum probability theory are not so interchangeable with propositions belonging to them should be implied by, and perhaps itself implies, the impossibility of cloning.

You're getting off track with this last sentence: The no-cloning theorem has no power to imply the Kochen-Specker result. No-cloning is always true for probability distributions, no matter what the character of arguments of the probability functions (i.e., whether they are "effects" or classical (Kolmogorovian) propositions belonging to the particle). Furthermore, no-broadcasting is generally true too, as long as the probability functions are not allowed to become too peaked. Simply see Spekkens' "toy model" paper.

Kochen-Specker is far deeper than no-cloning ... and far deeper than many of the standard phenomena of quantum information theory (teleportation, superdense coding, entanglement monogamy, etc.).

03-02-07 *My First Fortune Cookie in Waterloo* (to L. Hardy)

"You are going to pass a difficult test."

04-02-07 *QT Needs No Interpretation* (to W. G. Demopoulos)

Boy my ideas have significantly moved on since then!! (Or at least gotten more subtle/resilient ... if you can imagine such a combination.)

04-02-07 *The Painful Ambiguity of Language* (to W. G. Demopoulos)

<u>**NOTE**</u>: This letter was never finished or sent, though the part below was composed on this date.

Reading your notes, now I am VERY confused. I thought I had understood your point of view, but now I wonder. And when you had said in your earlier note, "What I have to say is pretty abstract and at the level of the 'framework' which I believe is implicit in your approach," I thought you were roughly right, but now I wonder about that too.

Demopoulosism 27: *The idea behind determinacy: Nothing can be colored without being some specific color. The terminology is perhaps derivative from W. E. Johnson (whom I've never read, but likely should have) who was apparently an important influence on Keynes and Ramsey. Johnson introduced the terminology of <u>determinates</u> falling under a common <u>determinable</u>, from which my example evidently derives.*

This must be the terminology Schiller was using in that quote of his from 1903 that I like so much [F. C. S. Schiller, "The Ethical Basis of Metaphysics," in his *Humanism: Philosophical Essays*, second edition, (Greenwood Press, Westport, CT, 1970)]:

> That the Real has a determinate nature which the knowing reveals but does not affect, so that our knowing makes no difference to it, is one of those sheer assumptions which are incapable, not only of proof, but even of rational defence. It is a survival of a crude realism which can be defended only, *in a pragmatist manner*, on the score of its practical convenience, as an avowed fiction. In this sense and as a mode of speech, we need not quarrel with it. But as an ultimate analysis of the fact of knowing it is an utterly gratuitous interpretation. The plain fact is that we can come into contact with any sort of reality only in the act of 'knowing' or experiencing it. As *unknowable*, therefore, the Real is *nil*, as *unknown*, it is only potentially real. What is there in this situation to sanction the assumption that what the Real *is* in the act of knowing, it is also outside that relation? One might as well argue that because an orator is eloquent in the presence of an audience, he is no less voluble in addressing himself. The simple fact is that we know the Real *as it is when we know it*; we know nothing whatever about what it is apart from that process. It is meaningless therefore to inquire into its nature as it is in itself. And I can see no reason why the view that reality exhibits a rigid nature unaffected by our treatment should be deemed theoretically more justifiable than its converse, that it is utterly plastic to our every demand—a travesty of Pragmatism which has attained much popularity with its critics. The actual situation is of course a case of interaction, a process of cognition in which the 'subject' and the 'object' determine each other, and both 'we' and 'reality' are involved, and, we might add, *evolved*. There is no warrant therefore for the assumption that either of the poles between which the current passes could be suppressed without detriment. What we ought to say is that when the mind 'knows' reality both are affected, just as we say that when a stone falls to the ground both it and the earth are attracted.

> We are driven, then, to the conviction that the 'determinate nature of reality' does *not* subsist 'outside' or 'beyond' the process of knowing it. It is merely a half-understood lesson of experience that we have enshrined in the belief that it does so subsist. Things behave in similar ways in their reaction to modes of treatment, the differences between which seem to us important. From this we have chosen to infer that things have a rigid and unalterable nature. It might have been better to infer that therefore the differences between our various manipulations must seem unimportant to the things.
>
> The truth is rather that the nature of things is not *determinate* but *determinable*, like that of our fellow-men. Previous to trial it is indeterminate, not merely for our ignorance, but really and from every point of view, within limits which it is our business to discover. It grows determinate by our experiments, like human character. We all know that in our social relations we frequently put questions which are potent in determining their own answers and without the putting would leave their subjects undetermined. 'Will you love me, hate me, trust me, help me?' are conspicuous examples, and we should consider it absurd to argue that because a man had begun social intercourse with another by knocking him down, the hatred he had thus provoked must have been a pre-existent reality which the blow had merely elicited. All that the result entitles us to assume is a capacity for social feeling variously responsive to various modes of stimulation. Why, then, should we not transfer this conception of a determinable indetermination to nature at large, why should we antedate the results of our manipulation and regard as unalterable facts the reactions which our ignorance and blundering provoke? To the objection that even in our social dealings not all the responses are indeterminate, the reply is that it is easy to regard them as having been determined by earlier experiments.

I don't know that I would go as far as Schiller and say that every aspect of matter is "determinable indetermination," but I certainly think the idea corresponds decently with the situation in quantum measurement. Take a complete orthonormal basis that corresponds to some quantum measurement that can be performed on a system. The basis as a whole (i.e., not the subspace spanned by it, but the collection)—I would say—corresponds to a determinable belonging to the object. (This is a variant of your terminology of "belonging to.") That is to say, the basis as a whole is among the hypothesized properties of the object—for it has something to do with how any agent can interact with the object. But what do the individual elements of the basis correspond to? Truth values of propositions belonging to the object? I would say no (just as apparently you would say no). Thus I would say they are "indeterminate of the object."

But I think that's probably a very different use of the words "determinate" and "determinable" than here:

Demopoulosism 28: *In philosophy of QM it's thought to be the lesson of K-S that some propositions are not determinately true or false. Since however their disjunction may always have probability* $= 1$*, it is said that the disjunction is true, but without any [disjunct?] being true or false. Thus the determinable property holds without any determinate which falls under it holding.*

For I think what you have in mind is that some quantum logicians would take the disjunction (i.e., the subspace spanned by the vectors) to be true OF THE OBJECT. That the disjunction's truth value is a property of the object (a property that belongs to the object) even if . . .

04-02-07 *Giving Up for the Night* (to W. G. Demopoulos)

I started to construct a reply to your notes from today, and then it became long and unwieldy and mostly confused. (I don't even want to show you the partial construction—it's pretty bad.) So, I think I'm just going to give up tonight … and indeed just give up until I see you in person. I think at this stage, it might be more fruitful to have a conversation at a blackboard rather than write.

06-02-07 *Physics, Economics, and Death by Interpretation* (to D. M. Appleby, C. M. Caves, and R. Schack)

How would you respond to someone who wrote this:

> Economics and physics fundamentally diverge, however, on an entirely different front: people. To a physicist, our existence is profoundly irrelevant to the structure of the universe: we are made of the same basic building blocks as both quinces and quasars and the universe would unfold according to precisely the same structural laws if we were to suddenly disappear.[1] Economics, on the other hand, is entirely different. Without people, economics is not merely "abstract"; it is simply non-existent, nonsensical. One obviously can't study the wealth of nations or the consumption of goods and services without tacitly assuming that there are humans[2] to produce and consume the goods.
>
> [1]I imagine there will be some astute reader who will point out that our present understanding of quantum mechanics argues for some special role of human observers. Without in any way wading into this particular miasma, the point is that the current ambiguity which makes such an argument defensible is nearly universally regarded by physicists as a problem with quantum theory, or at least our current interpretation of it.
>
> [2]Or aliens sufficiently similar to humans as to be, to all intents and purposes, the same thing.

Just wondering out loud within the earshot of some potentially like minds.

07-02-07 *Research Program* (to P. Busch)

Buschism 2: *I have read Marcus's papers but as I told him; I have more or less come round to seeing probabilities as a "logical" tool, for making uncertain or incomplete inferences (paraphrasing a quote Marcus gave from Maxwell's writings). But then this still has to be brought together with the ontology of the world out there.*

Yes, absolutely. That's the nub of the research program, the part that has the greatest potential. But to get this far—to this starting point really—we have had to have a hard, hard fight with the community to get the epistemic view of quantum states even to be taken seriously.

07-02-07 *Epistemic/Ontic – Subjective/Objective . . . and All That* (to P. Busch)

Buschism 3: *Well, well . . . it did take you guys a while to realize that you were in danger of "throwing the baby out with the bath water", didn't it?* ☺

I'm not sure I'm understanding the correct intonation I should be reading this with (e.g., I can see a smile on your face), but under the assumption that I am:

I would say, NO, it was the *community* that took the long time to *recognize* (or finally listen) that we had no intention of "throwing the baby out with the bath water". See, for instance, the bottom of the chart on page 5 and particularly the larger discussion on pages 5 and 6 of `quant-ph/0205039`. That was five years ago, and the goal was already articulated quite clearly there. What more can a poor worker do?

10-02-07 *Toy Model, 2* (to S. J. van Enk)

van Enkism 9: *If you want to violate Bell inequalities you either give up locality or realism: I think if you give up realism then you can't keep your underlying ontic state anymore . . . don't you agree?*

Yes . . . But what does that have to do with your paper? The reason you call it a "toy model" is 1) because there are underlying ontic states, and 2) there are "epistemic" states (for the ontic states) that satisfy some information theoretic requirement. No? What you find is that the requirement cannot be satisfied with "epistemic" states that are true-blue probability distributions—they must go negative. The trouble is then I don't know how to really think of these things as epistemic states any more. Thus, I'm not really sure in what sense this is an instructive "toy model" for QM after all.

10-02-07 *Inside and Outside* (to S. J. van Enk)

van Enkism 10: *I agree it's no longer knowledge about the ontic states. But I can view it as knowledge about the observables (i.e. the Q's): there is a constraint on how much one can know about those. In the case that the P's are all positive, the two constraints are equivalent; if not, then you have to use a trick: namely use Zeilinger/Brukner's measure of information.*

But you're right, going to negative probabilities changes the character. On the other hand, I don't see how you can ever violate Bell inequalities, if you don't change the character of the Spekkens model!

Have you ever thought about putting "half of the hidden variable" inside the observer? I'm thinking something like this: 1) The system has an ontic state (say like in the Spekkens model), but 2) the observer also has an ontic state (say, perhaps buried deep in his belly). And though the value of the observer's belly state is within him, it is completely inaccessible to his knowledge. That's what I mean by "half of the hidden variable" being inside the observer.

Now what about a measurement on the system? Maybe *instead* of a measurement giving partial information about the system's ontic state, like in the Spekkens model, the kind of measurement of interest tells something about the *relation* between the observer's belly state and the system's ontic state. For instance, a measurement might reveal partial information about the parity of the inside bits and outside bits.

Anyway, the crucial idea here is that when an observer makes a measurement on the left member of a bipartite system, there is no good sense in which there is a local hidden variable at the right-hand member signifying the truth value of the measurement. The outcome of a measurement only has some existence with respect to the hidden variable within the observer. In other words, the observer has to take his belly variable over to the right-hand system before a *local* hidden variable account of the right-hand situation is complete.

Maybe another way to put it is that there is a sense in which this is a nonlocal hidden variable theory (the observer always carries half of the hidden variable)—and he is always with either the left-hand system or the right-hand system, but never localized at both. So, though the hidden variable theory is nonlocal, it is nonlocal in an innocent kind of way.

Do you think one might get a Bell inequality violation out of toying with a kind of idea like that?

Just an idea; probably crazy.

12-02-07 *Lord Zanzibar* (to J. Christian & L. Hardy)

Dear Lord Zanzibar and Sir Lucien,

Here's that lovely quote I was telling you two about. But I misremembered it a little; it's from G. K. Chesterton's book *Heretics* and only quoted by James.

> There are some people—and I am one of them—who think that the most practical and important thing about a man is still his view of the universe. We think that for a landlady considering a lodger it is important to know his income, but still more important to know his philosophy. We think that for a general about to fight an enemy it is important to know the enemy's numbers, but still more important to know the enemy's philosophy. We think the question is not whether the theory of the cosmos affects matters, but whether in the long run anything else affects them.

My view of the universe is that it is many—that it ultimately cannot be unified, for it is alive and changing and creative in a very deep sense. Moreover, that reality is, to some not-yet well-understood extent, plastic: It can be molded by our actions. Thus, though humanity is quite well a Darwinian accident, now that it is here, it is a significant component of the universe that must be reckoned with.

The question is, with that in the open would a landlady let me through the door!

13-02-07 *Tegmark, 101 Years Ago* (to L. Smolin)

I'm sorry I missed your talk last Thursday; I had to give my own talk in London that day. It sounds like I quite missed something! But we will have a chance to discuss these things many times, as I have made a firm decision now that I will be coming to PI for an extended stay as soon as possible. More than discussing, though, I hope we will find a way to put some of these pragmatist ideas into solid, lasting physics—physics made of fantastic new equations and not just words.

At the moment though, let me send you some old words again. You know I'm preparing for this "pragmatism and qm" conference in Paris next week, and because of that I'm rereading some James and Schiller. Well, look at this nice tidbit I found in James today. It was as if he had been listening to Tegmark's talk himself. Really, not a lot has changed in 101 years for a certain strain of mind. (James' lecture was in 1906.) A modern like Tegmark uses a phrase like "logical system," "mathematical system," or "multiverse," but it boils down to nothing essentially different from the "Absolute" and the "mind of God" that had taken hold of the "rationalists" at the time. You'll see what I mean:

> [I]f you are the lovers of facts I have supposed you to be, you find the trail of the serpent of rationalism, of intellectualism, over everything that lies on that side of the line. You escape indeed the materialism that goes with the reigning empiricism; but you pay for your escape by losing contact with the concrete parts of life. The more absolutistic philosophers dwell on so high a level of abstraction that they never even try to come down. The absolute mind which they offer us, the mind that makes our universe by thinking it, might, for aught they show us to the contrary, have made any one of a million other universes just as well as this. You can deduce no single actual particular from the notion of it. It is compatible with any state of things whatever being true here below. And the theistic God is almost as sterile a principle. You have to go to the world which he has created to get any inkling of his actual character: he is the kind of god that has once for all made that kind of a world. The God of the theistic writers lives on as purely abstract heights as does the Absolute. Absolutism has a certain sweep and dash about it, while the usual theism is more insipid, but both are equally remote and vacuous.

14-02-07 *Rivers of Nows* (to G. L. Comer)

Hollow Flow

In Einstein rapids,
Instants, rivulets,
Shadows shake
Beneath the foam.

In carved canyons,
Sifted sandbars,
Imperfect memories
Attend the self-aware.

In quantum pools,
Non-waves crash,
For milky ways
And silt-filled streams.

In recollections,
Our reflections,
Are rivers of nows
And melting glaciers.

Gregory Lee Comer
02/13/07

Thanks for the poem. I'm glad I checked gmail! (I usually only use gmail when I'm away from home, at a really backwoods place.)

Rivers of nows. I love that phrase. Rivers made of droplets? So are there droplets of now? Carriers of now? Carriers of now. Whose now? My now. I am the carrier of my now. Maybe I should say, I'm the maker of my now. Makers of now. Whereupon synchrony, then? Communication. No communication, no global now; not even a quasi-local now.

Oh, you've carried me off today! And this snow-locked day at home probably isn't helping either. But I must resist. Too much work needs to be done.

15-02-07 *The Kochen-Specker Spectre* (to G. L. Comer)

Thanks for the article. Gregor Weihs will be one of my colleagues in Waterloo (though, he's at the university). He's very reasonable and thorough kind of guy.

Couple of tiny points about the article. I really disagree with blanket statements like this:

> Thus, unless one allows the existence of contextual hidden variables with very strange mutual influences, one has to abandon them — and, by extension, 'realism' in quantum physics — altogether.

It's the 'by extension' part that bugs me. For, I don't think that we quantum Bayesians have given up on realism at all. Quantum mechanics allows for quantum systems—things out there independent of the experimentalist. If they weren't out there for the experimentalist to perform experiments on, his actions in the laboratory would be as much of a koan as the sound of one hand clapping. And yet, there are no hidden variables (from the quantum Bayesian view). So, there is no 'by extension'—it's just a non sequitur.

I think John Sipe does a good job of summarizing how we qB's can let go of hidden variables at the same time as holding on to a deeper, more interesting realism. I'll paste in the section he wrote for his book below (wherein I've toyed with a couple of phrases to bring it further in line with my own thoughts).

> We know this for photons already, but the corroboration in a different system should help to convince doubting Thomases, as well as assure the rest of us.

A quibble with regard to the need for funding these kinds of things: For the skeptics who have not been convinced by experiment yet, they never will be. Nor, does a positive result really assure anyone the likes of me—if one is already certain of something, one doesn't go out of his way to test it. If there is a reason to do these experiments, it lies elsewhere: And that is to develop laboratory techniques for quantum information processing. Some QI protocols rely on KS for their very existence, and that's the real argument for using taxpayer money to do these things.

15-02-07 *Bayesian Strategies* (to R. Schack)

I'm looking forward to spending some time with you next week. I feel like I'm bubbling over with ideas, but of course can't articulate a darned thing.

I'm writing this note to list a few things that I'd like to think about while together with you.

First an operational note: I hope you know Paris well enough that we'll be able to negotiate the trip between the train station, the hotel (to check in and put away our suitcases), and the conference site in the allotted time. We arrive in Paris Nord at 12:53, whereas the conference starts up at 3:00.

Now, for things to think about.

1. I'd like to definitely further explore the conversation we started in completing the certainty paper, about "live" versus "dead" propositions. Also, to discuss what better to say to Timpson.

2. The issue that John Sipe wants to draw out of us: to what extent are we "consequence Bayesians" exclusively, or dualists between that position and "classical Bayesianism" (in his terminology).

3. I'd like to figure what to say to Lucien Hardy who repeatedly challenges me on his paper with Galvao, "Substituting a Qubit for an Arbitrarily Large Number of Classical Bits" (`quant-ph/0110166`). He somehow thinks this is a challenge to a Bayesian view of quantum states, and I just don't know what to say in defense.

27-02-07 *Ref Help* (to W. C. Myrvold)

Myrvoldism 5: *While you were here I asked you for a reference for the classical no- cloning theorem that goes via the invariance under Liouville evolution of the fidelity of two classical densities—that is, integral of* $\sqrt{f(x)g(x)}$*. You referred me to Caves and Fuchs, "How Much Information . . . ?",* `quant-ph/9601025`*, but it's not in there.*

Well, it's mentioned, even if it's not spelled out in detail. See the last paragraph of the paper, at the end of page 31 and the start of page 32. That paper was started in summer of 1995, just at the time that I had first realized the point. (I remember the moment perfectly; I was sitting in front of "tangelo," my computer, writing on my thesis, and my jaw dropped.) But I hadn't recalled that we waited so long before putting the paper on `quant-ph`. (Carl was really dragging his feet on that one, and I remember saying, "If we don't get this paper out quickly, Nathan Rosen may well never see it." Well, Nathan never saw it.)

I guess two publicly earlier references on the point are:

1. `quant-ph/9511010` (the no-broadcasting paper, pages 2 and,

2. `quant-ph/9601020` (my thesis, submitted Fall '95, pages 113 and 114)

There's probably longer discussions buried somewhere in my *Notes on a Paulian Idea*—if you want me to dig in there and find the appropriate stuff, let me know.

I was in Paris this week at a very nice meeting on pragmatism and QM. I met Hacking there for the first time; a wonderful guy. More importantly though, Rüdiger and I had many long discussions on the points you brought up at dinner in London. I will try my best to put those thoughts down for you, along with a reply to your last note, soon.

28-02-07 *Chris* (to A. Y. Khrennikov)

Khrennikovism 15: *Yes, it would be great! Thus I shall put you in the list of invited speakers that we shall print today. Then you will contact with me about whom will come?*

I'm just off the phone with Rüdiger Schack, and I asked him if he would be available in my stead. I told him that you would be able to pay his local expenses, but not the travel expenses. He became very intrigued about the meeting, and is working to rearrange his schedule—he does not know for sure whether he can yet. I think Rüdiger would be particularly good for the subject chosen for this year's meeting in that we have just prepared a paper making a direct comparison between our Bayesian view and older Copenhagen style views, and Rüdiger will have a presentation prepared on just that subject.

01-03-07 *Soul Tired* (to D. M. Appleby)

You are a powerhouse of living scientists: Your stamina and creativity amazes me. You have reached so far further on this problem (and allied problems) that I wonder if I will ever catch back up. I like your "navigation" analogy, which is the part of the note that I understood.

See what a horrible state I am in? Actually, I am quite excited—extremely excited—about the move to PI. It is absolutely clear that it will give me a new lease on life, and effectively set back the clock to the days when I first knew you (say, at the Oviedo meeting): Life, and particularly quantum foundations, was full of possibility then. But it is now getting there, and all the uncertainty in between, that is taxing my soul.

On other fronts, Paris was an extremely intense meeting for me. I was surrounded by pragmatists, real pragmatists, for once and it was a completely new experience. There were Deweyians, Peirceans, and even one Jamesian. There was a fellow who could recall detailed points in Wittgenstein's "On Certainty". That, plus the general intensity of Paris (along with the general hope of PI), too made me feel that the future will be bright again. Particularly useful were all the discussions with Schack about an alchemical world and the "potentest of all my premises."

In that regard, let me ask you this: Can you articulate why you feel that the study of SICs is profoundly important? I would like to hear your answer without tainting it with any contemporary statements of my own, i.e., why I think SICs are profoundly important. I reported all of those to Schack and for the most part I think they left him cold. So, I'm wondering how your version of things will come out. Your stamina on this problem, I suspect, arises from a deep understanding of something—something I myself have not yet grasped—and I would like to pinpoint that source in you.

Besides the various tidbits above, my working life has been filled mostly with the politician's work: Writing letters of recommendation, working behind the scenes to secure positions for good Bayesians (you're not the only one), getting the student-award program set up for the APS March meeting, working with PI to put together the foundations summer school, catching up on my editorial duties for QIC, crap like that. And like a good American politician, I even got stuck in a snowstorm overnight during a recent flight: Though in my case, I really did get stuck in a snowstorm, rather than slipping off with a mistress.

Kiki has been scrambling to complete all her uncompleted projects on the house, so that we might command a higher price. And daily we look through the real estate adverts for the Waterloo area, tabulating distances and whatnot.

On my flight from Paris, I read a small book *Wittgenstein: A Memoir* that contained a small biography by G. H. von Wright, a memoir by Norman Malcolm, and a complete set of Wittgenstein's letters to Malcolm. One thing struck me from the ebb and flow of W's letter-writing style: It had a certain something in common with yours. I never could put my finger on it, but at times (briefly), I felt like I was reading one of your letters. It made me wonder if Wittgenstein had influenced you deeply indeed.

01-03-07 *More Progress on New Directions* (to W. G. Demopoulos)

Thanks for the latest draft. I read a little of it during lunch—up to page 9—just before my lunchtime knap. Let me make some completely superficial remarks at this stage. I'll come back later with any more substantial remarks, after I get a chance to complete the document. [...]

I'm just recovering from my trip to Paris, where I had a thoroughly enjoyable, but intense time. Rüdiger Schack and I spent much time discussing what I keep calling "the potentest of my premises." I also met several very knowledgeable living pragmatists, which was useful for me, and finally had several conversations with Ian Hacking, whom I got to know for the first time at the meeting.

11-03-07 *Quantum Certainty* (to G. Quznetsov)

Quznetsovism 1: *On your "Subjective probability and quantum certainty" in LANL: You already can be not worried about these topics because all these your problems are eliminated by my book Logical Foundation of Theoretical Physics, Nova Science Publishers, N.Y. (2006).*

Thank you for saving us a lot of work. I will look at your book right away.

12-03-07 *Remarks on Ludwig* (to D. M. Appleby)

I've finally sat down to read your long Wittgenstein note seriously. I am really, really sorry about this:

Applebyism 11: *I think that after all this time (more than 20 years) I have got the poison safely neutralised, but with something like this one can never be totally sure. Which is why your comment, about similarities between my style and Ludwig's, worried me. I feared that the toxins were breaking out.*

It was only an offhand remark of mine!! Really. I certainly didn't mean to cause such a fear in you. You never speak like an oracle. If either of the two of us is guilty of it, it is I. So, please rest your soul: You are not *that* much like Wittgenstein. As long as you are a repository of some of his better thoughts, and can bring them to bear on physics, everything will be OK.

Applebyism 12: *I am not like your friend at Paris: I can't quote from the man verbatim (a pretty pointless achievement, it seems to me).*

Well, I didn't go quite that far. I had only said, 'There were Deweyians, Peirceans, and even one Jamesian. There was a fellow who could recall detailed points in Wittgenstein's "On Certainty".' I don't see anything wrong in being a Wittgensteinian in that sense.

Applebyism 13: *Wittgenstein was a ball-crusher: he tended to destroy the intellectual virility of those around him (I use the word "virility" deliberately: I get the impression that it was specifically the men around him who were chiefly at risk (Anscombe, I get the impression, was pretty weird, but I suspect she was like that before she met Ludwig)). And the effect wasn't dependent on personal contact. I mentioned the logical positivists, and the ordinary language philosophers. But aside from these there is a third school: the Wittgensteinians as they are often called. These are people who have fallen for the man completely. They're a pretty sad bunch of nonentities. But they are not just sad in the way that epigones are usually sad. They have lost something vital, located in the region of the crotch, and they all sing in the same kind of distinctively precious voice. Ludwig's castrati.*

I wonder if I can infer from this that you'll think I wasted $15 in buying G. H. von Wright's *Philosophic Logic* in a Denver bookstore the other day? I bought it for his chapter "The Epistemology of Subjective Probability", but of course have not read it yet. The squirrel keeps gathering nuts for the long Canadian winters.

12-03-07 *More Serendipity* (to G. L. Comer)

Comerism 15: *Do you know what I am now studying? Reichl's* Statistical Physics *book, in an attempt to understand better things like the Boltzmann equation. I used to hate that book. But now I really like it. Anyway, I've been reading about Liouville equation, etc.*

So the book was unexpected and serendipitous!

Actually more serendipitous than you might think. I've been thinking a little about what sorts of research pushes I might start to make after arriving at PI. And one thought that has occurred to me is that I think it is time to start working on a "quantum Bayesian" understanding of Bose-Einstein and Fermi-Dirac statistics. You see from a q-Bayesian point of view, symmetrization or anti-symmetrization is a *judgment*, nothing less, nothing more. I.e., it is nothing less or nothing more than a property of a proposed quantum state, and a quantum state is a judgment. So, the question then must be, if one *judges* either BE or FD, what is one judging? I want to get a much deeper understanding of that. (BE certainly looks as if it can be made to come out of an strengthier version of a finite quantum de Finetti theorem; but FD—maybe to be expected—is a completely wild mystery.) These considerations have been hitting me from several directions lately. One was discussions with the (eminent) philosopher Ian Hacking in Paris, who has recently taken a philosophical interest in the "making" of BECs. (If you don't recognize the name, see `http://en.wikipedia.org/wiki/Ian_Hacking`.) The other is discussions with Daniel Gottesman at PI; see this paper of his: `cond-mat/0511207`. But going back to Hacking, he asks the reasonable question: Surely the stability of cold, far away stars does not depend on anyone's judgment. The q-Bayesian needs a good, detailed answer to that question.

13-03-07 *Recent Book Review?* (to N. D. Mermin)

Someone at the APS March meeting (I can't remember who) told me that you had written a book review that had something tangentially to do with quantum Bayesianism. I thought they told me the most recent issue of Physics Today, but I can't seem it. (It could be that it appeared in January, in which case, I can't even find that issue of *Physics Today*!) Curiosity is killing the cat. Could you just send me the file if such a thing exists?

13-03-07 *Recent Book Review?, 2* (to N. D. Mermin)

That was a very nice review. Makes me want to read the book (and scoff at part of it). I liked several of your turns of phrase this time around.

I was also struck by this part:

> On the contrary, the reader is assured that quantum states are real states of affairs. "In some very real sense, the wavefunction of an object is the object." Or, less guardedly, "'The wavefunction of the atom' is a synonym for 'the atom'."

You know Charlie Bennett has been guilty of almost identical sentences before (and certainly remains guilty in spirit, as evidenced in Japan in November). I've told you the story before, haven't I?

15-03-07 *Attributed to Einstein, Incorrectly?* (to G. Will)

I am a regular reader of your column and enjoy it very much, even if I disagree with it often. This morning's column, however, left me in a position in which I could *finally* disagree with some authority! Thus I thought I would write you: One takes one's merit badges where one can.

Today's column started with the slogan "The only reason for time is so that everything doesn't happen at once," which you "attributed to Albert Einstein." However, I don't think that attribution is correct. I have been familiar with a variation of the phrase for many years, one promoted by the Princeton physicist (and Einstein associate from Einstein's later days) John Archibald Wheeler. "Time is nature's way to keep everything from happening at once," he would say. Wheeler was very fond of the phrase and put it in several publications, however he always attributed it to a graffito found on a wall in the Pecan Street Cafe in Austin, Texas. For instance, in Wheeler's 1989 paper, "Information, Physics, Quantum: the Search for Links," he cites it this way, "Discovered among graffiti in the men's room of the Pecan Street Cafe, Austin, Texas."

Of course, it could be the case that the phrase made it from Einstein to Wheeler indirectly, via a men's room, but I find it unlikely given Wheeler's involvement in the development of general relativity in the late 1950s onward.

With regard to the history of ideas, let me point out one other variation of the theme that comes from Louis Menand's book, *The Metaphysical Club*, a wonderful quadruple biography of William James, Charles Sanders Peirce, John Dewey, and Oliver Wendell Holmes Jr. and a very good introduction to American pragmatism. With regard to one of the meetings, Menand has this to say about Peirce,

> They assembled. Peirce did not come; they waited and waited; finally a two-horse carriage came along and Peirce got out with a dark cloak over him; he came in and began to read his paper. What was it about? He set forth ... how the different moments of time got in the habit of coming one after another.

15-03-07 *Attributed to Einstein, Incorrectly?, 2* (to C. M. Caves)

I sent the note below to George Will this morning, only to stupidly do a Google search immediately thereafter. I.e., I should have done it immediately before! Anyway, the web reveals the quote variously attributed to Einstein, Wheeler, and Woody Allen. My guess is that Woody Allen really is the originator, now that I've seen it suggested. Trouble is, no one seems to pin down when/where he said it. Do you or Karen have any friends who are big Woody Allen fans that might recall the source of the phrase?

16-03-07 *Sorry, Sorry, Sorry, Sorry* (to N. D. Mermin)

I was very impressed with your book review. I think it is because it expressed better than ever before what you see as the lesson of quantum mechanics. Or at least I felt like it got to the nub. Most particularly for me, I think it helped me pinpoint what I feel uncomfortable with in your view. If you can give me some time, I'll try to articulate that. (And tell you the Bennett story, etc.)

You are a good man David Mermin, and I feel sorry about being such a sorry disciple. I'll try to write more on more interesting matters soon.

19-03-07 *Quantum Computing* (to L. Ketchersid)

I don't mind your quoting me (or anything in my writings), but I don't see how the present quote ties in with the subject of your article.

I read your draft. I'll just make a couple of trivial comments that may be useful to you, and then sign off. (Sorry, but you've caught me at a bad time these last couple weeks, with some rather big life changes in the works. I will start to be more sociable again in the Fall, if you want to revisit these issues then.)

1) Your sentence, "A qubit is represented as a quantum object's nuclear spin (rotation)," directly contradicts your later sentences, "... qubits are of course represented by quantum particles. Photons, electrons, quantum dots and the current flow across weakly coupled superconductors (Josephine Junctions) are a few of the quantum materials tried as qubits." The second of the two is truer: A qubit can be made from just about anything, so long as it has at least two distinguishable states. Schrödinger's cat is a perfectly good qubit, as it can be found alive or dead under the appropriate measurement procedure. A qubit does not have to be a nuclear spin.

2) In the same sentence already quoted, those are Josephson junctions, not Josephine junctions. Josephine Junction is a town in Ontario.

3) I don't much like the imagery of "quantum parallelism" and think we have been missteering the public (and ourselves) a good long time with it. It's just a cheap way out; that's why everyone uses it. Some models of quantum computation—for instance measurement-based QC—clearly have nothing to do with parallelism ... so that already gives a proof-of-principle contradiction to the whole imagery. Have a look at these articles for your general education: `http://www.arxiv.org/abs/quant-ph/0003084` "A Quantum Computer Only Needs One Universe", and `http://www.arxiv.org/abs/quant-ph/0504097` "Cluster-State Quantum Computation".

4)

> "The roadmap presented by D-Wave Systems, Inc., at their demonstration evidences that quantum computing may follow a similar pattern, with an 'Online Quantum Computing Service' projected to be available in Q1 2008 and 'Enterprise Deployable System' available one quarter after that."

To propagate something clearly so farcical is dangerous, I think. A more reliable timeline, I would say, should you wish to quote something, can be found in the ARDA document, "'Quantum Computation Roadmap," which can be found here: `http://qist.lanl.gov/qcomp_map.shtml`. Look at page 4 of the Overview chapter, to see where we will probably really be by 2012. That's a far cry from an Online Quantum Computing Service.

5) On a different subject—i.e., I don't see how it's related to your present article—in your second note to me, you wrote, "I'd still be interested in putting some thoughts in this article from your paper on quantum mechanics as quantum information, specifically around the fact that some non-mathematical concepts are going to be required to describe what "it" is in order to get the computing community to take on quantum computing." I'm not quite sure what you're talking about, but if you are interested in what I see as the "essential (and ineradicable) incompleteness" of a quantum description of the world, let me recommend the following two (almost lay-) pieces to you. Maybe they'll tell you a little more on the subject, or at least give you some thoughts.

1. See Sections 4 and 5 of `http://www.arxiv.org/abs/quant-ph/0204146`.

2. See Sections 1, 5, 6, and 7 of the attached paper (which I don't have posted, but appeared in

this conference proceedings:
`http://proceedings.aip.org/proceedings/confproceed/889.jsp`).

But that's about all I can do for you now. If you want to "pelt" me with questions (as you said in your first email), it'll have to wait until sometime in the Fall.

Good luck on your article.

Larry's Preply

> My name is Larry Ketchersid, I am an old (in duration and age) friend of your father in law, Brad Lentz (from our Compaq days together). I have an interest in quantum mechanics and he has forwarded me one of your papers in the past.
>
> I run a security software company (`www.mediasourcery.com`), but in my spare time (usually between 1am and 2am) I write. I've written a book, *Dusk Before the Dawn*, and I am writing technology articles for a newsletter called *The Global Intelligencer* (`www.theglobalintelligencer.com`).
>
> I am working on my next article for the *Intelligencer*, and would like to do one on quantum computing. With D-Wave Systems demonstrating a quantum computer recently, it is a timely topic and one I have some personal interest in.
>
> The audience is not the most technical in the world, but I like to cite good sources (as I cited Mr. Schneier in my last article).
>
> Would you mind being pelted with questions and potentially quoted?

28-03-07 *An Anti-Fodor?* (to W. G. Demopoulos)

Thanks for the Fodor review of Frayn. I got a lot out of it, even though I read it in the wee hours (as I couldn't sleep—something that always happens when I really need to). Some remarks regarding our New York discussion later, but for the moment let me tell you about how his sentence, "For better or worse (I think, in fact, it's much for the better), almost nobody has 'a philosophy' any more," reminded me of a note I wrote to Joy Christian and Lucien Hardy recently. I'll paste it below. [See note dated 12-02-07, titled "Lord Zanzibar".]

It sounds like I don't go as far as Frayn goes, but on the other hand, it does seem pretty clear that I'm an anti-Fodor nevertheless.

More piffle later (his words), when I have some light to see by.

30-03-07 *Symmetry Considerations* (to C. H. Bennett)

Let me record a story while it's on my mind. You seem like a good repository for this one. The story's on my mind because the family and I are at Niagara Falls making our way to Waterloo for a short visit, and we saw the most brilliant rainbow through the Falls yesterday afternoon. They're just waking up as I write this. The Horseshoe Falls is 32 floors and a little hill's worth below me, just out the window to my left.

St. Patrick's Day was a couple of weeks ago, and Emma and I were having a discussion about leprechauns. I asked her if she thought they were real, and she said yes, though it seems for no strong reason. "And they'll take you to their gold if you catch them?" "Yep," she replied. "But, I don't believe there's a pot of gold at the end of the rainbow." "Why's that," I asked. "Because both sides of the rainbow are exactly the same. How could you make a distinction between the beginning and the end?"

I was a very proud father.

Say hello to Theo and the family for me.

01-04-07 *Bohm and Cash Value* (to W. G. Demopoulos)

Demopoulosism 29: *Any thoughts on this? It's from a recent email from Jeff.*

I think the criticism from the Bohmians and the Everettians will be something like this: "You've given your analysis of the significance of the quantum revolution. That's interesting, but there is a less radical alternative: we can continue to adopt the standard view of systems characterized in terms of their properties on Bohm's interpretation if we take position, and properties that supervene on position, as the only properties; alternatively, we can hold onto the standard view if we interpret superposition in terms of multiplicity on the Everett interpretation. So why should we accept your view?"

I had pretty much this reaction from Simon Saunders, David Wallace, and Harvey Brown to my talk at Oxford. And I have to say that I am still struggling with this – i.e., why I don't accept the Everett interpretation (it seems to me if you are going to be a Bohmian, you might as well be an Everettian, since you don't really need the trajectories – assuming you buy their decision-theoretic analysis of probability).

I won't answer you on Everett at the moment, but I've got a quick temporary solution with regard to Bohm. It's in the form of a note originally written to Hans Halvorson. Pasted below.

The main point I try to make is that one can make up *unobservable* ontologies underneath quantum mechanics ad infinitum. Bohmian mechanics is not unique in that regard: I could just as well say there is an individual angel guiding each quantum system, and that would be an ontology. But the Bohmians pretend to be doing science rather than something so fanciful because they have an equation. But so what?, I ask. If the equation is unobservable, it is no better than the angel if it doesn't have some further cash value in the sense of facilitating physical calculations. If there were some evidence that it did do that—facilitate calculations—I'd be all for it. (If the angel ontology facilitated calculations, I'd be all for it too.) But I've never seen any evidence of that sort.

The psychological origin of this criterion comes from my early interactions with Jeff Kimble. When I was first a postdoc at Caltech, he would never speak to me. I mentioned this to Mabuchi once and he said, "Oh you just have to beat him at something, and then he'll take you seriously." And as it happened, one day during one of his group meetings, I disagreed with Kimble on some physical point. When I was able to defend myself, he became a different person to me. And that's my point about Bohmianism. Let me take a standard problem of quantum mechanics—one still unsolved by all known means. If the addition of Bohmian trajectories were to facilitate the solution, I would take the trajectories seriously. They would remain, of course, unobservable, but their cash value would be clear enough to me and, hence, worth contemplating.

You see, for the physicist—as opposed to what I take for the average philosopher of science—consistency of a theory is not enough to give it credibility. It has to feel like it's going to give something new in the *next* step, not just tie up a loose end in an *old* one. I like the way Scott Aaronson put it in his blog a while ago. See the entry "Mistake of the Week: Belief is King" at `http://scottaaronson.com/blog/?cat=3D9`. Two relevant paragraphs in there are:

> The reason I'm harping on this is that, in my experience, laypeople consistently overestimate the role of belief in science. Thus the questions I constantly get asked: do I *believe* the many-worlds interpretation? Do I *believe* the anthropic principle? Do I

> *believe* string theory? Do I *believe* useful quantum computers will be built? Never what are the arguments for and against: always what do I *believe*? ...
>
> In my view, science is fundamentally not about beliefs: it's about results. Beliefs are relevant mostly as the heuristics that *lead* to results. So for example, it matters that David Deutsch believes the many-worlds interpretation because that's what led him to quantum computing. It matters that Ed Witten believes string theory because that's what led him to ... well, all the mindblowing stuff it led him to. My beef with quantum computing skeptics has never been that their beliefs are false; rather, it's that their beliefs almost never seem to lead them to new results.

My beef with Bohmian mechanics is where does it lead us further than the angel theory?

In the case of an ontology of objects and effects, or whatever you want to call it—i.e., the stuff you and I have been talking about—I feel it will lead to the NEXT step. And its cash value has already long been apparent to me. The conception told me that I should look for counterparts to almost all quantum information phenomena (e.g. no cloning theorem, teleportation, superdense coding, etc.) in Liouville mechanics. I and several others looked, and we have found. (See for instance the Spekkens paper I recommended to you.) One would like to see the conception lead to many more things still, but that's what should be required of any potential ontology. Bohmianism seems to have been stillborn in that regard. It's had a 50-year shot at it; it's time to move on.

That's my answer.

10-04-07 *Title and Abstract* (to Č. Brukner)

Let me apologize again for being so late on this. Title and abstract below. I hope they will work for you.

> **Good Coordinate Systems for Quantum Foundational Questions?**
>
> Recently there has been much interest in the quantum information community to prove (or find a counterexample to) the existence of so-called symmetric informationally complete measurements (SICs). In this talk we show that there should be even more interest. For, under a robust measure of orthonormality for operator bases (one that does not build in any symmetry at the outset), one can show that SICs, if they exist, come as close as possible to being orthonormal bases for the space of density operators. Moreover, in contrast to the usual expression of the superposition principle (where bases are taken to be orthogonal sets of state vectors), writing a superposition principle in terms of SICs leads to a more intrinsically-quantum representation for quantum states. This is because the basis states, rather than being the easiest to eavesdrop upon (as the usual ones are), are actually the hardest. Furthermore, such states fulfill a few other extremal properties that make them very interesting. Because of all this, writing the quantum-state space in these terms gives hope for a direct derivation of it from a plausible information-theoretic constraint principle—a principle along the lines of the Brukner-Zeilinger proposal of information limitation, but applied solely at the single system level. Various aspects of this problem will be discussed.

10-04-07 *The Story of the No-Cloning Theorem* (to A. Wilce)

Wilce-ism 4: *During our talk last week, you mentioned that you and Carl Caves were responsible for the law-of-large numbers strategy for proving the no-cloning theorem. I'd like to include a* *reference to this in our paper – where does it appear?*

The paper is this one: `http://www.arxiv.org/abs/quant-ph/9601025`. Its final resting place is:

- C. M. Caves and C. A. Fuchs, "Quantum Information: How Much Information in a State Vector?," in *The Dilemma of Einstein, Podolsky and Rosen – 60 Years Later (An International Symposium in Honour of Nathan Rosen – Haifa, March 1995)*, edited by A. Mann and M. Revzen, Annals of The Israel Physical Society **12**, 226–257 (1996).

It looks like Section 7 is the place, though I now wonder how much of the argument was us and how much of the argument was already folklore already long before then.

10-04-07 *Squeamish on Everett* (to W. G. Demopoulos)

Demopoulosism 30: *I'll look forward to what you say about Everett. Regarding it, I would have thought that no one would want to be stuck with such an absurd view unless they were hammered into it. But that appears not to be the case. I recall Harvey and Jeremy once trying to argue that it was no less absurd than the thought that there is a continuum of events, but I've never understood why they see this to be the same. If the issue were one of the continuum, then perhaps so. But that isn't what makes one balk at Everett.*

That is because it is a *temperament* that has essentially nothing to do with the details of quantum mechanics. And that temperament has only found a recent home in quantum mechanics. Read the James quote below to see what I mean. If you listen to one of Max Tegmark's talks on the beauty of many-worlds, you'll see little difference between his take on it and James' description of the Hegelians.

I've written a couple of things contra-Everett. They're not as tight of formulations as they should be, but they reveal my essential squeamishness with the idea. See Section 4, "Psychology 101," of `quant-ph/0204146`. Another place to look is in my *Notes on a Paulian Idea*; see notes to Howard Barnum dated 30 August 1999 and 5 September 1999, "It's All About Schmoz" and "New Schmoz Cola."

The problem, in the end, is that Everettism is simply empty.

12-04-07 *Effects of Effects* (to W. G. Demopoulos)

I'm sure this note will get to you too late for you to see it before the Bubfest, but let me wish you the best of luck with your talk. I'm biased of course, but I think it'll be one of the most important at the meeting. Let's hope this will be the beginning of a long list of effects arising from the recognition that effects are central for our understanding what QM is about.

I write this because I won't be able to come to the meeting after all. What's going on is that it's become clear that just too many things have to be done before we can put our house on the market [. . .] So, though the Bubfest represents probably the most important meeting for me all year long, I couldn't come to it in good conscience. I hope you will understand.

I hope you'll give me a full report of your talk and the reaction to it as you get a chance. And when I get to Waterloo, let's conquer the quantum world!

13-04-07 *Happy Bubfest* (to J. Bub)

It's with some sadness I have to write you this note: Happy Bubfest! Paradoxical, but necessary. The reason is I won't be able to come to the New Directions meeting this year. I really, really apologize and am kicking myself that this had to happen. What's happening is that I'm in the middle of buying/selling houses, in preparation for my move to the Perimeter Institute, and everything hit me at once and at last minute. My wife and I were up until after midnight last night negotiating the Waterloo house (our third offer finally got accepted), and our house here in Cranford now has to go on the market tomorrow. And with the latter it's been a mad dash to the finish line in getting parts of the house freshly painted and decluttered, etc., for showing tomorrow morning. Finally, yesterday afternoon it just became completely clear that I'd have to make a decision to stay at home this weekend. That's the story.

I know I'm missing the best foundations meeting this year, and it hurts (hurts me, hurts the program, everything). Still, at least I am confident you'll enjoy this well deserved honor of a meeting in your name. Thanks for all the inspiration over the years.

13-04-07 *Happy Bubfest* (to H. Barnum, A. Wilce, & M. Leifer)

I'm sorry I'm going to miss all you guys today and this weekend. (The story of my absence below.) [See 13-04-07 note "Happy Bubfest" to J. Bub.] The line-up of talks at this meeting looks fantastic, and on the top of my list is Howard's. Good luck with it. It has a chance of being a wake-up to the community, and I hope it will be. The philosophers don't seem to be very good at seeking counterexamples: All this talk about C^*-algebras "covering a *vast* range" of theories really grates, and I hope your talk will be a good splash of cold water for them. There's so much to be done, and it'd be great if they'd start using their thoughts more wisely. Lead the way!

13-04-07 *Relations and Information* (to B. C. van Fraassen)

I am so sorry I'm going to miss your talk at the Bubfest. I got caught up in all the stresses of a house sale/purchase, and it became clear that I could not afford to be away from home this weekend. Many of the talks look fantastic, but particularly the remark in your abstract, "It is a fascinating world in part because of Rovelli's reliance on the information-theory approach to the foundations of quantum mechanics ... " has me intrigued. If you have a paper version of the talk, I'd very much like to see it.

11-05-07 *Information Gain Disturbance* (to R. W. Spekkens)

Spekkensism 37: *What is a good reference for the following well-known result? The only set of pure states about which one can get information without creating a disturbance is a set of orthogonal states.*

That would be the Bennett, Brassard, Mermin PRL that came out soon after the Ekert protocol:

> C. H. Bennett, G. Brassard, and N. D. Mermin, "Quantum Cryptography without Bell's Theorem," Phys. Rev. Lett. **68**, 557–559 (1992).

11-05-07 *Information Gain Disturbance, 2* (to R. W. Spekkens)

Spekkensism 38: *I just had a look at it. They do show (around eqs. 3 and 4) that if two nonorthogonal states are left undisturbed, then no information is gained about them. It's obvious that the result doesn't apply if the states are orthogonal, but unfortunately, they don't say so explicitly. It would be great to find a reference that did say this explicitly. Can you think of one?*

Now that I think about it, for mixed states, the condition is no doubt that the set be a commuting set. Surely, somebody has pointed this out somewhere.

Just a short note: I've come in for a small break between mowing the left side of the yard and the right.

For mixed states one can gain information without disturbance even if they are noncommuting. So long as they are block diagonal with the same blocks. See Section 5 of `http://www.arxiv.org/abs/quant-ph/9611010`. Koashi later proved if and only if somewhere.

I'll be able to think about the fine details of your question and trawl my memory tomorrow morning. We've got to show the house to a potential customer tonight. That's why I'm scrambling for all to look beautiful.

11-05-07 *Big Drags and Little Drags* (to W. G. Demopoulos)

Demopoulosism 31: *I extracted a significant part of the paper and read it; I don't often do that, but the nature of the argument seemed to warrant this style of presentation.* [...] *I found the question period a little disappointing; Paul Teller said that he couldn't see how I was saying anything different from Bohr.*

Maybe he's right ... but the holy scriptures can be interpreted many ways. More importantly that doesn't bar us from trying to say things more clearly than Bohr ever could ... and we are definitely saying them more clearly. Anyway, seriously, I think I would say Paul is probably close to the right judgment. In fact, it strikes me that in our own discussions—the discussions between you and me—you are to Bohr what I am to Pauli. I.e., their divide is our (present) divide. For Bohr, the "device" was the repository of the effect; for Pauli the "device" should be considered a prosthesis of the agent.

14-05-07 *Information Gain Disturbance, 3* (to R. W. Spekkens)

Spekkensism 39: *I just had a look at [BBM]. They do show (around eqs. 3 and 4) that if two nonorthogonal states are left undisturbed, then no information is gained about them. It's obvious that the result doesn't apply if the states are orthogonal, but unfortunately, they don't say so explicitly. It would be great to find a reference that did say this explicitly. Can you think of one?*

Is this more like the statement you were looking for:

> On the other hand, if Eve definitely knows that the initial $|\psi\rangle$ is one of the orthonormal vectors $|e_n\rangle$, but she does not know which one of them it is, she can unambiguously settle this point by a non-demolition measurement [4], which leaves the state of the system unchanged.

It is from the top of page 3 of my old paper with Asher: `http://www.arxiv.org/abs/quant-ph/9512023`. I don't know how reference 4 had said things.

... just catching up.

14-05-07 *More Info Gain Disturbance Tradeoff* (to R. W. Spekkens)

Spekkensism 40: *All of this talk has jarred my memory. I now remember how at the end of one of your papers on state disturbance you show that the condition for information gain without disturbance is not commutativity, but rather commutativity on a subspace. I also remember that I had a problem with this argument, so I was led to dig up some old notes on this question of infogain-disturbance for mixed states which I wrote way back when I was working on cryptography with Terry. Here is what I said:*

At the end of his paper, Fuchs suggests that all that is required for a measurement to be non-disturbing is for the state of the system to be unchanged. However, this seems to me to be necessary, but not sufficient. A sufficient condition is that the state of any larger system of which the system is a part is unchanged. The reasoning is as follows: if the correlations between A and B are disturbed due to a measurement on B, then clearly one's predictions about the outcomes of measurements on B suffer, specifically, one has reduced predictability for measurements on the composite of A and B.

A natural measure of this revised notion of disturbance is the probability of failing a test for a purification of the state.

So, whereas Fuchs argues that one can gain information without disturbance for commuting density operators, and even for density operators that fail to commute (but do commute on some subspace), I would say that the notion of disturbance considered by him is an unnatural one. Under the revised notion of disturbance, I suspect that the only sets of density operators about which one can hope to gain information without disturbance are orthogonal density operators.

I think your question is an interesting one, and I don't know the answer. But I don't think—for a q-Bayesian, at least—that there can be a most-natural / least-natural distinction. These problems are driven by the assumption of what the agent knows and which systems he has in his possession and control. You imagine a situation where the sending agent has a reference system lying about and that he has a declared quantum state for the totality, even though he only sends part in one shot. I imagined a situation where the agent sent everything he has per shot. Just a different situation; neither is more fundamental or natural as far as I can see. It would be very nice to find info-disturbance questions for which the answers are 1) "iff orthogonal density operators" and 2) "iff commuting density operators." I always liked the achievement of the Holevo bound on accessible information in that it was "iff commuting."

15-05-07 *Couldn't Slice It* (to R. Schack)

Unfortunately, no matter how I tried to slice it, I couldn't make a small stay in London viable. So, I guess I won't be seeing you this trip after all. The trouble of course is my damned insistence on restricting myself to American Airlines. Bypassing any time in London and arriving in Newark at 10:00 PM, made the cost of the trip within ethical bounds. (Basically the lowest price I could have found anywhere, though of course other airlines would have given much better schedules.) Arriving for a small visit to you in London at 4:00 PM would have upped my price \$120, and arriving at 1:00 PM would have upped it \$220—and besides, I would have still gotten into Newark relatively late in the day. So, I just dropped the idea, and swallowed the idea of arriving at 10:00 PM (but a day earlier).

My existential state is complete misery at the moment. It is the true evil of money—not living the life of an Erdos, or a Wittgenstein, or a Tolstoy. Hardly a couple has even looked at our house, and it is already mid-May. And as you can guess, monetarily, I've got everything tied up in this house. I have no fluidity at all. So, between the Waterloo house pending (July 31 latest) and all the expenses of the flood damage (waiting even to file insurance claims, much less collecting on them), I am up in arms. And there's no great sign of relief in the real estate market here. So my behavior has become one of OCD for this dirty subject; not at all the life of an academic. Pray I survive to do science once again one of these days!

On better things, have a look at John Baez's blog "This Week's Finds in Mathematical Physics" (week 251, the latest edition). He gives a small explanation (very small, but not infinitesimal) of the quantum de Finetti theorem.

29-05-07 *Foils Is a Very Broad Term* (to D. M. Appleby)

Applebyism 14: *Rob did get in touch and I said I did want to go. However, I am feeling a bit worried. When you originally asked me I didn't pay much attention to the title* ["Operational Probabilistic Theories as Foils to Quantum Theory"]*. It is a workshop on quantum mechanics, you are going to be there, along with several other people I find interesting, so I automatically said "yes". But Rob has now sent me this:... At the end he speaks of bringing "everyone up to speed with what others are working on". But I am not working on operational theories.*

Anyway, I don't think you'd be an imposter at that meeting at all. And, looking carefully at Rob's call for abstracts, I couldn't find the word "operational" or "operationalism" at all. Probably it shows in the official title of the meeting ... but then that should have tweaked your fears long before the abstract request.

That aside, I view the issue of foils to quantum theory a very general question—a game that can be played whatever one's interpretational stance. And in the list of attendees that I saw, I would say at least Wootters, Kent, Caves, Barrett, and Leifer could not be counted as "operationalists." And in the case of Spekkens, and maybe Barnum, I'm pretty sure they only see it as a means to an end anyway—a kind of stopgap method for bringing them ultimately to some kind of realism.

In my own case, what I want to know, and what I want to focus thinking on during the meeting is what is the significance of the damned $\mathrm{tr}\, A^2 = 1$ and $\mathrm{tr}\, A^3 = 1$ conditions for defining the quantum state space. Who ordered that? Why? Particularly, when written in terms of an SIC expansion, what do they mean? For, I want to see the two operator equations as information theoretic constraints on sets of probabilities, and—I think—the best way to translate them into something of that flavor is to use SICs as the intermediary. Then the first condition is a constraint on a Rényi information. But what is the second equation?

What would be a foil theory to QM in this case? Drop the one condition while retaining the other. What would the resulting theory entail? At least, that was the sort of thing I envisioned as good busy work while waiting for a better or more natural question.

And because I was thinking I wanted to think about those kinds of things, much more so than "nonlocal boxes" and the like, I thought it'd be great if you were there—that maybe you'd share some of my interest in these questions. Moreover, I thought that you might get something out of thinking about all your SIC-existence work within this kind of context. So, scientifically I think the meeting would be fruitful for you.

31-05-07 *Vienna Traffic Lights* (to C. H. Bennett)

Noticed you're on the list for the Vienna meeting next week. When do you get there; when do you leave? We'll have to have some conversations near a traffic light and see if we can reproduce the phenomenon we noted in Tsukuba. (Contradictory to the point of debate though that sentence be.) [See 13-12-06 note to Schack, titled "More on Identity," for an explanation of this.]

11-06-07 *Objective Indeterminism* (to Č. Brukner)

I enjoyed talking to you the other night; I hope it is the sign of much more to come. At the moment I write this, I am over the Atlantic working my way back home. Particularly, I've been thinking about our little exchange on how one might have objective indeterminism at the same time as subjective probabilities—my view of course, that is, the one you took issue with. Anyway, it led me to dig through my old correspondence to see what I had actually written on the subject. Apparently not as much as I thought I had. Still, I thought I'd compile for you what I found, even as incomplete as the thoughts are at this stage. The file is attached.

The main letter to read is the second one, to Kirk McDonald. I wrote it in a fit of passion, as he had written an insulting letter to me (saying that my view boiled down to "physics = psychology"), but nonetheless, I think that letter best captures the point. Bayesian probabilities need not solely be "ignorance probabilities" (as I think you said) where the ignorance is of some actual existent, but rather probability in any context of uncertainty ... whatever the cause of the uncertainty. In the case of quantum measurement, the uncertainty is there because the outcomes do not pre-exist the measurement. Measurement is an act of creation, bringing something new into the world: That is the ultimate reason for the uncertainty. And what more can a poor quantum gambler do but express his beliefs about what will come into existence? Alice has her beliefs about an event; Eve has hers. They are not in conflict because the beliefs are not objective properties of the event.

Actually, while I'm on this subject, I think I'll also attach a little pseudo-paper of mine, "Delirium Quantum" (it appeared in an APS conference proceedings, but I never posted it on `quant-ph`). It describes in more detail the sort of sense in which I think nature is "on the make"—that is, being hammered out, being created, in quantum measurement interactions.

Thanks for organizing a great conference. I thoroughly enjoyed it and got so much out of the discussions with so many. Despite your weary words the evening of the banquet, I hope you'll organize another one soon!

12-06-07 *The Sweep and Dash of Mathematical Structures* (to M. Tegmark & C. H. Bennett)

I'm flying over the Atlantic, slowly making my way home, and I'm using the time to take care of various loose ends that arose at the conference. Below is the quote by William James with the highfalutin' words I told you both about. I thought it captured the point Charlie brought up with his question, but maybe not. Charlie can be the judge of that.

What James was talking about directly was a certain strain of philosophy at the time—a belief that the world arose from something called the Absolute. The name to look up in an encyclopedia if you're interested is "Absolute Idealism." Hegel's thought was an example of it, as was F. H. Bradley's.

James wrote these words in 101 years ago in 1906:

> [I]f you are the lovers of facts I have supposed you to be, you find the trail of the serpent of rationalism, of intellectualism, over everything that lies on that side of the line. You escape indeed the materialism that goes with the reigning empiricism; but you pay for your escape by losing contact with the concrete parts of life. The more absolutistic philosophers dwell on so high a level of abstraction that they never even try to come down. The absolute mind which they offer us, the mind that makes our universe by thinking it, might, for aught they show us to the contrary, have made any one of a million other universes just as well as this. You can deduce no single actual particular

> from the notion of it. It is compatible with any state of things whatever being true here below. And the theistic God is almost as sterile a principle. You have to go to the world which he has created to get any inkling of his actual character: he is the kind of god that has once for all made that kind of a world. The God of the theistic writers lives on as purely abstract heights as does the Absolute. Absolutism has a certain sweep and dash about it, while the usual theism is more insipid, but both are equally remote and vacuous.

In place of "absolute mind", as far as I can tell, you could insert Max's "mathematical structures" and little of the meaning would change. Now, of course, "mathematical structures" makes reference to equations, symbolic logic, and the like, whereas the Absolute does not. So it would seem to have a certain sweep and dash about it, far beyond anything the Absolute could muster. More accurately, it gives the appearance of being more impersonal and scientific than the theistic God. But, like James, I cannot help but feel that this is only an appearance. When a plan of the multiverse becomes so disconnected from what is seen in our actual universe, one might as well invoke a bearded old God—the two conceptions have no operational distinction, precisely because, as you pointed out (celebrated even), the ultimate, all-inclusive mathematical structure has zero information content.

James, by the way, in that same lecture makes the first use of the term "multiverse" that I know of—though he meant it in quite a different way than you guys.

Max, I did enjoy your talk (and even more so the PI version of it) and many of your comments, which gave me lots of giggles. Charlie says that's the best way to do science, and listening to you helped me clarify several of my own thoughts. I also liked your comments to the students at the round table too; they were on the mark.

12-06-07 *Quantum Chris* (to M. Tegmark)

You also asked me about my own view of quantum mechanics. For some reason, at that moment, I felt a little reluctant to talk about it. Let me try to make up for that, in case you're still interested in the answer.

Maybe the single best place to look for a starter is this paper: `quant-ph/0205039`. But that can maybe be supplemented with: `quant-ph/0404156` (particularly the introductory and concluding sections), and `quant-ph/0608190` (particularly the concluding section). A couple of other significant pieces of the story are told in these papers by Marcus Appleby and Matt Leifer: `quant-ph/0402015` and `quant-ph/0611233`. (FQXi, by the way, partially funds Leifer ... and thus, I would guess this kind of thought? Maybe you should watch where your dollars are going!!)

The view is a kind of realism about quantum objects, but one that strikes reality from the wave function. The significant, stand-alone property of quantum systems is instead that they are catalysts. They are catalysts that take part in the creation of events. It is a view in me that owes much to the John Wheeler of the 1970s and 1980s.

I hope that helps some.

16-06-07 *Article for Nature* (to M. Buchanan)

Funny you should ask for my thoughts on many-worlds; I'm not exactly a sympathizer. For instance, my talk at the *Fifty Years of Everett* conference coming up in September is to be titled "13 Direct Quotes from Everettian Papers and Why I Find Them Unsettling" (or at least that's the title I sent the organizers a few months ago). But, yes, we can talk if you like—though Tuesday or Wednesday would be better dates for me.

¿ I've read a few things that suggest to me that the Everett view (and I ¿ suppose there are many variations of it) has been gaining adherents in ¿ recent years. Is this true, and if so why?

It is true that the Everett view is gaining adherents. But I think it's powered mostly by a lack of imagination and a usual historical cycle working its way through. Putting it bluntly, it's just the newest species of the "serpent of rationalism." Read this little piece William James wrote 101 years ago for his Lowell Lectures:

> [I]f you are the lovers of facts I have supposed you to be, you find the trail of the serpent of rationalism, of intellectualism, over everything that lies on that side of the line. You escape indeed the materialism that goes with the reigning empiricism; but you pay for your escape by losing contact with the concrete parts of life. The more absolutistic philosophers dwell on so high a level of abstraction that they never even try to come down. The absolute mind which they offer us, the mind that makes our universe by thinking it, might, for aught they show us to the contrary, have made any one of a million other universes just as well as this. You can deduce no single actual particular from the notion of it. It is compatible with any state of things whatever being true here below. And the theistic God is almost as sterile a principle. You have to go to the world which he has created to get any inkling of his actual character: he is the kind of god that has once for all made that kind of a world. The God of the theistic writers lives on as purely abstract heights as does the Absolute. Absolutism has a certain sweep and dash about it, while the usual theism is more insipid, but both are equally remote and vacuous.

"The multiverse which they offer us, the mathematical structure that makes our universe by containing it within, might, for aught they show us to the contrary, have made any one of a million other universes just as well as this. You can deduce no single actual particular from the notion of it. It is compatible with any state of things whatever being true here below." My own feeling is that the MWI is simply empty of content—thus a dead end for physics.

Let me give you some links to pieces I've written to shore that feeling up a bit—ones written in a less formal, (hopefully) more entertaining fashion. See:

- My pseudo-paper `http://www.arxiv.org/abs/quant-ph/0204146`, particularly Section 4 of it (originally a letter to John Preskill), for my most sweeping discontent with the notion.

- My samizdat `http://xxx.lanl.gov/abs/quant-ph/0105039`. Just look in the index for "Everett" and then flip to the pages. Maybe pages 19–22, 92–93 ("Challenge to the Everettistas"), 356–358 and other letters to Preskill, 461–462 (letter to Spekkens), 472–473.

- And for something a little more serious, maybe the introduction and first couple of sections of this paper `http://xxx.lanl.gov/abs/quant-ph/0205039`.

The main point I try to get at there is that Everett (like most other interpretations) takes Hilbert space, state vectors, unitary evolution, inner products, tensor products, and all that mathematical machinery as the *starting point* of the interpretation, and then *contrives* a story around them. (And in the Everett case, it's the most trivial story—one that could have been written, and as the quote above shows, was in fact written, by 1906.) It should not be that way. It should be the opposite: The story should be written first, and one should be forced to the mathematical formalism from the story alone.

To give you some hint that this is not simply a pipe dream, have a look at the introduction to Rob Spekkens' "toy theory" paper: `http://www.arxiv.org/abs/quant-ph/0401052`. It's a beautiful piece, even though it's not quantum theory directly. What Rob does is start with a simple principle that "maximal information is not complete information" for a toy system and then looks at the properties of these states of information. The lovely thing is that they have *so many* properties that one might have thought were unique to quantum mechanics. And yet, there is no hint of parallel worlds in the theory at all. "Is that a coincidence?," one should ask. No, of course not—the toy theory is explicitly constructed with the idea that there is one true world and what one is speaking of is one's ignorance of it. But yet, as John Smolin points out, one could make a many-worlds interpretation of the toy theory! And he's right. But notice the order of things. The mathematical structure was forced by the information principle alone; the many worlds interpretation of it is a grotesque appendage. (Though John, being a sympathizer of MWI, would not call it grotesque as I did.)

Maybe a better person to ask this of is Howard Barnum. He can give you a detailed account of what he sees as positive in the newest papers, but also, he can pinpoint exactly where he thinks they ultimately fail in their goal (particularly, of deriving the Born rule for quantum probabilities).

That's enough for now, enough to get you started. Let's correspond again Monday or Tuesday about a good time to talk; I'm not quite sure what my schedule is going to be yet.

01-07-07 *First Einstein Quote* (to R. W. Spekkens)

Attached is part of the Einstein quote I was telling you about, from his "Reply to Critics" in the Schilpp volume. Unfortunately, I do not have the whole quote with me here. Where I write "granted" and quote him, that is the part where he describes what he means by "physicist B." What he is grasping to express there is, I'm pretty confident, a physicist like myself or Asher or Carl or Rüdiger, one for whom "unperformed measurements have no outcomes."

The main reason I brought this up tonight is I think you are right that Einstein didn't make a clear distinction between psi-epistemic and psi-supplemented: I would guess for him, that he was simply using the word "incomplete" in the restricted fashion of meaning psi-epistemic only. However, he did at least make one distinction that's pretty important to me: between "psi-epistemic about pre-existent properties" and "psi-epistemic about the consequences of interventions". I think he had that distinction pretty firmly in mind (probably from talking to Pauli), and in the present passages attempted to show that, upon the assumption of "the real factual situation at 2 being independent of what is done at 1," wave functions could not be "psi-ontic about the consequences of interventions." I.e., they could not be objective propensities or some such.

Had a nice long walk with Howard and Marcus tonight, talking about SICs and convex structures. This is already shaping up to be a really good meeting.

The More Pure Einstein

> **Granted:** "The individual system (before the measurement) has no definite value of q (or p). The value of the measurement only arises in cooperation with the unique probability which is given to it in view of the ψ-function only through the act of measurement itself."
>
> **Consider spatially separated systems S_1 and S_2 initially attributed with an entangled quantum state ψ_{12}.**
>
> "Now it appears to me that one may speak of the real factual situation at S_2. ... [O]n one supposition we should, in my opinion, absolutely hold fast: the real factual

situation of the system S_2 is independent of what is done with S_1. ... According to the type of measurement which I make of S_1, I get, however, a very different ψ_2 for [S_2]. ... For the same real situation of S_2 it is possible therefore to find, according to one's choice, different types of ψ-function.

If now [physicist B] accepts this consideration as valid, then [he] will have to give up his position that the ψ-function constitutes a complete description of a real factual situation. For in this case it would be impossible that two different types of ψ-functions could be coordinated with the identical factual situation of S_2."

01-07-07 *Second Einstein Quote* (to R. W. Spekkens)

And below is the second Einstein quote I mentioned tonight, along with a Pauli quote. It's a section from my new samizdat (a letter to Hans Christian von Baeyer). [See 02-01-06 note titled "The Oblique Pauli."] I can't believe I so botched my reporting of it tonight—my brain wasn't working. Anyway, this little quote came soon after the earlier, more technical quote I just sent you.

06-07-07 *Renner Monday* (to R. Schack)

I hope you'll arrive here early Monday morning. The schedule has been revised and Renato Renner will be giving the 10:00 talk before Ben Toner's on de Finetti theorems in the afternoon. The subject of Renato's is supposed to be something like "the de Finetti theorem as a precondition to doing science." Sounds fishy to me. It'd be nice if you'd be in the audience to help me out at those tough moments.

16-07-07 *Question, Possibly Addled* (to A. Wilce)

It was great to see you too. Your clever comments throughout the week were enjoyed as ever. And I'm glad too of your story about Harvey Brown. These guys should stop and think, in the way you suggested, about what actually does compel them *if anything* to the MWI—they rarely do. I think the class of examples in general convex set theories you bring up is great for cornering them on the subject.

About SIC-POVMs, yes, the definition does require that the elements of the POVM be rank-1. You ask, "if so, what advantage does that yield?" Aha, I caught you! The word is that that point was explained at a certain talk at Susquehanna University ... (Or at least I hope it was.) I don't think there was originally any motivation for that particular restriction, other than to keep the problem from being too easy. (Your construction, for instance, is just fine.) But now things are a little more compelling. My favorite reason for the restriction is that, by way of it, one comes geometrically as close to an orthonormal basis as one can on the positive cone. See Section 2 of the attached paper. So a SIC-set is a kind of stand-in for the idea of an orthonormal basis. That's got to be good for something, I think, though I've yet to be able to express completely why.

I think it'll also be the case that if one generalized the idea of minimum uncertainty states we talk about in Section 3 to generally mixed states, one will find again the rank-1 density operators are the only ones that will fulfill the criterion.

Maybe there are other reasons to prefer the symmetric sets of rank-1 states over constructions (like your own) made of mixed states. I should try to think of whether there are other reasons. For instance, would mixed-state constructions like yours wreak any havoc on their equations corresponding to (5) and (6) in the attached paper for defining pure states? Maybe they wouldn't?

Maybe they'd actually make for cleaner equations. That would intrigue me greatly if it could possibly be so.

Can you send me references, by the way, for your papers on topologizing test spaces? If you have any interest in exploring it further, I'd like to come back to your suggestions for generalizing Gleason: I.e., identifying or classifying or finding some interesting characteristic of those test spaces for which the frame functions must be continuous (so that one has no dispersion free states). Once at PI, I'd like to think much harder about that.

31-07-07 *New Address* (to M. G. Raymer)

Raymerism 1: *Thanks for including me on your list. I really enjoy reading your various papers and long, recorded email diatribes on QM.*

In my quantum state, my belief is that quantum states are not simply matters of belief, but I think the idea goes a long way toward dramatizing the matter in the right direction.

Thanks for the kind words. And you shock me that have read any of my samizdats! Very dangerous business …

But one thing to keep in mind about Caves, Schack, and me in our terminology: Try to resist the temptation to think that just because we categorize quantum states as "states of belief" that it means any unique individual can believe anything he wants to believe. I.e., something like, "I'll make up any quantum state I damned well please." If that's part of your aversion to the idea, then try to resist it. In the words of Marcus Appleby, "It's really hard to believe something you don't actually believe" and the same is true of the conception of quantum states as states of belief. When an experimentalist writes down a particular quantum state, he does it for good reason; it isn't made up on the fly, out of nothing. All we are saying is that no part of that "good reason" has anything to with some property intrinsic to the quantum system.

Looking forward to more discussions another day. Steven van Enk had invited me to give a colloquium at U. Oregon this year, but I had to drop out because of too many pressures. Maybe next year you guys will give me a second chance, and we can pick back up then.

01-08-07 *Your Conference* (to F. Topsøe & P. Harremoës)

Topsøe-ism 1: *Does this mean that you (and … ?) may be interested in our workshop "facets of entropy", cf.* `http://facetsofentropy.fys.ku.dk`*?*

Well, I didn't know about your workshop, but now that I do, indeed I am very interested. In fact, I had been meaning to write you and Peter (to whom I'll cc this note) for some time to ask you a question on a rather funky kind of "entropy" (though I dare use that word for this) that has been fascinating me lately. Truth is, I don't actually know what the object is, or whether it has any information theoretic interpretation at all. And I was going to ask you if you've ever seen anything like it *within* standard, classical information theory, i.e., outside of quantum considerations.

In particular, I was going to write up the note a little more formally in LaTeX and send a PDF to you once arriving at PI. But now that I'm writing you anyway, let me pose the question in a little sloppier way. I'll just refer you to the quantity on the left-hand side of Eq. (6) in `http://www.arxiv.org/abs/0707.2071`. Now, divorce it from its original motivating problem, and just imagine the coefficients c_{ijk} are fixed constants handed down from heaven. The question is, does that kind of quantity have any interesting information theoretic (or maybe game theoretic) meaning? Are there any constraints on the c_{ijk} needed in order to make the expression make sense information theoretically?

It strikes me that if I could get a handle on that *style* of quantity (i.e., somewhat independent of the particulars of the c_{ijk}) in a way completely independent of quantum mechanics, then I would have learned something deep.

But a potentially independent question. If you read the paragraph surrounding Eq. (6), you will find that it arises from a consideration to do with a quantum mechanical version of the Daróczy order-3 entropy. But the Daróczy order-3 entropy?? Who ordered that? Have you ever run across any actual use of that particular entropy before?

Now, that I've posed the question, I'll probably be somewhat silent for a while . . . but don't let that stop you from writing me even if I don't reply. It's just that I've got a lot to do to get my house in New Jersey sold and get moved up to Waterloo in the next 9 days. I'll be back in touch for sure, once I arrive at Perimeter.

02-08-07 *Perimeter Visit* (to H. Mabuchi)

Mabuchism 4: *I've been invited for a Perimeter colloquium — when would be a good time for me to come, in terms of your schedules?*

God knows with me. Particularly, until I fulfill my 50,000 mile quota for the year with American Airlines (so that I keep my platinum status), I'm likely to be a wild card . . . selling my soul to travel whenever the opportunity arises. And I'm running behind this year, only 32,000 so far. Pathetic, huh? Anyway, it means at the least I may set up a trip to Beijing before the year is out. Not quite sure when yet.

Here's a couple of blackout dates: [. . .] At the moment, Spring is wide open for me.

Clearly, the strategy ought to be that you just give me your dates, and I try my best to be at PI while you're around.

Congratulations on inheriting Ed Jaynes' office. Now here's a real task for you: Find the desk that Ed Jaynes actually sat at. If you can dig it up, you'll have to let me sit at it, at least for just a minute. Once upon a time, I had a chance to sit at Niels Bohr's desk while no one was looking, and I didn't take the opportunity. I've been kicking myself since.

But more congratulations than for the office, congratulations for the new position! Is it a fancy named professorship? If so, what's your name?

02-08-07 *The One-Belly Theory of the Universe* (to S. J. van Enk)

By the way, I started to compose a note to you several months ago, and then never came back to it. It was titled "The One-Belly Theory of the Universe." When I get to Waterloo, I'll finish it I promise—I think it's actually an important idea. Here's the upshot of it. Alice and Bob are at two ends of a lab, checking for Bell inequality violations. The question arises, are the detectors at both ends of the lab going "click" in this process. My answer is, it depends upon one's perspective. From Alice's perspective, her detector is certainly going click, as she collects the outcomes into her awareness. But also from her perspective, Bob's is NOT going click at all. As far as Alice is concerned, Bob has simply become entangled with the particles. The reason I make these remarks has to do with the last technical discussion we had—I think it may be the key to understanding . . . well, everything. In the next note, I'll at least send you the beginning of the note I had started.

Then you pressure me some in two weeks and I'll finally finish it. But you're so clever, I'm sure you'll see the idea right away … invalidating my needing to finish it after all. Still, I will.

"The One-Belly Theory of the Universe", first paragraphs, to be completed

van Enkism 11: *I'm still not sure how I would violate Bell inequalities with only positive probabilities and extra hidden variables in my belly. After all, the hidden variables of the system on Alice's end and in her belly, and the variables of the system on Bob's end plus his belly are still local hidden variables, aren't they?*

That's the wrong way to think about it. I don't know whether thinking about it in the right way will give rise to a Bell inequality EITHER, but at the very least I can point out that the above is the wrong way to think about it. Here goes.

What I'm going to say is prompted by this thought about the actual quantum situation. Go to any exposition of the Bell set up, and one will see the whole affair laid out in terms of *two* devices going click-click-click, one on Alice's side and one on Bob's side. Then one asks if the data can be "explained" by a local hidden-variable model. What that is taken to mean is whether the actually-observed frequencies are the ones predicted with near certainty by various i.i.d. distributions over the sequence of experimental runs (conditioned by the A and B devices' settings). Then one focusses on the single-shot distributions (for the various settings) and asks whether they can be derived as the marginals of a certain variety from a single deeper probability distribution. Thus arises the Bell inequality, and the conditional probabilities given by quantum mechanics violate it.

Then a sweeping claim is almost always made: That the Bell inequality was derived in a *theory-independent* fashion (aside from the assumptions of locality and the existence of a grand joint distribution that could be marginalized), and quantum mechanics—a particular theory—violates it.

But I'm now starting to think that the premises of the Bell derivation don't even fall within the framework of a quantum description of the whole thing. Thus, perhaps, it is no wonder that quantum theory violates it. Think Wigner's friend.

07-08-07 *Last Email from Bell Labs* (to A. E. White)

I'm just signing out, and I wanted to send you a short note to say thanks for "tolerating me" at the Lab for so long: I know that my research didn't exactly fit in with the present incarnation of Bell Labs and the other departmental interests. But the company nurtured me nevertheless, and I am grateful for my years there. I wish you all the best of luck in the future. If you're ever near Waterloo, Ontario, please visit us at the Perimeter Institute for Theoretical Physics.

15-08-07 *Title* (to L. Hardy)

"Quantum States as Uncertainty, pure and simple. But, Uncertainty about What?"

Probably the longest title you have, but I like it. Subjects include: Einstein's pre-EPR argument, contrast between frequency and Bayesian interpretations of probability, Dutch book argument, no-cloning and no-broadcasting theorem, example of classical no-cloning theorem and yes-broadcasting, standard (non-Spekkens) Kochen-Specker theorem, words on the Paulian ontology in light of KS, ending with fiducial measurements (SICs and MUBs) and the shape of quantum state space.

Does that fit well (or contrast well) with the other talks? I hope so.

20-08-07 *Rényi Order-3 and the Weird Object* (to F. Topsøe & P. Harremoës)

I never heard back from either of you concerning the note below. So, now that I am physically at Perimeter, I'll take the opportunity to send it again, just in case you didn't receive it. It is pasted below. [See 01-08-07 note "Your Conference" to F. Topsøe & P. Harremoës.] (Maybe you didn't get it because I sent it out too close to my departure time on the Bell Labs server.)

If you don't understand the question, let me know, and I'll write it up more formally for you. But also, while I'm here, maybe I can also ask the following. Do either of you know any properties of the Rényi and Daróczy order-3 entropies that set them apart from the pack of other Rényi and Daróczy entropies? Do the order-3 entropies have any *interesting* special properties that the others don't have?

21-08-07 *Rényi Order-3 and the Weird Object, 2* (to P. Harremoës & F. Topsøe)

Thanks for the replies. In case it helps to understand my main question, I attach a slightly more detailed description than my previous. Maybe it helps to set the question outside the context of my previous paper.

Peter wrote:

Harremoësism 1: *The result that* $\mathrm{tr}M^2 = 1$ *and* $\mathrm{tr}M^3 = 1$ *implies that* M *is a 1-dimensional projection can be derived as follows: ...*

For any odd $n > 3$ *one can replace the condition* $\mathrm{tr}M^3 = 1$ *by* $\mathrm{tr}M^n = 1$ *and get the same conclusion. Therefore I think that there is nothing special about the power 3 in the setup.*

Yep, I had understood that derivation and your caveat at the end for quite some time. Still, I call the Jones/Linden result a "remarkable theorem" because it strikes me as being like the no-cloning theorem: namely, trivial in a mathematical sense, but—I think—deep in physical meaning. Plus you would be surprised at the caliber of some people who were not aware of it until it was brought to their attention. For instance, neither Carl Caves, nor Dan Gottesman, nor Rob Calderbank, nor Beth Ruskai, nor Elliot Lieb!!! knew of that simple result—I checked with each one of them. Just one of those simple things overlooked by history (much like the no-cloning theorem until 1981).

Anyway, about the caveat, I'm not sure it makes such an impact on me. It may be the case that there is nothing special about the power 3 in the setup where "quantum states" are already assumed to operators M whose extreme points are characterized as above. But part of the goal for me is to jettison the starting point of operators and instead start at the level of a probability simplex. Then the question is to add interesting (or information theoretically motivated) constraints so that the extreme points of some convex set within the simplex are isomorphic to 1-dimensional projectors. Thus my focus on a function of the form W.

Of course, that question may have nothing to do with the (classical) Rényi order-3 entropy. But I had just wondered whether there's anything special about the order-3 one. Certainly the order-2 entropy has been studied to pieces. But why has no one ever moved up the chain to the next higher power? Why is interest lost at power-2?

Harremoësism 2: *I have attached a paper discussing the use of entropies of integer order in a quantum setting.*

Actually, you didn't attach it. Could I ask you to send it this time around?

Finally Flemming wrote:

Topsøe-ism 2: *As for my part, I will have it in mind, but guess it is the kind of thing you will have a greater chance of getting good comments to at precisely a workshop as the one we plan (VERY strong persons expressed an interest but I hesitate to say who as one never knows, except for the keynote speakers who already accepted to come, if they will really come. Sorry to disappoint you, hoping to see you for the workshop.*

Now that brings up a problem. It now looks like I won't actually be able to come ... so what you are saying is torture. I wish I could be there. The trouble is my colleague Appleby will have his Fall break October 20–28, and we had planned on his visiting PI during that time, for a rather intense exchange on SIC-states existence. Thus, I hope I can ask you and Peter, as friends, to pose the attached question to some of your knowledgeable colleagues and send me any feedback you get!

> We will consider probability vectors $\vec{p} = [p(1), p(2), ..., p(d^2)]$ on an event space of d^2 events, $d \geq 2$ a positive integer. Let c_{ijk} represent a given 3-index "table" of d^6 real numbers—the numbers need not all be positive, some may be negative in fact. We will assume that c_{ijk} is symmetric under interchanges of pairs of indices, and also invariant under cyclic permutations. (Eventually, as needed to make the question more interesting or well-defined, one may assume some other requirements on the c_{ijk}, but at the moment I'll leave that open.)
>
> Now let us define the following function on our probability simplex:
>
> $$W(\vec{p}) = \sum_{i,j,k} c_{ijk}\, p(i)p(j)p(k) \; .$$
>
> I chose the letter W for the function, in order to emphasize that it is a "weird object." The question is, does an object of this variety—or perhaps under specific, interesting choices for the c_{ijk}—obtain any kind of information theoretic meaning? It is a purely classical question as far as I can tell; nothing to do with quantum mechanics. That is my question. Can one find any information theoretic motivation or use for a function of the form $W(\vec{p})$? Has it ever been seen before?

21-08-07 *Your Bayesian vs. Frequentist Talks* (to R. Schack)

I just wrote the abstract below for the quantum foundations summer school here, coming up next week. I wonder if you can give me some inspiration on how to present the flaws in frequentism? Could I ask you to send me some sample presentations (or send me a pointer where I can download them) from your repertoire where you particularly bash the frequentists?

> Quantum States as Uncertainty, pure and simple. But, Uncertainty about What?
>
> David Deutsch implores us to "take quantum mechanics seriously." In these lectures we will take quantum mechanics *deadly* seriously, but not in a way that would please Prof. Deutsch. Here we lay the groundwork for viewing quantum mechanics as a branch of decision theory, specialized to decision-making agents *immersed* in an objective world of some particular characteristic—for need of a name, the quantum world. That is to say, the view presented here is that quantum mechanics is less a direct picture of the

world, and more a method of survival in it. Its statements about the world are therefore oblique, but nonetheless firm and, from some points of view, more exciting because of the creative ontology they seem to hint at.

Topics of the lecture will include: Einstein's pre-EPR argument for the incompleteness of quantum states, contrast between frequency and Bayesian interpretations of probability, Dutch book arguments for the structure of probability theory, the no-cloning and no-broadcasting theorems of quantum mechanics, classical no-cloning and yes-broadcasting examples, the quantum de Finetti representation theorem, the Kochen-Specker theorem, words on a Wolfgang Pauli'an style ontology in the light of Kochen-Specker, fiducial measurements for defining quantum states (for instance, SICs and MUBs), and the shape of quantum state space.

22-08-07 *Facts, Values and Quanta* (to D. M. Appleby)

I'm re-reading your "Facts, Values and Quanta" in preparation for my summer school lectures advertised below (which I have to give Tuesday and Wednesday). It's been a while since I've thought about these things! I'm learning a lot from you. I'm going to make the paper or the other version required reading for my tutorial group.

23-08-07 *Robin* (to M. Sasaki)

I understand that the time for your meeting in Boston is drawing near. I must apologize for doing this to you, but my early days here at PI are turning out to be so hectic that I am realizing I am going to have to cut some things from my travel schedule. I hope you will accept my apology.

On the other hand, I did not want to leave your conference high and dry, without any representation of "maximally quantum" sets of states! So I have arranged for an excellent speaker to be in my place, if you will accept that. He is Dr. Robin Blume-Kohout, one of the very founders of the SIC states, and he would talk on that subject, reporting some results from my recent paper with Appleby and Dang, and some results from his own papers on SICs; also he is hoping to have new numerical results to report before then. Robin has an impressive resume: He did his undergraduate honors thesis with Ben Schumacher at Kenyon College, he did his Ph.D. with Wojciech Zurek at Los Alamos, then he was a postdoc at Caltech with John Preskill. Now he is a postdoc with us at Perimeter Institute.

Please let me know if this is acceptable to you. He has his own travel funding from PI and will be able to pay his own expenses: He is just looking forward to the opportunity to meet some of your other speakers and introduce the subject of SIC-sets.

24-08-07 *Are You Nuts?* (to G. L. Comer)

Comerism 16:

> By the way, you need to read more about Alchemy. One of my big projects for the upcoming year is to familiarize myself much more with alchemical thought.

Are you nuts?!?

Changing lead to gold per se is not the interesting part of old alchemy. It's this: "The release of the substance by the man who transmutes it … is seen by the alchemist … as identical with the saving transformation of the man by the work." Transforming the metal transforms the soul—that was the real goal. In place of soul, put quantum state, and you can start to see where I'm coming from.

Yes, I am nuts. That's why the only place that would have me is PI (and even they aren't so sure).

Actually see the note below, that I wrote you two years ago! I've been nuts for a long time. [See note titled "Philosopher's Stone," dated 19 June 2005.]

24-08-07 *Leifer* (to G. Brassard)

I hope you're doing well. I'm finally in Canada and loving it! It's my fourth day in the office at PI, and it's just fantastic here. Let's hope I put these years to good use.

But the reason I'm writing right now is that I was just talking to Matt Leifer and he got me sad. He was telling me about his take on the hazards of doing foundational work before obtaining a faculty position—it's true, and it always brings sadness. Particularly because, in my eyes, the stuff we've all been involved with is just doing good physics. Doing good physics, period. And why should a physicist be ashamed of doing that?

24-08-07 *My Email* (to R. Schack)

No, I didn't get it. So, thanks for sending something, but try again! Frankly, I'm a little scared about presenting in any detailed way why one should drop frequentism—it's so ingrained in everybody, it strikes one as an almost lost battle to try to sway the masses. I gain new respect for your efforts over the years, as I try to figure out how on earth I'm going to do this.

25-08-07 *How Pleased!* (to R. Blume-Kohout)

How pleased I was to stumble across the poster of the students you had tutored and overhear a student debating the merits of a Bayesian approach to probability over a frequentist approach! It was the greatest feeling. Even some of the phrases in the poster were just gems. "Measurement: An action that tells you something about something." I'm probably reading more into it than I should, but I was particularly pleased by the choice of the word *action* in the definition. For the idea of measurement as action has taken on a much bigger role in my own thinking lately. In case you're interested, have a look at the letters "'Action' instead of 'Measurement'" and "Questions, Actions, Answers, and Consequences" and "Canned Answers" (all to Bas van Fraassen) in this file: `http://perimeterinstitute.ca/personal/cfuchs/nSamizdat-2.pdf`.

Action's where it's at!

26-08-07 *Your Note to Ingemar* (to D. M. Appleby)

Yes, I had a hard time following the point you really wanted to make to Ingemar. Also, I wasn't sure how I fit into the context of the discussion.

My reply to this particular part of Ingemar's note

> I expect that if I did settle the MUB question in $N = 6$ (say), then my feeling would be that I had found the correct way to look at an existing structure. *And* at a structure that existed also before Hilbert was born.

might simply have been this: That may be your feeling; it has a very strong tendency in everyone (including me). But it is only a feeling.

There is some (small, but I think instructive) analogy with issues surrounding the EPR criterion of reality:

> If, without in any way disturbing a system one can [gather the information required to] predict with certainty (i.e., with probability equal to unity) the value of a physical quantity, then there exists an element of physical reality corresponding to this physical quantity.

I already modified the language of EPR a little bit (adding the stuff in square brackets) in order to make it make any sense at all, but let me go a little further and change the language so that the discussion is more in line with the CFS-Bayesian take on certainty:

> If, without in any way disturbing a system, one can become *certain* of the value of a physical quantity (i.e., assigning probability equal to unity for the value), then there exists an element of physical reality corresponding to this physical quantity.

Well, CFS reject that. It is a category error—or more accurately an illegitimate move to marry distinct categories (epistemic and ontic) at a kissing point. Having the feeling of certainty does not make an element of reality so. Having certainty for the outcome of a quantum mechanical measurement does not make the outcome pre-exist the process of measurement, CFS say. That is the little point of quantum mechanics, I think. It is a species of the big point of pragmatism. And it is that which more directly impinges on Ingemar's feeling.

Now, I feel more secure in quantum mechanics than pragmatism in general, and to that extent am less secure in my assertion about $N = 6$ above. But some flavor of this discussion, or perhaps some careful tempering of it, will, I think, continue to stand with me ultimately. I thought briefly about cc'ing this note to Ingemar, but I think I'll just keep it between us for now (for no particular reason that I can identify other than that, for once, I'd like to think a little more before speaking more).

Back to work on my lectures.

05-09-07 *QF Seminars* (to L. Hardy)

My joke at the beginning of the note was going to be this:

> "Of course, I'd be very happy to organize the seminar. You know I always enjoy an opportunity to bias the random walk when I can."

... Or something like that. It takes a long time to hone a joke.

07-09-07 *Diploma Work on Gleason's Theorem* (to H. Granström)

Ingemar Bengtsson told me that you returned from the PI summer school "full of enthusiasm". If true, I'm glad to hear that we served a good purpose.

One thing that I do regret is that I didn't more diligently pursue an understanding of your ideas on how quantum measurements should be viewed in relational terms. My head was just too full of all the noise around me to think on deeper subjects. But, in fact, one of my first-year goals here at PI is to get a better handle on what I think about such accounts of measurement and how they compare and contrast with the "quantum Bayesian" account that colleagues and I have been trying to construct. So, I'd like to hear more about what you're thinking if you've got the time during my upcoming visit to Stockholm for Åsa's defense. I hope you do. I arrive in Stockholm (the airport at least) 9:30 AM Friday Sept 14 and depart the morning of Sept 19. I don't have a clue where I'll be during that range of time, but Ingemar should know how to put you in contact with me. As far as I know, my weekend is free.

At the moment, I'm not inclined to believe that a relational account can capture the real essence of quantum measurement—it seems to me too static and doesn't seem to capture the "birthy-ness" of quantum measurement outcomes, which is the deep point I think the KS theorem signifies (i.e., that they are little acts of creation in their own right)—but it's hard for me to really judge until I know more. Attached is one of my crazier pieces where I try a little to build a picture of what I mean by all this. [See "Delirium Quantum" `arXiv:0906.1968v1`.] At this stage, of course, everything is vague and just defines a direction of research, but maybe the document will give you some sense of what I'm thinking: That the universe is still under construction and the structure of quantum measurement is our biggest clue for that.

07-09-07 *Consciousness Essay* (to A. Kent)

Here's a transcript of the James essay I was telling you about, "Does 'Consciousness' Exist?". And here's the quote from it that I was trying to repeat:

> To deny plumply that consciousness exists seems so absurd on the face of it – for undeniably thoughts do exist – that I fear some readers will follow me no farther. Let me then immediately explain that I mean only to deny that the word stands for an entity, but to insist most emphatically that it does stand for a function. There is, I mean, no aboriginal stuff or quality of being, contrasted with that of which material objects are made, out of which our thoughts of them are made; but there is a function in experience which thoughts perform, and for the performance of which this quality of being is invoked. That function is knowing. Consciousness is supposed necessary to explain the fact that things not only are, but get reported, are known. Whoever blots out the notion of consciousness from his list of first principles must still provide in some way for that function's being carried on.

Here's a link to the "Are We Automata?" essay:

`http://en.wikisource.org/wiki/Are_We_Automata%3F`

07-09-07 *That Wheeler Quote* (to M. A. Nielsen)

My memory blurred yesterday. I was thinking of some quotes I had used in a later letter. Anyway, the quote was actually this.

From J. A. Wheeler (with K. W. Ford), *Geons, Black Holes, and Quantum Foam: A Life in Physics*, (W. W. Norton, New York, 1998):

> Many students of chemistry and physics, entering upon their study of quantum mechanics, are told that quantum mechanics shows its essence in waves, or clouds, of probability. A system such as an atom is described by a wave function. This function satisfies the equation that Erwin Schrödinger published in 1926. The electron, in this

description, is no longer a nugget of matter located at a point. It is pictured as a wave spread throughout the volume of the atom (or other region of space).

> This picture is all right as far as it goes. It properly emphasizes the central role of probability in quantum mechanics. The wave function tells where the electron might be, not where it is. But, to my mind, the Schrödinger wave fails to capture the true essence of quantum mechanics. That essence, as the delayed-choice experiment shows, is *measurement*. A suitable experiment can, in fact, locate an electron at a particular place within the atom. A different experiment can tell how fast the electron is moving. The wave function is not central to what we actually know about an electron or an atom. It only tells us the likelihood that a particular experiment will yield a particular result. It is the experiment that provides the actual information.

Or the single nugget of John's thinking that I wanted to extract: Unitarity "fails to capture the true essence of quantum mechanics."

08-09-07 *The More Complete Quote* (to A. Kent)

I just read James's "Are We Automata?" and am now moving on to "Does 'Consciousness' Exist?" I noted that the first of the two was written in 1879, while the second was written in 1904. Twenty-five years between the two. That, I note, is a little important because of these lines I just read, preceding the quote starting "To deny plumply ..." which I sent you yesterday:

> For twenty years past I have mistrusted 'consciousness' as an entity; for seven or eight years past I have suggested its non-existence to my students, and tried to give them its pragmatic equivalent in realities of experience. It seems to me that the hour is ripe for it to be openly and universally discarded.

Thus presumably in the first article, he was still treating "consciousness as an entity"—whatever that means. I suppose this was, at least in part, what you were referring to yesterday.

08-09-07 *Finished It* (to A. Kent)

I just wanted to record one thought, having finished the second of the two James essays. It is true that he argues in it that consciousness is a function, rather than an entity, but I suspect the resemblance between his doctrine and the functionalism Wallace speaks of ends at the selection of the word 'function' itself—i.e., there being no resemblance beyond that.

For instance, Wikipedia says this:

> An important part of some accounts of functionalism is the idea of multiple realizability. Since, according to standard functionalist theories, mental states are the corresponding functional role, mental states can be sufficiently explained without taking into account the underlying physical medium (e.g. the brain, neurons, etc.) that realizes such states; one need only take into account the higher-level functions in the cognitive system. Since mental states are not limited to a particular medium, they can be realized in multiple ways, including, theoretically, within non-biological systems, such as computers. In other words, a silicon-based machine could, in principle, have the same sort of mental life that a human being has, provided that its cognitive system realized the proper functional roles. Thus, mental states are individuated much like a

valve; a valve can be made of plastic or metal or whatever material, so long as it performs the proper function (say, controlling the flow of liquid through a tube by blocking and unblocking its pathway).

For James, as I understand him, the whole point of the article was to try to argue that consciousness does not reside on a material substrate. For material and mental, for him, are two distinct aspects of something that is neither. His philosophical playground wasn't the kind of physicalism that Wallace, for instance, seems to presuppose in his thought.

So I apologize for my quick judgment the other day, when I said, "He's probably talking about the same thing that Adrian called functionalism the other day."

10-09-07 *Several Agents* (to S. Hartmann)

Now I've read your note! Thanks for updating me on all. I'm glad you like your new home; I had expected you would. And your position sounds ideal. Use it as a chance to change the world!

Hartmannism 3: *Bayesianism always assumes that there is just one agent who has beliefs which are then updated. But what if there are several agents who have beliefs and one wants to combine these believes to a collective belief? Maybe it would be interesting to see how this works in a quantum setting.*

I agree that would be a very, very interesting topic. We have done a very little bit (infinitesimal, but nonzero) in that direction with this paper: `http://xxx.lanl.gov/abs/quant-ph/0206110`.

11-09-07 *Title and Abstract* (to A. Kent)

Will this fit the bill?

Title: 13 Quotes from Everettian Papers and Why They Unsettle Me

Abstract: 101 years ago William James wrote this about the Hegelian movement in philosophy: "The absolute mind which they offer us, the mind that makes our universe by thinking it, might, for aught they show us to the contrary, have made any one of a million other universes just as well as this. You can deduce no single actual particular from the notion of it. It is compatible with any state of things whatever being true here below." With some minor changes of phrase—for instance "mathematical structure" in place of "absolute mind"—one might well imagine morphing this into a remark about Everettian quantum mechanics. This point, coupled with the observation that the Everett interpretation has been declared complete and consistent for the selfsame number of years that its supporters have been trying to complete it, indicate to me that perhaps the Everett approach is more a quantum-independent mindset than a scientific necessity. So be it, but then it should be recognized as such. In this talk, I will try to expand on these suspicions.

11-09-07 *Arrival, Plans* (to I. Bengtsson)

This is just to let you know that I should be arriving at the Stockholm airport ARN at 9:30 AM, Friday September 14. . . .

First question: What should I do after arriving at the airport? Where should I proceed to? And by what means?

Second question: Have you drawn me up any kind of schedule? If so, if possible, I'd like to insure a little time to talk to Prof. Lindblad. Not long necessarily, I just wanted to meet him, as I have long respected him. Also, I'd like to build in a little time to talk to Helena Granström. She said some things at the summer school about "relational" ideas of quantum measurement that intrigued me, and I would like to have a chance to get her to expand on that. Beyond that, you can do with me as you will. Though I would like some time during the weekend to work and think on the talk I must give at the *50 Years of Everett* conference. That is going to be a very tough talk for me, as I am sure to be attacked most roundly while attempting to give it. (Abstract below.) [See 11-09-07 note "Title and Abstract" to A. Kent.] Thus, perhaps not too heavy of a schedule over the weekend, but also I'm not averse to interactions during it either.

11-09-07 *The World Is Made of Catalysts* (to L. Hardy)

Here's that Feynman quote I was telling you about:

> If, in some cataclysm, all of scientific knowledge were to be destroyed, and only one sentence passed on to the next generation of creatures, what statement would contain the most information in the fewest words? I believe it is the atomic hypothesis ... that all things are made of atoms ...

I came across it a few minutes ago as I was organizing my lecture for Tuesday.

18-09-07 *Shakespeare in Sweden* (to P. G. L. Mana)

Here's that Shakespeare quote I was trying to remember last night:

> These our actors,
> As I foretold you, were all spirits, and
> Are melted into air, into thin air:
> And like the baseless fabric of this vision,
> The cloud-capp'd tow'rs, the gorgeous palaces,
> The solemn temples, the great globe itself,
> Yea, all which it inherit, shall dissolve,
> And, like this insubstantial pageant faded,
> Leave not a rack behind. We are such stuff
> As dreams are made on ...

At least that's the part of it that John Wheeler always used when talking of quantum mechanics (though the stanza is a little bit longer).

20-09-07 *Further Reading* (to H. Granström)

Here's the further reading I was going to suggest to you. Go to pages 411 to 416 of [my samizdat] and look at the notes I wrote to Bas van Fraassen.

I would appreciate it if you would ultimately write me back with some commentary both on 1) the previous "delirium quantum" piece I gave you, and 2) these notes to van Fraassen. Tell me where I need to clarify. Tell me where you disagree. Pinpoint those places where my conception of measurement seems to disagree with yours, and also where they seem to agree instead. It would be valuable for me to get this information.

The two notes below, incomplete in comparison to our discussion the other day though they are, are the ones I had written to Steven van Enk on the Belly Theory. [See 10-02-07 note "Inside and Outside" and 02-08-07 note "The One-Belly Theory of the Universe" to S. J. van Enk.] Let me know if you get any good ideas. In a couple weeks I should have the time to collaborate on this if you wish (unless you find a quick counterexample!!).

Helena's Reply, "Some Random Comments on Delirium Quantum"

Enclosed is a document with some of the reflections I've come up with so far. It does not contain much of any expansions on my view (to the extent that I have such a thing as a 'view') of the interpretation of QM, but it does however contain a few loose thoughts provoked by the reading.

As I understand it, the Darwinist idea would apply to all worldly phenomena including immaterial ones as the laws of physics. This would mean that the Bayesian rule that quantum mechanics constitutes, is functional in the current context, but that may very well change.

I must admit I am not quite sure about the implications of this idea. Take gravitation as an example. If it one day turns out that the concept of gravitation is no longer functional as a guide about how to be in and interact with reality, would that necessarily be due to a change that had taken place in the minds of human beings, or could it be because of a gradual, evolutionary-type change in the factual interaction between massive bodies? (I regret using the word "factual" here, but I'm hoping that you get the distinction that I'm after, at least well enough to decide if you think that it's a meaningful one.)

Also, it would be interesting to know how the view of theories as "extensions of our biological brains" put forward on page 13 related to the statement quoted on page 12, that the laws of physics should be applicable to creatures "sharing none of our sensory modalities". If one were to take the idea that all that theories formulated by human beings do (an can possibly do) is to describe that way that a human being will experience and interact with her surroundings, the consequence would be that our theories are applicable only in relation to a very specific class of agents. What qualifies an agent to be a member of this class is not clear, though: just referring to some idealized humanity would probably be tending towards religion.

One aspect about the Darwinian idea that I find worth considering (given that I've understood correctly the sense in which you're using the term), is its inherent contextuality. That is, our eyes cannot be said to be a mechanism for seeing independently of context. Indeed, they have gotten their form in dialogue with caribou, mayfly and nuthatch; our tongues are a product of clear spring water and ripe plums—same thing with all our ways of perceiving and thinking about the world. All that we experience as meaningful, even the most abstract construction, we experience using thought that took form during millions of years on vast savannas, and under wet rocks.

As you also point out, this view provides great reason to question the idea of observer non-detachedness, and the idea that striving to find things out about the world, rather than about the nature of our interplay with the world, holds meaning.

Concerning the issue of abandoning the idea of truth as a symbolic correspondence, I fully agree that this is a reasonable direction to take. I would, however, like to see the casual interpretation of truth more expanded upon. I guess that this relates to my earlier question: exactly in what way do you consider the concept of justification to be, as you put it, temporal? From what I understand, though, the basic idea is one very much in accord with the Bayesian view, i.e. that "laws of physics" are rather guidelines for building a functional relationship with the world around us.

As for your interpretation of the index of POVM elements, I just printed out your further references. As was probably more than clear during our conversation, something about your statement about the indexes puzzles me, but I'll have to get back to you on that.

One of the ideas in the paper that I find particularly intriguing (and that I have thought about some myself, although not really getting anywhere with it as far as the theory of science is concerned) is what you refer to as radical pluralism. One of the most important qualities of the scientific method is probably its systematic reduction, its radical neglection of all aspects of reality that are not immediately relevant. Relevancy, it should also be said, is largely measured according to some criterion determined by the current world view and thereby to a large extent value laden.

I would say, however, that this categorizing is central just not to science but to western civilized thought in general. And many people would be prone to say that it has been quite successful. I guess that the problem is just one of ambition: Just as QM need not necessarily be discarded as a theory, but most likely has to be abandoned or at least severely revised as a theory about the way the world is, so does categorizing and neglecting not necessarily have to be abandoned as a scientific strategy, but we have to be aware what are the flaws and consequences of this approach and the limitations it puts on the scientific quest.

Another, more general, remark on the Bayesian view: I agree that several quantum "paradoxes" are lifted when the quantum state is regarded as a state of belief rather than an objective state of reality. I cannot say, however, that I've fully grasped it, more than superficially. That is, I think I understand most of what I've read on the subject (most of it written by you), but some things still trouble me, even though I cannot at the moment quite pin them down. I think it has something to do with the "updating of information" taking place during a measurement procedure. From my point of view, that is not a satisfactory description.

As for the asymmetry that I was complaining about during our talk. I think, again, that it comes down to a questions of aspiration, and maybe I am confusing the issues. There are, as I see it, (at least) two, namely:

1) How does one formulate a theory that captures the reciprocity and symmetry of interaction? Is this even possible within the current framework of what is considered a physical theory? (I ask this question for example in relation to the above comment about radical pluralism.)

2) How does one interpret quantum mechanics?

It is in no way obvious that the two are intimately related. That is, even though I would prefer to see a theory such as described in 1) formulated, it might be the case that QM does have a fundamental asymmetry built into it. This would mean that QM satisfactorily captures enough of some aspects of our (MY!) interaction with reality to be able to give accurate predictions, but is also in a fundamental way flawed, which may be part of what is causing all the confusion leading to emails such as this one.

I guess these notes sum up some, if not all, of my thoughts on your paper. Hopefully you will be able to get something out of them. Reading your text gave me several associations and ideas (not all of them relevant to expand on here) that I will try to take further, and I very much appreciate getting the opportunity to read it. On my way home from work I will pick up the two books by James that you referenced, for a start.

20-09-07 *Easy Questions* (to P. W. Shor)

I have a few small questions for you, and I hope you have the time to write me back fairly quickly. I'm preparing a talk for the "50 Years of Everett" meeting at PI. And I wanted to say a few words on the influence and/or lack of influence of the Everett view on various aspects of quantum information. I intend to be fair and balanced, and faithfully represent what I am told. With that in mind, I wonder if you would mind answering the following:

1) Did you know of the Everett interpretation before starting work on your factoring algorithm?

2) If so, was the many-worlds view or the idea of "parallel computations via parallel worlds" something that was integral to your thinking for finding the algorithm? If it was part of the main imagery that steered your mathematics, can you say in what way? If it wasn't part of your main imagery, can you say what was?

3) Would you say that the developments in quantum information and computation are evidence that something is really right about the Everett view? Or do you think the developments in QI are relatively neutral toward it?

I hope you have the time to answer me. I've got to give the talk Sunday!

Peter's Reply

Question 1) Did you know of the Everett interpretation before starting work on your factoring algorithm?

Yes.

Question 2) If so, was the many-worlds view or the idea of "parallel computations via parallel worlds" something that was integral to your thinking for finding the algorithm? If it was part of the main imagery that steered your mathematics, can you say in what way? If it wasn't part of your main imagery, can you say what was?

No, the idea was really more to use periodicity, and inspired by Simon's algorithm.

Question 3) Would you say that the developments in quantum information and computation are evidence that something is really right about the Everett view? Or do you think the developments in QI are relatively neutral toward it?

You should have heard my after-dinner talk in Japan. Both the Everett view and the Copenhagen view are misleading in thinking about quantum computation (although misleading in quite different ways).

20-09-07 *Easy Questions* (to D. R. Simon)

I just sent the note below to Peter Shor. [See 20-09-07 note "Easy Questions" to P. W. Shor.] I know I don't know you as well as Peter, but I wonder if I might ask you the same questions. Just in every place where I ask about Peter's algorithm, let me instead ask you about yours. Thanks so much if you can answer these.

By the way, do you have any interest in visiting us at the Perimeter Institute in the coming year? If so, let me know.

Dan's Reply

No problem–I'll do my best to answer them. Thanks very much for the invitation, but my interests have drifted about as far away from quantum physics as they can get by now, and having a toddler in the family makes travel less attractive than it used to be, so a visit to your neck of the woods would be pretty hard for me to justify. Hope you're having fun, though . . .

Question 1) Did you know of the Everett interpretation before starting work on your quantum algorithm?

Who's Everett, and what's his interpretation?

Question 2) If so, was the many-worlds view or the idea of "parallel computations via parallel worlds" something that was integral to your thinking for finding the algorithm? If it was part of the main imagery that steered your mathematics, can you say in what way? If it wasn't part of your main imagery, can you say what was?

I was approaching the problem purely from a computer scientist's perspective. I learned the absolute bare minimum of physics I needed to be able to understand the computer science question, which (as I saw it) was, "these crazy people are claiming that if you add these very-weird-yet-theoretically-physically-implementable functions to a computer, then you should be able to do amazing things with them. Prove them right or wrong." I actually started out trying to prove that quantum computing was useless, and eventually narrowed down the difficult, unsimulateable part to, "rotate, compute, rotate". That helped guide my search for a computationally interesting quantum algorithm.

From my perspective, though, the "interpretation" of the quantum mechanical operations I was given was irrelevant—I was told that a quantum computer could do these things, and it was my job to figure out how computationally useful "these things" were.

Question 3) Would you say that the developments in quantum information and computation are evidence that something is really right about the Everett view? Or do you think the developments in QI are relatively neutral toward it?

As a non-physicist, I'm perfectly comfortable living with only the haziest mental model of quantum reality. Distinctions between different mental models that are experimentally indistinguishable are altogether lost on me. For that matter, I wonder why physicists, whose mental models have (or at least should have) all the precision of the mathematical formulae underlying them, would care about fuzzily unquantifiable comparisons among fuzzily unquantifiable mental models.

(I'm assuming here that the "interpretations" in question here aren't experimentally distinguishable–else they'd be "theories", right?)

20-09-07 *Easy Questions* (to L. K. Grover)

I just sent the note below to Peter Shor, trying to compile something interesting to say at the Everettfest. [See 20-09-07 note "Easy Questions" to P. W. Shor.] I wonder if I might ask you some similar ones—I hope you've got a little time to answer these, as whatever your answers may be, I think they'll bring an aspect to the meeting that no one else will be representing.

Simply, in place of where I ask Peter about the factoring algorithm, would you answer similar questions pertaining to your search algorithm and any of the other algorithms you developed? If you can do this, it'd be much appreciated!

Lov's Reply

Sorry, I had missed your message — only just got it — hope your talk went well.

20-09-07 *Easy Questions* (to D. Gottesman)

I just sent the note below to Peter Shor, trying to compile something interesting to say at the Everettfest. [See 20-09-07 note "Easy Questions" to P. W. Shor.] I wonder if I might ask you some similar questions—I hope you've got a little time to answer these, as whatever your answers may be I think they'll bring an aspect to the meeting that no one else will be representing.

Simply, in place of where I ask Peter about the factoring algorithm, would you answer similar questions pertaining to your work on the stabilizer formalism (or anything else you want to mention)? If you can do this, it'd be much appreciated!

Daniel's Reply

Question 1) Did you know of the Everett interpretation before starting work on stabilizer codes?

Yes, certainly.

Question 2) If so, was the many-worlds view or the idea of "parallel computations via parallel worlds" something that was integral to your thinking for finding the algorithm? If it was part of the main imagery that steered your mathematics, can you say in what way? If it wasn't part of your main imagery, can you say what was?

There wasn't imagery, per se, although there was intuition. Mostly it came about by accident. I was trying to study degenerate codes, and it seemed to make sense to think about codes whose degeneracies were characterized by Pauli identities – e.g., Z_1 and Z_2 act the same, so $Z_1 Z_2$ acts as the identity. I tried writing down a code with lots of degeneracies, and was surprised to see that it corrected a variety of different errors without any extra effort on my part. I had some intuition that anticommutation was the right thing to look at – I'm not completely sure why. It's possible the intuition had some genesis with "incompatible observables" à la Copenhagen, but certainly I was not thinking about that explicitly.

I can't say that any Everettian idea was at all relevant.

Question 3) Would you say that the developments in quantum information and computation are evidence that something is really right about the Ev-

erett view? Or do you think the developments in QI are relatively neutral toward it?

Really wrong isn't an option?

In any case, as I believe I have told you before, I subscribe to the pantheistic interpretation, that all interpretations are valid (excluding those which have experimental differences from standard QM). I think work in quantum computation supports that – sometimes it is helpful to think about one interpretation to understand a QI development, at other times a different interpretation is most helpful. In that sense, I would say QI has been mostly neutral towards Everett.

There's one Everettian idea, however, that I think has been very strongly supported by quantum information, which is that basically everything is unitary. I tried to think of supporting arguments for this view, though, and had trouble. The "Church of the larger Hilbert space" supports it in the sense that says we can always think of evolution as unitary, but also opposes it in the sense that we can do this whether the system has a real-world purification or not. Quantum error correction kind of supports it in the sense that it says we should be able to build arbitrarily large subspaces which, with appropriate control, behave arbitrarily close to unitary, but again that's not really the same as saying the underlying dynamics without control are unitary. Perhaps the strongest argument is the study of decoherence mechanisms in real systems, where interaction with the environment always seems adequate to account for the decoherence.

On the other hand, in a quantum computer, while we frequently think of a standard computational basis for convenience, there really is no preferred basis most of the time, and this creates a large regime that seems resistant to a "many-worlds" interpretation.

I think one big impact of QI work for foundations is that it changes the list of what are considered signature quantum behaviors. People outside of QI frequently seem to think that Planck's constant and the Schrödinger equation are the be-all and end-all of quantumness, and that view seems totally incompatible with QI work, since we get lots of quantum behavior without ever mentioning either. This is very harsh on some interpretations (like Bohmian, which depends on a wave equation), but Everett doesn't seem to depend on those much.

20-09-07 *Easy Questions* (to J. Preskill)

I just sent the note below to Peter Shor, trying to compile something interesting to say at the Everettfest at PI this weekend. [See 20-09-07 note "Easy Questions" to P. W. Shor.] I wonder if I might ask you some similar questions—I hope you've got a little time to answer these, as whatever your answers may be, I think they'll bring an aspect to the meeting that no one else will be representing.

Simply, in place of where I ask Peter about the factoring algorithm, would you answer similar questions pertaining to your work on security proofs in quantum crypto (or anything else you think worth mentioning)? If you can do this, it'd be much appreciated!

John's Reply

In my zeal to reply, I seem to have inadvertently deleted your message, but not before reading the questions.

1) Did you know about many worlds when . . . ?

I've known about it since 1973. I was a junior at Princeton and read a book I saw in the university bookstore, edited by DeWitt and Graham, called *The many-worlds interpretation of quantum mechanics*. I think the book was quite new at the time. It included a reprint of Everett's paper. (I was working on a "junior paper" about Bell inequalities, which seemed timely because the Freedman-Clauser experiment had been published just months earlier.)

2) Do you think the many-worlds interpretation influenced your work on . . . ?

No.

3) Does recent work on quantum information strengthen the case for the many-worlds interpretation? Weaken? Is it neutral?

Neutral.

[Yes, I don't usually answer you so promptly, but I'm waiting to board an airplane and I'm kind of bored.]

20-09-07 *Easy Questions* (to A. Kent)

I just sent the note below to Peter Shor, trying to compile something interesting to say at the Everettfest at PI this weekend. [See 20-09-07 note "Easy Questions" to P. W. Shor.] I wonder if I might ask you some similar questions—I hope you've got a little time to answer these, as whatever your answers may be, I think they'll bring an aspect to the meeting that no one else will be representing.

Simply, in place of where I ask Peter about the factoring algorithm, would you answer similar questions pertaining to your work on security proofs in quantum crypto (or anything else you think worth mentioning)? If you can do this, it'd be much appreciated!

Adrian's Reply

1) Did you know of the Everett interpretation before starting work on quantum information theory?

Sure did.

2) If so, was the many-worlds view or the idea of "parallel computations via parallel worlds" something that was integral to your thinking for finding the algorithm? If it wasn't part of your main imagery, can you say what was?

Nope. As for mental imagery, I'm not sure there's any one big thing — lots of confused images of vectors and spheres and squashings and twirlings and things.

3) Would you say that the developments in quantum information and computation are evidence that something is really right about the Everett view? Or do you think the developments in QI are relatively neutral toward it?

Entirely neutral.

20-09-07 *Easy Questions* (to A. K. Ekert)

I just sent the note below to Peter Shor, trying to compile something interesting to say at the Everettfest. [See 20-09-07 note "Easy Questions" to P. W. Shor.] I wonder if I might ask you some similar questions—I hope you've got a little time to answer these, as whatever your answers may be, I think they'll bring an aspect to the meeting that no one else will be representing.

Simply, in place of where I ask Peter about the factoring algorithm, would you answer similar questions pertaining to your entanglement-based quantum key distribution protocol? If you can do this, it'd be much appreciated!

Artur's Reply

Question 1) Did you know of the Everett interpretation before starting to work on your key distribution protocol?

Yes and I was intrigued by it.

Question 2) If so, was the many-worlds view or the idea of "parallel computations via parallel worlds" something that was integral to your thinking for finding the algorithm? If it was part of the main imagery that steered your mathematics, can you say in what way? If it wasn't part of your main imagery, can you say what was?

Sometime in the mid 1989 I read the EPR paper and my attention was drawn to the sentence "... If, without in any way disturbing a system, we can predict with certainty ... the value of a physical quantity, then there exists an element of physical reality corresponding to this physical quantity." This was a definition of perfect eavesdropping. I guess I was lucky to read it in this particular way. This was my starting point. Thinking about locality, reality and security was in a way going in the opposite direction than Everett but it was very productive nonetheless.

Question 3) Would you say that the developments in quantum information and computation are evidence that something is really right about the Everett view? Or do you think the developments in QI are relatively neutral toward it?

Yes, QI enhances my predilection for the Everett view.

20-09-07 *Easy Questions* (to A. C. Yao)

I just sent the note below to Peter Shor, trying to compile something interesting to say at the Everettfest at the Perimeter Institute this weekend. [See 20-09-07 note "Easy Questions" to P. W. Shor.] I wonder if I might ask you some similar questions—I hope you've got a little time to answer these, as whatever your answers may be, I think they'll bring an aspect to the meeting that no one else will be representing.

Simply, in place of where I ask Peter about the factoring algorithm, would you answer similar questions pertaining to any of your early work on quantum Turing machines and communication complexity? If you can do this, it'd be much appreciated!

Andrew's Reply, "Easy Questions on Early Quantum Computing"

Quick answers to your questions:

1. Yes, I was aware of the Everett interpretation since college days.
2. No, the Everett interpretation was not on my mind when I did my work on quantum Turing machines and quantum communication complexity.
3. I am inclined to think that QI developments are relatively independent of the interpretations of quantum mechanics.

Hope this found its way to you in time!

20-09-07 *Easy Questions* (to H. J. Briegel)

I just sent the note below to Peter Shor, trying to compile something interesting to say at the Everettfest. [See 20-09-07 note "Easy Questions" to P. W. Shor.] I wonder if I might ask you some similar questions—I hope you've got a little time to answer these, as whatever your answers may be, I think they'll bring an aspect to the meeting that no one else will be representing.

Simply, in place of where I ask Peter about the factoring algorithm, would you answer similar questions pertaining to your work on cluster-state computation? If you can do this, it'd be much appreciated!

I will send Robert a separate note, as I would like your answers to be independent of each other.

Hans's Reply

> I guess it is far too late to answer this e-mail, which I have just stumbled over, searching in my mailbox for something else ...
>
> I was aware of the many world interpretation long before I started working on quantum information and in particular on measurement-based quantum computation.
>
> I never liked the Everett interpretation and it certainly did not play any role in our studies on cluster states and what they could be used for.
>
> Later however, once the one way model had been established, I thought indeed that the one-way quantum computer might be a good playground to challenge different ontological preferences, i.e. interpretations of q.m., and in particular the many-world interpretation. I think we even discussed this at some point.
>
> As you know very well, Andrew Steane then wrote a note entitled "A quantum computer needs only one universe" which pretty much expressed my views on the subject, too. So I did not find any strong need to elaborate on this.
>
> Did anything new come out of the 50th anniversary party?
>
> I hope you had an interesting meeting, but I also hope that the number of many-world believers has not increased by too many.

20-09-07 *Easy Questions* (to P. A. Benioff)

I just sent the note below to Peter Shor, trying to compile something interesting to say at the Everettfest at the Perimeter Institute this weekend. [See 20-09-07 note "Easy Questions" to P. W. Shor.] I wonder if I might ask you some similar questions—I hope you've got a little time to answer these, as whatever your answers may be, I think they'll bring an aspect to the meeting that no one else will be representing.

Simply, in place of where I ask Peter about the factoring algorithm, would you answer similar questions pertaining to your own work on unitary quantum computation? If you can do this, it'd be much appreciated!

Paul's Reply

Here are my answers to your questions:

1. I knew of Everett's work before my work on quantum computation.
2. His work was not integral to mine and did not play a role.
3. I do not think developments in QI show anything about the validity or nonvalidity of Everett's work.

Hope your talk goes well. Also I hope to see you sometime soon.

20-09-07 *Easy Questions* (to D. P. DiVincenzo)

I just sent the note below to Peter Shor, trying to compile something interesting to say at the Everettfest at PI this weekend. I wonder if I might ask you some similar questions—I hope you've got a little time to answer these, as whatever your answers may be, I think they'll bring an aspect to the meeting that no one else will be representing.

Simply, in place of where I ask Peter about the factoring algorithm, would you answer similar questions pertaining to any of your early work in quantum information (say, the gates papers or unextendable product bases)? If you can do this, it'd be much appreciated!

David's Reply

Question 1) Did you know of the Everett interpretation before starting to work on your algorithms?

Yes.

Question 2) If so, was the many-worlds view or the idea of "parallel computations via parallel worlds" something that was integral to your thinking for finding the algorithm? If it was part of the main imagery that steered your mathematics, can you say in what way? If it wasn't part of your main imagery, can you say what was?

No.

I think that I am relatively "interpretationless", the rules of quantum mechanics (viz., Charlie's stone tablets) speak for themselves, to me. Or perhaps I prefer the Schrödinger 1935-6 interpretation, summed up by, "poor pussy".

Question 3) Would you say that the developments in quantum information and computation are evidence that something is really right about the Everett view? Or do you think the developments in QI are relatively neutral toward it?

In my view, neutral.

20-09-07 *Easy Questions* (to R. Cleve)

I just sent the note below to Peter Shor, trying to compile something interesting to say at the Everettfest at PI this weekend. [See 20-09-07 note "Easy Questions" to P. W. Shor.] I wonder if I might ask you some similar questions—I hope you've got a little time to answer these, as whatever your answers may be, I think they'll bring an aspect to the meeting that no one else will be representing.

Simply, in place of where I ask Peter about the factoring algorithm, would you answer similar questions pertaining to your work on communication complexity (or anything else you think worth mentioning)? If you can do this, it'd be much appreciated!

Richard's Reply

This might be too late to be useful to you. My answers are below:

Question 1) Did you know of the Everett interpretation before starting to work on your algorithms? [communication complexity]

I had a vague idea of "many worlds" interpretations as corresponding to many universes in superposition.

My viewpoint of the quantum information framework is more along the lines of "probability theory with minus signs". (Or "probability theory on steriods" ☺.)

Probability theory already gives a notion like "superposition", but without interference occurring.

I know that PT is different in that one can choose to think of a probabilistic state as actually being in a definite state, about which we are ignorant. Quantum states cannot be viewed that way.

Question 2) If so, was the many-worlds view or the idea of "parallel computations via parallel worlds" something that was integral to your thinking for finding the algorithm? If it was part of the main imagery that steered your mathematics, can you say in what way? If it wasn't part of your main imagery, can you say what was?

It wasn't part of my imagery. My imagery was based on Bell inequality violation stuff.

Question 3) Would you say that the developments in quantum information and computation are evidence that something is really right about the Everett view? Or do you think the developments in QI are relatively neutral toward it?

Neutral. Whatever works intuitively to help inspire is fine with me.

20-09-07 *Easy Questions* (to D. Deutsch)

I know you've written about this adequately, but Adrian Kent suggested I ask you too nevertheless. So, I think I will.

I just sent the note below to Peter Shor, trying to compile something interesting to say at the Everettfest. [See 20-09-07 note "Easy Questions" to P. W. Shor.] I wonder if I might ask you some similar questions—I hope you've got a little time to answer these, as whatever your answers may be, I think they'll bring an aspect to the meeting that no one else will be representing.

Simply, in place of where I ask Peter about the factoring algorithm, I wonder if you would answer similar questions pertaining to your own participation (and any other algorithms you were involved with)? If you can do this, it'd be much appreciated!

David's Reply

My replies to the questions, mutatis mutandis, would be:

Question 1) Did you know of the Everett interpretation before starting to work on your algorithms?

Yes.

Question 2) If so, was the many-worlds view or the idea of "parallel computations via parallel worlds" something that was integral to your thinking for finding the algorithm? If it was part of the main imagery that steered your mathematics, can you say in what way? If it wasn't part of your main imagery, can you say what was?

Yes.

Question 3) Would you say that the developments in quantum information and computation are evidence that something is really right about the Everett view? Or do you think the developments in QI are relatively neutral toward it?

In a sense. I think the case for Everett was already watertight before quantum computation. Quantum computation provided new, more dramatic, forms of the same arguments, and also provided some better tools for understanding the multiverse.

20-09-07 *Easy Questions* (to R. Jozsa)

I just sent the note below to Peter, trying to compile something interesting to say at the Everettfest. [See 20-09-07 note "Easy Questions" to P. W. Shor.] I wonder if I might ask you some similar ones—I hope you've got a little time to answer these, as whatever your answers may be, I think they'll bring an aspect to the meeting that no one else will be representing.

Simply, in place of where I ask Peter about the factoring algorithm, I wonder if you would answer similar questions pertaining to your own participation (and any other algorithms you were involved with)? If you can do this, it'd be much appreciated!

Richard's Reply

Nice to hear from you after such a long time! And congrats on your move back into rarefied academia! — I'm sure it much better suits the nature of your main research inclinations. I'm not sure my answers to your questions will be of much interest but here they are:

Question 1) Did you know of the Everett interpretation before starting to work on your algorithms?

I've known of the Everett interpretation since the mid 1970's and never really adopted/liked it, even from outset. It always was (and still is) a very vague and incomplete framework to me.

Question 2) If so, was the many-worlds view or the idea of "parallel computations via parallel worlds" something that was integral to your thinking for finding the algorithm? If it was part of the main imagery that steered your mathematics, can you say in what way? If it wasn't part of your main imagery, can you say what was?

I'm not aware that the Everett ideas have ever played any significant role in my thinking on quantum things. I don't have a clear impression of any particular imagery that I could name, underlying or guiding my quantum thoughts.

Question 3) Would you say that the developments in quantum information and computation are evidence that something is really right about the Everett view? Or do you think the developments in QI are relatively neutral toward it?

I do not see that any quantum comp/info developments particularly support the Everett view in any way compared to any other prospective interpretations.

Hope you have a good talk on Sunday!

20-09-07 *Free Will* (to Å. Ericsson)

For Renouvier's argument that I was telling you about, see . . . [15-08-08 note titled "Free Will and Renouvier" to R. Schack].

Also, here's another little passage I happen to have in my files. (Read it slowly and three times over; I think it's worth it.) LaTeX it up if you want slightly easier reading.

From W. James, "Some Metaphysical Problems Pragmatically Considered," in his *Pragmatism, a New Name for Some Old Ways of Thinking: Popular Lectures on Philosophy*, (Longmans, Green and Co., New York, 1922).

Let me take up another well-worn controversy, *the free-will problem.* Most persons who believe in what is called their free-will do so after the rationalistic fashion. It is a principle, a positive faculty or virtue added to man, by which his dignity is enigmatically augmented. He ought to believe it for this reason. Determinists, who deny it, who say that individual men originate nothing, but merely transmit to the future the whole push of the past cosmos of which they are so small an expression, diminish man. He is less admirable, stripped of this creative principle. I imagine that more than half of you share our instinctive belief in free-will, and that admiration of it as a principle of dignity has much to do with your fidelity.

But free-will has also been discussed pragmatically, and, strangely enough, the same pragmatic interpretation has been put upon it by both disputants. You know how large a part questions of *accountability* have played in ethical controversy. To hear some persons, one would suppose that all that ethics aims at is a code of merits and demerits. Thus does the old legal and theological leaven, the interest in crime and sin and punishment abide with us. 'Who's to blame? whom can we punish? whom will God punish?'—these preoccupations hang like a bad dream over man's religious history.

So both free-will and determinism have been inveighed against and called absurd, because each, in the eyes of its enemies, has seemed to prevent the 'imputability' of good or bad deeds to their authors. Queer antinomy this! Free-will means novelty, the grafting on to the past of something not involved therein. If our acts were predetermined, if we merely transmitted the push of the whole past, the free-willists say, how could we be praised or blamed for anything? We should be 'agents' only, not 'principals,' and where then would be our precious imputability and responsibility?

But where would it be if we *had* free-will? rejoin the determinists. If a 'free' act be a sheer novelty, that comes not *from* me, the previous me, but *ex nihilo*, and simply tacks itself on to me, how can *I*, the previous I, be responsible? How can I have any permanent *character* that will stand still long enough for praise or blame to be awarded? The chaplet of my days tumbles into a cast of disconnected beads as soon as the thread of inner necessity is drawn out by the preposterous indeterminist doctrine. Messrs. Fullerton and McTaggart have recently laid about them doughtily with this argument.

It may be good *ad hominem*, but otherwise it is pitiful. For I ask you, quite apart from other reasons, whether any man, woman or child, with a sense for realities, ought not to be ashamed to plead such principles as either dignity or imputability. Instinct and utility between them can safely be trusted to carry on the social business of punishment and praise. If a man does good acts we shall praise him, if he does bad acts we shall punish him,—anyhow, and quite apart from theories as to whether the acts result from what was previous in him or are novelties in a strict sense. To make our human ethics revolve about the question of 'merit' is a piteous unreality—God alone can know our merits, if we have any. The real ground for supposing free-will is indeed pragmatic, but it has nothing to do with this contemptible right to punish which has made such a noise in past discussions of the subject.

Free-will pragmatically means *novelties in the world*, the right to expect that in its deepest elements as well as in its surface phenomena, the future may not identically repeat and imitate the past. That imitation *en masse* is there, who can deny? The general 'uniformity of nature' is presupposed by every lesser law. But nature may be only approximately uniform; and persons in whom knowledge of the world's past has bred pessimism (or doubts as to the world's good character, which become certainties if that character be supposed eternally fixed) may naturally welcome free-will as a *melioristic* doctrine. It holds up improvement as at least possible; whereas determinism assures us that our whole notion of possibility is born of human ignorance, and that necessity and impossibility between them rule the destinies of the world.

Free-will is thus a general cosmological theory of *promise*, just like the Absolute, God, Spirit or Design. Taken abstractly, no one of these terms has any inner content, none of them gives us any picture, and no one of them would retain the least pragmatic value in a world whose character was obviously perfect from the start. Elation at mere existence, pure cosmic emotion and delight, would, it seems to me, quench all interest in those speculations, if the world were nothing but a lubberland of happiness already. Our interest in religious metaphysics arises in the fact that our empirical future feels to us unsafe, and needs some higher guarantee. If the past and present were purely good, who could wish that the future might possibly not resemble them? Who could desire free-will? Who would not say, with Huxley, 'let me be wound up every day like a watch, to go right fatally, and I ask no better freedom.' 'Freedom' in a world already perfect could only mean freedom to *be worse*, and who could be so insane as to wish that? To be necessarily what it is, to be impossibly aught else, would put the last touch of perfection upon optimism's universe. Surely the only *possibility* that one can rationally claim is the possibility that things may be *better*. That possibility, I need hardly say, is one that, as the actual world goes, we have ample grounds for desiderating.

Free-will thus has no meaning unless it be a doctrine of *relief.* As such, it takes its place with other religious doctrines. Between them, they build up the old wastes and repair the former desolations. Our spirit, shut within this courtyard of sense-experience, is always saying to the intellect upon the tower: 'Watchman, tell us of the night, if it aught of promise bear,' and the intellect gives it then these terms of promise.

Other than this practical significance, the words God, free-will, design, etc., have none. Yet dark tho they be in themselves, or intellectualistically taken, when we bear them into life's thicket with us the darkness *there* grows light about us. If you stop, in dealing with such words, with their definition, thinking that to be an intellectual finality, where are you? Stupidly staring at a pretentious sham! "Deus est Ens, a se, extra et supra omne genus, necessarium, unum, infinite perfectum, simplex, immutabile, immensum, aeternum, intelligens," etc.,—wherein is such a definition really instructive? It means less than nothing, in its pompous robe of adjectives. Pragmatism alone can read a positive meaning into it, and for that she turns her back upon the intellectualist point of view altogether. 'God's in his heaven; all's right with the world!'—*That's* the real heart of your theology, and for that you need no rationalist definitions.

Why shouldn't all of us, rationalists as well as pragmatists, confess this? Pragmatism, so far from keeping her eyes bent on the immediate practical, foreground, as she is accused of doing, dwells just as much upon the world's remotest perspectives.

See then how all these ultimate questions turn, as it were, upon their hinges; and from looking backwards upon principles, upon an *erkenntnisstheoretische Ich*, a God, *a Kausalitätsprinzip*, a Design, a Free-will, taken in themselves, as something august and exalted above facts,—see, I say, how pragmatism shifts the emphasis and looks forward into facts themselves. The really vital question for us all is, What is this world going to be? What is life eventually to make of itself? The centre of gravity of philosophy must therefore alter its place. The earth of things, long thrown into shadow by the glories of the upper ether, must resume its rights. To shift the emphasis in this way means that philosophic questions will fall to be treated by minds of a less abstractionist type than heretofore, minds more scientific and individualistic in their tone yet not irreligious either. It will be an alteration in 'the seat of authority' that reminds one almost of the protestant reformation. And as, to papal minds, protestantism has often seemed a mere mess of anarchy and confusion, such, no doubt, will pragmatism often seem to ultra-rationalist minds in philosophy. It will seem so much sheer trash, philosophically. But life wags on, all the same, and compasses its ends, in protestant countries. I venture to think that philosophic protestantism will compass a not dissimilar prosperity.

21-09-07 *Easy Questions, RPWS1* (to P. W. Shor)

Thanks very much. What you've already said was very useful.

But could I ask you to expand on this (just for me personally):

Shor Thing 1: *You should have heard my after-dinner talk in Japan. Both the Everett view and the Copenhagen view are misleading in thinking about quantum computation (although misleading in quite different ways).*

I hate I missed that! Could you expand briefly on what you said? Or was the talk recorded and available somewhere? I am really, really curious.

Peter's Reply

I believe I said that the Bohm interpretation was like the man that the man in the balloon asked directions from, that Deutsch's intelligent quantum computer would have to answer "I forget," and that the Copenhagen interpretation was responsible for my success (as this is the reason that nobody discovered the factoring algorithm before me). I don't believe that I mentioned the spiders in the basement of the castle in the forest.

Maybe you should ask Charlie what I said. I'll expand if I can find my notes.

22-09-07 *Easy Questions, RPWS2* (to P. W. Shor)

What I was hoping particularly was that you'd expand on this statement:

Shor Thing 2: *Both the Everett view and the Copenhagen view are misleading in thinking about quantum computation (although misleading in quite different ways).*

Since this is an Everett meeting, do you mind relating at least that one. How do you see it as misleading when it comes to quantum computation?

Peter's Reply

Computer scientists who hear about the Everett interpretation construct a mental model that a quantum computer is many worlds in parallel that can all interact, so that you should be able to do polynomial-depth exponential number of processors classical computation. This is the exponential analog of the complexity class NC, and is much, much more powerful computationally than the real class BQP.

The Copenhagen interpretation, on the other hand, leads people to think about collapse of the wave function as some kind of actual real process, which is also very misleading.

27-09-07 *Easy Questions, RDG* (to D. Gottesman)

Thanks for the detailed reply. I didn't get a chance to use it in my talk—I ran out of time—but I had a good chunk of your Answer to #3 inserted into a transparency. Sorry I didn't get to it. There is indeed a certain methodological analogy between purifying states and introducing scalar and vector potentials in E&M. And by my own criterion in the talk, it's something I should take note of. I was going to say that, but then ran out of time.

27-09-07 *The Old Foil* (to J. Preskill)

I didn't get a chance to roll in many of the replies to my Everettian questionnaire in my talk (other than Shor, Simon, Deutsch, and Jozsa's replies), but I did nonetheless use you as a foil in my discussion on quantum cosmology in it. In case you'd be interested to see it, here's the link: `http://pirsa.org/07090068/`. I fell a little flat in my presentation of how the "external" system can be extended all the way around the observer—and how the very reason we use quantum mechanics is because we are within the universe, not external to it, and that nothing about that changes when we get to cosmology—and so, I have every bit as much right to write down a wavefunction for the universe as an Everettian (more so really), but at least the points are all there. I think I need some drama lessons. Anyway, thanks for being the foil again, 11 years later.

27-09-07 *The Joint-Stock Society* (to H. R. Brown)

Thanks for your remark just before Adrian's talk. I enjoyed it, and would ultimately like to pursue your point in a (relatively, never too) serious discussion.

Here are two further quotes of James that I had prepared for the talk, but didn't get a chance to actually show. They have to do with the way James is thinking about "chance"—not in a Lewisian sort of way, as a synonym for objective numerical probabilities—but as a statement of an ultimate pluralism in things and a rejection of the block-universe conception. At the moment, I tend to think that does indeed seem to capture the endpoint of my quantum research program—and it is something your joke pretty accurately reflected!

> [Chance] is a purely negative and relative term, giving us no information about that of which it is predicated, except that it happens to be disconnected with something else—not controlled, secured, or necessitated by other things in advance of its own actual presence. As this point is the most subtle one of the whole lecture, and at the same time the point on which all the rest hinges, I beg you to pay particular attention to it. What I say is that it tells us nothing about what a thing may be in itself to call it "chance." It may be a bad thing, it may be a good thing. It may be lucidity, transparency, fitness incarnate, matching the whole system of other things, when it has once befallen, in an unimaginably perfect way. All you mean by calling it "chance" is that this is not guaranteed, that it may also fall out otherwise. For the system of other things has no positive hold on the chance-thing. Its origin is in a certain fashion negative: it escapes, and says, Hands off! coming, when it comes, as a free gift, or not at all.
>
> This negativeness, however, and this opacity of the chance-thing when thus considered *ab extra*, or from the point of view of previous things or distant things, do not preclude its having any amount of positiveness and luminosity from within, and at its own place and moment. All that its chance-character asserts about it is that there is something in it really of its own, something that is not the unconditional property of the whole. If the whole wants this property, the whole must wait till it can get it, if it be a matter of chance. That the universe may actually be a sort of joint-stock society of this sort, in which the sharers have both limited liabilities and limited powers, is of course a simple and conceivable notion.

And

> The more one thinks of the matter, the more one wonders that so empty and gratuitous a hubbub as this outcry against chance should have found so great an echo in the hearts of men. It is a word which tells us absolutely nothing about what chances, or about the modus operandi of the chancing; and the use of it as a war cry shows only a temper of intellectual absolutism, a demand that the world shall be a solid block, subject to one control,—which temper, which demand, the world may not be found to gratify at all. In every outwardly verifiable and practical respect, a world in which the alternatives that now actually distract your choice were decided by pure chance would be by me absolutely undistinguished from the world in which I now live. I am, therefore, entirely willing to call it, so far as your choices go, a world of chance for me. To yourselves, it is true, those very acts of choice, which to me are so blind, opaque, and external, are the opposites of this, for you are within them and effect them. To you they appear as decisions; and decisions, for him who makes them, are altogether

> peculiar psychic facts. Self-luminous and self-justifying at the living moment at which they occur, they appeal to no outside moment to put its stamp upon them or make them continuous with the rest of nature. Themselves it is rather who seem to make nature continuous; and in their strange and intense function of granting consent to one possibility and withholding it from another, to transform an equivocal and double future into an unalterable and simple past.

28-09-07 *Easy Questions, RHJB* (to H. J. Briegel)

Thanks for the belated reply. Too late for the talk, of course, but still enlightening. The funniest chain of replies I had were from Peter Shor and Dan Simon. Shor said, "No I wasn't thinking about parallel worlds, I was thinking about periodicity and Simon's algorithm." Then Simon said, "Everett? Who's Everett? And what's his interpretation?" Another interesting dualism came from the separate replies of Deutsch and Jozsa on the Deutsch-Jozsa algorithm—you can imagine how that played out.

28-09-07 *Truth?* (to G. L. Comer)

Comerism 17: *I teach Intro to Physics 111. It's for physics majors; a one credit hour course just to get freshmen into the flow of the program. Today we talked about the nature of TRUTH! A few were distressed when I said I don't believe in truth.*

> I don't believe in Elvis
> I don't believe in Zimmerman
> I don't believe in Beatles
> I just believe in me
> Yoko and me

Apt. You made me think again on the pragmatist conception of truth. "I just believe in me."

01-10-07 *The Joint-Stock Society* (to A. Wilce)

Thanks for the encouragement about my talk. It came off a little flatter than I had hoped, so it was nice at least to hear that you thought it was fun. Particularly, I think I could have done much better in getting the point across that quantum cosmology presents no problem for the quantum Bayesian, but you live and you learn . . . and I have a proclivity for saying things over and over, so eventually I'll get it right.

You might enjoy two of the further quotes that I ran out of time to present. They start to make the point of what James had in mind when he used the word "multiverse"—it certainly wasn't the big block universe the Everettians have in mind. [See 27-09-07 note "The Joint-Stock Society" to H. R. Brown.]

01-10-07 *The Joint-Stock Society, 2* (to A. Wilce)

Wilce-ism 5: *What do you make of Adrian's "real world" branching-histories proposal?*

Do you remember my transparency where I made fun of "speculative ontologies (before the very last moment)". Adrian's is well before the moment.

01-10-07 *Shakespeare in Sweden, 2* (to P. G. L. Mana)

Thanks for relieving the mystery of PIPPO.

Manalogue 12: *Speaking of Wheeler, I read that he once said "Philosophy is too important to leave to the philosophers". Do you know if he was joking or meant that seriously? I was cordially disappointed when I read that.*

Yes, he certainly said that, and I think he certainly meant it. But what do you think he meant by it? Why did it disappoint you?

I don't know if you will enjoy my new talk, but it is on PIRSA: `http://pirsa.org/07090068/`.

01-10-07 *A Quote You May Like* (to W. C. Myrvold)

Myrvoldism 6: *I arrived back in London to find a copy of David Mermin's new book* Quantum Computer Science *waiting for me. Browsing through it, the following caught my eye (p. 38):*

> Before drawing extravagant practical, or even only metaphysical, conclusions from quantum parallelism, it is essential to remember that when you have a collection of Qbits in a definite but unknown state, *there is no way to find out what that state is.*
>
> If there *were* a way to learn the state of such a set of Qbits, then everyone could join in a rhapsodic chorus. (Typical verses: "Where were all those calculations done? In parallel universes!" "The possibility of quantum computation has established the existence of the multiverse." "Quantum computation achieves its power by dividing the computational task among huge numbers of parallel worlds.") But there is no way to learn the state. The only way to extract any information from Qbits is to subject them to a measurement.

I do like it! Thanks. I'm sorry I didn't get a chance to talk to you more this meeting. I'm also sorry my talk came out a little flatter than I had wanted it to (there were several points that I didn't think I emphasized correctly).

Since you're an aficionado of "chance" let me forward a note I had written to Harvey Brown in the aftermath of the meeting. It contains two quotes that I didn't get a chance to read in my talk. I think they decently capture the contrast between James's notion of chance and a David Lewis style chance, and the contrast between James's multiverse (his usage should get priority in any case, as he invented the term) and the limp, pale "multiverse" of the Everettians (a big block universe, whose 'multi' aspect is nothing other than the possibility of viewing it from any of its facets)—a dead, lifeless place.

The week that Brian Skyrms is in London, I'd like to come visit you all during some of it. Keep me abreast.

03-10-07 *Nonlocality Again?* (to J. Barrett)

If you have time, I'd really like to follow up on the discussion we started at lunch … in private, so we can hear each other think. The reason is, I think statements like "Bell inequalities have nothing to do with quantum mechanics" and "their derivation can be posed independently of whether the world operates according to quantum mechanics, and one sees then that they are simply violated by quantum mechanics" or some such forms (as I think you were saying), are incorrect if one is already taking a quantum-Bayesian-like stance. That is, I think I can argue that the usual derivation is simply inoperative from that world view. It takes a completely different world view to get a Bell dilemma going. This is something I've been thinking about a while but I've never tested it flesh and blood on anyone, nor have I written much about it. So, you're the perfect candidate and I would enjoy talking about it with you.

Below is a sketch of what I'll say. (Clearly I never finished my promised notes to van Enk.) [See notes to van Enk titled "Inside and Outside" and "The One-Belly Theory of the Universe".]

03-10-07 *Wave Function of the Universe and Sipe* (to S. J. van Enk)

van Enkism 12: *Last night we had dinner with Sipe (Toronto) and he was saying how during a talk you had written down a wave function of the universe, something like:*

$$|\psi_{\rm universe}\rangle$$

I maintained you'd never assign a pure state to the universe, in fact not even to the best ion in Wineland's ion trap. Please tell me I'm right! In other words, I'm sure you must have used some qualification when you wrote down $|\psi_{\rm universe}\rangle$. *What was the context here?*

I've been meaning to write you. We have voted that we would like you to give a quantum foundations seminar here (to talk on your "toy model"). They're Tuesdays at 4:00. Take your pick, most slots are open. The sooner you can come the better, and of course we would pay for everything.

I did write down a pure state, but that was just meant to be symbolic of a quantum state as a whole. In practice, no, *most* people who "accept quantum mechanics" (in the Fuchsian sense) would not write down a pure state for the external universe (to themselves)—but, one cannot forget that that statement is ultimately dependent upon a prior. I can imagine an extreme case where 1) one accepts QM (i.e., as an addition to decision theory), but 2) has an extreme belief of certainty about some particular question one can ask of the external world. Then that hypothetical agent might well indeed write down a pure state for the external world.

Note the use of "external world" when I'm talking about writing down $|\psi_{\rm universe}\rangle$. The point I was trying to make in the lecture is that that is all one needs for doing quantum cosmology. And that really is all one wants. In the Quantum Bayesian view, all the Born rule signifies in any case is a statement of "coherence" in a sense closely analogous to de Finetti's. The agent writes down his beliefs about baryon number, say. He writes down his expectations for the matter distribution in this era of the universe. He writes down his expectations for the Hubble constant. And so on and so on. Then he distils all those expectations into a quantum state assignment. All that is doing for him is telling what he should expect for all the other questions that he might later ask. For instance, what does he expect the mean inhomogeneity in the cosmic microwave background to be? His belief about that should be coherent with all of his other beliefs.

I tried to make the whole point dramatic in the talk, but I think it kind of came out a flop. I'll send a link in a minute. I drew a picture of an agent and a quantum system near him. Then I made the quantum system bigger, and pointed out that nothing changes. Then I made it bigger and bigger, all the while saying nothing conceptually changes. Finally, I had the system completely surrounding him, and made the point that even there nothing changes. Here's the way I wrote John Preskill the other day:

> I fell a little flat in my presentation of how the "external" system can be extended all the way around the observer—and how the very reason we use quantum mechanics is

> because we are within the universe, not external to it, and that nothing about that changes when we get to cosmology—and so, I have every bit as much right to write down a wavefunction for the universe as an Everettian (more so really), but at least the points are all there. I think I need some drama lessons.

Here's the link to the talk `http://pirsa.org/07090068/`.

03-10-07 *Getting the Word Out* (to S. Aaronson)

Aaronsonism 10: *Well, from my perspective, it's about information, probabilities, and observables, and how they relate to each other.*

Congratulations! With one case of corporate abuse, you've made more of an imprint of that idea on the world than all my years of evangelizing combined! And exponentially more so. You're a dream come true. Thank Darwin's soup for Scott Aaronson!

I sure wish you had stayed at PI.

03-10-07 *Getting the Word Out, 2* (to S. Aaronson)

Aaronsonism 11: *I'm so happy you like the infamous quote (though I think it worked better in its original context). Your talks and papers are a large part of what gave me the courage to talk about quantum mechanics this way. Indeed, if you scroll down to the "Further Reading" section of the plagiarized lecture (*`http://www.scottaaronson.com/democritus/lec9.html`*), you'll see "Pretty much anything Chris Fuchs has written."*

That was very sweet of you. I hadn't looked at your lecture before, but I already like it. Particularly, this phraseology comes through to me:

Aaronsonism 12: *So, what is quantum mechanics? Even though it was discovered by physicists, it's not a physical theory in the same sense as electromagnetism or general relativity. In the usual "hierarchy of sciences" – with biology at the top, then chemistry, then physics, then math – quantum mechanics sits at a level between math and physics that I don't know a good name for. Basically, quantum mechanics is the operating system that other physical theories run on as application software (with the exception of general relativity, which hasn't yet been successfully ported to this particular OS). There's even a word for taking a physical theory and porting it to this OS: "to quantize."*

I think that's right on the mark, particularly if one particularizes math to "decision theory". I hope that comes through about halfway through this lecture, `http://pirsa.org/07090068/` (starting around page 28 in the PDF transcript, at least).

"It is not a physical theory in the same sense ...." It's hard to get that across at foundational conferences!

03-10-07 *Aspects of Lunch* (to M. A. Nielsen)

Thanks for telling me about Scott's blog yesterday. I looked it up last night during a fit of insomnia and saw the commercial on YouTube. It blows my Capt. Stabbin story away by miles and miles (and miles and miles)! Of course, I had a general disgust with the business practices of the ad company (and the CEO's ridiculous denial of plagiarism in the *Sydney Morning Herald*). But, in contrast, I was also quite tickled by the exact message that they did copy—that quantum mechanics is about information and probabilities. The creeps couldn't have had a better accident! To get that idea into pop culture would be so wonderful—it won't happen easily, of course, but this commercial at least gave it a new epsilon.

So, I wrote Scott with my pleasure (though I didn't tell him about the captain!), and he wrote me back the nice note below. It took me quite by surprise to learn that even I had an epsilon role in that too. ... And that one really is an epsilon. Still, these are my lucky days, Capt. Stabbin and Capt. Scott!

I then looked at the actual lecture. It is nice, particularly the philosophy. A much better quote from it—one that I think strikes particularly deep—is from the paragraph just before the infamous one:

> So, what is quantum mechanics? Even though it was discovered by physicists, it's *not* a physical theory in the same sense as electromagnetism or general relativity. In the usual "hierarchy of sciences" – with biology at the top, then chemistry, then physics, then math – quantum mechanics sits at a level *between* math and physics that I don't know a good name for. Basically, *quantum mechanics is the operating system that other physical theories run on as application software* (with the exception of general relativity, which hasn't yet been successfully ported to this particular OS).

I think that's a very good way of putting it. I'm sure I'll try to say these kinds of things to Alain Aspect (again), and he'll think I'm just as crazy as he has the last couple of times.

03-10-07 *Feynman and Bell* (to C. M. Caves)

Once upon a time you told me a story about the reason Feynman does not cite Bell in his early quantum computing paper—namely, at the spot where he derives a Bell inequality. As I recall you said it was because Feynman claimed that he had told Bell of the argument sometime before his own publishing of it. Is that the story you told me? Can you fill in details? If you got that second hand, who did you get it from?

I ask because I related it to Alain Aspect at lunch and he gave several reasons to doubt it. So I just want to get the facts straight hereafter. It could be that Aspect is accurate and you are too, given Feynman's proclivity for simply making stories up that made him look better than he already was. (I've compiled several of these—so I know they exist.)

If you could write me back before dinner time when I have to eat with Aspect again, that would be great!

Carl's Reply

> Maybe you're having a late dinner.
>
> This was in a talk Feynman gave at Caltech in the early 80s. He presented the hidden-variable model for a qubit that colors the Bloch sphere and then showed you couldn't do this with two qubits. Feynman would never have paid attention to what Bell did, but I believe he did say that he told Bell about this before Bell did his stuff.
>
> There is a chance that this talk was published in Caltech's *Engineering and Science* magazine, in which case you might find it relatively easily at that web site. It is almost certain that some transcript of the talk exists in the Feynman archives at Caltech, so if you're really serious, you could track it down, I think.

Read Gleick's biography. It's really about how Feynman defined himself in terms of stories that had a grain of truth, but were always embellished to put him in what he perceived as the best possible light. Ralph Leighton transmitted these stories unaltered in his Feynman books. Murray got into trouble in the *Physics Today* Feynman issue precisely because he made this point.

04-10-07 *Feynman Question* (to J. Preskill)

Yesterday, I had this conversation with Carl Caves (and Alain Aspect). [See 03-10-07 note "Feynman and Bell" to C. M. Caves.] I wonder if you can shed any further light on it. Did you happen to be at the same talk? Do you have any recollection? Also, do you have easy access to the magazine or archives Carl mentions; if not could you give me a name of someone I can contact?

Thanks for the help.

John's Reply

Well, I remember hearing Feynman give a talk in the early 80's on the foundations of quantum theory, called "Negative probability." A version of this was later published in a book, but I don't have a copy handy. I don't recall the talk well, except that I remember that I was not impressed by it. (I heard it in a filled auditorium at MIT, so maybe it was before I left Harvard in 1983.) Maybe Carl heard a similar talk, or maybe he is thinking of a different one.

Anyway, I don't regard Feynman's failure to cite Bell as evidence that Feynman thought he had the idea first. He often did not cite people in those days. I talked to him often about confinement in QCD, and pointed out to him that his ideas about magnetic disorder had been anticipated by 't Hooft, Polyakov, and others (whose work was actually deeper in my opinion), but he still did not cite the earlier work when he wrote about the subject. He just didn't want to bother.

By the way, I have a more vivid recollection of a talk that Alain gave at Caltech in the mid-80s, in which he quoted Feynman's statement: "I cannot define the real problem, therefore I suspect there's no real problem, but I'm not sure there's no real problem." For some reason this seemed very funny, and it got a big laugh. But no one laughed harder than Feynman (I was sitting next to him in the front row.)

04-10-07 *Renewing Interest in Aristotle* (to P. Goyal)

Reviewing my Pauli notes, I do indeed see that I should be a little more interested in Aristotle and his potentia, and try to figure out what he is getting at with the idea. See Pauli's letter to Jung (dated 27 Feb '53), starting on page 142 of the collection I gave you (and reprinted below). Also see the entry from Heisenberg's "Wolfgang Pauli's Philosophical Outlook," on page 62.

In case you want to follow up on our lunchtime conversation (on how I want I want to view quantum measurement), I might suggest my samizdat *My Struggles with the Block Universe*, where I wrote a few letters on the subject to Bas van Fraassen.

Letter from Pauli to Jung, 27 February 1953

I cannot anticipate the new *coniunctio*, the new *hieros gamos* called for by this situation, but I will nevertheless try to explain more clearly what I meant with the final part of my Kepler essay: the firm grip on the "tail"—that is, physics—provides me with unhoped for aids, which can be utilized with more important undertakings as well, to "grasp the head mentally." It actually seems to me that in the *complementarity of physics*, with its resolution of the wave-particle opposites, there is a sort of *role model or example of that other, more comprehensive coniunctio.*[119] For the smaller *coniunctio* in the context of physics, completely unintentionally on the part of its discoverers, has certain characteristics that can also probably be used to resolve the other pairs of opposites listed on p. 3. The analogy is on these lines:

Quantum physics.	Psychology of the individuation process and the unconscious in general.
Mutually exclusive complementary experimental setups, to measure position as well as momentum	Scientific thinking – intuitive feeling.
Impossibility of subdividing the experimental setup without basically changing the phenomenon.	Wholeness of man consisting of consciousness and unconsciousness.
Unpredictable intervention with every *observation.*	Change in the conscious and the unconscious when consciousness is acquired, especially in the process of the *coniunctio.*
The result of the observation is an irrational actuality of the unique occurrence.	The result of the *coniunctio* is the *infans solaris*, individuation.
The new theory is the objective, rational and hence symbolic grasping of the *possibilities* of natural occurrences, a sufficiently broad framework to accommodate the irrational actuality of the unique occurrence.	The objective, rational, and hence symbolic grasping of the psychology of the individuation process, broad enough to accommodate the irrational actuality of the unique individual
One of the means used to back up the theory is an abstract mathematical sign (ψ), and also complex figures (functions) as a function of space (or of even more variables) and of time.	The aid and means of backing up the theory is the concept of the unconscious. It must not be forgotten that the "unconscious" *is our symbolic sign for the potential occurrences in the conscious, not unlike that (ψ).*
The laws of nature to be applied are statistical laws of probability. An essential component of the concept of probability is the motif of "the One and the Many."	There is a generalization of the law of nature through the idea of a self-reproducing "figure" in the psychic or psychophysical occurrences, also called "archetype." The structure of the occurrences that thus come into being can be described as "automorphism." Psychologically speaking, it is "behind" the time concept.
The atom, consisting of nucleus and shell.	The human personality, consisting of "nucleus" (or Self) and "Ego."

I should like to add just a few epistemological remarks to this provisional schema. By allowing for occurrences and the utilization of possibilities that cannot be apprehended

[119] I had interesting discussions about these matters with Mr. M. Fierz, to whom I am most grateful.

as predetermined and existing independent of the observer, the type of interpretation of Nature characteristic of quantum physics clashes with the old ontology that could simply say "Physics is the description of reality,"[120] as opposed to "description of what one simply imagines."[121] "Being" and "nonbeing" are not unequivocal characterizations of features that can be checked only by statistical series of experiments with various experimental setups, which in certain circumstances are mutually exclusive.

In this way, the confrontation between "being" and "nonbeing" that was begun in ancient philosophy sees its continuation. In antiquity, "nonbeing" did not simply mean not being present but in fact always points to a *thinking problem.* Nonbeing is that which cannot be thought about, which cannot be grasped by thinking reason, which cannot be reduced to notions and concepts and cannot be defined. It was along these lines, as I see it, that the ancient philosophers discussed the question of being or nonbeing.[122] And it was especially along these lines that the process of becoming and the changeable, hence also matter, appeared in a certain form of psychology as nonbeing—a mere *privatio* of "Ideas." By way of contrast, Aristotle, evading the issue, created the important concept of *potential being* and applied it to *hyle.* Although hyle was actually "nonbeing" and simply a *privatio* of "form" (which is what he said instead of "Ideas"), it *was* potentially "being" and not simply a *privatio.* This is where an important differentiation in scientific thinking came in Aristotle's further statements on matter (he clung firmly to the Platonic notion of matter as something passive, receiving) cannot really be applied in physics, and it seems to me that much of the confusion in Aristotle stems from the fact that being by far the less able thinker, he was completely overwhelmed by Plato. He was not able to fully carry out his intention to grasp the potential, and his endeavors became bogged down in the early stages. It is on Aristotle that the peripatetic tradition and, to a large extent, alchemy is based (*vide* Fludd). Science today has now, I believe, arrived at a stage where it can proceed (albeit in a way as yet not at all clear) along the path laid down by Aristotle. The complementary characteristics of the electron (and the atom) (wave and particle) are in fact "potential being," but one of them is always "actual nonbeing." That is why one can say that science, being no longer classical, is for the first time a genuine theory of becoming and

[120] *Einstein's* words.

[121] *Einstein's* words.

[122] You got involved in this old discussion when you came across the Neoplatonist formula that evil is "nonbeing," is simply a *privatio boni.* Your characterization of this statement as "nonsense" [*Answer to Job*] I attribute more to the bad habit of modern theologians of using old words whose meaning they have long ceased to understand rather than to the original statement itself. For me personally, modern theologians are totally uninteresting, but on the other hand it seems to me *imperative* in such discussions to go back to the original roots of the words and expressions used.

What the ancients meant when they said "nonbeing" was what we would more accurately describe today as "irrational" or "dark."

Now ever since Socrates and Plato, Good has been understood and considered as *Rational* (the virtues are even teachable!), unlike Evil, which does not lend itself to any conceptual definition—a great idea, or so it seems to me. According to this interpretation, the latter regards Good in the same way that matter regards the ideal ("being") mathematical object. With Plato, matter is actually *defined* as that which distinguishes the empirical object from the ideal geometrical object. What they both have in common is the Comprehensible, the Positive, the Good in the empirical body; what makes them different—matter—is the Incomprehensible, later Evil. Hence, matter has only the *passive* function of adopting the geometrical ideas hypostasized as "being" (it is the "receptacle" or "wet nurse" of these ideas). Thus, in later Platonism the *privatio boni* means: Expressed in general terms and understood from the point of view of the "*one*," unchangeable "being" idea, *like Euclid's geometry*, Evil can be *rationally* characterized as the absence of Good, the lack of ideas.

(It is odd how reading your books always transports me back to antiquity. It is obviously a personal effect you have on me; before reading *Aion*, I was not all that interested in antiquity.)

no longer Platonic. This accords well with the fact that the man who is for me the most prominent representative of modern physics, Mr. Bohr, is, in my opinion, the only truly non-Platonic thinker[123]: even in the early '20s (before the establishment of present-day wave mechanics) he demonstrated to me the pair of opposites "Clarity-Truth" and taught me that every true philosophy must actually start off with a *paradox*. He was and is (unlike Plato) a *dekranos*[124] *kat exochen*, a master of antinomic thinking.

As a physicist familiar with this course of development and this way of thinking, the concepts of the gentlemen with the stationary spheres[125] are just as suspect to me as the concepts of "being" metaphysical spaces or "heavens" (be they Christian or Platonic), and "the Supreme" or "Absolute."[126] With all of these entities, there is an essential paradox of human cognition (subject-object relation), which is not expressed, but sooner or later, when the authors least expect it, it will come to light!

For these reasons I should like to suggest also applying the Aristotelean way out of the conflict between "being" and "nonbeing" to the concept of the unconscious. Many people still say that the unconscious is "nonbeing," that it is merely a *privatio* of consciousness."[127] (This probably includes all those who reproach you with "psychologism.") The counterposition is that of placing the unconscious and the archetypes, like ideas in general, in supracelestial places and in metaphysical spaces. This view strikes me as equally dubious and contradictory to the law of the Kairos. This is why I have opted for the third road in my analogy schema in interpreting the unconscious (as well as the characteristics of the electron and the atom) as "potential being."[128] It is a legitimate description by man for potential occurrences in the conscious and as such belongs to the genuine symbolic reality of the "thing in itself." Like all ideas, the unconscious is in *both man and nature*; ideas have *no* fixed abode, not even a heavenly one."[129] To a certain extent, one can say of *all* ideas *"cuiuslibet rei centrum, cuius circumferentia est nullibi"* (the center of all things—a center whose periphery is nowhere), which, according to ancient alchemistic texts, is what Fludd said of God; see my Kepler article, p. 174. As long as quaternities are kept "up in heaven" at a distance from people (however pleasing and interesting such endeavors, seen as omens, may be), no fish will be caught, the *hieros gamos* is absent, and the psychophysical problem remains unsolved.

The psychophysical problem is the conceptual understanding of the possibilities of the irrational actuality of the unique (individual) living creature. We can only come close to dealing with this problem when we can synthetically resolve the pair of opposites "materialism-psychism" in natural philosophy. When I say "psychism," I do not mean "psychologism" nor something peculiar to psychology[130] but simply the opposite of

[123] The English philosopher A. N. Whitehead once said that the whole of European philosophy consisted of footnotes to Plato.

[124] "Double-head"—nickname for disciples of Heraclitus given by disciples of Parmenides.

[125] I have Parmenides and Kepler in mind.

[126] This is an allusion to Indian philosophy. Even those Indian philosophers who, like Prof. S. Radhakrishnan, avoid applying the word "illusion" to the empirical world have no other way of commenting on the Mysterium of the connection between "ultimate reality" and the empirical world, except to call it "Maya."

The Absolute always has the tendency to place itself at an immeasurable distance from man and nature. I happily quote your own words [*Answer to Job*]: "Only that which affects me do I acknowledge as real. But what does not affect me may as well not exist."

[127] Cf. also *Psychologie and Religion*, p. 153.

[128] Cf. ibid., p. 186 below: archetypes as formal possibility.

[129] This point of view was also put forward by Mr. Fierz in the discussion referred to.

[130] As a psychologist, you have an understandable aversion to all forms of reality that are not just psychic. And just as everything that King Midas touched turned to gold, everything you looked at seemed to me to turn psychic

materialism. I could also have said "idealism," but that would have restricted it in time to the famous currents of philosophy prevailing in the 19th century after Kant. These currents (including Schopenhauer), as well as the whole of Indian philosophy, fall into this category of "psychism."

But as the alchemists correctly surmised, matter goes just as deep as the spirit, and I doubt whether the goal of any development can be absolute spiritualization. Sciences made by man—whether or not we wish or intend it and even if it is natural sciences—will always contain *statements about man.*[131] And that is also precisely what I was trying to express with the analogy schema in this section.

Thus the aim of science and of life will ultimately remain man, which is actually the note on which your book *Answer to Job* closes: In him is the ethical problem of Good and Evil, in him is spirit and matter, and his wholeness is depicted with the symbol of the quaternaty.

It is today the archetype of the *wholeness* of man from which natural science, now in the process of becoming quaternary, derives its emotional dynamics. In keeping with this, the modern scientist—unlike those in Plato's day—sees the rational as both good and evil. For physics has tapped completely new sources of energy of hitherto unsuspected proportions, which can be exploited for both good and evil. This has led initially to an intensification of moral conflicts and of all forms of opposition, both in nations and in individuals.

This wholeness of man[132] seems to be placed in two aspects of reality: the symbolic "things in themselves," which correspond to "potential being," and concrete manifestations, which correspond to the actuality of "being." The first aspect is the rational one, the second the irrational one[133] (I use these adjectives analogously, as you did in the typology theory for the characterization of the various functions.) The interplay of the two aspects creates the process of becoming.

Is it in keeping with the Kairos and the quaternity to call these fragments of a philosophy "critical humanism"?

04-10-07 *Feynman Question* (to K. S. Thorne)

Yesterday, I had the conversation below with Carl Caves (and Alain Aspect). [See 03-10-07 note "Feynman and Bell" to C. M. Caves.] I wonder if you can shed any further light on the issue. Carl thinks that you were at the same lecture. Do you have any recollection? Does your memory bear Carl's remark out, or do you have a dissenting memory? Now that I've brought the issue up with Aspect, I feel obligated to try and get it straightened out.

Thanks for any help you can give.

---

and only psychic. This aversion to the nonpsychic was probably also one reason why you did not mention the psychophysical problem in your book *Answer to Job*. However, in the passage already quoted in *Aion* (p. 372), you put forward a point of view on the ultimate unity of physis and psyche that coincides with mine. See also note below.

[131] Cf. my Kepler essay, p. 163, n. 7.

[132] This gives rise to the question very closely connected with the psychophysical problem: Is the archetype of wholeness restricted to man, or does it also manifest itself in nature? See your essay "Der Geist der Psychologie," Eranos Jahrbuch 1946, p. 483f, where you treat the archetypes as not just psychic.

[133] The older ancient philosophers since Parmenides have correspondingly described concrete phenomena as "nonbeing." By way of contrast, all general concepts and ideas with unchangeable characteristics ("form" in Aristotle), especially *geometrical* concepts, were "being." There are ancient astronomical papers that set themselves the task of *"saving" phenomena* $\sigma\omega\ \zeta\epsilon\iota\nu\ \tau\alpha\ \varphi\alpha\nu\iota o\mu\epsilon\nu\alpha$. Apparently, they did not use the word "explain." I am not going into the question of pure mathematics here.

Kip's Reply

My memory is really lousy. I do remember Feynman's lecture, but I have no memory of what he may or may not have said about the relationship of his own thoughts about this to Bell's.

It is true that there might be an audio tape of Feynman's lecture in the Caltech Archives, but it was not routine to tape lectures in those days. If there is a tape, it is because it was Feynman speaking.

04-10-07 *The Surprise* (to G. Brassard)

It was such a pleasant surprise to see you last night—it really shocked me. And I had a great time just before Aspect's talk [finally!] getting a chance to discuss some of the deeper issues about what is ontic and what is epistemic within quantum mechanics.

We didn't get a chance to get anywhere near this far, but I think if I had to put into a slogan what's going to be ultimately found and quantified in this research program of mine, it's this: That the ontic of quantum systems is that they are CATALYSTS. That is their conceptual role. The thing that is intrinsic to quantum systems themselves (and the thing dimensionality is ultimately a quantification of) is that they bring about transformations in things external to them. Quantum systems are transformers. There is an element of Mermin's "correlation without correlata" in this idea, but it is a much more active thing, and it is careful to relegate quantum states to the epistemic (which Mermin does not do). Also, it shares a small piece of similarity to Rovelli's relationalism, but ditto what I just said about Mermin.

Anyway, there are deep things to discuss, and I hope we'll get a much longer chance soon. I'll work hard to get to Montréal in the spring if we can home in on a good time for both of us.

05-10-07 *Easy Questions, RLKG* (to L. K. Grover)

Groverism 2: *Sorry, I had missed your message — only just got it — hope your talk went well.*

You might answer anyway if you get the chance. I got replies from many; it'd be nice to know your answers too ... for the day when I become a historian.

05-10-07 *My Sick Questions* (to D. M. Appleby & S. T. Flammia)

See attachment. I'm sending it to you too Steve, because it gives a little more explanation (though not much more than epsilon) for why I'm asking some of these questions.

Now, it's time for PI's Friday Wine and Cheese. I love this place!

SICk Questions?

A Small Attempt to Deepen Our Understanding of These Bases

Preliminaries

I will alternatively call a set of normalized states $|\psi_i\rangle \in \mathcal{H}_d$ or the set of projectors associated with them $\Pi_i = |\psi_i\rangle\langle\psi_i|$, with index i running from 1 to d^2, "SIC" or "a SIC" if and only if

$$\mathrm{tr}\,\Pi_i\Pi_j = |\langle\psi_i|\psi_j\rangle|^2 = \frac{1}{d+1} \quad \forall i \neq j \; . \tag{69}$$

In all questions that follow I am NOT restricting myself to Weyl-Heisenberg covariant SICs. (Though I hope that the Weyl-Heisenberg SICs will come out as the answer to one or more of these questions.)

Needless to say, we don't even know if SICs exist. But the spirit of all the following is, "*Supposing* they do exist, can one show properties X, Y, and Z?"

A SIC-Schmidt? 1

Recall the usual Schmidt decomposition theorem. Given a state $|\psi_{AB}\rangle$ on a bipartite system with Hilbert space $\mathcal{H}_A \otimes \mathcal{H}_B$ (each component with dimension d), there always exists an orthonormal basis $|i\rangle$ on $\mathcal{H}_A$ and an orthonormal basis $|i'\rangle$ on $\mathcal{H}_B$ such that,

$$|\psi_{AB}\rangle = \sum_{i=1}^{d} \alpha_i |i\rangle|i'\rangle \ . \tag{70}$$

QUESTION: Under what conditions does a bipartite state $|\psi_{AB}\rangle$ have a decomposition of the form

$$|\psi_{AB}\rangle = \sum_{i=1}^{d^2} \beta_i |\psi_i\rangle|\psi_i'\rangle \ , \tag{71}$$

for some SICs $\{|\psi_i\rangle\}$ and $\{|\psi_i'\rangle\}$? Like with the usual Schmidt decomposition theorem, is it always possible? If not, give a characterization of the special cases where it can be done.

A SIC-Schmidt? 2

But maybe a Schmidt-like theorem is not best posed at the state-vector level. Maybe instead it lives most naturally at the density operator level.

Thus, QUESTION: Under what conditions will a bipartite density operator ρ_{AB} have a decomposition of the form

$$\rho_{AB} = \sum_{i=1}^{d^2} \gamma_i \, \Pi_i \otimes \Pi_i'; \ , \tag{72}$$

where $\{\Pi_i = |\psi_i\rangle\langle\psi_i|\}$ and similarly $\{\Pi_i'\}$ are two SICs? Is it always possible? If not, give a characterization of the cases where it can be done.

Give Me an ONB

Given an orthonormal basis $|i\rangle$, how can one characterize the closest SICs? (How can one characterize the farthest?) Here's one idea that comes to mind. Given a SIC $\{|\psi_i\rangle\}$, introduce a partition of it into d sets of d vectors. Relabel them $\{|\psi_{ij}\rangle\}$, i and j now both running between 1 and d. Then tabulate this number

$$F = \sum_i \left(\sum_j |\langle i|\psi_{ij}\rangle|^2 \right) . \tag{73}$$

The larger this number, the closer the SIC to the original orthonormal basis. How large can this quantity be? Could it be that, *by a miracle*, the absolute max of F is achieved by a Weyl-Heisenberg SIC, i.e., $|\psi_{ij}\rangle = X^i Z^j |\psi\rangle$, for some fiducial state $|\psi\rangle$.

A SIC von Neumann Entropy

The von Neumann entropy of a density operator ρ can be defined by the following procedure.

1. Introduce an orthonormal basis $|i\rangle$, with $\Pi_i = |i\rangle\langle i|$, $i = 1, \ldots, d$.
2. Tabulate $p(i) = \mathrm{tr}\rho\Pi_i$, and then consequently
3. Tabulate the Shannon entropy $H = -\sum_{i=1}^{d} p(i) \log p(i)$ of the distribution.
4. Finally minimize H over all orthonormal bases $|i\rangle$.

The resulting minimal such entropy is the von Neumann entropy $H(\rho) = -\mathrm{tr}(\rho \log \rho)$, and the orthonormal basis that achieves it is the eigenbasis of ρ.

However, we can ask a similar question of SICs. What is the SIC-entropy of a density operator ρ? It would be defined by the following procedure.

1. Introduce a SIC $\{|\psi_i\rangle\}$, with $\Pi_i = |\psi_i\rangle\langle\psi_i|$, $i = 1, \ldots, d^2$.
2. Tabulate $p(i) = \mathrm{tr}\rho\Pi_i$, and then consequently
3. Tabulate the Shannon entropy $H = -\sum_{i=1}^{d^2} p(i) \log p(i)$ of the distribution.
4. Finally minimize H over all SICs $\{|\psi_i\rangle\}$, to define a function $S(\rho)$.

Does the SIC-entropy $S(\rho)$ have any interesting functional form? Could it be a multiple of the von Neumann entropy? What is the relation between the optimal SICs for this procedure and the eigenbases of ρ?

Counting Common Elements

Suppose one has two nonidentical SICs $\{\Pi_i\}$ and $\{\Pi'_i\}$. What is the maximal number of common elements between the two sets? If we can't give the number precisely, can we bound it in any interesting way?

Really, Just Give Me an ONB

Going back to the question in "Give Me an ONB." Actually it was motivated by the following question. Suppose one is given an arbitrary SIC. Is there any method of deriving a canonically interesting (or interesting class of) orthonormal basis from it $|i\rangle$ from it? Question "Give Me an ONB" was an attempt to tackle this in one way. Maybe there are others. The over-riding reason for this question is that I think we are accustomed (at least subconsciously, if not logically) to thinking of Hilbert spaces as coming equipped with a standard orthonormal basis. Think of the phrase, "computational basis." I want to break that mentality down somewhat, by first equipping the cone of positive operators with a SIC and then taking it from there. But there's no denying that orthonormal bases are useful. So I'd like a standard construction of one or more to fall out of a SIC ... in something of an analogy to the way the Schmidt orthogonalization procedure gives us a way to go from an arbitrary basis to an orthogonal one.

A SIC-Gleason Theorem

Let $d \geq 3$ and $\mathcal{P}$ be the set of one-dimensional projectors $\Pi = |\psi\rangle\langle\psi|$. We will call a function $f : \mathcal{P} \to [0,1]$ a SIC-frame function if for any SIC $\{\Pi_i\}$,

$$\sum_{i=1}^{d^2} f(\Pi_i) = 1 \; . \tag{74}$$

Can one show that for each SIC-frame function, there is a unique density operator ρ such that

$$f(\Pi) = \frac{1}{d} \mathrm{tr}\, \rho \Pi \; ? \tag{75}$$

This question was on my mind a long time ago, and ultimately led to `quant-ph/0306179`, where we showed that it does not work if $d = 2$. However, I have recently regained hope that it may work in $d = 3$ or greater.

05-10-07 *Start of an Answer* (to P. Goyal)

Goyalism 1: *Since the operational approach to QT is so important to my thinking, I would like to ask you to give some thought to the question of how someone without knowledge of the quantum formalism (QF) might discover/implement a SIC.*

But maybe this is simply impossible. You see, I would be quite keen on the possibility of trying to derive the quantum formalism from a set of postulates where SICs are taken as basic primitive givens, for this has a strong built-in attraction, namely that the outcome probabilities of a single measurement completely determine the state of the system one is measuring. However, to proceed along this direction in a well-motivated way, the challenge would be to motivate SICs purely operationally (which is of course easy with PVMs since we have paradigmatic examples like SG measurements to abstract from).

Thanks again for the question. It's helped focus my thoughts. Here's a little start of an answer maybe.

What does it mean to be a quantum system? Here's one way I might tackle the question. It means that there is some *special* action I can take upon a system that has d^2 consequences for my experience, and for which I feel I should structure my uncertainties for those consequences in the following way.

1) If I perform the action once, and get outcome i, then if I perform the same action again, the uncertainties I find reasonable for a second outcome j are

$$p(j|i) = \frac{1}{d} \qquad \text{for} \quad j = i \tag{76}$$

$$p(j|i) = \frac{1}{d(d+1)} \qquad \text{for} \quad j \neq i \; . \tag{77}$$

2) More generally, I (subjectively) accept the following theory of priors $p(i)$ for the consequences of this kind of action. That valid priors form the convex hull of these two equations:

$$\sum_i p(i)^2 = \frac{2}{d(d+1)} \tag{78}$$

$$\sum_{i,j,k} c_{ijk}\, p(i)p(j)p(k) = \frac{d+7}{(d+1)^3} \; , \tag{79}$$

where the coefficients c_{ijk} have been hard won through previous experience, and, of course, have some very remarkable properties. (We shouldn't know this yet, but they are the structure coefficients for the Jordan algebra generated by a SIC.)

And that's pretty much it. If one can give a better motivated argument for those wacky equations—that would be the hard part!!—then one would at least have the start of an operational theory based on SICs. The main reason I wanted to spell it out like this, however, has to do with our conversation yesterday. Mathematically at least, ingredient 1) above is really just a minor modification of your postulate of repeatable measurements. As we discussed yesterday, in the worldview of "quantum measurements revealing pre-existent properties" the postulate of repeatable measurements is pretty well motivated. But then I don't find that worldview tenable because of the Kochen-Specker construction (in conjunction with locality). So the question that should be thrown back at me is: What, then, from the alchemical worldview—that's what I'll call my view, for want of a pithier name at the moment—what from the alchemical worldview motivates this looser kind repeatability hypothesis? *I don't know.* I don't know, but at least I did say this is only the start of an answer.

Now, you may ask, the above certainly can't be all of quantum mechanics? But it comes pretty close, and this something I'll probably need to explain to you at the board. For instance, one might say, we'll you've only hypothesized one kind of action you can take on a system. What are the other ones? (The answer should be all other POVMs, but how does one get there?) In fact the answer is not so difficult once one has this much of the framework. One can answer: Actions are in one to one correspondence to the refinements one can make to a general (non-boundary) $p(i)$. And in that way, one recovers all POVMs. I'll explain that at the board.

07-10-07 *Pragmatism* (to J. E. Sipe)

Sipesm 10: *This seems to me the real strength of a realist approach (i.e., one in which the abstract elements of the theory refer to what actually exists in the world), even if it is something as weak as Putnam's "internal realism." It gives a narrative in the strong sense (i.e., not a "just-so story").*

I thought what I have been talking about *is* something as weak as Putnam's "internal realism"? (Though I would call it powerful and liberating, rather than weak.) It is "pragmatism," and a lot of learned people out there say that internal realism is a species of the same—I think I even learned that from Putnam!

10-10-07 *The Writing Side of My Brain* (to H. R. Brown)

I enjoyed the conversation today. You've challenged me, and I hope to be able to eventually answer your questions in a convincing way. ... At least in a way that's convincing for me, if not for you. At the moment, I am not even to that first stage yet!

In the meantime, let me give you a link to some letters I wrote to Bas van Fraassen expressing my point of view on the word "measurement." As you get a chance, I hope you will look at the letters to him in `http://www.perimeterinstitute.ca/personal/cfuchs/nSamizdat-2.pdf`. The writing side of my brain is, I believe, a little clearer than the speaking side of my brain, and since I'd like to continue this conversation with you, I'd like to make our starting point as clean as possible.

10-10-07 *When No One is Looking* (to H. R. Brown)

Let me also give you a link to this paper of Matt Leifer's "Conditional Density Operators and the Subjectivity of Quantum Operations": `http://xxx.lanl.gov/abs/quant-ph/0611233`. He does a better job of doing what I was trying to argue to you the other day (and a little bit today).

11-10-07 *Modernizing James* (to J. E. Sipe)

Sipesm 11: *Hmmm.... OK, but internal realism does allow for narratives. Pragmatism, at least in a certain sense, does too. I don't see how the Bayesian approach to quantum mechanics that you and co-workers are developing will result in a narrative for the universe.*

Well, somehow I see our q-Bayesian program as a beautiful example (and better justified species, in fact) of Jamesian pragmatism! Do a search in this document on the word "James". Some of the stuff in the XX instances that pulls up might surprise you.

The narrative is that the world is a creative, plurality. That is what I want ultimately to come out of the q-Bayesian program. Two sketches of a manifesto below. [See 17-06-04 note titled "Preamble" and 12-02-07 note titled "Lord Zanzibar".]

11-10-07 *Hi!* (to R. E. Slusher)

I've been missing you too. Particularly as I've been plunging into trying to refine the idea that what is ontic of a quantum system is that it is a catalyst. It is a little core that transforms the world external to itself. Your grimaces when I say these silly things would be much appreciated—you helped keep me on the straight and narrow! I would have written you sooner, but a) you never gave me your email address, and b) despite my looking, I could never find it on the web! I'm glad you finally sent it to me.

Here are three of my recent talks that you might enjoy:

- `http://pirsa.org/07080042/`
- `http://pirsa.org/07080043/`
- `http://pirsa.org/07090068/`

I hope Georgia's ultimately living up to your expectations, and that you and your wife are both happy there. Drop me more notes as you get a chance.

12-01-07 *Critchley* (to me)

- Frank Critchley, Paul Marriott, and Mark Salmon, "On Preferred Point Geometry in Statistics," J. Stat. Planning & Inference **102**, 229-245 (2002).

18-10-07 *Copyrights?* (to N. D. Mermin)

Good to hear from you! I was just thinking about you today. I'll tell you why, but first: I'm glad to hear about your recovery from knee surgery. I never imagined you were going through that.

Here's why I was thinking about you. Do you think one can get a noncolorable set (in the Kochen-Specker sense) of quantum states ALL of which are maximally entangled states on some bipartite system?

A consistent set of histories (in the Griffiths sense) is *just* a POVM (the elements being the histories). (Not an answer to your question, but something I felt like saying.) So all of the hullabaloo G makes over consistent sets is simply to prefer certain kinds of POVM.

I'm glad to hear you'll come visit us, and I'm glad I've got that in writing!

18-10-07 *Noncolorable Histories* (to N. D. Mermin)

Merminition 168: *OK, I see what you mean. But you would never say that the results of measuring a POVM were there (modulo a framework), whether or not the information was actually acquired. So I take it as a purely formal remark that, however, misses what is essential for Griffiths.*

Well, I suppose my take on it is that Griffiths is just deluded. The histories formalism is full of sound and fury, but in the end signifies nothing. That thing which is "essential" for Bob is, in the end, just of no consequence for quantum interpretation. For me the essential question is whether there are "noncolorable" sets of consistent sets of histories. Sets of sets. Essentially the KS question, just now applied to histories. If so, there is no good sense in which one can even say that within a consistent set one history is TRUE (using Bob's way of writing it). TRUE is only relative to the consistent set. And what determines the consistent set under attention? The agent—nothing more and nothing less than that which sets an orthonormal basis in the usual formulation of quantum mechanics. It is just that the agent now is turning his attention to the class of POVMs that Bob prefers to single out (i.e., sets of "histories") rather than the POVMs that Bohr was concerned with (i.e., sets of orthonormal bases).

I tried to say this better in `http://xxx.lanl.gov/abs/quant-ph/0105039`, in the single (long) letter there to Griffiths, starting on page 178. Looking back at it, it is a horrible job, but maybe I still massaged some issues the right way there.

On your more technical question, yes I think one can generalize consistent sets to sequences of POVMs with a Lüders collapse rule in between. Carl Caves did it once upon a time—as I recall—but never published, and then I think someone else published something similar. I'll try to find that reference for you tomorrow.

So good to have you back! Keep thinking about the new KS question I asked you. I am hoping it is useful for readdressing the issue of the objectivity of unitaries.

18-10-07 *Digging Up Bones* (to N. D. Mermin)

In case it is useful to you, here is Bob's reply to that old letter of mine. I really had to dig to pull this one up in my system. It was dated June 13, 1997.

Most relevant to your present query are these words of Bob's:

> Attempts to work out consistency conditions for POVMs has been attempted by Oliver Rudolph in Hamburg. His earlier work was enormously complicated and the results uninteresting. He claims to have made further progress, but I haven't looked at it. My own opinion is that POVMs (and density matrices) represent calculational tools which can certainly be useful for certain purposes; however, I don't see any reason to employ them as "basic events" in a sample space, and hence no point in working out consistency conditions for them.

Have fun in Oregon. I think I give a colloquium in Eugene in February (either before or after Australia). I go to China for the first time Nov 1. When I first went to Japan you told me not to eat the fugu. Any advice for China?

30-10-07 *Talk Still?* (to J.-Å Larsson)

Larssony 2: *I would like to spend* <u>*some*</u> *time before arriving reading and thinking about SICs.*

OK, I'll change the schedule then. Of course, the *best* single paper to look at is `http://xxx.lanl.gov/abs/0707.2071`. A whole lot of interesting things happened while Appleby was visiting. For instance, he classified all Weyl-Heisenberg SICs in $d = 3$. Lane Hughston has also thrown in looking at algebraic geometry aspects in $d = 3$. He'll give a talk on that today, and in a couple of days, you should be able to find it on PIRSA if you want to see it. Steve Flammia has had some good number theoretic ideas too (which would be a little difficult for me to explain). And me, when I'm not learning from everyone else, I've just been plodding along trying to see if my reduction in equations to $3d$ (instead of the original d^2) doesn't fail in $d = 24$. There is a fear in me, since a related conjecture explored by Joe Renes fails there. Any idea how to make the attached *Mathematica* code "Old Notebook" more efficient? Basically all I'm trying to do is minimize the function `EC` and then check that the vector that minimizes it makes the matrices `TT` and `SS` look right. (The matrix `SS`, for instance, should have 1 in the top left entry and $1/(d + 1)$ in all the rest.) The first cell just basically finds me a good random seed, and then in the second cell I use that seed to verify that my vector has all the properties it should have. Anyway, this method can be pushed to work all the way up to about $d = 18$ if one has patience. But there's probably a much better way to do it that would squeak out at least 10 more dimensions. For instance, Renes's notebook which checks the other conjecture pushes out to $d = 23$ without problem. On the other hand, I've been too stupid to modify mine to work like his (I just cannot figure what's wrong), and Renes himself has gone missing!

Anyway, so glad you're interested in thinking about SICs! (The "official" pronunciation now being Sikhs . . . also to connote their religious aspect.)

05-11-07 *Holevo Hirota* (to D. Gottesman)

I just got this letter from Holevo this morning,

> If I am correct, next June Hirota will be 60. This is an important age, notably in Japan. I am not sure how better to mark this date, perhaps with a collection of papers in a dedicated journal? What is your opinion, perhaps you have better or more concrete suggestions. In any case I would be happy to support any reasonable initiative.

and it creates in me the following idea. (I'm trying to be creative, not having it in me to be an editor or any similar thing at the moment.) What would you think about PI hosting a small meeting (birthday party) in honor of Hirota for his 60th birthday? He has been an indefatigable defender of quantum information in Japan, and has brought significant funding to the field for the QCMC conferences, and supported the likes of Holevo in Russia's troubled financial times. Anyway, I'm just thinking something small (like 10 people or less) composed of some of his best scientific friends, like Holevo, Bennett, Yuen, etc. In fact it would be a good excuse for finally getting Holevo to visit us, and similarly with Charlie. And maybe we could even unearth Helstrom, etc.

What do you think? Does PI have an easy mechanism (and a small budget) for making such a thing happen?

07-11-07 *Listening in Beijing* (to J. W. Nicholson)

After hearing of your eating the fugu, I felt a new urgency to listen to your music. That first one (i.e., two) is a lot of fun! It sort of put me in the same mood as when I was watching one of those old, cheesy light-hearted Italian flicks, the kind one used to find on TV in the early days of HBO. I don't know how to articulate the feeling better than that. The second seems to represent your *Rubber Soul* transition. How do you hold so many styles in your head, man? I only got one, and it alone gets burdensome at times.

Now I be off to the office. I'm gonna crack this problem of quantum mechanics, I tell you. Visiting the Temple of Heaven yesterday and the Chinese apothecaries, and thinking about their practices at both, gave me renewed strength to think about alchemy and the analogy in it of quantum state preparation and measurement. When I can make the point precise, people will listen.

… OK, I probably shouldn't have listened to that *Rubber Soul* stuff so early in the morning.

08-11-07 *Hirota's Birthday* (to A. S. Holevo)

Holevo-ism 2: *If I am correct, next June Hirota will be 60. This is an important age, notably in Japan. I am not sure how better to mark this date, perhaps with a collection of papers in a dedicated journal? What is your opinion, perhaps you have better or more concrete suggestions. In any case I would be happy to support any reasonable initiative.*

I'm not opposed to your suggestion—I think it is a good idea—but I just don't have the stomach myself to be an editor (or co-editor) of yet another special issue for a while. On the other hand, if you would like to pursue an issue as editor, I'm quite sure that QIC (*Quantum Information and Computation*, the journal I am associated with) would be more than happy to have you edit a special issue, and I think I could easily help facilitate that for you.

But here's another idea that could be concurrent with that, or separate from it, either way, that I'd be happy to pursue personally. How about a small scientific "birthday party" for Osamu at PI? The sort of thing I am thinking is a small meeting of maybe 10 or so colleagues, some of Osamu's best friends or greatest influences, "Osamu Hirota, between Distinguishability and Noncausality". For instance, you, Charlie Bennett, Yuen, and some others? You and I could be co-organizers, but the administrative staff would take care of almost all the mundane affairs of the meeting like travel details for the participants, etc. And we would have a pleasant banquet with some nice wine in PI's Bistro. Our main duty would be in choosing the participants and contacting them with invitations, etc.

What do you think of such an idea? I have already contacted Daniel Gottesman and he was happy with the idea of something like that (I thought it best to get his opinion before pursuing things further). If it is a kind of thing you too find worth pursuing, I will write an official proposal for PI. If the conference committee agrees, then we should be able to cover most (if not all) of our participants' expenses. Let me know what you think, and if you are in agreement, also send me a list of suggested participants so that we might starting thinking about how to structure my proposal.

I am in Beijing, by the way, and my connection into PI's intranet is so slow, that I'll probably have to wait until getting back next week before pursuing anything further. But it'd be nice to get your commentary before then.

08-11-07 *Uncle Fierz Needs You* (to H. C. von Baeyer)

Greetings from Beijing! I have been meaning to write you for ages, but one thing would always lead to another, and I would always end up remembering just at a time when I was not at my computer. Anyway, having a long, contemplative walk around the Temple of Heaven yesterday and visiting a Chinese apothecary apparently made my mind disciplined enough that I'm writing you now.

The subject is, I would very much like you to give us a visit at PI, and when you're not just imbibing the excitement and atmosphere, use the time to start hitting your Pauli-Fierz project in a detailed way. By being together physically for discussions, I think it could be a great experience for both of us. More than ever I feel like I've got to get my understanding of quantum measurement into shape—measurement as release of the stone—and the best starting point, I am really convinced, must be the Pauli – Fierz – Jung – von Franz discussions.

I have some visitor funds I need to spend before the end of December, and so I think that is the perfect spur for trying to get together for some long conversations and scholarship. I know this is short notice, but I hope you can come (and be interested in coming for the project I propose!). I would be able to pay your travel expenses, put you up in a PI apartment, and provide a per diem for your meals. Come 1 week, 2 weeks, 3 weeks, or even 4, whatever amount of time you can afford. The more the better, the more we could get done.

So please do think about it. If it helps, have a look at a typical dinner menu for the Bistro and its wine list and browse the cultural venue and maybe take a virtual tour of the facilities. Also take note of the Friday afternoon wine and cheese socials, and that's not even to mention all the physics, physics, physics that'll be all around you all the time.

- W. Heisenberg, "Wolfgang Pauli's Philosophical Outlook," in his book *Across the Frontiers*, translated by P. Heath, (Harper & Row, New York, 1974), pp. 30–38.

> The elaboration of Plato's thought had led, in neo-Platonism and Christianity, to a position where matter was characterized as void of Ideas. Hence, since the intelligible was identical with the good, matter was identified as evil. But in the new science the world-soul was finally replaced by the abstract mathematical law of nature. Against this one-sidedly spiritualizing tendency the alchemistical philosophy, championed here by Fludd, represents a certain counterpoise. In the alchemistic view "there dwells in matter a spirit awaiting release." The alchemist in his laboratory is constantly involved in nature's course, in such wise that the real or supposed chemical reactions in the retort are mystically identified with the psychic processes in himself, and are called by the same names. The release of the substance by the man who transmutes it, which culminates in the production of the philosopher's stone, is seen by the alchemist, in light of the mystical correspondence of macrocosmos and microcosmos, as identical with the saving transformation of the man by the work, which succeeds only 'Deo concedente.'" The governing symbol for this magical view of nature is the quaternary number, the so-called "tetractys" of the Pythagoreans, which is put together out of two polarities. The division is correlated with the dark side of the world (matter, the Devil), and the magical view of nature also embraces this dark region.

11-11-07 *A Question on Gleason's Theorem for SICs* (to Z. Ji)

Yes, maybe you do not understand the statement of the problem. For, as you state it below, the standard Gleason theorem would not be correct either—for that theorem too can be posed solely in terms of rank-1 operators alone. Then your argument would have gone:

> The point is, von Neumann measurements consist of rank-one operators only, the function could be $f(A) = \mathrm{rank}(A)/d$, and $\sum f(\Pi_k) = 1$ will trivially hold for all $\{\Pi_k\}$ being an orthonormal basis. But the rank function is not linear and cannot be written as required.

The key is that I am only considering functions whose domain of definition is on the rank-1 projectors. After one gets a characterization of them, perhaps one will want to extend their domain (and it will be doable uniquely if they turn out to be linear), but at the outset the domain of definition is the set of rank-1 projectors.

The statement is: Let $d \geq 3$. Suppose f is any given function from the rank-1 projectors to the range $[0, 1]$ with the property that $\sum f(\Pi_k) = 1$ whenever the $\{\Pi_k\}$ form a SIC. Then can one show that there always exists a density operator ρ such that $f(\Pi) = (1/d)\mathrm{tr}(\rho\Pi)$?

About your example, when restricted to the proper domain of definition there is indeed a density operator with the desired property, namely the maximally mixed state. And then that function f will have a unique linear extension to other operators.

Perhaps it would be helpful for you to look at this old paper of ours, where we considered a precursor question, but with qubits: `http://xxx.lanl.gov/abs/quant-ph/0306179`. The section relevant to what we are talking about above is Section IV.

12-11-07 *Autumn in Beijing* (to D. B. L. Baker)

One day last week, as I was walking through a park watching the leaves fall and the Chinese children play with them—a sentimental scene from every year and every place—I thought I would write you a note with this title. Imagine Frank singing that. Of course, I thought I would write the note to you that very day, but as of now I'm making my way from Hong Kong to Anchorage. That's the way I write now, always in delayed mode. [See 03-02-06 note "Red Spears" to D. B. L. Baker.]

I hope you're doing well. I thought you might enjoy a few pictures I took during my stay in Beijing. For the first time in my life this trip, I actually took a camera with me. Pay close attention to what's in the right hand of the Chairman Mao talisman. After leaving that market, and thinking about it a little, I decided I could kick myself for not trying to buy that as a little decoration for my new house. How many opportunities I've missed in life!

27-11-07 *PI QI Group Meeting Today (Yesterday)* (to M. Mosca & L. Sheridan)

Here a couple of those old van Enk papers I was talking about:

- `http://xxx.lanl.gov/abs/quant-ph/0207142`
- `http://xxx.lanl.gov/abs/quant-ph/0410083`

It would be good to get together and talk about issues to do with "self-calibration." I'd like to see how it fits in my worldview that "quantum operations are Bayesian too". You probably have no clue what I'm talking about, but you can read about it here (in the form of debate with Caves, Mermin, Schack, etc.): [some unknown pages in this samizdat]. The banter there still remains better than any of the more formal stuff I've written.

By the way, what does research on "the fundamental object of conscious existence" mean?

27-11-07 *Tables of Contents* (to M. Mosca & L. Sheridan)

… just thinking again about yesterday's talk. For fun I just looked in both Nielsen and Chuang and David Mermin's books on quantum computing. I did an index search on "energy conservation" and "conservation laws". Didn't find anything in either book on either topic.

29-11-07 *Adam's Conversation* (to J.-Å Larsson)

See page 83, note titled "I See Why Bit Commitment," in:

`http://arxiv.org/abs/quant-ph/0105039`.

29-11-07 *Much Better* (to W. G. Demopoulos)

I just finished reading the final version of your paper and actually feel better about it this time around. I'm not sure what you changed, but I remember being bothered by more aspects before … and today I detected almost nothing that got in the way of my appreciation. I will forward on the paper to John Sipe, for I think it clarifies some aspects of my ongoing debate with him. I will also forward it on to Carl Caves because I think page 15's discussion of indeterminacy exposes some dangers in his ways of thinking about the timeless properties of quantum systems.

Where I do take issue with what you write is the very difficult issue of probability 1. If I understand you correctly, I disagree with the first sentence of the first full paragraph from page 22:

> The representation of an elementary particle as a function which, when presented with an experimental configuration, yields an effect, is interchangeable with its representation as a class of propositions only when the effects are predictable with 0-1 probability.

For, I would say, not even then. That is the point of the attached paper, `quant-ph/0608190`, which you didn't seem to get the point of the last time I sent it to you. It is also the point of my discussions with Bas van Fraassen on pages 411 to 417 (and in much greater detail elsewhere in the collection) of `nSamizdat-2.pdf`.

30-11-07 *Relationalism vs Pragmatism at PI* (to B. C. van Fraassen)

I've been meaning to write you for a long time, and the note below from my colleague Nielson on Perimeter Institute's sabbatical program has helped spur me to finally take action. (Our last conversation was interrupted by the great April Nor'easter floods in New Jersey; my basement took 23,000 gallons of water just as I put my house on the market—you were at the Bubfest that very same weekend. That on top of the market bubble bursting led to a lot of pain between then and now. … Anyway, that's my excuse for the silence.)

But I'm established in Waterloo now, and I'd like to increase the rate of our understanding of what a relational view of QM is all about. Thus I had been meaning to invite you for some visits if you've got the time. For short terms, I could pay all your expenses from my visitors budget. But something like the sabbatical program below would be much better still!

In case you're not familiar with PI, I'd say, take a look at a typical dinner menu for the Bistro and its wine list at […], browse the cultural venue at […], and maybe take a virtual tour of the facilities at […]. Also take note of the Friday afternoon wine and cheese socials. Beyond that, of course, are all the people. With regard to philosophy Harvey Brown will be here for the coming year, and there's everyone in London and Toronto. So, I think you could have some good fun.

Think about both propositions and let me know.

05-12-07 *The Misak Book* (to R. W. Spekkens)

Spekkensism 41: *I saw this book while browsing the Oxford University Press website, and thought that you might be interested.*

> **New Pragmatists**
>
> Edited by Cheryl Misak, University of Toronto
>
> Pragmatism is the view that our philosophical concepts must be connected to our practices — philosophy must stay connected to first-order inquiry, to real examples, to real-life expertise. The classical pragmatists, Charles Sanders Peirce, William James, and John Dewey, put forward views of truth, rationality, and morality that they took to be connected to, and good for, our practices of inquiry and deliberation. In this volume, some of our very best contemporary philosophers explore this and develop the pragmatist project, showing that pragmatism is a strong current in philosophy today.
>
> Contributors: Jeffrey Stout, Ian Hacking, Arthur Fine, Cheryl Misak, Huw Price, David Macarthur, David Bakhurst, Terry Pinkard, Danielle Macbeth.
>
> March 2007 — 208 pages — Clarendon Press
>
> 978-0-19-927997-5, HARDBACK £25.00/$45.00

Thanks for pointing the book out: It definitely needs to be in the collection. (Look at the beautiful bookshelves, in fact, that I just had built in my house. PICT0380 particularly, captures the part of the library devoted to pragmatism.) Also, it was nice to learn from the advert that Misak is in Toronto—I hadn't realized that.

10-12-07 *SICs, FQXi, & the Way Chris Thinks* (to D. M. Appleby)

Applebyism 15: *Are you available to talk? I am getting really hung up on this 500 word summary. My mind has got jammed. I don't like what I have written so far. But I can't think of anything to put it in its place. And I badly want to get back to SICs. Perhaps you could help me to unblock myself.*

Applebyism 16: *The proposed research will form part of a larger project, to develop a novel way of looking at quantum mechanics. Classical physics is based on the correspondence theory of truth: it is supposed that each symbol in the theory is the token for an element of reality (for instance, the symbol E, as it occurs on paper, is the token for an actually existent object, the electric field vector). Wave function collapse makes it very difficult to reconcile that idea with quantum mechanics. However that has not stopped people trying. In fact most work in the foundations of quantum mechanics consists in a variety of ingenious attempts to preserve the classical assumption, that the constructions of mathematical physics in general, and the quantum state in particular, should be conceived as being in one-one correspondence with mind-independent realities. It appears to us, however, that the real message of quantum mechanics is that we need to abandon this rather simple-minded way of thinking about physical theories in favour of something richer, and subtler, and potentially much more fruitful. Instead of thinking of the quantum state as a peculiar kind* *of physical object, we take it to have a fundamentally probabilistic significance. Furthermore we take an epistemic, or Bayesian view of probability. So although the quantum state encapsulates our expectations regarding the world, and to that extent makes a statement about the world, it is not the depiction of something in the world (it cannot be such a depiction because of the way it changes discontinuously consequent on learning a measurement outcome). Preliminary work along these lines has been reported in previous publications by two of the investigators. However, a great deal more remains to be done.* [...]

I saw two movies this week, one titled "Dr. Goldfoot and the Bikini Machine" and one titled, "Dr. Goldfoot and the Girl Bombs." The first (1965) was starred by Vincent Price and Frankie Avalon; the second (1966) was starred by Price and the singer Fabian. Anyway, the fun thing was that Avalon and Fabian were employed by the "Secret Intelligence Command" and were known as SIC-men.

I'm tinkering on your draft to see how it would come out in my own voice. I'll send you the result tomorrow. You're under no obligation to keep any of those changes; I'm just doing it to give further ideas, and perhaps making the hard right turn a little more dramatic. ... ...

Below is the result of my tinkering with your draft proposal. I'm sorry to get this back to you so late, but the quantum gravity meeting actually turned out to be interesting and distracting! (Have any doubts that SICs are important? Patrick Hayden today presented a proposed toy-model solution to the so-called black-hole information paradox by him and John Preskill that made use of 2-designs on finite dimensional Hilbert spaces. He said, "imagine the black hole enacts a random unitary." I said, "Imagine instead a demon in the hole that measures a SIC and outputs a quantum state corresponding to his result." The two expressions are equivalent.)

Anyway, the passages below are what your draft inspired me to write. They may be indicative of nothing but my own take on the deeper reasons for the research. I tried to express that as best I could. The count in this version stands at 556 words. The main thing I tried to capture a little better was the hard right turn we talked about on the phone the other night. What I really wanted to say is that our understanding of QM is really doomed without SICs. And that what we're sikhing is a true bending of our worldview. I wanted to say to FQXi, "you're really called for here!" I don't know that I really succeeded at those goals, but that's the sort of thing that was on my mind, as I modified emphasis away from density operators and made it a little more toward probabilities.

I'll send it to you now without tinkering further. By the way, I didn't incorporate any of Lane's last suggestions, as I didn't know what they were when I started this project. Anyway, as I told you last night, feel free to completely trash this version. I have no emotional attachment (mostly it was an exercise in clarifying my own thinking), and ultimately want whatever will turn out with hindsight to have been the best move! I.e., I want you to win at all costs!

> The proposed research forms part of a larger project to develop a novel way of looking at quantum mechanics. Classical physics is based on the correspondence theory of truth: It is supposed that each symbol in the theory is a token for an element of reality. Wave-function collapse upon the acquisition of information, however, makes it difficult to reconcile this idea with quantum mechanics. Nonetheless, this has not stopped many researchers from trying—much work in quantum foundations consists in a variety of ingenious attempts to preserve the classical assumption that quantum states should be conceived as being in one-one correspondence with mind-independent realities. In contrast, it appears to us that the real message of quantum mechanics is that we need to abandon this way of thinking in favour of something richer, subtler,

and potentially of great significance for our worldview. Instead of thinking of quantum states as peculiar kinds of physical objects, we take them to have a fundamentally epistemic significance, particularly along Bayesian lines. So although quantum states encapsulate our expectations regarding the world, and to that extent make statements about the world itself, they are not the depiction of something in the external world. Preliminary work along these lines has been reported in a number of earlier publications by the investigators.

The deepest development of this idea, however, is significantly impeded by the present formulation of quantum mechanics. In fact, from our perspective, the usual Hilbert space formulation of quantum mechanics is a good part of the whole interpretational problem, as it insinuates a fundamental distinction between quantum states and the probability assignments they entail. Thus we seek a mathematically elegant formulation of quantum mechanics in which the main objects are probability assignments, rather than quantum states. This calls for a deeper understanding and classification of the operator bases allowed within the set of quantum states. Based on several arguments, we believe the so-called "symmetric informationally complete" sets of states (SICs) are the most fundamental such bases and thus should be our starting point. There is only one catch: Do SICs exist? As it turns out, this is an extremely nontrivial mathematical problem, with an origin 35 years ago in coding theory. Recently though, much progress has been made on the issue, with deep connections to other areas of quantum information theory and algebraic geometry—so much so that with concerted effort, one imagines light at the end of the tunnel. For instance, SICs are now known (numerically) to exist in Hilbert spaces up to dimension 45, and analytic constructions have been given up to dimension 12.

The first phase of our project is to settle the existence question and to acquire much needed mathematical insight into the geometrical and group-theoretical structures exhibited by SICs. The second phase will involve a number of applications, particularly getting back to the motivational roots of this problem, as well as issues in quantum tomography, cryptography, and a variety of other problems in quantum measurement theory. The Investigators all have well-established track records for innovative work in quantum theory, and have variously undertaken a number of successful preliminary investigations that are relevant to the proposed research. As a consequence we feel our chance of success is high, and even if only partial success is achieved the results obtained would still amply justify the investment.

11-12-07 *Last Night – Seminar – Teleportation* (to M. Knechtel)

Thanks for the interest.

Yes, you do have to have a "stack of raw building blocks" at both ends of the teleportation scheme. For instance, if one wants to teleport the quantum state of an electron, then one needs 1) the original electron situated near Alice, 2) a "raw" electron also situated near her, and 3) finally a further raw electron situated near Bob (that is "entangled" with Alice's raw electron). At the end of the protocol, the quantum state that was associated with the original electron will now be associated with the electron in Bob's possession.

What this means quite literally is that any information one had about the original electron is now relevant to the other electron instead. It's not nearly as exciting as the word "teleportation" might have indicated. "My information is no longer about this, but instead about this other thing far away."

Hope that helps.

Marguarite's Preply

> Good round table last night. Thank you for your input and your humour. I just wanted to clarify teleportation. It sounded to me like the only way teleportation works is if there is, for example, a stack of building blocks at this end resembling a structure of some sort and a stack of building blocks in a pile at a distance. The structure does not teleport from one place to another, but the information about how to assemble the building blocks at the other end, or how the original structure is built, is what gets transported and then the building blocks can be formed into a similar looking structure. Is that correct? My brain needs to process info in examples I am familiar with.

11-12-07 *Any Comments on This as a Proposal?* (to L. Hardy)

It's almost 500 words, the question is even at this stage, how do you think it would fly for Marcus?

> The proposed research forms part of a larger project to develop a novel way of looking at quantum mechanics. Classical physics is based on the correspondence theory of truth: It is supposed that each symbol in the theory is a token for an element of reality. Wave-function collapse upon the acquisition of information, however, makes it difficult to reconcile this idea with quantum mechanics. Nonetheless, this has not stopped many researchers from trying—much work in quantum foundations consists in a variety of ingenious attempts to preserve the classical assumption that quantum states should be conceived as being in one-one correspondence with mind-independent realities. In contrast, it appears to us that the real message of quantum mechanics is that we need to abandon this way of thinking in favor of something richer, subtler, and potentially of great significance for our worldview. Instead of thinking of quantum states as peculiar kinds of physical objects, we take them to have a fundamentally epistemic significance, particularly along Bayesian lines. So although quantum states encapsulate our expectations regarding the world, and to that extent make statements about the world itself, they are not the depiction of something in the external world. Preliminary work along these lines has been reported in a number of earlier publications by the investigators.
>

The Investigators all have well-established track records for innovative work in quantum theory, and have variously undertaken a number of successful preliminary investigations that are relevant to the proposed research. As a consequence we feel our chance of success is high, and even if only partial success is achieved the results obtained would still amply justify the investment.

11-12-07 *Why I Care* (to S. T. Flammia)

Below is a draft of a "500-word" research summary that I helped Marcus write yesterday for his FQXI application. [See 11-12-07 note "Any Comments on This as a Proposal?" to L. Hardy.] Of course I know you'll disagree with some of it (the part about light at the end of the tunnel, particularly), but maybe the first paragraph and the first half of the second paragraph will shed some light on why I actually care about this problem. We are doing important things, even if we spin our wheels 98 percent of the time, and I hope you never lose sight of that. I feel very lucky that I arrived at PI at the same time as you. Seriously.

12-12-07 *For Lane Hughston* (to me)

> On the windowsill of my home on an island in Maine I keep a rock from the garden of Academe, a rock that heard the words of Plato and Aristotle as they walked and talked. Will there someday arise an equivalent to that garden where a few thoughtful colleagues will see how to put it all together and save us from the shame of not knowing "how come the quantum"?
>
> — John Archibald Wheeler

14-12-07 *No Subject* (to C. Snyder)

I know you'll never be able to capture it on paper the way you did in conversation, but I thought your description of your morning coin tossing contained a particularly deep idea. Could you, would you, please, take a shot at writing it down? I also liked that distinction—if I remember it correctly—between "expressing yourself" (in the form of a coin toss) and "expressing what you think of yourself" (in the form of an action with a predictable consequence, like pushing the pint across the table). Say it all again!

If you're interested, you can find my description of the inveterate gambler and the nurturing-wives and bad-girlfriends penal colonies in this talk: `http://pirsa.org/05070097/`. I think I tell the story of the Jewish mystic in that talk too (couldn't figure out the right way to spell "moyal", so I just called him "mystic"). Also, a couple of stories you might enjoy (and ones that potentially indicate why I liked your story last night) can be found in the attached pseudo-paper.

It was good seeing you again!

Christian's Reply, 11-04-12, "Data Sets and Who We Think We Are"

> Long time no chin wag.
>
> I came across a piece of ephemera, a napkin to be exact, with your handwriting on it the other day. It reminded me that I have neglected (for five years) to get back to you about my thoughts on creating a random binary data set (dropping coins on the shitter) and how that informs the self. To be honest, I have nothing too earth-shattering to report (for further reading on "not too earth-shattering" see my reports on chicken vs. egg and tree in forest). That being said, through the skein of ones and zeros I have managed the kernel of an idea that might be worth some beer if you're around in the next bit.

21-12-07 *Do You Know This Guy?* (to G. L. Comer)

`http://en.wikipedia.org/wiki/Rick_Norwood` ?? Ran across him while reading about Nietsche, Schopenhauer, and "the will"—"the will" being the only part of those three that I really care about. Maybe I should title my book, in contrast to Schopenhauer, *The World as Wills and Representation*. Be sure to take note of the additional S.

22-12-07 *Postdoc Positions* (to H. Price, G. Bacciagaluppi, and others)

It looks like I missed a lot of activity the day I was away from home last week. Luckily, Lucien says I'm absolved of my sins. Anyway, I promise to be more active during the next level of culling. That's the real purpose of this message.

But I also wanted to comment on one line of Huw's, because it seems like a fun thing to do. Namely, this:

Pricey Quote 2: *I agree with Guido that foundations and French philosophy is a very unpromising mix.*

For, I would say, "Ah, but if the French philosophers were Renouvier, Boutroux, and Bergson, that might just be a different story! ... Because ... ahem ... I actually do think they're a promising mix for quantum interpretation problems." But alas, I looked at the guy's CV and found no Renouvier or Boutroux. So, he fell off my list too.

22-12-07 *One More Comment!* (to W. C. Myrvold)

Sometimes it takes me a long time to answer an email. But until I do, my correspondent's mail sits faithfully in my inbox with me from time to time reading over it again. Such was this morning. Anyway, after all this time, I find I've not much to say: I didn't find a lot in your note that I did (or could) disagree with. Maybe in fact my only point of departure from you would be with the penultimate sentence, where you write "assumption – that spatially separated systems have independent physical states — is wrong." For, I would go further and say "the assumption that systems have physical states is wrong." More accurately, I would say the lesson of the conjunction of EPR, Bell, and Kochen-Specker is that the assumption that systems have physical states is perhaps not wrong, but rather so limp that it's not worth propping up if one desires real progress in physics.

However, by this rewriting I only mean that the assumption that systems have *intrinsic dynamical* (i.e., time-changing) states is off track—"intrinsic" being the most important word. The main point about this, is that it still leaves the door open for an ultimately realist construal of quantum systems—though one, I think, along more exotic lines than the usual realist has a taste for. For instance, I can still imagine some kind of relational account of quantum mechanics like Spekkens desires as a possibility. I myself don't think that's the right direction, but I see it as a remaining possibility. My own favorite imagery at the moment has to do with a metaphor of catalysts—I want to see quantum systems as something like catalysts, or when I'm feeling particularly poetic, "philosopher's stones." That timeless property to enact change on that which they interact with is their only intrinsic property. Catalyst, philosopher's stone, hyle (as that which underlies change), words like that, are an attempt to express the ontic character I toy with as underlying quantum mechanics.

By the way, for the fun of it, let me record some quotes of William James that give his take on indeterminism. I feel they capture my own take on indeterminism in quantum theory. (So, when you see that Aristotelian word above, don't think Peirce, but think James ... at least in relation to me.)

> [Chance] is a purely negative and relative term, giving us no information about that of which it is predicated, except that it happens to be disconnected with something else—not controlled, secured, or necessitated by other things in advance of its own actual presence. As this point is the most subtle one of the whole lecture, and at the same time the point on which all the rest hinges, I beg you to pay particular attention to it. What I say is that it tells us nothing about what a thing may be in itself to call it "chance." It may be a bad thing, it may be a good thing. It may be lucidity, transparency, fitness incarnate, matching the whole system of other things, when it has once befallen, in an unimaginably perfect way. All you mean by calling it "chance" is that this is not guaranteed, that it may also fall out otherwise. For the system of other things has no positive hold on the chance-thing. Its origin is in a certain fashion negative: it escapes, and says, Hands off! coming, when it comes, as a free gift, or not at all.
>
> This negativeness, however, and this opacity of the chance-thing when thus considered *ab extra*, or from the point of view of previous things or distant things, do not preclude its having any amount of positiveness and luminosity from within, and at its own place and moment. All that its chance-character asserts about it is that there is something in it really of its own, something that is not the unconditional property of the whole. If the whole wants this property, the whole must wait till it can get it, if it be a matter of chance. That the universe may actually be a sort of joint-stock society of this sort, in which the sharers have both limited liabilities and limited powers, is of course a simple and conceivable notion.

and

> The more one thinks of the matter, the more one wonders that so empty and gratuitous a hubbub as this outcry against chance should have found so great an echo in

the hearts of men. It is a word which tells us absolutely nothing about what chances, or about the modus operandi of the chancing; and the use of it as a war cry shows only a temper of intellectual absolutism, a demand that the world shall be a solid block, subject to one control,—which temper, which demand, the world may not be found to gratify at all. In every outwardly verifiable and practical respect, a world in which the alternatives that now actually distract your choice were decided by pure chance would be by me absolutely undistinguished from the world in which I now live. I am, therefore, entirely willing to call it, so far as your choices go, a world of chance for me. To yourselves, it is true, those very acts of choice, which to me are so blind, opaque, and external, are the opposites of this, for you are within them and effect them. To you they appear as decisions; and decisions, for him who makes them, are altogether peculiar psychic facts. Self-luminous and self-justifying at the living moment at which they occur, they appeal to no outside moment to put its stamp upon them or make them continuous with the rest of nature. Themselves it is rather who seem to make nature continuous; and in their strange and intense function of granting consent to one possibility and withholding it from another, to transform an equivocal and double future into an unalterable and simple past.

Wayne's Preply, from 09-02-07

Woke up this morning and had a thought: I don't think I adequately expressed *why* I don't think that your view commits you to using probabilities only for bets whose outcome has an effect on you.

The worries about Wigner's friend and associated paradoxes, which you expressed as saying you don't find events in the density matrix, come from construing the quantum state ontologically. But for you, a density matrix is a compendium of probabilities regarding all the experiments that might be performed on the system. Use it to extract the probabilities of outcomes of experiments that are actually performed (whether or not the outcome affects you); the rest — probabilities of outcomes of experiments that could have been performed, but weren't — are irrelevant to any decisions you make.

However: that means that the response that you started to make to Brian's question about EPR-Bell correlations — which, I think, was that as far as you are concerned the correlations don't exist until you compare the results (at which time the experiments are all in your backwards light cone) — is not available to you. Which is good, I think, because it permits you to use such correlations as clues to what the world outside the purple line is like.

We associate with EPR-Bell experimental setups certain credences about the outcomes of the measurements. These are credences that we, as Bayesians, have learned through experience (by conditionalizing on the results of experiments) are more appropriate than certain other credences (such as those yielded by the toy theories that Bell constructs in his original paper) for such setups.

These credences have an interesting feature: they can't be mixtures of probability assignments on which the outcomes at the two ends are probabilistically independent. That is, these correlations are different from classical correlations. We can imagine a world in which the experiments had turned out differently — in which classical correlations sufficed. But we don't live in such a world.

The degrees of belief that we learn, through experience, to associate with a given physical situation, tell us something about that situation (that is the lesson, I think, of the two islands). I think that the conclusion we ought to draw from EPR-Bell experiments is that Einstein's separability assumption — that spatially separated systems have independent physical states — is wrong. This is perfectly compatible with an absence of action-at-a-distance, and compatible with special relativity. It is of course not the only possible conclusion, but it's the one that I think is best supported by all available empirical evidence.

27-12-07 *A Question in Two Keys* (to H. Price)

1) If you have a preference, how would you spell "Price-ian"? Pricean? Price-ian? Prician? (I only give the last as a possibility, even though I really dislike it, because I recently read about the views of Duns Scotus and saw it called Scotism … completely bastardizing the last name. So, I don't know, maybe it's common in philosophy to go so far.)

2) Where do you have a more elaborate description or working out of your key metaphor than in the research proposal you sent me?

> The project begins with the hypothesis that science and philosophy have often been dominated by a shallow and misleading conception of the relation of the information we use and process to the world we inhabit. Thought, language and scientific theory are often viewed as passive mirrors, which (when all goes well) offer a kind of image of some facet of that world. On this view, the factual content of thought is simply what the image reveals about the world. This project aims to show that this passive, one-way, conception of factual information is both mistaken in itself, and a major obstacle to a proper understanding of seemingly independent matters of great importance in philosophy and physics. The project offers an alternative view of factual information, as an active, practical resource, shaped not only to the contours of our environment, but also, crucially, to a range of different aspects of our own needs, natures and situations. In place of the dominant metaphor of information as a *mirror* or *picture*, the project substitutes the metaphor of a *key*: a practical, two-ended device, shaped at one end to the outlines of some part of the environment, and at the other end to the shape and needs of its users.

I'd like to read more about it in preparation for what I'll say in Sydney.

Hope you had a nice holiday. Attached are two pictures of the new Waterloo Library of Pragmatism! I'll be thinking about your keys in there.

Huw's Reply

> Did I ever send you the draft Introduction to my planned collection of essays? It doesn't have the key metaphor explicitly, I think, but does have some working out of the ideas – copy attached.
>
> Re #1, I guess "Pricean" makes most sense! There's "Pricey", too, but while I'd like to think my views are valuable, I also like to emphasize how economical they are, compared to their metaphysical rivals – so I'm torn on that one ;-)
>
> Looking forward to seeing you! I've got my head down trying to finish a written version of my Everett talk – I promised the editors I've had it done by the end of the month.

27-12-07 *A Little Christmas Pragmatism* (to W. G. Demopoulos, J. E. Sipe, & R. W. Spekkens)

For Christmas fun, I've been reading Edward C. Moore's book, *American Pragmatism: Peirce, James, and Dewey*. And I came across a passage on pages 35 and 36 that made me think of all three of you. Therefore, for a little more Christmas fun, it seemed worthwhile to type it into my computer. The result is attached.

As I perceive it, there is an affinity between this description of Peirce's form of realism and Bill's take on a quantum system as a "function." Though Bill seems to want to de-anthropocentrize (or de-agentize) the idea a little more than the pragmatist might. Anyway, it has been to the extent of this overlap that I have been endorsive of Bill's work (if I can coin a term). So, I'm not reporting anything particularly new here, I just liked Moore's articulation better than my own.

To put this passage in the context of my discussion with John, I would say: Part of the message here is that Peirce is analogous to a "consequence Bayesian" when it comes to percepts, whereas he is analogous to a "traditional Bayesian" when it comes to concepts. The two doctrines peacefully coexist for him, as I believe they peacefully coexist for me.

The Orientation Toward Pragmatism

> With the above statement of Peirce's realism as a background it is not difficult to see what he means by saying that pragmatism "could scarcely have entered a head that was not already convinced that there are real generals [['universals' in today's terminology, Chris]]" (5.503). Pragmatism is a method for defining general concepts (5.8). If one is a nominalist and believes that there is no such thing as "triangularity" anywhere—that triangularity is only a fiction—then there is no place that he can look to see what triangularity really is. But if he is a realist and believes that triangularity may be found in any triangle, then he knows how to define it; it may be defined as part of what one will experience when one examines a triangle.
>
> It is at this point that we must get a firm grasp on the elusive doctrine of immediate perception. Triangularity may be defined as a part of the experience of a triangle because "the percept is the reality" (5.568). "The experience of a triangle" and "a triangle" are epistemologically identical. Therefore, if we list all of the possible experiences one might have of a triangle, these experiences *are* the triangles.
>
> Now how would we go about it if we wanted to list these experiences? We could just state the bald list of experiences, but the list by itself might not suffice to enable the individual for whose benefit the definition is being made actually to obtain those precise experiences. To insure that he would have the proper experiences, perhaps the best approach would be to prescribe for him a certain action such that, if he accomplished it, he would then be confronted by the required experience. Such a prescription would be a plan or a guide for action. One who performed the prescribed action would have the requisite experience and would then know—by experience of it—the property being defined. Of course, such a plan for action would necessarily be complex, but if it is sufficiently detailed so as actually to give a perceptual acquaintance with the property being defined, then it would serve as a definition. Peirce gives an example of this procedure:
>
>> If you look into a textbook of chemistry for a definition of *lithium*, you may be told that it is that element whose atomic weight is 7 very nearly. But if the author has a more logical mind he will tell you that if you search among

> minerals that are vitreous, translucent, grey or white, very hard, brittle, and insoluble, for one which imparts a crimson tinge to an unluminous flame, this mineral being triturated with lime or witherite rats-bane, and then fused, can be partly dissolved in muriatic acid; and if this solution be evaporated, and the residue be extracted with sulphuric acid, and duly purified, it can be converted by ordinary methods into a chloride, which being obtained in the solid state, fused, and electrolyzed with half a dozen powerful cells, will yield a globule of a pinkish silvery metal that will float on gasolene; and the material of *that* is a specimen of lithium. The peculiarity of this definition—or rather this precept that is more serviceable than a definition—is that it tells you what the word lithium denotes by prescribing what you are to *do* in order to gain a perceptual acquaintance with the object of the word (2.330).

One might generalize this approach by holding that a concept may be defined by prescribing that: If you act in a certain manner, then you will have certain experiences, and the sum of the ideas resulting from these experiences constitutes the meaning of the concept being defined. The development of this thesis leads to Peirce's version of pragmatism.

Such a theory of meaning can only be accepted if one believes that concepts are real, that is, if he believes that the concepts have a real external counterpart. If he believes this, and wants to know where to look for this counterpart, then a pragmatic definition will give him a practical guide for actions that will result in an experience of the counterpart. But if he does not believe that concepts are real, then when he follows out the pragmatic definition he will not believe that what he experiences will be the external counterpart, or the referent of the concept, for he does not believe that the concept has a referent. In short, to accept pragmatism is to accept metaphysical realism with reference to concepts.

As Peirce says (1.27), the realist-nominalist controversy is a question to which only two answers are possible: yes or no. If one admits that concepts are general ideas [[i.e., universals again]] and then asks, is there anything in reality that stands in a one-to-one relation to the concept, an affirmative answer is only possible on a realist position; a negative answer relegates concepts to the realm of fictions. It follows from this that pragmatism could not be accepted by anyone who does not also accept metaphysical realism, and that the former could scarcely have entered the head of anyone who did not already understand the latter (5.503).

28-12-07 *A Little Christmas Pragmatism, 2* (to W. G. Demopoulos)

Demopoulosism 32: *I found the quote from Peirce very suggestive. I think Moore's commentary is not so good though. Perhaps he has elsewhere explained metaphysical realism, but it strikes me that one can understand what Peirce is saying without using that notion.*

Perhaps I was a little over-enthusiastic for the passage—it is true that I don't really know what one (and, say, Peirce in particular) means by metaphysical realism. Attached are three things I dug up in light of your points. 1) Moore's original article, from which the chapter I read yesterday appears to be only a minor modification (save for the stuff about Quine and Carnap). [Edward C. Moore, "The Scholastic Realism of C. S. Peirce," *Philosophy and Phenomenological Research* **12**, 406–417 (1952).] In it, he says a little of what he means by "metaphysical realism" with respect to Peirce.

2) An interesting rebuttal by Ralph Bastian. [Ralph J. Bastian, "The 'Scholastic' Realism of C. S. Peirce," *Philosophy and Phenomenological Research* **14**, 246–249 (1953).] 3) A review of Moore's book (with particular emphasis on the same passage as yesterday) by Richard Rorty. [Richard M. Rorty, *Ethics* **72**, 146–147 (1962).]

Demopoulosism 33: *I also think that you're right to see an affinity between Peirce's remarks on lithium and the idea of an effect. The atomic weight is an eternal property of lithium, but what Peirce emphasizes is not this but the way it interacts with things that may be taken to test for it. It is relevant but incidental to this account – the emphasis on effects – that we have knowledge of lithium by performing such tests. All of which is what I think you mean when you say I would de-agentize Peirce while still enjoying your endorsiveness.*

No, the issue isn't "knowledge" as a point of conflict between you and me (I, like you, do consider that incidental, though I would couch the issue in terms of 'belief' rather than 'knowledge' ... being a good follower of Richard Jeffrey), but rather that there is an agent behind the actions Peirce is speaking of. That is to say, you want to define "effect" without reference to one of my favored terms, "consequence for the agent."

In any case, thanks for keeping me honest! I'll comment on your earlier note to me on "certainty" once I return to the real world from holiday mode.

28-12-07 *Qbit* (to N. D. Mermin)

In case you haven't seen it yet, Scott Aaronson wrote a review of your quantum computing book on his blog: `http://www.scottaaronson.com/blog/?p=296`. I found it fun that he raised the standard complaint that I've now heard (probably) ten times over.

31-12-07 *A More Intelligent Model* (to J. B. Lentz & S. J. Lentz)

Here's the YouTube link to the commercial:

- `http://www.youtube.com/watch?v=saWCyZupO4U`

Here's the *Sydney Morning Herald* story:

- `http://www.smh.com.au/news/technology/professor-claims-ad-agency-cribs-lecture-notes/2007/10/03/1191091161163.html`

Here's Scott's original blog:

- `http://scottaaronson.com/blog/?p=277`

02-01-08 *Conference* (to A. Y. Khrennikov & J.-Å. Larsson)

I was just looking at the conference venue and noticed that Cabello is in your invited speaker list, along with Jan-Åke and myself. Thus the following idea came to mind. If there's interest, maybe one of the themes of the meeting could be a special focus on the import and implications of the Kochen-Specker theorem, and maybe the latest technical developments with it too. I also happen to know that Ingemar Bengtsson and Helena Granström are working on issues to do with the KS theorem themselves. So that's two more. If there's any room in the speaker list (and if you're interested in the idea), maybe some of the remaining speaking slots could be tilted in that direction. If you want any suggestions for other speakers in that regard, I could probably develop a few further ideas for speakers in that specialty. (You both know I'm always more than eager with ideas!)

03-01-08 *Jerusalem Probability Workshop December 2008* (to M. Hemmo)

I apologize for taking so long to get back to you. When your first note came I was deeply under the gun on many things and fell behind in my correspondence. But then when your second one came I had already moved into the Christmas vacation with my family. Anyway, I am here now, and I want to thank you for the invitation. It would be an honor to honor Itamar! So, yes, please do count me in. I haven't been to Israel in some years, and can already feel a visit may lead to great inspiration.

Please keep me up to date as the planning proceeds.

03-01-08 *20 Years* (to G. L. Comer)

Didn't we meet in Fall of '89?

Comerism 18: *So, what's this about there being no spacetime?*

You provoked this retort in me. "Yeah, there's only coordinate charts. Sometimes they can be stitched together, in which case we call it spacetime. Sometimes they can't, and then we call it quantum mechanics." I'm sure that's way off the mark in formulation, but there's a little of me that thinks there's a grain of truth in it.

04-01-08 *Screech!* (to G. Bacciagaluppi & H. Price)

Well, I had purchased the tickets!!! I apologize, I had completely spaced on the Feb 4 meeting! But at least I've emended things now. I changed my flight to leave on the same schedule but on Feb 5.

Bacciagaluppism 2: *Is that a live option?*

Now, you know I like that language. Very Jamesian of you Guido! I immediately thought back to beginning of James's essay "The Will to Believe":

> [L]et us call the decision between two hypotheses an *option*. Options may be of several kinds. They may be — 1, *living* or *dead*; 2, *forced* or *avoidable*; 3, *momentous* or *trivial*; and for our purposes we may call an option a *genuine* option when it is of the forced, living, and momentous kind.
>
> 1. A living option is one in which both hypotheses are live ones. If I say to you: "Be a theosophist or be a Mohammedian," it is probably a dead option, because for you neither hypothesis is likely to be alive. But if I say: "Be an agnostic or be a Christian," it is otherwise: trained as you are, each hypothesis makes some appeal, however small, to your belief.

About a year ago, Rüdiger Schack, Carl Caves, and I had a heated debate on whether a probability assignment of unity (i.e., certainty) could be made for a *dead* option (i.e., one that has already passed and thus couldn't have been otherwise than it actually was). I.e., whether talk of probability was even sensible in that situation. For Huw's potential entertainment, I'll paste an excerpt from my take on the issue below. [See 13-12-06 note titled "Offline Discussion" to R. Schack.]

Huw, by the way, I finally nabbed a copy of *Facts & the Function of Truth*. It looks like the presentation will be a little tough-going for me (my lacking the proper vocabulary at this point), but I'll try to get my head around it some nonetheless.

06-01-08 *21 Years Ago* (to H. J. Bernstein)

Finally, finally after all these years, I ran across a copy of the book you edited with Marcus Raskin, *New Ways of Knowing*. In it I read your article "Idols of Modern Science", and as always, felt much in tune with your way of thinking. And you were already thinking those things more than 21 years ago! It was a great article.

Accordingly, I've updated my long-in-the-making document *The Activating Observer* to reflect what I most liked in your article. You can see the result starting on page 9 of the attached (all lovingly typed in with my own two hands). In connection with those passages, you might also enjoy reading or re-reading Pauli's letter to Markus Fierz, dated 10 August 1954, starting on page 96. [See 02-01-06 note "The Oblique Pauli" to H. C. von Baeyer.] Pauli's words in that letter are very reminiscent of your own.

Thanks for stimulating my mind once again old friend.

Quotes from:

- H. J. Bernstein, "Idols of Modern Science and the Reconstruction of Knowledge," in *New Ways of Knowing: The Sciences, Society, and Reconstructive Knowledge*, edited by M. G. Raskin and H. J. Bernstein, (Rowman & Littlefield, Totowa, NJ, 1987), pp. 37–68.

> In their quest to extract consistency from nature, scientists relentlessly pursue very particular and specialized knowledge.

and

> As a physicist, I began this essay with critical self-examination of science as a particular form of organized human behavior. In this light, one aspect stands preeminent. The scientific study of the world upholds experience as the final arbiter of knowledge. Not any experience, but only the specially controlled and preconditioned experience of experiment. Science entails as much creativity, originality, and as many "free inventions of the human spirit" as other intellectual activities (like art, poetry, philosophy, or social studies), but always inventions which can be checked against the experience of nature; not direct, emotional experience like smelling a rose or hiking to exhaustion in the High Sierras or "psyching out" the answer by intuition, but rather as stylized, conventionalized and, indeed, bizarre behavior which traps nature and emphasizes its regularity. Think of the most ordinary scientific operation, such as finding the length of this page with a ruler. You use an instrument of great complexity, with a straight edge supplied by a brass strip held in the fine groove of a specially stamped and printed piece of wood, calibrated against an arbitrary standard. For more detailed knowledge

of the world, science obviously goes beyond the simple rule, but note how value-laden even that device is: could any but an industrialized and commercialized society provide so many millions of brass and wooden copies of a central arbitrary definition of length, or the training and attitudes needed to use it correctly?

and

Physics shows as much variety and method as any science. Indeed, the first attack on a new problem is to try all the tricks that previously worked; conversely, every new trick is quickly applied to all the currently interesting problems if it succeeds on any one of them. There are always new techniques and new approaches being invented. But some form of mathematics always appears, so we might attempt to deduce a general method from this fact. At least one eminent theoretical physicist, Eugene Wigner, has marveled at the "unreasonable effectiveness" of mathematics very extensively, and that mathematical elegance and newly created mathematics are often guides to new physical theories. It is as if Nature herself were secretly, somehow, mathematical ... and man's creation of mathematics mimics nature's creation of phenomena.

But from the present point of view, it is rather bizarre behavior of experiment which projects consistency onto nature. We are, in effect, making phenomena appear rational for our own intellectual and emotional pleasure. Current scientific data are the result of manipulations of natural objects with the specifically numerical outcome of measurement. While doing scientific experiments we do not assemble those rare substances and produce those unusual conditions in order to "groove on the vibrations." Men's and women's minds invent facts of science through their intellectualized, and mathematized, perceptions of phenomena. It is not at all surprising that the highly similar invention of mathematics—with its emotional, nonrational, and unconscious motivation, its own search for consistency as opposed to Truth, and its insistence on producing a rational outcome—has great power and relevance in science. Out of the vast range our minds possess, mathematics and science seem to have tapped the self-same mode.

Asking why the world turns out to be so mathematical is almost like wondering how vegetables come to be so well-suited to feeding animals. Nature's construction of all the organic forms (we now know) is of a piece; of all the various ways to combine elements of earth, only certain carbon-based molecules, controlled by extraordinarily similar genetic codes, form the compounds of all life. Compatibility is no mystery. What sunlight streaming through the biosphere has done for animals and plants, nonrational inspirations flowing into the human mind have done for science and mathematics. What seems most marvelous in this is the "unreasonable effectiveness" of emotions in producing rationality both in mathematics and in physics.

and

To Einstein, the good of physics resided precisely in its objective ability to comprehend reality, not to manipulate it. Only contemplative rationality could serve the morally commendable goal of pure knowledge. In the light of Forman's analysis, Einstein's choice was to reject the standard science, with its hidden acceptance of political pressure, in favor of older values of objective realism. He would not have put it this way; he did not identify the Copenhagen (acausal) interpretation with world politics, but simply with an epistemological error in science itself—namely, confusing study of what we know with a study of what actually is. But most physicists could conveniently relegate such issues to philosophy. They substituted their own construction, knowledge of the universe, in the place of the real world itself as object of investigation *without* taking full responsibility for the power of making real that which they would choose to know. The quantum physicists hoped to banish unverifiable analogies and fictions. But moral visions are also fictions, images, and analogies. In bypassing them (as in ignoring the question of *what* to make real) they excluded this whole realm of thought. Without addressing any moral implications, they took quantum mechanics and its interpretation as the very definition of disciplinary excellence.

The consequent events were extraordinary. Quick to apply the "best" new theories to nuclear puzzles (once they solved those of atomic electrons), physicist hurtled us willy-nilly into a new age, fraught with powerful new dangers. In 1928, barely two years after Born invented the statistical interpretation, Gamow applied quantum mechanics to nuclear physics; in fact, his data on alpha decay happened to start from Uranium-238. In the thirties, experimentalists discovered fission, presaging nuclear energy; the Manhattan Project, triggered by a letter from Einstein to Roosevelt, eventually made World War II our first nuclear war.

and

In the case of quantum mechanics, the defining shift from "it explains" of classical physics to "it works" inspired a different sort of debate. For many years Einstein argued that quantum mechanics was physically incomplete, that there were elements of physical reality which it could not represent. Bohr argued that only the actual results of experiments could be considered real—and these results all obey the probabilities given by quantum mechanics. Both Bohr and Einstein realized that physics had discovered a limit to its own knowledge of reality. Neither of them realized that this limit posed questions of moral dimensions: not whether we were slipping from an old morality of objective (and omniscient) knowledge but new questions, questions about knowledge that works: "Works for what?" "For whom?" "Knowledge to what end?"

All of these questions arise because the quantum revolution entailed not merely abandoning a priori definitions of reality (upon which Einstein seemed to insist) but adopting a new direction of gaze as well—one which is self-reflexive of the fact that it involves a choice. Jauch compares the phenomena of nature to random messages, waiting to be deciphered by scientists:

> But since the code is not absolute, there may be several messages in the same raw material of the data, so changing the code will result in a message of equally deep significance in something that was merely noise before and *conversely*: In a new code a former message may be devoid of meaning. Thus a code presupposes a free choice among different, complementary aspects, each of which has equal claim to *reality*, if I may use this dubious word.

That physics has found itself selecting a reality may seem striking. For our archeological approach, however, the cross-linkage of parallel developments in several fields is even more important. We might even say the analysis could only be correct if the realization that we create reality were reached simultaneously in many aspects of modern culture.

and

> Consider again quantum mechanics, where the problems of measurement theory remain unresolved after more than fifty years: How much does the experimenter control reality? What attributes of the experimenter are relevant for the exercise of this control? How different would physics be if *more* of the experimenter were allowed into the science, if more of the motivation and social connections were considered part of the experiment itself? These are some of the questions that can now be posed within the discipline of physics.

07-01-08 *What You've Written* (to B. C. van Fraassen)

Could you send me all that you've written so far on relational quantum mechanics, à la Rovelli etc.? The title of my talk at the PIAF meeting in Sydney is "Relational Quantum Mechanics, Jamesian Pragmatism, Pricean Pragmatism, and What I Want from This Collaboration," and I want to use the better part of the time to give a survey of the first proper noun in that.

Please send me everything you have!

Bas's Reply

> I really have only the paper I gave at the conference, it was the end of an evolution involving two mss. and a day with Carlo and others in France last year, but I have improved it a bit more since the conference, and attach the version that is to appear in Foundations of Physics.
>
> But fyi I am attaching the paper by Groenewold that I think presages Rovelli's — as I think is visible as soon as we compare the equations — amazingly early for a discussion of information theory in this context!!

08-01-08 *What You've Written, 2* (to B. C. van Fraassen)

Thanks. I've printed them out now. You might be interested in Nancy Cartwright's '72 opinion of Groenewold. I'll attach the pdf. [See N. Cartwright, "Review of *Quantum Theory and Beyond* by Ted Bastin," Phil. Sci. **39**, 558–560 (1972).]

08-01-08 *Many Worlds Note* (to B. C. van Fraassen)

Whatever happened of this note from 2006?

van Fraassenism 12 : *I read a couple of student papers about recent work on many worlds interpretations, and talking with them and others I kept thinking about just what the appeal could be. Late one night I wrote up the worry, it's just two pages — what do you think?*

Did you modify it, publish it, get any devastating feedback on it?

Let me bring this paper by Alex Wilce to your attention. Attached. [See A. Wilce, "Formalism and Interpretation in Quantum Theory,"] The discussion on page 3, I think, captures the crucial issue for me:

> Thus, we have two problems, somewhat in tension with one another. If we view quantum mechanics as a linear dynamical theory, in which physical states are wave

functions, evolving according to the Schrödinger equation, then the theory's analytical apparatus is not especially problematic (Hilbert spaces were, after all, *invented* to describe just this sort of thing); but its probabilistic content seems mysterious and *ad hoc*. If, on the other hand, we accept the theory's minimal probabilistic interpretation as unproblematic, then it is the theory's formal apparatus that seems mysterious and *ad hoc*.

For purposes of this paper, I'll refer to the former problem as the *problem of interpretation*, and to the latter problem as the *problem of the formalism.* Both have proved remarkably refractory, withstanding decades of sustained, and often brilliant, effort by physicists, mathematicians, and philosophers of science, and, in the process, generating substantial technical literatures. It is quite remarkable, therefore, that these two obviously related problems have been pursued somewhat in isolation from one another. Superficially, perhaps, this is understandable, as each problem begins where the other wishes to end; nevertheless, when a tunnel is being dug through a mountain, it is usual for those working from opposite sides to coordinate their efforts.

In this paper, I want to urge that each project has something to contribute to the other. It has become increasingly clear in recent years that many of the most puzzling "quantum" phenomena—in particular, phenomena associated with entanglement, and including, as I'll show, a version of the measurement problem—are in fact quite generic features of essentially all non-classical probabilistic theories, quantum or otherwise. This suggests that many of the interpretive ideas that have been advanced in connection with quantum mechanics can be carried over to a much more general setting. This exercise has something to offer to both foundational projects. On the one hand, an interpretation of quantum mechanics that can't be made sense of absent certain special structural features of quantum mechanics, is potentially a source of fruitful ideas with which to approach the problem of the formalism. On the other hand, if an interpretation can be kept aloft even in the thin atmosphere of a completely general non-classical probabilistic theory, then perhaps it has little to tell us about the physical content of quantum theory. To compress this idea into a slogan: a completely satisfactory interpretation of a physical theory should be capable of yielding (or at least, constraining!) its own formalism.

Namely, despite all the posturing of the Everettians, the pages and pages of elaborated formalism, I simply see *nothing* uniquely implied by quantum mechanics in the ontology they offer us. Quantum mechanics makes the view no more compelling than it was 101 years ago, when William James wrote:

> [I]f you are the lovers of facts I have supposed you to be, you find the trail of the serpent of rationalism, of intellectualism, over everything that lies on that side of the line. You escape indeed the materialism that goes with the reigning empiricism; but you pay for your escape by losing contact with the concrete parts of life. The more absolutistic philosophers dwell on so high a level of abstraction that they never even try to come down. The absolute mind which they offer us, the mind that makes our universe by thinking it, might, for aught they show us to the contrary, have made any one of a million other universes just as well as this. You can deduce no single actual particular from the notion of it. It is compatible with any state of things whatever being true here below. And the theistic God is almost as sterile a principle. You have to go to the world which he has created to get any inkling of his actual character: he is the kind of god that has once for all made that kind of a world. The God of the theistic writers lives on as purely abstract heights as does the Absolute. Absolutism

has a certain sweep and dash about it, while the usual theism is more insipid, but both are equally remote and vacuous.

I.e., I'm willing to call Many Worlds little more than a modern species of the genus.

09-01-08 *Wednesday, just before Toronto* (to D. M. Appleby)

I haven't said hi in a while either. Some people rise to the holidays; myself I was buried by them. I'm only now working my way back out. I drop the in-laws off at the Toronto airport this afternoon.

It's great to hear that you are ploughing on in $d = 5$. Myself I spent a little bit of the holidays working on $d = 6$ finally. I got three independent eigenvectors out of your happy unitary and started to work out the equations for the fiducials. Two levels of elimination finally gave me some linear relations between the coefficients, but I haven't gotten a chance to finish that up yet. I want to get that before Wednesday, because I have to give the colloquium here, and I want to close with Steve's "constructible number" hypothesis if it's true. One thing's for sure, though, the Grassl "solution" (quotes because I only presently trust the 3rd and 6th components of it) is definitely not an eigenvector of happy unitary. It had been my hope that it would be, and that that would help me eliminate a couple of equations on its own.

The title and abstract for the colloquium are below. I'm also giving it in Bristol the following week. One thing I wanted to ask you. Would you mind if I advertise your tomographic result showing that SICs are sometimes optimal there? You never did publish that, did you? If you don't mind my saying something, could you send me a precise statement of the theorem?

I'm glad to hear there's a small number of parameters in the triple products of $d = 5$. There's no chance that the parameters can be adjusted so that *all* triple products (of distinct projectors) have the same real part, is there? How I would love that to always be the case! In $d = 3$, looking at your old notebook though, it looks like "all but nine" is the best one can do. So this leads to another question that perhaps can be explored in $d = 5$. Might it possible to make all but 25 have the same value (the real parts that is), and the remaining 25 have all the same of another value?

In general, one can ask can any useful bound be put on the maximal number of Re(triple products) all obtaining the same value? What does that tell us about the shape of Hilbert space?

09-01-08 *Pragmatism at the Perimeter* (to L. Smolin)

Well, the Waterloo Library of Pragmatism is finally open for business! Look at these beautiful solid-oak bookshelves I had built in my house! Sadly, I've only now ordered Unger's book for it, but I *have* ordered it, and I pick it up in Toronto today after dropping my in-laws at the airport. I'll come to your seminar tonight—but to warn you—I might be a little late.

Going back to the theme of the library, I'd like to discuss a couple of things with you when you get a chance. What I'd really like to get straight in my mind is how to ultimately shake off any last vestige of a "block-universe" conception in (the next) physical theory. You know that I think pragmatism has its heart in the right place, but it doesn't have the technical brawn; on the other hand, I feel strongly that quantum mechanics shows some of the technique, but it's only a first hint of the direction we need to go.

Thus, I have wondered whether:

1. You might have any interest in a little semi-periodic discussion session on the confluence of subjects, with emphasis on the pragmatism side of things? It might consist of us two,

probably John Sipe and Philip Goyal, maybe a couple of others. Maybe Appleby when he's visiting, etc. I haven't thought about the format too much yet, but if you have some interest, maybe we could talk about this.

2. Might it be interesting to have a small meeting at PI this year on the subject? The title I've played with in my head is "Pragmatism at the Perimeter." I'm not sure who I'd invite, but Ian Hacking and Cheryl Misak from U. Toronto phil. dept, Unger, Michel Bitbol, Chris Timpson, Rüdiger Schack, Marcus Appleby, and Huw Price come to mind pretty quickly. And you probably have some ideas too. Would you be interested in co-organizing something along these lines with me?

Those are the questions. As I say, as you get a chance, I'd like to talk about these things some more.

10-01-08 *Philosophy Books To Get Rid Of* (to W. G. Demopoulos)

Do you have any interest in having any of these books?

1. Harald Høffding, *A History of Modern Philosophy*, Vol. 2, paperback, Dover.

2. Donald W. Sherburne, *A Key to Whitehead's Process and Reality*, paperback, Indiana University Press, 1966.

3. John Dewey, *The Philosophy of John Dewey: The Structure of Experience*, edited with intro and commentary by John J. McDermott, paperback, G. P. Putnam, 1973.

4. John Dewey, *The Philosophy of John Dewey: The Lived Experience*, edited with intro and commentary by John J. McDermott, paperback, G. P. Putnam, 1973.

I had double copies in my library. If you want any, I'll reserve the ones until I see you again. Otherwise they'll be taken to The Old Goat for 50 cents credit or so. (They're all in good shape, it's just I know I won't get anything for them.)

Høffding, in case the name doesn't ring a bell, had been Bohr's philosophy mentor in Copenhagen. Some historians make a big to-do about his influence on Bohr.

11-01-08 *Tomorrow? Sunday?* (to S. T. Flammia)

Are you going to be in at PI tomorrow or Sunday? I think I've got a good method for bounding the max number of identical triangle areas. A little cubing of the identity, a little combinatorics, a little Schwarz inequality (or maybe arithmetic-geometric mean inequality), and poof! Or so it seems. Anyway, it'd be nice to talk it through with someone. Unfortunately, I've got a social engagement this evening, and then housework preparing for Emma's party tomorrow, but sometime in the afternoon I'll become free.

15-01-08 *Brain Pulp: Quotes on Planck* (to M. A. Nielsen)

> Planck traced the discovery of his vocation to the teaching of an instructor at the gymnasium, Hermann Muller, who awakened an interest, which became a passion, to 'investigate the harmony that reigns between the strictness of mathematics and the

multitude of natural laws.' In 1878, at the age of twenty, Planck chose thermodynamics as the subject of his doctoral dissertation, which he wrote in four months. He recalled that his professor at the University of Munich, Philipp von Jolly, had counselled against a career in physics on the ground that the discovery of the principles of thermodynamics had completed the structure of theoretical physics. That had not dissuaded Planck, who had his compulsion and also an objective far removed from the principal ambition of today's physicists. He had no wish to make discoveries, he told Jolly, but only to understand and perhaps to deepen the foundations already set. — J. L. Heilbron

Many kinds of men devote themselves to Science, and not all for the sake of Science herself. There are some who come into her temple because it offers them the opportunity to display their particular talents. To this class of men science is a kind of sport in the practice of which they exult, just as an athlete exults in the exercise of his muscular prowess. There is another class of men who come into the temple to make an offering of their brain pulp in the hope of securing a profitable return. These men are scientists only by the chance of some circumstance which offered itself when making a choice of career. If the attending circumstance had been different they might have become politicians or captains of business. Should an angel of God descend and drive from the Temple of Science all those who belong to the categories I have mentioned, I fear the temple would be nearly emptied. But a few worshippers would still remain—some from former times and some from ours. To these latter belongs our Planck. And that is why we love him. — A. Einstein

15-01-08 *What I Think I Mean by Pluralism and Indeterminism* (to L. Hardy)

It's the idea of a joint-stock society, rather than a universe. Quotes below. [See 27-09-07 note titled "The Joint-Stock Society" to H. R. Brown.] Don't forget to forward to Nielsen.

15-01-08 *Potentest of Premises* (to L. Hardy)

I never did send you that note on the potentest of my premises, did I? The note I just sent you on the joint-stock society conception of nature reminded me of that. [See 15-01-08 note titled "What I Think I Mean by Pluralism and Indeterminism" to L. Hardy.] Anyway the short of an answer to you is below. [See 17-06-04 note to H. Mabuchi titled "Preamble."] It is that, the key physical element of quantum theory—that is, that in our interactions with the world there is creation—must ultimately be distilled, and then, to it, added a Copernican principle that there is nothing particularly special about us, other than our perspectives. We have evidence of the creation because we partake in it, but we cannot be the whole story. I can't think of a more exciting and more positive conception of nature than that it always, everywhere, and without exception, creates.

20-01-08 *Q&Q* (to T. Slee)

Thanks for the compliments, but I'm not fooling myself: I thought the radio show came out pretty boring honestly. I hope the Rogers Cable version worked better, with its 40 minutes of more material and untrimmed explanations. Also the visuals should have helped on some jokes.

Slee-ism 1: *I think I'd like to try reading some of your papers at some point and see if I can understand what you are on about if that's possible. I didn't quite see how the "quantum mechanics describes the information in a system" rather than "quantum mechanics describes a system" is more than a linguistic sidestep, but I know there's physics behind what you do and if there is something accessible I'd be interesting in reading it.*

Well, I wouldn't use the phrase "QM describes the information in a system." I only make (louder and, I hope, more consistent) the old time-honored observation of Einstein: That a quantum state cannot be a property inherent in a system—owned by it and it alone—but rather must be something else, of the flavor of one's information. Else QM would imply action-at-a-distance and a load of other conceptual difficulties (Wigner's friends and so on). The research program I push, and which I think has had decent success, is to build up the structure of quantum mechanics from that idea alone, along with an adequate answer to the deeper question, "Information about what?"

I'd be flattered if you'd read a paper of mine or two. Let me give this one as maybe the best starting point:

`http://xxx.lanl.gov/abs/quant-ph/0205039`.

For a study in the sociology of my developing views, you might have some fun with

`http://xxx.lanl.gov/abs/quant-ph/0105039`.

Particularly the correspondence with Mermin and Peres, might be useful. And finally further fun can be found (if you like Sudoku) in this paper by Rob Spekkens:

`http://xxx.lanl.gov/abs/quant-ph/0401052`.

He doesn't reconstruct quantum mechanics by any means, but he does demonstrate that many of the phenomena touted in quantum information studies are simply generic to the idea of information (a better word would be "simple uncertainty for whatever the reason"). As Rob puts it in his abstract, "The diversity and quality of these analogies is taken as evidence for the view that quantum states are states of incomplete knowledge rather than states of reality." The only place where Rob and I differ is that he would ultimately like to revert back to hidden variables in his hoped for reconstruction of QM, whereas I argue vigorously that it's time to move on. Reality is trying to tell us something really interesting with quantum phenomena—something far more interesting than hidden variables—and we should listen.

21-01-08 *Value Added!* (to H. C. von Baeyer)

If you do indeed arrive on March 24, it'll be a great day for alchemical ideas in QM! It looks like Marcus Appleby—one of my two toppermost intellectual soulmates at the moment—will be arriving the very same day. Marcus also has a deep interest in Pauli, Jung, Fierz, alchemy, ... and SIC-POVMs! So, we'll have a wonderful time, I'm sure.

21-01-08 *Potential Topic of Discussion* (to R. Schack)

I'll let you know Thursday or so when I plan to arrive in Egham. In the mean time let me send you this little drunken thing I just wrote up (a consequence of my disappointment with Kiki's $8,000 counters in the kitchen). If you've got nothing on the agenda for us to talk about when

I visit, then maybe this is a worthy subject. The point is, I think I'm homing in better on the idea that the Born rule is "an addition to coherence," in contrast to the usual idea that "it is a probability setting rule."

Looking very much forward to seeing you!

Hidden Assumption in Coherence Arguments?
(21 January 2008)

Suppose there is an agent who believes that if he takes a certain action it will result in one of n consequences for him, and he deems the probabilities of those consequences $p(i)$. The $p(i)$, of course, are all nonnegative and $\sum p(i) = 1$, as demanded by coherence.

Alternatively, consider some *other* action that the agent might perform with consequences j (drawn from a potentially different number m of consequences). Furthermore suppose the agent has a firm set of beliefs for which consequence j he would find if he had first found i in the other action previously considered. That is, suppose the agent has a family of probability distributions $p(j|i)$ that he feels are acceptable degrees of belief. To say it again, $p(j|i)$ is the probability of consequence j for the second action, supposing the agent finds consequence i for the first.

Question: Given all that was described above, does coherence make any requirements on the agent's unconditioned probability assignment for j? That is, can we infer what the agent ought to assign for $p(j)$ straight out from the $p(i)$ and the $p(j|i)$? If we had dropped the language of "actions" and "consequences," and substituted "observed" and "found," I think most people familiar with Bayesianism would say we could: If i were some "event" in the usual language, with probability $p(i)$, and $p(j|i)$ were the probability of another event j, given knowledge of i, then

$$p(j) = \sum_i p(i)p(j|i) \tag{80}$$

would be the assignment demanded by coherence for j itself.

But consider i the outcome of some SIC-POVM measurement, and let j denote the outcomes of some *other* SIC-POVM. Then one might well be in possession of $p(i)$ and $p(j|i)$, without anything initially further. If so, what should one assign for $p(j)$? That depends. If one really is making the measurement of i intermediately (but somehow not becoming aware of the outcome), then one should assign a $p(j)$ as in Eq. (80) above. But suppose one has all the information above and goes straight for the jugular—i.e., one wants to calculate the probability of a j result, knowing full well that one is not going to perform the intermediate measurement of i. Then quantum mechanics still gives a means for calculating the $p(j)$, but it is an interesting modification of the above. That one will make the intermediate measurement or not actually makes a difference for how one should calculate one's ultimate probabilities! Also—and this is *quite* surprising—it makes a difference in a very controlled way. Taking the $p(i)$ and the $p(j|i)$, one just modifies the formula above to

$$p(j) = (d+1)\left(\sum_i p(i)p(j|i)\right) - \frac{1}{d}\,, \tag{81}$$

where d is the dimensionality of the Hilbert space. That is, the probability one *should* assign is given by the one would imagine as coming about by a normal coherence argument $p'(j)$, but then "stretching" it according to $(d+1)p'(j) - \frac{1}{d}$. It is as if quantum mechanics gives a *reward* for not actually performing the first measurement i. One can take advantage of the conceptual device of using the $p(j|i)$ for calculating and ultimate $p(j)$, but one is rewarded in comparison to the classical standard if one does not bother to actually take the action to collect a value for i. I mean by "reward" that one is allowed more certainty generally for one's answer than would be expected classically.

All of this makes me wonder if there is a hidden assumption of "reality" in the standard Dutch book argument based on conditional bets that I had not previously appreciated. I don't have an answer, but that's the sort of thing I'd like to discuss in my brief time in Egham.

In contrast, suppose the measurement of j was of the character of a von Neumann measurement consisting of rank-1 projection operators (while i still denotes the outcome of a SIC-POVM). Then the modification to standard coherence would be

$$p(j) = (d+1)\left(\sum_i p(i)p(j|i)\right) - 1\,, \tag{82}$$

Again, this is a deviation from the classical formula, but in a controlled way.

Why such simple modifications to coherence!?!? Why does QM reward us for *not* performing the intermediate actions we so freely imagine for use in our calculations?

Wilder idea: Is this the source of the power of quantum computation? That we have more certainty about the consequences of our actions than a classically honed intuition expects we ought to have?

21-01-08 *Talk and Diverse* (to P. G. L. Mana)

As long as you send me your abstract two weeks in advance of your talk, it will be enough time for me. What are the precise dates you'll be visiting?

Manalogue 13: *I am studying Schrödinger's equation and its 'second quantized' form in this period. There are some nice results which can be easily derived from Holevo's convex framework (we soon need to find an appropriate name for this framework, since 'convex', 'vector', or 'r-p' are misinformative or uninformative names).*

First, it can be shown that any physical ('ontic') theory behind the wave function cannot be founded on particle-like entities only, but needs field-like entities as well. More precisely, the physical objects behind the wave function must have a continuum of degrees of freedom, hence cannot be just particles. I know of Beltrametti and Bugajski's extension (which is a special case of a theorem by Holevo from the '80s), but the above is really a mathematical proof. Which is also interesting, because what is proven is partly 'metaphysical'!

This sounds similar to Lucien's "excess ontic baggage" result. He never posted the paper on the archive. If you haven't heard of it before, you might ask him for a copy of the paper.

We will have many things to talk about during your visit. Unfortunately, I can have no extra mind now, as I am preparing to give a PhD exam in England this week, then I come home for one day before departing for the Sydney meeting, where I will talk on "Relational QM, Jamesian Pragmatism, and Pricean Pragmatism." Particularly, wish me luck for the latter!

23-01-08 *In Town* (to R. Jozsa)

I should let you know I'm in town. I just had one of those kinds of sleeps that one can only have in a foreign hotel in an upside-down time zone after a sleepless flight. They're the best sleeps of the year! Now I think I'll slowly wake up, get a shower, and wander out for some food. I've still got a lot of reading to do in the thesis, so most of the rest of my day ought to be taken up with that. Did you have any particular plans for me that I should be aware of, though? Or should I just plan to be a free agent today?

23-01-08 *Old Books* (to R. Jozsa)

While I'm thinking about it, I don't want to forget: Are there any used or antiquarian book stores within walking distance of the hotel? I'd particularly appreciate ones with good philosophy sections. Maybe I'll tool around there while you're busy tomorrow morning. There's a running joke at PI, that Daniel Gottesman won't read anything that's not published electronically, and I won't read anything that's not at least a hundred years old.

24-01-08 *Counter-Bayesians!* (to J. A. Smolin)

You've got to have a look at this article:

> "When Several Bayesians Agree That There Will Be No Reasoning to a Foregone Conclusion," by Joseph B. Kadane, Mark J. Schervish, Teddy Seidenfeld, *Philosophy of Science*, Vol. 63, No. 3, Supplement. *Proceedings of the 1996 Biennial Meetings of the Philosophy of Science Association*. Part I: Contributed Papers (Sep., 1996), pp. S281–S289.
>
> **Abstract:** When can a Bayesian investigator select an hypothesis H and design an experiment (or a sequence of experiments) to make certain that, given the experimental outcome(s), the posterior probability of H will be lower than its prior probability? We report an elementary result which establishes sufficient conditions under which this reasoning to a foregone conclusion cannot occur. Through an example, we discuss how this result extends to the perspective of an onlooker who agrees with the investigator about the statistical model for the data but who holds a different prior probability for the statistical parameters of that model. We consider, specifically, one-sided and two-sided statistical hypotheses involving i.i.d. Normal data with conjugate priors. In a concluding section, using an "improper" prior, we illustrate how the preceding results depend upon the assumption that probability is countably additive.

24-01-08 *Bohm-Biederman Correspondence* (to R. Jozsa)

The name of the artist was Charles Biederman. Here's the Amazon.com link:

`http://www.amazon.com/Bohm-Biederman-Correspondence-Vol-Creativity-Science/dp/0415162254`.

25-01-08 *Bristol, 3 AM* (to D. Gottesman)

The other day, after talking to you about how the usual Bayesian "law of total probability" gets modified in the context of quantum measurements when one uses a SIC representation of it all, I wrote this little bit of poetry in my notebook:

> WILD SPECULATION: This little reward for a physical step not taken is ultimately responsible for the power of quantum computation.

What it's referring to is this. Suppose $p(i)$ gives a quantum state in a SIC representation, i.e., it is the probability for getting outcome i for some imagined SIC measurement. Now consider an arbitrary PVM measurement consisting of rank-1 projection operators, labeled by j—this is the measurement that one is *actually* going to perform. Finally consider the probability for an outcome j that one would write down if one *imagines* first measuring the SIC and finding i; I'll write that as $r(j|i)$. I emphasize "imagines" because one is not really only going to do the i measurement; we're just going to use these numbers as conceptual pieces in deriving a number $q(j)$ representing the probability for the outcomes of the j measurement that we're actually going to perform. Putting it all together, the answer turns out to be

$$q(j) = (d+1)\left(\sum_i p(i)r(j|i)\right) - 1,$$

where d is the dimension of the Hilbert space. That is to say, one can calculate $q(j)$ by an ever slight change of the law of total probability. Slight change mathematically, but big change conceptually. For the upshot of the transformation $x \to (d+1)x - 1$ is that it spits out a probability distribution that is a little more pure (a little less mixed) than one would have imagined classically. That's the reward I was talking about.

Anyway, I'm writing all this down mostly because I feel like writing something down at this funny hour. But I've also been rereading the Steane paper that I had told you about. It is: `http://xxx.lanl.gov/abs/quant-ph/0003084`. I find that I had pretty severely misquoted it when talking to you. I'd be curious to get your reaction to the real thing, if you feel like reading it.

25-01-08 *Morning Report* (to J. E. Sipe)

Well, I'm up to page 148 in Morris's book now. [Charles Morris, *The Pragmatic Movement in American Philosophy*.] My opinion seems to be different than what I thought you expressed last week: I think it's mostly a throw-away book; pretty worthless really. It is hardly "the clearest explanation of American pragmatism ever written" that the attached review claims it to be!!! [See R. Ginsberg, "Review of *The Pragmatic Movement in American Philosophy* by Charles Morris," *Annals of the American Academy of Political and Social Science* **396**, 184–185 (1971).] Still, at least I did get a little thought out of pages 128–136 on Mead's cosmology, which I hadn't appreciated before as having some similarity to James's "joint-stock society" conception of nature. To the extent that I understand it, I like it.

I've been thinking, maybe a much more relevant thing for us to tackle would be to jointly read, H. S. Thayer's massive history of pragmatism and its roots, *Meaning and Action*. I have it on my shelf at home and have read bits throughout, though not a complete linear reading yet. I think it is excellent and much more worthy than the present junk.

28-01-08 *Thinking about Unitarity* (to K. Wiesner)

I looked at some of your papers with Crutchfield over the weekend. I see why you might be interested in the things we talked about at dinner the other night. We should have you come by PI to give us a talk sometime, maybe next Fall if you've got the time.

Let me point out the two papers of my own that might be most relevant for further thinking about the stuff we discussed the other day. I'd say, this:

`http://xxx.lanl.gov/abs/quant-ph/0205039`

and this

`http://xxx.lanl.gov/abs/0707.2071`.

After meeting with Schack right after Bristol, I'm even more hopeful that the representation of unitarity I showed you will help unlock some doors in thought.

In all, good meeting you!

29-01-08 *Knowing Me, Knowing Huw* (to H. Price)

… God, that's a bad ABBA pun, and you must have already heard it hundreds of times in your life … but given my excitement, it's the best I can do! (Ouch, I did it again.) No need to send me more reading for my flight, I've already got plenty of it, and it's all by Huw Price!

Seriously, I am very excited since reading your "Naturalism without Mirrors" on my flight back from Bristol the other day, and I've got about 10 more of your papers printed to read (and reread). At least at this stage, I couldn't find a single thing in the said article that I didn't like. I was very, very impressed: You are an amazingly clear thinker, and I am sorry I had not appreciated your depth of thought before. I knew that I was attracted to some of your ideas previously, but I think my mind wasn't quite prepared the last time I was looking at your stuff (on naturalism and truth).

Particularly I'm excited by this: I now think you far outstrip me in clarifying what it is *I* really want out of quantum mechanics. It was probably captured best by this passage:

> Very crudely put — ignoring, for example, all the obvious grounds for holism — the explanatory project goes something like this. We find our speakers disposed to say "P" (i.e., 'P' appears in the list of statements on the left of the model). We now ask, "Why do they say that?"; and in general (without pretending that this distinction is sharp) we look for an explanation that refers both to features of the speakers, and to features of their natural environment. Note that in our own case, this attitude always looks sideways on, or ironic. We say that P, and then wonder why we said so, how we came to be making a claim of that kind — looking for something deeper as an answer, of course, than merely "Because we realised that P". (This is the kind of irony characteristic of practitioners of the human sciences, of course, who cannot help but view themselves as examples their own objects of enquiry.)

For I would say what I have been on about the last few years, is thinking of the interpretational issues of QM as a *laboratory* for this very kind of thought:

> Very crudely put, the explanatory project goes something like this. We find our agents disposed to accept the structural features of quantum mechanics into their catalogue of probability assignments. We now ask, "Why do they say that?"; and in general (without pretending that this distinction is sharp) we look for an explanation that refers both to features of the speakers, and to features of their natural environment.

So, indeed, I'm really looking forward to fleshing out some serious ideas with you in this collaboration. It's a much more specific project than the one you have in mind, but I think it'll be a very instructive laboratory, and maybe you would get something out of my prods.

Anyway, that paper went down fairly easily for me (probably because it was only an introduction, rather than a technical article), and was enough to hook me. I've since reread "Naturalism without Representationalism" and again come away with the feeling that I am indeed a subject naturalist. But there I understood your arguments far less well. You will have to walk me through some. At the moment, I'm on the paper with Quasi-Realism in the title, which you co-authored with someone. I hope to have two or three more papers read by the time we see each other in Sydney.

29-01-08 *Wittgenstein, Etc.* (to R. Jozsa)

Jozsa-ism 3: *It was certainly a pleasure to catch up last week and I hope you had a good trip back!*

I just wanted to send you a link to the must-read book I mentioned about Wittgenstein/Popper (titled "Wittgenstein's Poker"): [...] (the American edition appears to have a really ghastly poker picture on the cover! ... unlike the UK edition). Also the recent Beatles compilation CD I mentioned (titled "Love" put together by George Martin), most recommendable.

So, hope you like these, and look fwd to maybe seing you again in Waterloo sometime this year.

Thanks for that—I'll certainly be getting both. It was good seeing you too. I'm on my way to Australia now; very busy week!

I enjoyed talking with your student Ashley too. But watch out, the guy has Everettian tendencies. (He said it's his favorite interpretation.) Remember it's part of your duty as his mentor to disillusion him of that! Be sure to give him a complete education!

31-01-08 *Tracking Last Night* (to H. Price)

It dawned on me that the part of last night's discussion centering on whether there might be two possible threads to follow when focussing your 'naturalism without mirrors' project onto quantum mechanics ... It dawned on me that that issue tracks pretty well with Chris Timpson's discussion on pages 26–28 of the attached paper [C. G. Timpson, "Quantum Bayesianism: A Study"], where he discusses potential ontologies that might underly the quantum Bayesian effort of Caves, Schack, and me. It's easy reading, and just three pages: Tell me whether you think whether I got it right that it tracks our conversation, or whether I'm still missing something.

31-01-08 *Tracking Last Night, 2* (to H. Price)

It doesn't look like you read far enough. I would think the paragraph starting with, "It would seem that the cleanest setting for the proposal is ..." on page 28 captures a good bit of what you really have going on in the back of your head: the universe is just a big block of facts (with no easy local description), and it is our perspectival limitations that give rise to the use of QM and potential explanations of the need for that use in terms of retrocausation. The retrocausation is an artifact of our perspectival situation; the ontology—the end result of the Copernican project—though is that of a block.

31-01-08 *Potentest of My Premises* (to E. G. Cavalcanti)

Hi (I'm sorry I've already forgotten your first name again),

Below are the relevant quotes about a Copernican Project based on agency. [See 15-01-08 note "Potentest of Premises" to L. Hardy.] There's also a little more context for them in the attached pseudo-wacky-paper-thing. [See "Delirium Quantum" `arXiv:0906.1968v1`.] Sorry, it's not much to go on yet. You'll see some resemblance—I think—between the James quotes below and the remark you made in Vienna that impressed me.

02-02-08 *Practicing French* (to R. Schack)

Here's an article that you and Friedemann might use as a focus for your morning French practice ["Bruno de Finetti: l'Origine de Son Subjectivisme," by Simona Morini]. I just stumbled across it as I was preparing for my PIAF talk. Is there anything of interest in the paper? See also attached quotes for my own talk. I'm going to talk on the modified coherence stuff this morning. I think I put together a pretty nice talk on it. I hope it stands up in the face of Howard Wiseman … and Carl Caves!

> *Very* crudely put … the explanatory project goes something like this. We find our speakers disposed to say "P" (i.e., 'P' appears in the list of statements on the left of the model). We now ask, "Why do they say that?"; and in general (without pretending that this distinction is sharp) we look for an explanation that refers both to features of the speakers, and to features of their natural environment. Note that in our own case, this attitude always looks sideways on, or ironic. We say that P, and then wonder why we said so, how we came to be making a claim of that kind - looking for something deeper as an answer, of course, than merely "Because we realised that P". (This is the kind of irony characteristic of practitioners of the human sciences, of course, who cannot help but view themselves as examples their own objects of enquiry.)
>
> — Huw Price, "Naturalism without Mirrors"

> *Very* crudely put, the explanatory project goes something like this. We find our agents disposed to accept the structural features of quantum mechanics into their catalogue of probability assignments. We now ask, "Why do they say that?"; and in general (without pretending that this distinction is sharp) we look for an explanation that refers both to features of the speakers, and to features of their natural environment.

03-02-08 *Tsallis and Daróczy* (to O. J. E. Maroney)

Tsallis's 1988 entropy can be found here:

`http://en.wikipedia.org/wiki/Tsallis_entropy`

A little report on Daróczy's 1970 entropy can be found on pages 30–34 of here:

`http://arxiv.org/abs/quant-ph/9601020`

cf. Eq. (2.130).

03-02-08 *Decoherence* (to M. Schlosshauer)

It was good meeting you. I was just looking at some of your papers, and noticed various lines with the sentiment of this one (from your comment on Wiebe and Ballentine), "This leads the authors to the general conclusion that decoherence is not essential to explanations of the classical behavior of macroscopic systems. We show that these claims are not warranted ...." I would be curious to know your reaction to Johannes Kofler's two most recent entries on the archive: `http://xxx.lanl.gov/find/quant-ph/1/au:+Kofler/0/1/0/all/0/1`. Is it really being done without decoherence, or is it, as you were saying in yesterday's conversation, there in a hidden way?

04-02-08 *Tsallis, Daróczy, Gibbs & Shannon* (to O. J. E. Maroney)

Maroneyism 1: *Fair 'nuff!*

Of course, if I wanted to be pedantic, I could always say that if information theorists insist on calling the Gibbs entropy, Shannon information, there's no reason condensed matter theorists can't call the Daróczy information, Tsallis entropy!! ☺

Have a look at Eq. (3) on page 6 of

`http://arxiv.org/abs/quant-ph/9601025`.

Notice which name comes first in the line below that.

05-02-08 *Q&Q, 2* (to T. Slee)

In LA at the moment, on the way back to Waterloo from Australia.

Slee-ism 2: *I confess the bit that puzzles me comes right in the first three words of that section "When two systems ..." I just don't understand what "two systems" means.*

I could see that in the earlier blog entry you gave me. It's true: That's where your lack of familiarity with quantum information shows. One wavefunction does not mean one system. The notion of system is prior to any talk of wavefunctions. Two spins are two spins: They may be assigned a single entangled wavefunction (to describe one's knowledge of them), say, but they remain two spins. Operationally, a system is defined by the parts of the whole that can be manipulated separately. Formally, that is captured by writing down a tensor product Hilbert space $\mathcal{H}\otimes\mathcal{H}$ when describing the whole. One $\mathcal{H}$ belongs to one component, one to the other, and $\mathcal{H}\otimes\mathcal{H}$ belongs to the whole. A unitary operation on the left-hand system, but no action on the right-hand system, would be captured by a bipartite unitary $U\otimes I$ — U being the local unitary on the left, and I being the identity operator on the right. An action on the right, but not on the left, would be denoted by $I\otimes U$. "Local operations and classical communication (LOCC)" is the bread and butter of all quantum information theory. "Bipartite" is a common adjective in the field, not of my invention.

Slee-ism 3: *A single closed system has a state vector, no?*

No. A good Copenhagenist wouldn't say that (after a flavor, I am no more than a Copenhagenist myself). Wavefunctions are not properties systems possess independent of considerations of what an observer knows about them. Consequently a perfectly isolated system may be described by a pure state by one observer, but a density operator by another observer, and still a different density operator by another. It simply depends upon what one knows. This sort of situation arises all the time in quantum crypto. Alice, the preparer, writes down a pure state for her system; Eve, the eavesdropper, writes down a density operator. Nothing to do with ensembles: There's only one copy of the system. Instead, it has everything to do with knowledge or information.

Slee-ism 4: *But the main frustration I felt was that, while you repeated in a couple of places that you reject hidden variable theories (hooray!) I couldn't get what you were putting in their place (boo!). . . . didn't get the answer to "information about what?"*

All I can say is have patience. That is the research program. The whole bit about information is only the first part of the program: It's the bushwhacking to clear the weeds—to make clear that it's not the quantum state that is the objective property of a system. In the end, the "information about what" will be of the flavor of Bohr's answer, but finally made precise. And as far as the ontology, what does the system have when there is nobody considering it? That's neither the information, nor what the information is about. But something else. My presently favorite image is that—at a very deep level—quantum systems are catalysts. That is their ontological role.

By the way, I now have a DVD of the public performance. It's way way better than the radio program. If you want to see Tony again, I could lend it to you.

Now, I fly.

08-02-08 *Chipping at the Block* (to J. A. Vaccaro)

It was good meeting you last week. I hope my personality didn't come off as too audacious the one day we talked . . .

But I've been having another crazy idea lately. I'm thinking about organizing a meeting at PI on issues in pragmatist philosophy (perhaps with Lee Smolin), and I've been thinking about titling it, "Pragmatism at the Perimeter: Chipping at the Block Universe." In that regard, I've become quite taken with your painting "Broken Block". Three (not necessarily intersecting) questions about it:

1) Would you send me a higher resolution .jpg of it, so that I might view it more closely?

2) Are you interested in selling it? I'm starting to fancy it in my home library of pragmatism. See attached photos (though wall color subject to change).

3) If said conference materializes, would you be averse to its being used in some way as a logo for the meeting?

Just exploring the issue.

Joan's Reply

> It was a pleasure to meet you as well. I seem to have the impression that you are fearless in your research so I didn't find you too audacious in person!
>
> Regarding the painting, I am rather chuffed that you are interested in it. And I am delighted about the connection with chipping away at the block universe. At the moment it is sitting in a pile in a cupboard somewhere so you are most welcome to have it, for free of course. I would be happy to send it to you. Just let me know of

the address. It is not very big, perhaps 10in x 8in. It's not framed either. I would be extremely chuffed if you happened to use it for a logo. Golly.

The workshop idea sounds interesting.

08-02-08 *Chipping at the Block Universe* (to L. Smolin)

I'm back from Australia now if you want to pick up talking about pragmatic things. Particularly, I'm thinking harder about that conference idea I mentioned to you. In fact I think I'd like the running theme of it or its focus to be on arguments con (and for fun, a couple of talks pro) the "block universe" conception. Thus I've tweaked the title a little bit to "Pragmatism at the Perimeter: Chipping at the Block Universe," (and a few variations thereof) and have found myself staring at this painting of Joan Vaccaro's as a potential logo

`http://members.optusnet.com.au/j.vaccaro/gallery/`.

PI conference proposals are due Feb 15. If you have an interest, we should talk very quickly.

I read the first half of Unger's book, btw. It was hard for me to see precision in a lot of it, but I did pick up a couple of ideas that were novel to me and I liked in the chapter on time.

10-02-08 *Invitation and Potential Anti-Block Universe Conference, 1* (to C. Misak)

We have never met, but I have two friends, Huw Price and Harvey Brown, who recommend you very highly and suggested that I contact you. I am a researcher at the Perimeter Institute for Theoretical Physics in Waterloo (see our website at `http://perimeterinstitute.ca/` if you've never heard about us), who has a great private interest in pragmatism—particularly Jamesian, Deweyian, Rortyan—believing that the interpretational issues of quantum mechanics lead us straight up that path. Witness the library I just had built for the subject in my new home in Waterloo! (See attached photo; two books edited by you can be seen in the center section, fourth shelf from the top.)

Anyway, I write to you for two reasons.

1) Harvey and I would like you to give us a visit sometime this Spring, and, if you will agree, we'd very much like to you give us a seminar on Peirce and his ideas on chance, indeterminism, tychism, and such stuff.

2) Lee Smolin (also at PI) and I are thinking hard about organizing a conference here, tentatively titled "Pragmatism at the Perimeter: Chipping at the Block Universe". The reason is that a few us here think our studies in quantum foundations and quantum gravity lead in a natural way to abandoning the block-universe picture. However, we're somewhat at a loss about how to directly incorporate that insight more deeply into our physics. Thus it seems like a good time to build a larger community of colleagues we could talk to in this regard, and we're thinking an event like this might help kick off the effort. PI has a large budget for visitors and conferences.

The question is who might we invite as speakers? I have a decently strong knowledge of classical pragmatism and thinkers, but I am not so familiar with the crowd of *living* (non-emeritus) pragmatists (and Bergsonians)—i.e., ones who might best contribute to a meeting a like this. Do you have any recommendations? Or, can you point me to someone who would be in a better position to make recommendations? . . . keeping in mind that the main topic of the meeting will be what's wrong with the block-universe conception and how one might formalize the idea of the opposite.

So, 1) I hope you will give us a visit, and 2) any suggestions you can give regarding the conference will be most appreciated!

10-02-08 *Invitation and Potential Anti-Block Universe Conference, 2* (to C. Misak)

Misakism 1: *As for people you might invite to the conference (apart from Huw), I'd consider Arthur Fine and Ian Hacking. Both of course can talk physics. Arthur is a self-described pragmatist, while Ian is only described as a pragmatist by me and others.*

That is already helpful. I had, by myself, thought of Hacking (whom I met at a "pragmatism and quantum mechanics" meeting in Paris last February, a wonderful guy!), but I had not thought of Fine. Would he be a pragmatist who waves the banner of the universe being on the make? Or would he be a mushy pragmatist like Huw, who accepts the methodology and the anti-representationalist point on truth, but *rejects* the "joint-stock society" conception of nature (as James put it)?

Misakism 2: *Someone who is less well-known, but is nonetheless excellent is Randy Dipert at SUNY Buffalo. He knows Peirce's mathematics very well.*

I will look into Dipert right away.

I'm not necessarily looking for people who know anything of the details of quantum mechanics. Particularly, too much thought on the mysteries of QM might be a bad thing on their resume! Clouding the view, so to speak. If the meeting materializes, I would like several of the participants to indeed be immersed in the classical literature. For instance, an ideal participant might be Ralph Barton Perry, if it weren't too late for that. And Richard Rorty would have been wonderful. I have wondered whether we might still be able to attract Hilary Putnam, or whether he's too old now. It would be great to have an expert on Peirce's metaphysics (that seems easy, given the input you've already given), but also one on James's, one on Dewey's, and one on Mead's. One on Bergson's? One on Deleuze's? . . . Maybe I shouldn't push it too far! But certainly a good grounding on all the classical pragmatists would be most helpful.

About your talk here, just pick a few possible dates: our regular quantum foundations seminar is every Tuesday at 4:00, and you could take one of those slots. The sooner the better! We'd love to talk to you.

The attached document won't reveal too much of my particular interests, but it may help you to see how I see pragmatism as fitting into the bigger game (for me) of quantum issues. It is a teaching proposal I wrote several years ago, for a potential joint position between physics and philosophy.

Thanks for the prompt response. I'm grateful, and will let you know how things develop wrt the conference, and if you have more ideas please do let me know.

10-02-08 *Dues Request, and a Question* (to D. M. Hester)

Thank you for letting me know that my William James Society membership has expired. I will renew right away.

In the meantime, I'd like to ask you a question. I am now a researcher at the Perimeter Institute for Theoretical Physics in Waterloo, Canada (see our website at `http://perimeterinstitute.ca/`), and a colleague, Lee Smolin, and I are thinking hard about organizing a conference here, tentatively titled "Pragmatism at the Perimeter: Chipping at the Block Universe". The reason is several of us here think our studies in quantum foundations and quantum gravity lead in a natural way to abandoning the block universe picture. However, we're somewhat at a loss about how to directly incorporate that insight more deeply into our physics. Thus it seems like a good time to build a larger community of colleagues we could talk to in this regard, and we're thinking an event like this might help kick off the effort. PI has a large budget for visitors and conferences.

The question is who might we invite as speakers? I have a decently strong knowledge of classical pragmatism and thinkers—witness my home library on the subject in the attached photo—but I am not so familiar with the crowd of *living* (non-emeritus) pragmatists (and Bergsonians)—i.e., ones who might best contribute to a meeting a like this. Do you have any recommendations? Or, can you point me to someone who would be in a better position to make recommendations? ... keeping in mind that the main topic of the meeting will be what's wrong with the block universe conception and how one might formalize the idea of the opposite.

Thanks for any help you can give!

11-02-08 *Potential Anti-Block Universe Conference* (to D. M. Hester)

Sorry to continue bothering you with this, but you're my only connection to the world of William James. Let me expand on the question I sent you yesterday: Below is part of a conversation I had with Cheryl Misak yesterday. [See 10-02-08 notes "Invitation and Potential Anti-Block Universe Conference, 1 & 2" to C. Misak.] It says a little more about the cross-section I'm thinking of for the proposed meeting.

What are your thoughts on Tom Burke? I was favorably impressed by his book *Dewey's New Logic*. Might he fill the shoes of an expert on Dewey's metaphysics I mention below? Or are their better choices?

Micah's Reply

> Hacking and Fine are good choices. Putnam is too, but he is so busy, and his wife does not ambulate as well as she used to. You can try, but I suspect you will get a polite decline.
>
> Burke is good; Ray Boisvert at Sienna wrote a book on Dewey's metaphysics (though he hasn't written much on it since). John McDermott would have something to say, but I' don't know that he would be able to make given his schedule.
>
> What about someone like Christopher Hookway? Russel Goodman at New Mexico might be good as well.
>
> I'm just brainstorming ... as for James's metaphysics, Bill Gavin at Southern Maine might be a good choice, and Richard Gale (now in Knoxville) is always a kick.

11-02-08 *Anti-Block Meeting Invitees (working list)* (to L. Smolin)

Here's where I've gotten so far in my thinking about who might be invited to this meeting. I'll go ahead and send this malleable list even at this stage, so that we might have a starting point to discuss things tomorrow.

I'm open to loads of suggestions and dollops of advice. Please give. The point of the meeting, as I see it, is to get PI people to stop thinking in block-universe ways. If we can surpass that barrier, the thought is, our theory-making intuitions will be opened to grander vistas. But the first step is to get a glimpse of what's over the barrier, and that's what this meeting should be mostly about. We add a little talk on quantum mechanics (witness Bitbol, Fine, Shimony, and Price) to bring the focus back in—to give some sense that the issue is relevant to existing physics—but the bigger point is peering over the barrier, so that we can get to the next physics.

I hope we can get together tomorrow.

- Michel Bitbol — director CNRS, École Polytechnique, Paris. Philosopher of physics, organizer of recent international meeting "Pragmatism and Quantum Mechanics."

- Raymond Boisvert — Siena College. Author of *Dewey's Metaphysics*; see attached review. [See William M. Shea, "Review of *John Dewey's Theory of Art, Experience and Nature: The Horizons of Feeling* by Thomas M. Alexander and *Dewey's Metaphysics* by Raymond D. Boisvert," Am. J. Edu. **98**, 83–88 (1989).]

- Arthur Fine — University of Washington. Philosopher of science with a long history of influential research in quantum foundations; author of *The Shaky Game: Einstein Realism and Quantum Theory*; pragmatist credentials stated vividly by Richard Rorty, who called him "my favorite philosopher of science".

- Richard Gale — University of Pittsburgh. Expert on James's metaphysics. Vita found here: `http://www.pitt.edu/~rmgale/vita.htm`. See also attached review of one of his books. [See Gerald E. Myers, "Review of *The Divided Self of William James* by Richard M. Gale," Philosophy and Phenomenological Research **64**, 491–494 (2002).] He looks fantastic actually; comes recommended by a contact in the William James Society.

- Russell Goodman — University of New Mexico. Author of *Wittgenstein and William James*. Vita found here: `http://www.unm.edu/~rgoodman/Vitae.html`.

- Ian Hacking — University of Washington. Renowned philosopher of science, with a deep interest in the history of probability and chance. Author of 11 books. In a recent paper, "On Not Being a Pragmatist: Eight Reasons and a Cause," he tries to fend off his fellow philosophers who classify him as a pragmatist, but regardless of the reasons for them he has well explored a set of thoughts quite relevant to this meeting.

- Louis Menand — Harvard University. Author of the Pulitzer prize winning *The Metaphysical Club*—ostensibly a biography of Peirce, James, Dewey, and Oliver Wendell Holmes Jr., but one of the deepest and far ranging explorations of pragmatism that I have read.

- Cheryl Misak — University of Toronto. Influential scholar of Peircean pragmatism.

- Huw Price — Sydney University. Perhaps the most influential Australian philosopher of science, and our partner in the PIAF (PI–Australian Foundations) collaboration. Deeply pragmatist about methodology, philosophy of language, and the meaning of truth, he is a surprise in his ideas about time (on which he has published extensively): He may be the one pragmatist on earth who believes in the block universe picture!

- Hilary Putnam — Harvard University. The most famous pragmatist in this list without question! Deeply influential in all branches of philosophy, and a philosopher who has given a significant amount of thought to quantum mechanics.

- Abner Shimony — Boston University. His credentials in quantum mechanics are well known. But also he is a great admirer of Peirce's metaphysics.

- Roberto Unger —
- Another expert on William James's metaphysics —
- Expert on George Herbert Meade's metaphysics —
- Expert on Bergson's metaphysics —
- ??? Who else ???

12-02-08 *Conference, 2* (to A. Y. Khrennikov)

I apologize!! I long since forgot about this. Below are the few lines you requested:

> We will also encourage a discussion of the significance and meaning of Kochen-Specker style theorems and the issue of contextuality in quantum mechanics, as recently there has been a resurgence of interest in these issues in the quantum information and foundations communities. To this end, there will be a special session on the topic organized by C. A. Fuchs. Speakers will include J. Emerson, C. A. Fuchs, I. Bengtsson, J-Å. Larsson, J. A. Smolin, and others.

I'm so sorry, I was late on this. I hope you will still add it to you conference webpage.

12-02-08 *Anti-Block Meeting Invitees (working list), 2* (to L. Smolin)

Lee Smolinism 1: *These all sound like good people, but the problem is that this is sounding like a philosophy conference and the people whose minds you want to change are not likely to go to pure philosophy talks. You can go ahead anyway and make it as interesting as possible, and at least form a network of alliances of people and ideas. To that end I would broaden it in the direction of other sciences with analogous or homologous issues like biology and economics. Or you can focus it on the relevant physics issues concerned with time and invite people with the full spectrum of views from pro-blockers to believers in evolution of laws and make it a conference to discuss and argue differences of opinions.*

I recognize the truth in what you say. On the one hand, I worry that my working list is too overtly philosophical, but on the other hand, I worry about fostering once again the usual stalemate that one finds at foundational meetings. I guess I was imagining something different at this conference: One that would lay the groundwork for people not too familiar with the subject of a different worldview from the usual one presented in our physics training.

At some point, one just has to jump off the diving board, I think to myself. I'm reminded of the diary entry William James wrote when he was on the brink of suicide in 1870. [See 05-08-02 note "The Spirit that Breathes Life" to G. L. Comer.] At some point, one simply must *choose* to start physics afresh, to obdurately pursue the anti-block picture. It, like free will, is a *choice* one must make before one can have it.

I'm just coming in to the office now (once I get my car out of the snow). And I'm sure to be in a more sober-talking mood by then. We can hammer this out!

12-02-08 *Chipping at the Block, 2* (to J. A. Vaccaro)

Well, I'm very flattered that you'd honor me with your painting. I'll take it! Simply send it to my PI address below; it'll be better protected from the weather that way (rather than chancing the mail man leaving it on my porch in the snow). It'll look great near all my volumes on William James (the philosopher who invented the very phrase "block universe"):

> What does determinism profess? It professes that those parts of the universe already laid down absolutely appoint and decree what the other parts shall be. The future has no ambiguous possibilities bidden in its womb; the part we call the present is compatible with only one totality. Any other future complement than the one fixed from eternity is impossible. The whole is in each and every part, and welds it with the rest into an absolute unity, an iron block, in which there can be no equivocation or shadow of turning. ...
>
> Indeterminism, on the contrary, says that the parts have a certain amount of loose play on one another, so that the laying down of one of them does not necessarily determine what the others shall be. It admits that possibilities may be in excess of actualities, and that things not yet revealed to our knowledge may really in themselves be ambiguous. Of two alternative futures which we conceive, both may now be really possible; and the one become impossible only at the very moment when the other excludes it by becoming real itself. Indeterminism thus denies the world to be one unbending unit of fact. It says there is a certain ultimate pluralism in it; and, so saying, it corroborates our ordinary unsophisticated view of things.

He also invented the word "multiverse", though he used it in a very different sense than the Everettians do.

I keep my fingers crossed that the conference will materialize. The difficulty is that I want it to be particularly philosophical, and PI may not be the right venue for that. Despite Lee's warnings, I'm finding it difficult to give up on the idea. Thus I'm starting to half toy with the idea of seeing if a philosophy department might throw in with us. We'll see.

14-02-08 *What To Do About Lewis?* (to R. Schack)

Now, I've got a new urgency! Sorry to worry you. I just haven't been able to keep up with my obligations, in the face of all this damned construction around me. It was worse when I got back from Australia than when I left.

To your question: I'm not sure that apples and apples are being compared. The argument you gave me a few days ago, is essentially the one of Lewis's paper, if I understand correctly. And it's the one Wayne Myrvold has spit back at us on several occasions: That the hypothesis of a chance is a hypothesis like any other. Consequently, one can have a (subjective) "credence" about it and update accordingly in the light of new evidence.

Schackcosm 100: *What saves her from an infinite or finite regress is the fact that she is a good subjectivist Bayesian. Her belief is her belief and does not need to be justified. There is thus no need for her to give an unambiguous description of the experimental setup that she is repeating. Consequently, my whole anti-Everett argument falls apart.*

There is no need to give an unambiguous description of how to produce the chance if she is treating it like a hypothesis, of which she is gaining confidence by finding the truth values of various ancillary propositions (i.e., the outcomes of those experimental trials). This is no different from any (valid) conditioning. By finding the truth value of *this* proposition, I update my degree of belief for *that* proposition, but I am under no obligation to give an exact description of the origin of that proposition. I am under no obligation to further discuss the mechanics of what might physically make it true or false.

This is why I think you are comparing apples to oranges. Your earlier argument—the one you attempted at the Everett meeting—was an attempt to attack elsewhere. It was an attempt to attack the logical coherence of the "truthmaker" for the chance. ("Truthmaker" is actually a technical term in some nonpragmatist philosophies; see attached paper of Huw Price. See also attached plays-on-words by me; I found much in the Price article that would be of value to us.) The usual "truthmaker" for a Lewisian chance is "identical chance situation," whatever that might mean. Your attack was on the "What means identical?" part of it, and the argument went like this. To specify identical situations, one must supply a precise description of those situations. But it is not good enough to give a classical description for a preparation device. For, despite Bohr's exhortations, a classical description is not a precise description of a preparation. One would have to supply the machinist with more than classical drawings if one wants him to build the device one truly has in mind. And that more precise description would require quantum states. And so one has an infinite regress in journey to find a precise description of a preparation. That is to say, the only coherent truthmaker available for a chance is a quantum state, and the only coherent truthermaker for a quantum state is another, more all encompassing quantum state. And so on, and so on. So goes your argument.

But that has nothing to do with the Myrvoldian-style distraction expressed above, which is just a species of the original Lewis argument: That chances are something we can have subjective credences about. Your argument is not in contestation of that, but rather, "What would make a chance true in the first place?" I.e., even supposing Lewis and Myrvold are not flawed, what are these things we imagine we're building up credences for? Answering that question leads to the infinite regress you point out.

The only thing I see potentially as a flaw in the argument is the Everettian's move to simply stop the regress by declaring a quantum state for the universe. I think that might be partially why Simon Saunders is so bold as to say only the Everettian view solves all the deep issues in the interpretation of probability. He is implicitly asserting that probability will ultimately only make sense if chance makes sense.

But that said, you know my own opinion is that there is simply nothing at all in the Everettian view; it really is "sound and fury signifying nothing". They act as if it hangs together, but I don't even see it rise at all from the flat ground. Thus, when they declare, "See, there's no problem at all," they're not saying anything that's actually consistent.

Anyway, that's my thought. If you spot a flaw in it, let me know.

18-02-08 *Hirota Meeting Proposal* (to Perimeter Institute)

Conference Proposal: Osamu Hirota, between Distinguishability and Noncausality
Principle Organizers: Christopher A. Fuchs and Alexander Holevo

Synopsis

Osamu Hirota has been a key figure in bringing two generations of quantum information theorists together—old QI and new QI—who might not have otherwise been so easily aware of each other. His tireless conference organization, particularly the major semi-annual QCMC series, fundraising for visitor programs to Japan, and establishment of the QCMC awards for theorists and experimentalists in quantum information and computing, have been no small components in making this community what it is. Thus, in honor of his 60th birthday (an important birthday in Japan), we would like to hold a small conference at PI, the participants being some of his best friends. It so happens that those friends are some of the key figures in quantum information, and this is a very good excuse to attract them to PI to report on what they are thinking.

By old QI, we mean the first era of studying the classical-information carrying capacities of quantum channels and the distinguishability of quantum states in the early 1970s. The key papers during that time being written by Levitin, Holevo, Belavkin, Helstrom, Yuen, Kennedy, Lax, and others. By new QI, we mean everything after the discovery of quantum teleportation in 1993, the time when it was realized that the successful transmission of quantum states could be an end in itself. In the first days of the newer era, these were completely separate communities. But the international Quantum Communication, Measurement, and Computing conferences organized by Hirota saw an end to that. Perhaps a personal anecdote will help convey the importance of these meetings. In 1996, a topic of great interest with the newer generation was the classical-information carrying capacity of a set of nonorthogonal quantum states, for which the answer was not known. In fact, an amazing quantum effect—the superadditivity of capacities—had only recently started to be understood in this connection in that community. But at the 1996 QCMC meeting, to which Hirota had drawn Alexander Holevo to after his not being involved in QI issues for many years, it became clear that this "new" effect was in fact quite old. It was reported in a 1978 paper by Holevo, but the paper somehow fell off the map and was simply unknown to those of us in new QI. Soon after this meeting, progress was rapid, and we can thank it for bringing Holevo and several others back to the field. Stories like this abound and make Osamu Hirota's contribution to the quantum information community very honorable indeed.

Research Areas Benefited

A broad range of quantum information studies at PI should benefit from the meeting. The invited speakers—Charles Bennett, Peter Shor, Alexander Holevo, etc.—will virtually ensure that. But, the focus is likely to lean toward capacity and superadditivity issues in their various guises. There may also be discussion on the foundations of quantum information itself (particularly in D'Ariano, Ozawa, and Fuchs's talks). One long-standing open problem that many of the participants have contributed to is the issue of the minimum entropy-making inputs to tensor product quantum channels: That will most certainly be a hot topic of discussion. Several researchers at PI and IQC, I am quite sure, will be poised to build on what they learn from the talks and discussions.

Relevance and Timeliness of Event

The timeliness of the event is dictated by Hirota's 60th birthday, which is in June. The relevance is that their deep friendship with him will bring some of the world leaders in quantum information to PI to share their thoughts.

To emphasize the caliber of the invitees, we list their associations here in more detail than can be given in the space set aside for it on page 6. Charles Bennett—one of the very fathers of new-QI, having been a co-discoverer of several of the most important effects in the field: 1) quantum teleportation, 2) super-dense coding, 3) the B92 quantum crypto protocol, 4) entanglement distillation, 4) the entanglement assisted capacity, and the list goes on. John Smolin—also from IBM Research, seminal contributions in all aspects of quantum information theory, especially through the power of his numerical work (it would be hard to count the number of interesting quantum information items first found by his "minimizer", for instance the five-qubit code). Alexander Holevo, played a role much like Charles Bennett, but in old-QI. Jeffrey Shapiro is director of MIT's historical Research Laboratory of Electronics. Masanao Ozawa and Horace Yuen were the first to prove that the so-called "standard quantum limit" to measuring successive positions of a particle could be exceeded; since both have had long distinguished careers in many aspects from the very theoretical to the quantum optical sides of quantum information. Masahide Sasaki is the director a major quantum information laboratory in Japan. Peter W. Shor, founder of the quantum factoring algorithm and the first to discover the existence of quantum error correcting codes.

Desired Outcomes

A report of the state of the art in various quantum channel questions—from the IBM Research team (represented by Bennett and Smolin), the Pavia team (represented by D'Ariano), the efforts at MIT (represented by Shor and Shapiro), the Tohoku team (represented by Ozawa)—should be of benefit to all. A worthwhile goal would be to make good progress on one or more of the additivity issues.

19-02-08 *These Eyes* (to D. M. Appleby)

Applebyism 17: *It is true: I had forgotten about Hans, and yes I would really like to see him. As you say, my purview, like yours, is much much bigger than SICs.*

And I should keep you up to date on what I've been thinking: It is what I think is maybe THE ultimate reason for our studying SICs. I now have a good sense in which a SIC representation of quantum states gives the very best unentangling possible between Bayesian probability theory and what is different in quantum mechanics. It is clean and simple, and had been right in front of me for over a year. Below is a weak summary of it. [See 25-01-08 note to D. Gottesman titled, "Bristol, 3 AM."] Sorry that it's not more detailed, and I don't want to take the time to write it more properly now (showing the sense in which this is the best possible disentanglement, etc.). But in my mind, this (and also the similar representation of unitarity) are now the real reasons I use for justifying the study of SICs.

At the PIAF lecture in Sydney, I put all this in Dutch book terms, but unfortunately there's only an audio file of the lecture here: `http://idisk.mac.com/centre.for.time-Public?view=web`. I think one really needs visuals. We can talk in detail when you get here.

There's all kind of poetry and prose that little equation evokes in me:

C: "World, I need your help factoring this large number."

W: "Fine. Push on me the right way, and I'll cough up the answer for you."

C: "But be warned, I'm in a hurry."

W: "Then you too be warned. Be gentle, don't push on me more than you have to; I'll give you a reward in the end."

19-02-08 *These Eyes, 2* (to D. M. Appleby)

Applebyism 18 : *Also, am I right to assume that the reduction in entropy (if that is the measure of "mixedness" you are using?) as compared with what you would have classically is greatest possible for a SIC?*

No, it's that the quantum "residue"—the last remaining hint of quantum mechanics, thought of as a deviation from the law of total probability—is the smallest. I.e., when using a SIC in the Bureau, one gets an expression for the j measurement in terms of the i measurement that is as close in form as possible to the law of total probability. There is still a deviation from it, but that deviation is functionally as small as possible—and that I presume in some shape, form, or fashion, represents the core of quantum mechanics. It is a hidden expression, I think, of the source of the Kochen-Specker theorem: unperformed measurements have no results.

Applebyism 19 : *I find this interesting for another reason as it touches on a question I discussed with Lane, possibly in a note I forgot to copy to you. We were speculating whether SICs are really and genuinely what they superficially seem to be: namely, the maximally symmetric rank d^2 POVM. The reason I thought they might not be is the triple products, which seem to be quite nasty for $d > 3$. I was wondering if there might be a POVM in which, the squared moduli of the overlaps are not all the same, but in which the triple products are nicer. Perhaps even a POVM in which the triple products are all the same? If it is true (as I think it might be) that the triple products are more fundamental than the overlaps such a POVM might have a better title to the term "symmetric" than SIC. At any rate it might have an equally good title.*

I find that question interesting too. But for the present problem, it is the symmetric measurements in our usual sense (of any rank)—rather than the tri-SIC measurements if they exist—that touch closest to the Bayesian representation. I show why in the colloquium I gave here: `http://pirsa.org/08010004/`. It's only the symmetric measurements (of any rank) that give a quasi-diagonal transformation between the P and Q functions, so to speak. And then, the rank-1 symmetrics further minimize the constants as much as possible.

So, the most important layer for the questions that titillate me—the ones about this issue of total probability—is that we first satisfy SICness completely. Thereafter, we try to satisfy tri-SICness as close as possible in one or another senses.

It would have been lovely if we could have had them both at once, SICness and tri-SICness! But there's certainly something to be learned here by finding that our easiest fantasies are being blocked by something.

19-02-08 *Speaking of "Blocked by Something"* (to D. M. Appleby)

Here's a lovely quote I ran across this weekend in William James's 1904 review of F. C. S. Schiller's book *Humanism*. (Humanism was Schiller's word for pragmatism.)

> But humanistic empiricism will have many other steps forward to make before it conquers all antagonisms. Grant, for example, that our human subjectivity determines *what* we shall say things are; grant that it gives the "predicates" to all the "subjects" of our conversation. Still the fact remains that some subjects are there for us to talk about, and others not there; and the farther fact that, in spite of so many different ways in which we may perform the talking, there still is a grain in the subjects which we can't well go against, a cleavage-structure which resists certain of our predicates and makes others slide in more easily. Does not this stubborn *that* of some things and not of others; does not this imperfect plasticity of them to our conceptual manipulation, oppose a positive limit to the sphere of influence of humanistic explanations? Does not the fact that so many of our thoughts are retroactive in their application point to a similar limit? "Radium," for example; humanistically, both the *that* and the *what* of it are creations of yesterday. But we believe that ultra-humanistically they existed ages before their gifted discoverers were born. In what shape? There's the rub! for we have no non-humanistic categories to think in. But the *that* of things, and their affinity with some of our *whats* and not with others, and the retroactive force of our conceptions, are so many problems for Humanism over which the battle is sure to rage for a long time to come.

19-02-08 *Octahedra in Higher D* (to S. T. Flammia & D. Gottesman)

Are there any standard names for higher dimensional analogs of regular octahedra? Analogs in any sense, I suppose. But particularly, polytopes with $d(d+1)$ vertices whose ambient space is a d^2 dimensional linear vector space? Does that kind of object have a name?

19-02-08 *Octahedra in Higher D, 2* (to S. T. Flammia & D. Gottesman)

Flammia-ism 1: *I don't know of any such object. The only generalization of the octahedron that I know of is called the cross polytope, and it is simply the polytope of the vectors having unit 1-norm. If the ambient space has dimension d, then it has $2d$ vertices, so it isn't what you are looking for.*

Well, it might be, and I'm just asking the question in a confused way. What I'm really asking is this. Take a complete set of MUBs and connect the projectors to make a polytope. Does that kind of polytope have a name? Bengtsson and Ericsson called it "the complementarity polytope" when they discussed it in their paper, but I was wondering whether there is a more common name for the structure, if one strips away considerations about it being embedded in the set of quantum states.

19-02-08 *Lunch at 12:10?* (to S. T. Flammia)

Flammia-ism 2: *I'm at UNM until Friday, then I'm going on the ski trip Monday. I'll be in next Tuesday, the 25th.*

OK, I'll see you next Tuesday. You're probably going to wince when you see this, but here's the conference proposal I ended up submitting for us. Lucien got a chuckle from my verbal report of it, and told me he'd let me know before it goes to committee if there's anything too outrageous in it.

Conference or Workshop Program Proposal

Name of Conference or Workshop:
Seeking SICs: An Intense Workshop on Quantum Frames and Designs at PI

Principal Organizers:
Steven T. Flammia and Christopher A. Fuchs

Topic and Research Area:
Quantum Foundations, Quantum Information Theory

Synopsis (Please make this accessible to non-experts. See sample proposal.)
What is the shape of Hilbert space? More precisely, what is the geometry of the set of quantum states, thinking here of quantum states as a subset of the Hermitian operators? What symmetries does this set have? This question is of deep importance to several issues in quantum information theory, and it is of deep importance to a surging school of thought in quantum foundations, the quantum Bayesian approach. We propose an intense workshop to settle, or at least make significant progress with regard to a seemingly simple, but extremely recalcitrant, version of this question: The question of the existence of minimal symmetric informationally-complete (SIC) sets of pure quantum states.

The question is simply this: Take the set of pure quantum states (one-dimensionsal projection operators) for a d-level system; these operators span the d^2 dimensional space of Hermitian operators. Can one create a regular simplex (the higher dimensional analog of a regular tetrahedron) of d^2 vertices with elements drawn from this set? This is seemingly an almost trivial question—one of the most basic questions one can ask of a convex set—but it has a long unsolved history, ranging back, in one guise or another, at least 35 years. A related question, and a kind of scratchpad for the more pressing problem, is the question of existence of "complete sets of mutually unbiased bases (MUBs)"—a kind of higher dimensional analog of regular octahedra—in composite dimensions. In all, these are examples of so-called "2-designs" and "tight frames" with very specialized properties, hence the subtitle of our workshop proposal.

SICs and MUBs, if and when they exist, are already known to have some remarkable properties, both for quantum information processing and quantum foundations. For instance, thinking of them as measurements that can be performed in the laboratory, they are known to be optimal for certain ways of quantifying efficiency in quantum tomography. And SICs in particular may be used to form "maximally sensitive" alphabets for eavesdropping detection in quantum cryptography. For foundational purposes, SICs, if and when they exist, satisfy a sense of being as close to an orthonormal basis in the space of density operators as that structure will allow, and give rise to phase-space representations of quantum states and unitary evolution that are as simple as they are allowed to be in such representations. Furthermore, both SICs and MUBs may provide deeper insight into and new techniques in quantum computation, as both structures appear to have very interesting connections to the Clifford group. Thus there is ample (and ever growing) reason for trying to settle this question of existence.

The idea of the meeting is to gather the best people in quantum information theory who have given this problem significant thought, put them all in one place, and see progress made, damned be, by any means! We'll start off with a fiery rendition of Henry V's St. Crispin's day speech:

> This story shall the good man teach his son;
> And Crispin Crispian shall ne'er go by,
> From this day to the ending of the world,
> But we in it shall be remembered—
> We few, we happy few, we band of brothers;
> For he to-day that sheds his blood with me
> Shall be my brother; be he ne'er so vile,
> This day shall gentle his condition;
> And gentlemen in England now-a-bed
> Shall think themselves accurs'd they were not here,
> And hold their manhoods cheap whiles any speaks
> That fought with us upon Saint Crispin's day.

roll up our sleeves, brace for the scars, and get to work. Each day (save the first) will consist of two morning talks, each on some aspect of the problem, with the afternoons reserved for round-table/chalkboard working sessions in the Alice Room. The simple idea is to run the troops into the breach opened by these last few years of research, and finally defeat this cantankerous problem!

What research areas at Perimeter Institute will benefit from the event and how? How does this event benefit your own research?

Both Quantum Information and Quantum Foundations research at PI will benefit for the reasons described in the synopsis. In the case of Flammia, the problem has been a significant part of his research in the last few years. In the case of Fuchs, it's now a religious quest—being a significant ingredient in his sought-for interpretation of quantum mechanics.

Please include a justification of the relevance and timeliness of the event (feel free to explain in technical terms).

The earliest known posing of the SIC problem was in 1973 by Lemmens and Siedel in the context of the maximal number of "equiangular lines" that can be supported by a vector space. In real vector spaces, an upper bound of $d(d+1)/2$ on the answer could be proved, and in complex spaces a similar bound of d^2 could be similarly proven. Early on, however, it was understood that the upper bound generally could not be achieved in the real case; in fact, the actual maximal number turned out to be a very complicated function of d. Because of this, perhaps, it was thought to be similarly so in the complex case, and interest in the problem languished—until 1999 it was only known that the complex-case bound could be achieved in dimensions 2, 3, and 8. With the study of Renes et al. in 2003, however, all that changed: Numerical work now indicates that SICs exist in dimensions 2 through 47, and analytic constructions (most via the help of computer algebra packages) exist in dimensions 2 through 14. Thus progress has been very rapid. At least 46 papers on the `quant-ph` archive cite the original Renes et al. paper, and something like 10 of those have been devoted in an substantial way to the existence problem. Of the related problem with MUBs, over 100 papers on the archive have the words "mutually unbiased bases" somewhere in the record.

Here at PI, at least three residents have devoted a significant amount of brain pulp to the SIC existence problem (Blume-Kohout, Flammia, and Fuchs) in the last couple years, with brief forays by some others (Gottesman, Hardy). Also we can list several visitors of PI that have given a significant amount of time to the problem (months to years in some cases): D. M. Appleby, L. Hughston, J.-Å. Larsson, H. Barnum, C. M. Caves, M. Roetteler, A. J. Scott, and W. K. Wootters. The point is the problem has interested many who have walked in these corridors. It is simply time to settle it if at all possible.

What are the goals and desired outcomes of the conference or workshop?

To amass as much new information about SICs and MUBs as possible, and possibly to prove existence of SICs in all finite dimensions (or at least an infinite class of dimensions).

For the invited participants and speakers please include their full name and affiliation.

D. Marcus Appleby	Queen Mary University of London
Howard Barnum	Los Alamos National Laboratory
Ingemar Bengtsson	Stockholm University
Robert Calderbank	Princeton University
Carlton M. Caves	University of New Mexico
Steven T. Flammia	PI
Christopher A. Fuchs	PI
Markus Grassl	University of Innsbruck
David Gross	Imperial College
Lane Hughston	King's College London
Andreas Klappenecker	Texas A&M University
Martin Roetteler	NEC Laboratories
Andrew J. Scott	Griffith University
Peter W. Shor	MIT
Neil J. A. Sloane	AT&T Research
William K. Wootters	Williams College

20-02-08 *Your 60th Birthday* (to O. Hirota)

Alexander Holevo made me aware that your 60th birthday will happen soon. It is in June, if I am not mistaken? Thus, in your honor, we would like to organize a small "birthday party" for you here at the Perimeter Institute.

In that regard, we have just written a detailed conference proposal and submitted it. It is titled, "Osamu Hirota, between Distinguishability and Noncausality." If it is accepted by the conference committee at PI, then we would be very much honored by your attending the meeting. I should know shortly whether we will get the funding.

Under the assumption that it will be approved, let me tell you a little bit about the proposal. Preliminarily, I have listed the following colleagues as invited speakers:

Charles Bennett
Mauro D'Ariano
Christopher Fuchs
Osamu Hirota
Alexander Holevo
Debbie Leung

Masanao Ozawa
Masahide Sasaki
Jeffrey Shapiro
Peter Shor
John Smolin
Horace Yuen

We probably have room for 1 or 2 more invited speakers if you would like to add anyone to the list. Perhaps further colleagues or important students from Japan? Or others that we have forgotten?

If the proposal is approved, we should be able to cover everyone's travel and local expenses, and we would also be able to have a nice banquet for you here at PI's Black Hole Bistro.

An important question for you to be thinking about, is what dates you would like it. The meeting should be 3 days long, but when? If you approve, please also send me a range of dates for which it would be possible. Summer is a very busy time for the facilities here at PI, so I may have to fight for an empty slot in the planning. Thus, the more possible dates you have the better.

I hope you will accept our proposed birthday gift for you! You have been a wonderful friend over the years.

25-02-08 *Newsletter Submission* (to E. Goheen)

Goheenism 1: *We would like to prepare an article on the recent PIAF workshop and what this new partnership/project means for PI for the March edition of our newsletter, Inside the Perimeter. Lucien suggested I might be able to ask you a few questions about it.*

Here are my answers finally. I'm sorry for the delay.

Goheenism 2: *What is the partnership, who is involved?*

It's called PIAF (and pronounced as the name of the great French chanteuse Edith Piaf) but stands for the PI-Australian Foundations partnership. The participants on the Australian side are Sydney University, the University of Queensland, and Griffith University, with principle investigators Huw Price and Stephen Bartlett at Sydney, Gerard Milburn at Queensland, and Howard Wiseman at Griffith. The partnership will fund three postdoctoral positions based in Australia, all with significant visiting periods at PI. Thus, between faculty, existing postdocs, new postdocs, and graduate students, there's probably on the order of 15-20 people involved.

Goheenism 3: *How did this project come to be?*

It was the brain-child of Howard Burton, really. Howard recognized that the PI quantum foundations effort cannot live in a vacuum if it is going to achieve its potential. This is because quantum foundations is unique among the research areas pursued by PI in that, outside our walls, there simply isn't much of an infrastructure for the field. This contrasts with string theory, for instance, where there are several internationally recognized research centers for it (PI, Princeton, Stanford, Caltech, etc.). Thus a flow can be established for incoming and outgoing postdocs at those institutions. But quantum foundations is isolated in comparison—PI might just be the end of the career for many a good quantum foundations researcher. Thus, if we really want the field to flourish, part of our effort should be of the outreach variety, making physics department around the world aware of the return one can get from quantum foundations research, and to convince them it's worth investing some of their own resources to this field. PIAF represents our first effort in that direction.

Goheenism 4: *How will PI benefit from these types of partnerships?*

The benefits should be manifold, and not only for the reasons already mentioned. PIAF also establishes a vigorous visitor program between our institutions, and we can all imagine the benefits of that. Sometimes a calculation long processed in the back of one's mind simply needs a jolt of crisp, wintery Ontario air to bring it to life. Sometimes too a heated mid-Winter (i.e., mid-Summer!) discussion at a sidewalk cafe in Sydney might be just the thing to thaw loose a key idea previously frozen away. Thus we expect many good things to come from this collaboration. Finally, PIAF intends to establish the premier annual international meeting in our subject. In general relativity, there are the famous Marcel Grossman meetings; in quantum information, there were the famed Torino meetings; in quantum foundations, there will be PIAF!

Goheenism 5: *How did the first workshop go? Are there more planned in the future?*

It was fantastic, far exceeding expectations. The original intent for this meeting was for it to be a kind of "kick-off meeting", establishing what the various researchers would like to get out of this collaboration. In the end, it somewhat-spontaneously turned into a full-fledged research conference with about 35 participants (17 speakers), with a lively round-table discussion one session. Our next meeting will be here at PI and will be the first of the international series described above. This year's theme will be, "Time and Quantum Foundations." But the theme will change yearly, so stay tuned! Particularly, as it has been noticed that Hawaii lies exactly halfway between Waterloo and Sydney on the geodesic ...

I hope these were the sorts of answers you were looking for.

26-02-08 *Great News* (to A. Wilce)

That's great news indeed about your tenure! Well deserved and all that old boy, harrumph. ... But, for a serious note: You are now in a position of security, and that is a call to do something great with your life. Don't pass up the opportunity. If you were hammering away at quantum mechanics already, it's time now to pull out the jackhammers. We've got to understand this damned theory! We've got to understand it by any means!

So, indeed, very great news from you! Give my regards to your wife.

I'm soon off for a whirlwind tour of Eugene, Oregon. One day flying there, and one day flying back, all for the opportunity of spreading the word of SICs for one day in the middle.

28-02-08 *Even a Title* (to D. Gottesman)

And here's the title I'll give the talk, whenever I do give it: "Dressing Richard Feynman in Bayesian Clothes". It just came to me. Despite the title, it'll be a chalk board talk with plenty of equations.

29-02-08 *Seattle Note* (to H. B. Dang)

One of our postdoc candidates (Piero Mana) impressed me very much in many ways during his visit here. Particularly, I learned that he carried a sheet of paper in his pocket marked off with 365

$\times$ 75 squares — each square was to represent a day in his expected lifespan. He told me he kept it with him to remind him of the urgency of life and so that he would not forget to prioritize.

29-02-08 *Past the Halfway Mark* (to R. Schack)

Schackcosm 101: *Exchangeability is not a property of the world, but it depends on the agent's prior judgement.*

I would say "rather," rather than "but".

Schackcosm 102: *The concept of chance is therefore simply redundant in a classical deterministic theory.*

That's not quite what you want to say. You've already pointed out how the idea of chance in a deterministic theory is simply inconsistent. "Unneeded" perhaps, rather than "redundant".

Schackcosm 103: *It turns out that the attempt to define such a preparation procedure leads to the same regress as in the classical case. The state prepared by any preparation device depends on the quantum state of the preparation device itself. To guarantee that the same system state is prepared in each trial, one has to make assumptions about the quantum state of the preparation device, which means that one has simply moved the problem up one level. This leads to a regress as claimed.*

Why are you always so terse? This is a significant point of the paper. It seems to me that you could expand it to the level of our verbal discussions.

Schackcosm 104: *From the perspective of a full quantum Bayesian theory the answer is that objective quantum states, and therefore the objective wavefunction of the universe, have no useful place in quantum theory.*

And in fact cause great trouble.

29-02-08 *Readers' Rights* (to R. Schack)

Schackcosm 105: *Instead of two fundamental concepts—objective quantum states and decision-theoretic preferences—and their awkward connection via the principal principle, we now have a single fundamental concept. This translates into much greater conceptual and mathematical simplicity.*

I think it would be within the reader's rights to ask: Now why, really, is that an awkward connection? It still looks very natural to me. How have you convinced me that it's awkward? So much of what you think and feel is left silent in your papers. Is it really that I'm carried away by your oratorical skills in our personal conversations, and when it all boils down, the content is what you have recorded on these pages?

Schackcosm 106: *In the quantum Bayesian approach, the prior is a single density operator on $\mathcal{H}_n$. In the many-worlds approach, this prior is a probability distribution over all density operators on $\mathcal{H}_n$, a much more complex mathematical object*

I like something of the flavor of this, but it is the same mathematical object (the representation theorem gives the isomorphism). What are you really trying to say when say that it's more complex?

I doubt I was very helpful but those are the most thoughts I've been able to muster this morning. (I'm in Seattle now; just finished with a long talk with a soldier going back to Iraq. I would love to see George Bush tarred and feathered.)

Send me the next iteration of the paper; I'll try to think a little more deeply once I'm back in Ontario.

03-03-08 *t.tex* (to R. Schack)

Your use of "t" for the names of almost all files is as mysterious to me as the word "magma" for the most all inclusive algebraic structure in Bourbaki. (Any idea why they use that name?)

I read the appropriate areas; sorry for the delay. It's better now. Send it off—not much more to do. But I do continue to fear that the regress argument will still not be accepted by most. Why *must* one assign a quantum state to a preparation device? At that point it loses its role as a preparation device, a Bohrian would say. But this paper is not written for the Bohrians, I suppose.

08-03-08 *Chipping at the Block, 3* (to J. A. Vaccaro)

Dear JV, (just looking at your art page again, where I see you call yourself that),

I don't know how I can thank you enough. The piece is just gorgeous, and as I said before I'm very flattered that you'd let me have it. It'll hold a place of honor in my library.

Things are starting to look good for the conference too. John Sipe contributed a crucial idea that I think will make it start to look favorable in the eyes of PI, and Lee Smolin now seems to be pretty on board after hearing that. So, soon, I'll put a formal proposal in with PI. The idea is to have the philosophers read formal papers on some issue exposing cracks in the block universe conception, and then have physicists reply. The papers would be prepared well in advance of the meeting, so that the chosen physicists would have to time to develop a relevant response, explaining how something the philosopher said might be relevant (or not) with respect to a given issue, or rather arguing that the philosopher is only spouting some antiquated 19th century idea that has since been made very unlikely by modern physics, etc. If at all possible, I'll get your painting into the conference poster.

I'll write again when the painting arrives.

10-03-08 *Stabilizer States* (to M. G. Raymer)

My, it takes me a long time to reply to emails, doesn't it?! I'm sorry. But thanks for the hospitality in Oregon; I really enjoyed the trip. I was also impressed by your sensitivity to "pragmatic" issues. Attached is a picture of the Waterloo Library of Pragmatism, aka Chris's study—you'll see I'm quite serious!

Thanks also for the note. It sounds exciting! Is it true? Like Caroline Thomson said of me, I really do not have an intuition. Honestly, I didn't understand why you say "the answer is independent of the angle." Have you tried passing it by the van Enk test? If it gets that far, then it'll probably be a hop skip and a jump from a formal proof, and I'll try to weigh in on that. In the meantime, I have learned of a result saying that in finite dimensions, there are no SIC fiducial states with equal amplitudes, nor even such states with periodic amplitudes. So, if your ansatz does work out in the infinite limit, that will be quite interesting. For it would mean the infinite limit comes about in a nontrivial way.

10-03-08 *That Paper* (to M. G. Raymer)

Also here's the paper I was telling you about on the eight-port detector being able to measure all Weyl-Heisenberg covariant POVMs (making use of an appropriate "parameter" state in one port): `http://lanl.arxiv.org/abs/0708.4094`.

12-03-08 *Reality Check* (to A. Kent)

Kentism 8: *I was really calling just to be quite sure we've reached closure on the possibility of you contributing to the many worlds book.*

I held off on replying to you because I had hoped there was some chance I'd pull through and have something relevant written by now. But reality rears its face again. I think, honestly, there's not a chance I'd have something finished by "end of March (absolutely final firm deadline)". So, thanks for encouraging me, but I will disappoint you again.

In the end, these foundational wars—weighing one stale point of view against another stale point of view—just get old. What new physics comes from the effort? What new vista opens before our eyes? A complete rewrite of quantum mechanics is called for, and none of those guys see it. Nor will they ever. So, I think it is better for me to keep going on my own way.

17-03-08 *0803.1264* (to C. H. Bennett, G. Brassard, and J. A. Smolin)

Bennettism 32: *This looks like the kind of thing you (and CBH) were looking for. Do you understand what their convex framework of theories is, and how they define entanglement within it without automatically limiting the theory to standard quantum theory? Also, is their convex framework broad enough to encompass theories like Smolin's Pangloss universe, or Intelligent Design?*

To answer Charlie's question, the convex framework certainly encompasses a Pangloss universe (even if it's not exactly John's version), simply because it contains quantum mechanics. And the quantum world—we're bound to eventually learn—is surely the best of all possible worlds.

18-03-08 *Application* (to H. B. Dang)

I am presently in the Austin airport, delayed—perhaps indefinitely—by thunderstorms. Makes for a very miserable day. But Appleby will arrive at PI Sunday for a week, and then he's coming again for two months in the summer. So, I have something to look forward to.

Dangism 3: *I guess what I'm still missing is how probabilistic quantum mechanics can result in a more intuitive formulation.*

Intuitive is not necessarily the watchword. Reread my `quant-ph/0205039`. I just want to get at the core of what QM is telling us. And that core, by conventional standards, might appear to be the conjunction of two or three *seemingly* contradictory statements (like, for instance, is the case with special relativity). The point of a probabilistic representation is that it most directly gets at the (correct) meaning of the quantum state and the correct meaning of the Born rule. With the underbrush cleared away, then one should be able to more easily see the true forest.

18-03-08 *Needing a Little Jung Myself* (to D. M. Appleby)

I should record this snippet of a dream while I happen to be thinking of it again. (Emma and I were just talking about the importance of dreams.) I remember little of last night's dream except that, in it, I thought I was giving a particularly eloquent exposition of what I was thinking about quantum mechanics. And included in that exposition was a phrase that went like this: "The structures that *act* on Hilbert space—density operators, unitaries, and such—are the ones that represent the epistemic. The things that *live* in Hilbert space are the ones that represent the ontic."

I have no idea what that means, particularly as I cannot think of anything that "lives in Hilbert space". Clearly I'm making a distinction between $\mathcal{H}$ and $B(\mathcal{H})$, and saying the ontic/epistemic cut resides there. But what "lives" in $\mathcal{H}$?

By the way, our flights were indeed canceled. We are having to stay in Austin tonight. I've been amused by your latest notes on $\sqrt{3}$ and such.

19-03-08 *More Spam* (to D. M. Appleby)

Just reading the Barack Obama's speech from today before knocking off to bed. Came across these lines, which I like:

> Understanding this reality requires a reminder of how we arrived at this point. As William Faulkner once wrote, "The past isn't dead and buried. In fact, it isn't even past."

... particularly if you read them out of context and think about QM.

20-03-08 *Jungian Analysis* (to D. M. Appleby)

Applebyism 20: *I have managed to find a few more minutes. Your dream is interesting because it seems on the face of it to represent almost the opposite of what you consciously think. At least it does if one reads the word "live" the way I would naturally read it. As I would understand it the only things that "live" in Hilbert space are vectors. But in your waking life you would never say that the state vector has ontic significance (curiously, though, the density matrix is said to have epistemic significance: so to that extent the dream seems to agree with what you consciously think).*

Yeah, that's exactly what troubles me. What beside vectors "lives" in Hilbert space? I thought to myself, "Well, does dimensionality 'live' in the space?" If so, that seems like a forced usage of the word. On the other hand, for instance, one might say that maximal sets of equiangular lines do live in the space. Is that part of what the dream was trying to bring to the surface? This much is for sure: I have long (many years) puzzled over why quantum mechanics seems to be built on a two layer structure: the states (density operators) are not just in a vector space, but in a vector space $B(\mathcal{H})$. ($\mathcal{H}$ being the bottom layer, and $B(\mathcal{H})$ floating above it.) What is the significance of that very basic statement? My interpretation of the dream is that it was aiming at an answer to that question. And if so, there may be a little progress here. For, I had never thought of the ontic/epistemic cut as perhaps having anything to do with the $\mathcal{H}\,/\,B(\mathcal{H})$ cut before. But now I find myself taking this as a direction worth exploring.

20-03-08 *Group Meeting* (to D. Gottesman)

I should give something of an abstract since my title is so uninformative. It is below:

> In this talk, I'll add some details on why I'm so interested in the existence of SIC (symmetric informationally complete) sets of quantum states. Some *leisure* readings relevant to the talk, in case you're interested, are this old paper by Feynman,
>
> `http://projecteuclid.org/euclid.bsmsp/1200500252`.
>
> Also Chapter 1 of Volume III in his *Lectures on Physics*, and finally, his original article on quantum computing, Int. J. Theor. Phys. **21** (1982), page 467.

24-03-08 *Those Pages* (to H. C. von Baeyer)

Could you send me an electronic version of the translation you made of the Pauli lecture? I.e., the one you gave me a paper copy of when we first spoke yesterday. I had only read half of that this morning, but I forgot to put it in my backpack so I could read the rest of it tonight.

See you tomorrow at about 11:00. I'm really enjoying your being around here; I'm already hoping we can lure you back.

Hans's Reply, 24-03-08

> Chris, "those pages" sounds a bit scurrilous, like "that woman", but here they are.
>
> I'm having a great time. My conversations, including dinners with Marcus, are helping me to formulate questions and projects. I'm thinking very hard!
>
> > **Wolfgang Pauli: The influence of archetypal concepts on the formation of Kepler's scientific theories.**
> >
> > (In *Wolfgang Pauli: Das Gewissen der Physik*, Charles P. Enz and Karl von Meyenn, eds., Vieweg 1988, p. 509)
> >
> > *[Pauli reports in a passive voice on a lecture he delivered to the Psychology Club of Zurich in 1947/48. He poses the question: What is the bridge between a scientist's intuition and the development of scientific concepts and theories? He uses Kepler as an example. He cites Plato's notion that the feeling of satisfaction evoked by the understanding of nature stems from the "coming into congruence" of pre-existing, innate images in the human psyche with the observation of external objects and their behavior. Kepler calls such images archetypal. This notion agrees largely with Jung's introduction of the same word into psychology. Archetypes could also be called symbols, and furnish the sought-after bridge.*
> >
> > *Pauli analyzes Kepler's work, starting with the identification of the three-dimensional sphere as symbol of the trinity of the Christian deity and of the Sun as symbol of God the father. Thus the insistence on the Sun as the*

center of the universe turns out to be an expression of religious fervor. Pauli emphasizes that there is no hint of quaternity in Kepler, and relates this omission to the absence of the concept of time from most of his system.

Kepler's work was attacked vehemently by the respected Oxford physician and Rosicrucian Robert Fludd, who tried to restore the quaternity. For Pauli this is a symbol of the completeness of experience, which includes emotional components in addition to material ones, and is thus superior to the scientific point of view. What follows is my translation of the three concluding paragraphs of Pauli's essay.]

Finally there is the attempt to connect this problem originating in the 17th century with today's commonly expressed wish for a more unified *Weltbild* or world picture. First it is suggested that the significance of the pre-scientific stage of thinking for the development of scientific understanding should be accounted for. This step can be accomplished by complementing the study of scientific insights on the external world by the study of the inner meaning of these insights. While the former aims to adapt our understanding to external objects, the latter should illuminate the archetypal images used in the development of scientific concepts. Complete understanding would seem to be achieved only by combining these two directions of investigation.

Secondly, it is pointed out that modern microphysics has led to the result that today we have natural sciences, but no longer a scientific world picture. This could be alleviated by progress toward a unified total world picture in which the sciences are only a part. Indeed, modern quantum physics has begun to return toward the quaternary point of view that opposed the nascent science of the 17th century by treating the role of the observer in a more satisfactory manner than classical physics. In contrast to the "detached observer" of the latter, the former postulates an uncontrollable interaction between observer or apparatus and the observed system in the course of every measurement. In this way the deterministic description of phenomena becomes impossible. According to modern physics an observation, which makes specific choices and interrupts the game that is proceeding according to predetermined rules, is in essence not an automatic process, and can be compared to a creation in the microcosm, or with a transformation with unpredictable outcome.

The reaction of the discovery on the discoverer [or of observation on the observer][134], which leads to transformative religious experiences, and for which alchemy as well as the heliocentric idea furnish useful examples, transcends science. It can only be captured by symbols which simultaneously express the emotional side of experiences through images and furnish a vivid relationship to all human knowledge and to the actual process of discovery. Precisely be-

[134]The German words are *Erkenntnis auf den Erkennenden.* (I trying to translate them, I found out that currently there is no online etymological dictionary in German.) Ordinary dictionaries yield *Erkenntnis* = knowledge, perception, recognition, realization, insight, discovery and cognition. A hint comes from *Erkenntnistheorie* which is simply epistemology or theory of cognition.

In ordinary conversation, *erkennen* is to recognize something or someone, with an overtone of recovering something you knew beforehand (Plato). But I think that element is not dominant here. Since Pauli writes in the preceding about *Beobachtung* and *Beobachter*, which are simply observation and observer, I put those in square brackets. Intuitively I still go with discovery.

cause the possibility of such symbolism has become estranged in our time, it might be of interest to go back to another time which did not yet know about the mechanics we now call classical, but which enables us to provide proof of the existence of symbols with simultaneous religious and scientific functions.

[Finally I translate the epigraph attached to this piece by the editors of the memorial volume. It is from a letter written three years after the lecture and exemplifies the unique role of Pauli's correspondence with Markus Fierz.]

"I came upon Kepler as a trinitarian and Fludd as a quaternarian, and felt a resonance between their polemic and my own inner conflict. I have certain traits of both, but now, in the second half of my life, I should switch over to a quaternary attitude. The problem is that the positive value of the trinitarian attitude may not be sacrificed in this move ...

By the way, I would like to remark that back in Hamburg my journey to the exclusion principle had to do with just this difficult switch from 3 to 4: namely the necessity of ascribing to the electron, besides its three translations, another, fourth degree of freedom. To struggle through to the understanding that contrary to the naïve attitude a fourth quantum number is a property of the same electron — this was actually the principal labor ..."

[Fierz replied modestly that he himself was not as far along in his journey from three to four, that he didn't know whether he was a trinitarian or a quaternarian, and that he might never know. But by this very admission Fierz reveals himself as the ideal mediator between the divine Pauli and the rest of us.]

25-03-08 *Those Pages, 2* (to H. C. von Baeyer)

> But I want to say one thing to the quantum information community. I want you to listen to me; I'm going to say this again. [finger wagging] I did not have intellectual relations with those pages [pause] Mr. Pauli's. I never told anyone to venture into alchemy, not a single time, never. These allegations are false, and I need to go back to work for the quantum information community ...

Thanks, I got them last night and finally read them. There is some good stuff there. I'm particularly intrigued by his remarks (of a flavor I have seen before, but this brings it up again) that, "The reaction of the discovery on the discoverer [or of observation on the observer], which leads to transformative religious experiences, and for which alchemy as well as the heliocentric idea furnish useful examples, transcends science." The reaction of the discovery on the discoverer? The Bayesian would say, yeah, that's just the transformation of one's subjective beliefs from $P(h)$ to $P(h|d)$. But he means something more or something else than that.

On my end, I became very frustrated looking for the originals of the Bohr-Pauli letters. They should have been in my files under B, P, or F (for Folse, who gave them to me). But they're simply missing—very unusual for me.

25-03-08 *Funny Thing I Found on the Web* (to H. C. von Baeyer)

While trying to find Henry Folse's website (so I might recover my missing Bohr-Pauli correspondence), I came across the following article by Robert Pirsig, "Subjects, Objects, Data and Values":

http://www.moq.org/forum/Pirsig/emmpaper.html. Kind of funny, given that I just bought the 25th anniversary edition of *Zen and the Art of Motorcycle Maintenance*.

25-03-08 *Pauli-Bohr Exchange* (to H. C. von Baeyer)

See, I did have them once! Below is a letter from Henry Folse, dated 2 April 2001, explaining that they were written in English and had some handwritten marginalia by Pauli.

How on earth could I lose these gems?!?

Letter from H. J. Folse, dated 2 April 2001

> You're quite right that this an interesting exchange between Bohr and Pauli. I suspect that many have ignored them because of the late date.
>
> The letters are in English and typed, but at least on one Pauli inserted several comments in handwriting. Since it's about 15 pages or so, I've photocopied and mailed all four of them to you at your Bell Labs address. The copies are too poor to scan very easily. The Pauli letters are photocopies of the originals; the Bohr letters are photocopies of Bohr's carbon copies.
>
> Hope you enjoy reading them.

25-03-08 *That Fierz Paper* (to H. C. von Baeyer)

Here's a link to the Fierz article I was telling you about that had such an influence on me. It's reprinted in full on pages 405–407 of http://www.perimeterinstitute.ca/personal/cfuchs/SamizdatSE.pdf.

In this case I've pieced together why I can't find the original. It's because I possessed it before the fire and haven't replaced it. But where the correspondence went (which I obtained after the fire) still eludes me.

See you later this morning.

25-03-08 *Another Reference* (to H. C. von Baeyer)

The chapter by Inga R. Gammel, "Mission Impossible? Wolfgang Pauli's Idea of a Neutral Language," in *Towards Otherland: Languages of Science and Languages Beyond*, edited by R. E. Zimmermann and V. G. Budanov:

http://www.upress.uni-kassel.de/online/frei/978-3-89958-107-2.volltext.frei.pdf

looks potentially relevant to our discussions. (I haven't read it yet; just noting it.)

25-03-08 *The Coin Tosser* (to D. M. Appleby)

Looking over the note [to Christian Snyder titled "No Subject," dated 14-12-07], I see I missed something crucial in my report to you tonight. An action with a predictable consequence, he told me, "expresses what you think of yourself." I said I thought it was particularly deep, but really, I guess, I just thought it was particularly interesting. It certainly does have an affinity with my general orientation that any action initiated by one's bodily motions, and with a predictable consequence, might as well be thought of as an extension of one's body to begin with it.

26-03-08 *(Purely) Measurement-Based Quantum Computation* (to H. C. von Baeyer)

Here a set of good articles on the subject.
Here is Nielsen's elementary exposition of the idea:

`http://arxiv.org/abs/quant-ph/0504097`

Here is a kind of review article by the inventors (Robert Raussendorf and Hans Briegel), but with prettier pictures than Nielsen's:

`http://arxiv.org/abs/quant-ph/0301052`

and a shorter version of the same:

`http://arxiv.org/abs/quant-ph/0207183`

Here is Steane's important conceptual paper that makes use of this kind of computation to put a nail in the many-worlds idea:

`http://arxiv.org/abs/quant-ph/0003084`

Here's a Zeilinger paper on making a 4-qubit cluster state:

`http://arxiv.org/abs/quant-ph/0507086`

And here's one doing an experimental demonstration of Deutsch's algorithm with such states:

`http://arxiv.org/abs/quant-ph/0611186`

There's plenty more out there to read on the subject, but this will get you started.

27-03-08 *Fantastic Quote* (to H. C. von Baeyer)

That was a fantastic quote you sent to Marcus last night of Pauli comparing evil and acausality. Could you send it to me? I was surprised by Pauli identifying hyle with nonbeing. Very different from F. C. S. Schiller's use of the term, and very different from what I find in my book, *The Concept of Matter in Greek and Medievel Philosophy*. Particularly the chapter, "Matter as Potency."

Hans's Reply, 28-03-08

> Chris, I'll reply as soon as I find a Greek etymological dictionary. Hyle means matter, but Pauli implies that its roots mean something negative. I'll check it out – fortunately I attended a German humanistic boarding school where Latin and Greek were compulsory for six years.
>
> I REALLY enjoyed PI, have banished the Demon, and have already started stocking my library with Pauli material. Thank you for inviting me, and thank you especially for introducing me to Marcus who is clearly a unique person — not only intellectually but humanly as well.

Hans's Further Reply, "Pauli Reassessment," 03-04-08

Pauli died on 15 December 50 years ago. It occurred to me that one might write a reassessment of his legacy in PT or something.

The elements of such a piece would be:

Downplay Jung. The late Pauli gave plenty of evidence that while he owed a great debt of gratitude to Jung, he was fed up with Jungians.

Downplay Pauli effect and Pauli anecdotes in favor of his serious legacy. The principal witness to the idea that Pauli took his effect seriously was Fierz, and he is dead.

Divide the Pauli legacy into two parts: The private part asks how his dreams and beliefs influenced the creation of new scientific concepts. Gerald Holton is the expert on that, and his invention, the "thematic content" of science, deals with it well. The public part is Marcus's concern: the re-connection of the rational with the irrational in our world picture, the "coniunctio" of inner and outer, the healing of the cut between subject and object ...

I feel that your program is a step in the right direction. Consider this good quote from a letter to Fierz (1953):

> Einstein has neither the courage nor the mental agility to admit the essential incompleteness of science within life – *and for this reason* speaks erroneously about the incompleteness of quantum mechanics within physics.

In other words, accept Copenhagen and go on to larger questions.

What do you think about this idea? I feel comfortable about writing everything except the last part – your work.

Hans's Preply to Marcus Appleby, "Pauli's Darkness," 26-03-08

Pauli's own footnote in his letter to Richard von Weizsaecker 5 May 1953:

> I also see certain parallels between evil and the acausal. Both are, after all, the "dark", in a manner of speaking, which escapes the rational ("enlightened") order of things. Just like the acausal, evil must also be recognized as real — in contrast to neoplatonism, which wanted to declare both evil and matter unreal, by calling the latter hylae (non-being) and the former, euphemistically, privatio boni = absence of good. Just like observation in quantum mechanics, there are instances in life where "the calculation doesn't compute" (e.g. Plato in Sicily). One can neither get rid of these instances, nor avoid them by fleeing into the other side of the pair of opposites. One can only approve of them and accept them into a symbolic reality.

In the interest of speed I took some liberties in translating, and I don't know what he is talking about in the second half. Plato screwed up in Sicily and had to return home in disgrace. The point of the passage is that Pauli uses in one passage evil, dark, and acausal.

Hans's Preply to me, "Postprandial Nugget," 26-03-08

Pauli to Jung 27 May 1953: "... It was, if I am not mistaken, in 1931 that I got to know you personally. At that time I experienced the subconscious like a new dimension ... "

27-03-08 *Exposing the Cracks in the Block Universe* (to J. A. Vaccaro)

I got your great painting in the mail yesterday. Thanks again so much; I'm so tickled with it. The painting made it briefly to my house yesterday, but at the moment, I have it propped on my office desk at PI. I started thinking after taking it home that it'd be nice to show it off to more people for a while, before it lives out the rest of *my* life in my quiet library.

Some questions if you don't mind my asking. I notice it's signed JV00; do you recall what month you painted it? Can you articulate your intention for painting it? What concept you were trying to capture? (I've already explained my own reason for wanting it. But I'm sure you were trying to express something completely different in painting it. And I'm just curious.)

02-04-08 *Need Flammiazation* (to S. T. Flammia)

When in the hell are you going to be back?

04-04-08 *Hirota's Birthday Party* (to A. S. Holevo & the invitees)

Dear colleague,

Alexander Holevo and I would like to invite you to a three-day scientific birthday party at the Perimeter Institute for Theoretical Physics, June 25–27, in honor of Osamu Hirota's 60th birthday. The meeting, "Osamu Hirota, a True Quantum Communication Channel," plans to be a relaxed venue where we'll be able to interact and convey what we each think is presently the most exciting (or most perplexing) in quantum information theory. Our budget should be able to cover your travel and local expenses, should you need it.

The proposed speaker list includes, along with yourself,

Charles Bennett (confirmed)
G. Mauro D'Ariano
Steven van Enk
Christopher Fuchs (confirmed)
Alexander Holevo (confirmed)
Debbie Leung
Masanao Ozawa
Masahide Sasaki
Jeffrey Shapiro
Peter Shor (confirmed)
John Smolin
Horace Yuen

Please confirm with me whether you will be able to come enjoy Professor Hirota's birthday.

The PI facilities may also be able to accommodate a few of us for a limited time before and after the meeting (up to two weeks) for extended collaboration. When you reply to this note, please let me know whether you might like to stay longer than the meeting, and we will see what can be done. PI can be a very good place for thinking and gaining new ideas!

Best regards,

Chris Fuchs (and Alexander Holevo)

04-04-08 (to T. A. Brun)

On behalf of the GQI executive committee, I am pleased to let you know that your student Bilal Shaw was the winner of the APS March Meeting Best Student-Presentation Award in the theory category. Could you please pass the word on to him?

The judging panel consisted of Prof. John Sipe, chair (Toronto), Dr. Howard Barnum (LANL), Prof. Dagmar Bruss (Duesseldorf), Prof. Barry Sanders (Calgary), Prof. Lorenza Viola (Dartmouth), and Prof. Harald Weinfurter (Ludwig Maximilians, Munich). The candidates were judged on four equally weighted categories: content, clarity, style, and q&a. All the candidates were, in fact, very strong in comparison to many, many more-senior speakers at the meeting, but Mr. Shaw's presentation was deemed the best.

The award will be announced in the next issue of *The Quantum Times*. The award carries a 500 USD cash prize which will be presented to the winner through the American Physical Society, but comes from funds established by the Perimeter Institute for Theoretical Physics in Waterloo, Canada. Also, PI would like to invite Mr. Shaw to Canada to give a longer version of his presentation. Thus, please put him in contact with me so that we can make arrangements for a visit.

06-04-08 *Librarians* (to O. Hirota)

I am glad you are happy.

Holevo pointed out to me that between 6–11 July, there is an IEEE Symposium on Information Theory in Toronto. So, he will stay at PI the two weeks preceding that (roughly 22 June to 5 July), and then he will go to the IEEE meeting.

As I said, I will be happy to show you my library. You know, I have told you how important I think the philosophy of William James, John Dewey, and F. C. S. Schiller is for our understanding of quantum mechanics (it was quantum mechanics that pushed me toward them). That philosophy has the name "pragmatism" and my library has nearly 400 on books on some aspect of the subject. In the middle of the shelves is a volume I've recently purchased titled *Contemporary Japanese Philosophical Thought*, published in 1969. Chapter 3 of it is devoted to pragmatism and related philosophies from 1901–1925. What is interesting is that I found that there was actually a Japanese pragmatist of some renown. His name was Tanaka Odo. Perhaps your son with an interest in philosophy can explain to us the particularities of Tanaka Odo's views!

08-04-08 *PIAF Invitation* (to the invitees)

The Perimeter Institute for Theoretical Physics in Waterloo, Canada and three Australian universities (University of Sydney, University of Queensland, and Griffith University) have recently banded together to seed growth in the field of quantum foundations. In the long run, this PI-Australian Foundations (PIAF) collaboration has as its biggest objective to make it possible for physicists and philosophers to pursue sustainable academic careers in quantum foundations. More immediately though, within our portfolio of activities, we plan to establish a major international conference for the yearly exposition of the best work in quantum foundations. This year's meeting "The Clock and the Quantum: Time in Quantum Foundations", will be held in Waterloo, 28 September to 2 October, 2008, and we are hoping to give the series a very strong start by having an outstanding set of invited speakers.

In that regard, we would be honored if you would be one of those invited speakers. All your travel and local expenses would be covered by PIAF. Would you be able to come? For your reference, here are the other invitees:

Samson Abramsky	(Oxford U.)
Yakir Aharonov	(Tel Aviv U.)
Julian Barbour	(Oxfordshire)
Harvey Brown	(Oxford U.)
Phil Dowe	(U. Queensland)
Brian Greene	(Columbia U.)
Gerard 't Hooft	(U. Utrecht)
Matthew Leifer	(IQC, Waterloo and PI)
Paul Kwiat	(U. Illinois, Urbana-Champagne)
John Norton	(U. Pittsburgh)
Wayne Myrvold	(U. Western Ontario)
Roger Penrose	(Oxford U.)
John Preskill	(Caltech)
Carlo Rovelli	(U. Mediterranee)
Lee Smolin	(PI)
Roderich Tumulka	(Rutgers U.)
William Unruh	(U. British Columbia)
Lev Vaidman	(Tel Aviv U.)
Anton Zeilinger	(U. Vienna)

Please let us know as soon as possible if you will join us (so that we may set the poster printing in motion). We believe this promises to become an important conference series, and your participation would be a great coup for us.

Sincerely,

Chris Fuchs, Lucien Hardy, and Ward Struyve (the local organizers)

Organizing Committee

Guido Bacciagaluppi	(U. Sydney)
Christopher Fuchs	(PI)
Lucien Hardy	(PI)
Ward Struyve	(PI)

Advisory Committee

Stephen Bartlett	(U. Sydney)
Gerard Milburn	(U. Queensland)
Huw Price	(U. Sydney)
Howard Wiseman	(Griffith U.)

08-04-08 *PIAF Invitation* (to M. S. Leifer)

Matt, I'll also add a word of personal encouragement: This conference *needs* you, so I hope you can come. Like I told Lucien, "if his work on conditional density operators ain't about time in quantum mechanics, nothin' is." And you'd be the only representative of that point of view.

09-04-08 *Yo Yo and JFK on Wiki* (to L. Hardy)

Thanks for reminding me. Impressive. I wish I had gotten the opportunity to meet the guy.

The frame of this also reminds me in turn to look up the James bang quote I told you and Vanessa about. Here it is:

> It is a common belief that all particular beings have one origin and source, either in God, or in atoms all equally old. There is no real novelty, it is believed, in the universe, the new things that appear having either been eternally prefigured in the absolute, or being results of the same *primordia rerum*, atoms, or monads, getting into new mixtures. But the question of being is so obscure anyhow, that whether realities have burst into existence all at once, by a single 'bang,' as it were; or whether they came piecemeal, and have different ages (so that real novelties may be leaking into our universe all the time), may here be left an open question, though it is undoubtedly intellectually economical to suppose that all things are equally old, and that no novelties leak in.

It comes from his book, *Some Problems of Philosophy: A Beginning of an Introduction to Philosophy*, published soon after his death in 1910.

14-04-08 *Your Dad* (to L. Wheeler Ufford)

I learned the news of your father's passing away today. It has been a very sad day for me. But I have him very literally to thank for my career: The questions I have worked on these many years were the questions he asked so many years before that. I was lucky enough to meet him in 1983 and absorb those questions. He was a very great man.

14-04-08 *John Wheeler's Death* (to G. L. Comer)

In case you hadn't heard about it yet:

"John A. Wheeler, Physicist Who Coined the Term 'Black Hole,' Is Dead at 96"

`http://www.nytimes.com/2008/04/14/science/14wheeler.html?scp=1&sq=Wheeler&st=nyt`

14-04-08 *Sad Day* (to D. Overbye)

Thank you for the nice article on John Wheeler today. It is a sad day for me. His thoughts have pushed me for years.

One minor inaccuracy, I believe; I don't know if it is too late for you to fix it. I believe it was Bryce DeWitt who coined the term "many worlds" rather than John. I believe Wheeler himself always called it "the relative state formulation of quantum mechanics."

14-04-08 *Times and the End of Time* (to W. P. Schleich)

I became very disorganized, and I apologize for keeping you waiting. But today, with the sad news of John Wheeler's passing away, I was shaken back to business. John was a very great man, and how lucky I was to meet him in 1983. He provided the questions that have framed my career ever since. Mostly at the moment, I feel like I should work harder: It is what I owe him for his wonderful gift.

Thanks again for inviting me to Ulm. The MPQ has kindly offered to pay for my transatlantic flight; so I'll make those guys the major part of my visit. But I would still like to come to Ulm and give a talk if you will have me ... and if I can synchronize my family's schedule with the window of time you'll be in town. It'd be nice to spend a night in Ulm and get you guys revved up about the SIC representation of quantum states.

I should have a precise schedule worked up in a couple of days. I'll get back in touch then if it looks like I'll be able to come to Ulm July 21 or July 22, say.

I know this day has probably been rough on you. I could see how close you were to John in Princeton, Feb 2006.

14-04-08 *Epistemic Meeting* (to H. Westman)

Westmanism 1: *There has been some interest circulating about getting together and talk about the epistemic interpretation of QM (à la Spekkens) and whether or not is it possible. It could be that one could construct a no-go theorem or perhaps a concrete working model.*

It struck me that "the" is an awfully singular word. So I thought it would be fun to revisit my own early uses of the word. Here are a couple of instances I dug from my `quant-ph/0105039`. Thus the word did have some currency before Spekkens, and particularly before it was hijacked to the purpose of hidden variable theories.

Still, yes, it would be fun and informative to discuss these things. It's just a question of me finding the time in these coming weeks.

12 December 1999, to John Preskill, "Freedom"

> **Preskillism 11:** *Free will usually means the ability of conscious beings to influence their own future behavior. Its existence would seem to imply that different physical laws govern conscious systems and inanimate systems. I know of no persuasive evidence to support this viewpoint, and so I am inclined to reject it.*
>
> Can't agree with your second sentence. When you think of physical law, you should say the chant epistemic, epistemic, epistemic. Then you can chime in with MLK: free at last, free at last, thank god, I'm free at last!
>
> Had fun talking to you the other day.

20 March 2000, to Paul Benioff, "Small Addendum"

> I agree with you wholeheartedly that in quantum mechanics the "randomness" of measurement outcomes is NOT epistemic. However that does not preclude my view that all probabilities (including quantum mechanical ones) are epistemic in nature. They quantify how much we can say about a phenomena based upon what we know. It so happens in the quantum world that we cannot tighten up our knowledge to the point of removing all ignorance (about the consequences of our interventions), and in that sense the randomness is ontological—it is a property of the world that was here long before we ever showed up on the scene. But it takes epistemic tools to describe that property. That's the direction I'm coming from.

26 January 2001, to Jeremy Butterfield, "Worlds in the Everett Interpretation"

Anyone who knows me knows that I am rather down on attempts to interpret quantum mechanics along Everett-like lines. I think the most funny and telling statement of this in the present context is that, whereas Mr. Wallace speaks of "Everettians," I often speak of "Everettistas." Thus, I am almost surprised that you sent me this paper to referee.

My difficulties come not so much from thinking that an Everett-like interpretation is inherently inconsistent or that parallel worlds tax the imagination too much. It's more that this line of thought strikes me, at best, as a complete dead end in the physical sense. At worst, I fear it requires us to tack on even more ad hoc structures to quantum theory than we already have. (Here, I'm thinking of a preferred basis for the Hilbert space and a preferred tensor-producting of it into various factors.) For these reasons, among umpteen others, I have always been inclined to an epistemic interpretation of the quantum state. Doing this has helped me (personally) to focus the issue to asking, "What is this *property* of the quantum world—i.e., reality—that keeps us from ever knowing more of it than can be captured by the quantum state?" To that extent, I consider myself something of a realist who—just as David Deutsch—takes the wavefunction absolutely seriously. BUT absolutely seriously as a state of knowledge, not a state of nature. I do well believe we will one day shake a notion of reality from the existing theory (without adding hidden variables, etc.), but that reality won't be the most naive surface term floating to the top (i.e., the quantum state). When we have it, we'll really have something; there'll be no turning back. Physics won't be at an end, but at a beginning. For then, and only then, will we be able to recognize how we might extend the theory to something bigger and better than quantum mechanics itself.

21-04-08 *Born's Rule?* (to R. Laflamme)

Rüdiger told me last week that you're planning to do some experimental test of the Born rule. I'd like to learn more about that, particularly as it impinges on our quantum Bayesian program. If you've got some time this week or next, I wouldn't mind an introduction to the ideas and what's being done.

22-04-08 *Ariana Margaret Blume-Kohout* (to R. Blume-Kohout & M. E. Blume-Kohout)

Congratulations. It takes me back years. It's a truism that your life will change, and it is a truism that it will change for the better. Myself, I believe that life and creation is the big principle in the universe. Tell Ariana Margaret that—that her birth played a crucial part in making the universe fly. She should understand that about herself.

23-04-08 *Dylan Quote on Time* (to S. Weinstein)

The first thing you notice about New Orleans are the burying grounds—the cemeteries—and they're a cold proposition, one of the best things there are here. Going by,

> you try to be as quiet as possible, better to let them sleep. Greek, Roman, sepulchres—palatial mausoleums made to order, phantomesque, signs and symbols of hidden decay—ghosts of women and men who have sinned and who've died and are now living in tombs. The past doesn't pass away so quickly here. You could be dead for a long time.

24-04-08 *PIAF Abstract* (to L. Hardy)

Hardyism 2: *Does time exist between measurements?*

Pauli would be very proud of you for including his question. Here was his own version of it (from a 1947 letter to Markus Fierz):

> I'm more and more expecting a further revolutionizing of the basic concepts in physics. In connection with this particularly the manner in which the space-time continuum is currently introduced into it appears to me to be increasingly unsatisfactory. ... Something only really happens when an observation is being made, and in conjunction with which, as Bohr and Stern have finally convinced me, entropy necessarily increases. Between the observations nothing at all happens, only time has, "in the interval", irreversibly progressed on the mathematical papers.

More serious comments on all manner of things later.

24-04-08 *Topos Theory Today* (to L. Hardy)

Here is my own *present* feeling about the research program of Doering, Isham, and associates. It seems to be a significant amount of mathematical obfuscation for saying, in the end, something that has been tried, tested, and debated since 1935, but generally in more accessible language: It is that something ascribed probability one should also be ascribed an element of reality. By implication, some aspect of a pure quantum state then corresponds to an element of reality. Here's the way Roger Penrose put the essential point:

> One of the most powerful reasons for rejecting such a subjective viewpoint concerning the reality of $|\psi\rangle$ comes from the fact that whatever $|\psi\rangle$ might be, there is always—in principle, at least—a *primitive measurement* whose **YES** space consists of the Hilbert-space ray determined by $|\psi\rangle$. The point is that the physical state $|\psi\rangle$ (determined by the ray of complex multiples of $|\psi\rangle$) is *uniquely* determined by the fact that the outcome **YES**, for this state, is *certain.* No other physical state has this property. For any other state, there would merely be some probability, short of certainty, that the outcome will be **YES**, and an outcome of **NO** might occur. Thus, although there is no measurement which will tell us what $|\psi\rangle$ actually *is*, the physical state $|\psi\rangle$ is uniquely determined by what it asserts must be the result of a measurement that *might* be performed on it.

What I have been left wondering is what does the category theoretic approach add to that essential point? Particularly, in what way—and for what compelling reasons—is their approach any less ad hoc than any of the other 500 approaches to quantum logic? (And I would guess there really are easily 500 other approaches along those lines, without exaggeration.) And what is the grand plan for where it'll lead (beyond saying we ought to get rid of the continuum)? Neither has ever come across to me. Though admittedly I have never worked hard to let it come across to me either: Instead, because there was no immediate (subjective) mental "hook" to it for me, I treated it as somewhat like a patent clerk receiving another detailed plan for a perpetuum mobile. Complicated, very complicated, interesting move, ingenious, I never thought of it that way ... ... but ultimately doomed to failure. Red stamp.

John Wheeler was too much of an influence on me: "The solution is not in some magical mathematics, but in some magical idea. A magical idea we've yet to see." (paraphrase)

So, there that's what I feel about the research program—as I say, *presently*. But, just because I'm guessing category theory will be barren in this particular usage of it, it does not mean that I deem category theory itself barren. Lee, for instance, has told me more than once how I might need it for my own research program. Maybe he's right. And it is always good to have a table of integrals about.

24-04-08 *An Entry That Made Me Giggle Again* (to L. Hardy)

Just inserted this one. [See 13-05-04 note "10 Lines and MaxEnt" to R. Schack.] Made me think about Moses wandering the desert for 40 years! Just no place we can call our home.

24-04-08 *Which Stern?* (to H. Atmanspacher)

I found a quote in one of your papers from a 1947 letter from Pauli to Fierz (it is a quote I had known from one of Laurikainen's books, but your version is more complete):

> More and more I expect a further revolution of basic notions in physics, where I am particularly dissatisfied with the way in which the spacetime continuum is introduced at present. (Of course it is ingenious to disband time from ordering causal sequences and — 'as once in May' — use it as a romping place for probabilities. But if one replaces ingenious by impudent, this is not less true. In fact, something happens only during an observation, where — as Bohr and Stern finally convinced me — entropy increases necessarily. Between observations nothing happens at all, only time has reversibly proceeded on our mathematical papers!) This spacetime continuum has now become a Nessus shirt which we cannot take off again! (Instead of 'Nessus shirt' you can also say 'prejudice', but this would, first, sound too harmless and, second, shift the mistake too much from a mere conception to a judgment.)

I wonder if you can tell me a couple of things about it?

1) Which Stern is Pauli referring to?

2) What is a "Nessus shirt"?

The main question is 1), as I'm preparing a better-indexed version of my "Notes on a Paulian Idea" and I want to re-post it at the same time as the posting of my new samizdat (another 500 pages, roughly May 10).

By the way, I'll be in Munich July 23 - August 9, letting my children (and wife) visit with the grandparents. I'll take a desk at the MPQ in Garching, but I don't believe I am committed to too much time there. Would there be any interest in having me give a seminar in Freiburg? I could talk about these very symmetric quantum measurements we have been spending so much time on at PI, and relate them to quantum foundations problems.

I hope all is well with you.

Harald's Reply

> Thanks for your note, good to hear from you! Of course, by all means we should organize something while you are in Germany in summer. We can make detailed plans at Paris in June, where you and I will meet anyway. If you want to have a definitive schedule earlier, please let me know.
>
> Stern is Otto Stern (of the Stern-Gerlach experiment).
>
> The Nessus shirt refers to Greek mythology, see
>
> http://en.wikipedia.org/wiki/Shirt_of_Nessus.
>
> A powerful metaphor for a present that brings harm and mischief.

25-04-08 *Which Stern?, 2* (to H. Atmanspacher)

Thanks! I figured it was Otto Stern, but I seemed to have recalled another Stern that Pauli once referred to, and I wanted to make sure I didn't make a mistake.

Yes, let's plan in June; see you in Paris. I think it'd be fun to come to Freiburg for a day or a day and a night.

05-05-08 *Appleby Papers to Look At* (to K. Martin)

05-05-08 *Kant Cola* (to M. Friedman)

It was good meeting you. I certainly appreciated your sympathetic ear for Quantum Bayesian ideas.

I thought I'd get your email address from the web so that I'd have it in my address book. Seeing your interest in Kant (and hearing the things you laughed at last night!), maybe you'll get a chuckle from this diary entry of mine: page 140 of http://www.perimeterinstitute.ca/personal/cfuchs/SamizdatSE.pdf (that's actually page 162 in machine counting, if you include preface and title pages etc.). Or you can simply search on the phrase "Kant Cola".

From 27 February 1996 note "Kant Cola" to Greg Comer

> Kiki and I went into the Outrèmont area Friday evening in search of an interesting restaurant ... and what a find we made! Let me tell you a strange little story. During the summer of 1985, I was reading a book by C. F. von Weizsäcker titled *The Unity of Nature*. Most of the book was about quantum mechanics and Kantian philosophy. Apparently it spurred me to have the following dream. I was in a little hole-in-the-wall joint somewhere in Austin; my old friend David was there, also John Simpson and

Marshall Burns. The place really stood out in my mind because of the Bohemian feel to it: dark, smoky, mystical almost. The night wasn't filled with much of interest: David only wanted to talk about getting drunk, John only wanted to talk about finding a girl, and Marshall only wanted to talk about philosophy. In those days John didn't drink alcohol, so, at some point, when he asked for a drink, I thought we'd be out of luck. But upon looking around, I saw a refrigerator in the middle of the bar near the pool table. We walked over to it and took a look. It was filled with all different sorts of vegetable drinks. John grabbed one, and I looked through it for something more interesting. At the very back, I found one lone can of "Kant Cola." That was written on the label, along with a small portrait of Immanuel Kant. I opened the can, took a drink, ... and, for a miraculous moment, I understood all the intricacies of the world—I understood the necessity of quantum mechanics. When I came out of my trance, the can was empty and I knew that I would never see the light again. Then I awoke. I was so taken with this dream that the next day I sketched out the layout of the joint and made a record of the dream. That was over ten years ago.

So back to the restaurant of Friday. The place was called "City Pub"; it was such a strange little place: dark, smoky, mystical almost. The food was excellent—far better than it should have been for the price. Each option in the place was only $4.99. I had steak, fries, and a vegetable. Kiki had potato soup, quiche, fries, and veggie. They had a special on beer, three for the price of one (so we had six). The music was some sort of strange mesh of things that I suspect you'd only hear in some little bar in Germany where everyone wears black. Anyway, we had quite a time there. However, just a little while before leaving I started to note how similar this place was to the place in my dream 10 years ago. I told Kiki the whole story. Then I looked around and—strangely enough—there was a refrigerator in the middle of the room near the pool table! I was so taken by this that upon my way to the restroom, I took a look into it. What a disappointment: it only contained beer. However, the restroom did have a surprise for me. In the middle of all the graffiti (about Québec's hoped for independence) was something written in bold black letters:

De nobis ipsis silemus
— *E. Kant*

That made my evening. I wrote down the words so that I wouldn't forget and went home to look up my old notes on the dream. Sure enough, there were similarities in the layout of the two places, and moreover, I saw that the name of the original place in my dream was "Hole in the Wall Pub." Very strange. I asked Rüdiger Schack to translate the words for me, and he came up with "About ourselves we remain silent."

05-05-08 *The Hilary Had No Clothes* (to A. Wilce and H. Barnum)

Yesterday at the Demopoulos Bash, I saw Hilary Putnam for the first time. My God, how I was looking forward to it. The title of the talk was "Quantum Mechanics and Ontology," and I had been wondering all week what flavor of subtle pragmatic consideration it would end up expressing on that subject. Well, I set myself up for the singular biggest hero-worship crash I ever had in my life. The guy—this year's version of him anyway—is a friggin' Bohmian and deeply under the influence of Tim Maudlin. I was clinically depressed the remainder of the afternoon. I didn't even seek the energy to talk to or meet with him; maybe better to let him pass through my life like a wraith.

He spoke briefly about information-based approaches to quantum foundations, like Clifton-Bub-Halvorson and your own efforts, and maybe my own and Bill Demopoulos's, I don't know. He ended his brief survey by declaring them either "instrumentalism with post-modern sauce" or "positivism with post-modern sauce"—I don't remember which as he was using both terms in the talk, but it was one of the two. Either way, it was equally insulting.

I guess I write you because I remember the little conversation we three had about him in Atlanta at a fast-food restaurant of some sort.

Recovering, but sad again for having recorded this,

05-05-08 *Pages, Coffee!, and Stairs* (to R. Schack)

I just posted an updated collection. Your name appears several more times now. We're up to 623 pages at the moment.

I'm in a London hotel, and I'll drive back to Waterloo as soon as I get a new cup of coffee in me and get a shower. I just discovered my first cup was wasted: It was decaffeinated!

I've been at the Demopoulos Bash the last two days. Yesterday, there was a very fine talk by Allen Stairs titled "A Loose and Separate Certainty." You can guess the subject: our quantum Bayesian program, and particularly our certainty paper. I hadn't realized how photogenic we three are! Anyway, as indicated, the talk was quite good, but what it indicated about our paper was not so: The guy was genuinely confused by the logic/goals/layout of the paper. And in most of the cases, I could really tell that we were the cause. For instance, he spent five minutes arguing that "Gleason's theorem could not be the greatest triumph of Bayesianism" hanging on that dreadful sentence Carl insisted on. Stairs' only sin was that he read the sentence literally, and then pointed out that there was nothing to bar an objectivist about probabilities from the premises of Gleason's theorem. And so it went with several things. I had a long lunch with him, and then sat next to him at the dinner. He strikes me as being very sympathetic to the program (and sympathetic to the idea of preserving locality at all costs); he just wants to get things straight. I invited him to stay a couple or three weeks at PI and encouraged him to write a "critical article" on us. My guess is, if he delves into this further, it won't end up being so critical, as simply clarifying.

By the way, Hilary Putnam was an absolutely huge disappointment. See story below. [See 05-05-08 note titled "The Hilary Had No Clothes" to A. Wilce and H. Barnum.]

08-05-08 *Triple Products in Dimension 3* (to D. M. Appleby)

Now, that is really cool! I think there is indeed no need to bother with a picture. I think I can figure out a good way to present this. It'll be in the context of finding the algebraically simplest possible equations for quantum state space.

As I say, I had intended to present the talk as joint work with you. I hope you won't mind: I know that I can be something of a wildcard in a talk and you may not (or quite probably will not) agree with everything I say. Actually another option is that I can up-front present the technical work as joint work with you, but make a clear statement that you may not agree with anything beyond that: Time will tell. That'd probably better as I intend to soon write this conceptual piece with business about modifications of Dutch-book coherence when it comes to SICs, etc., and I had intended to write that on my own.

Among the things I want to emphasize is the contrast between what I see as my own foundational program and the convex sets approach of Lucien and Barnum, Barrett, Leifer, Wilce, etc.:

1. They at the outset take measurements as linear maps. I, on the other hand, want to first establish a Bureau of Standards and think of measurements as refinements of probabilities w.r.t. the BoS. Linearity comes secondarily when disparate agents come to agreement that they are performing the same measurement.

2. Best measurement for BoS must be the SICs or Super-SICs. But they give no natural tensor product structure. This tracks metaphorically with the de Finettian / Applebyan idea that "probabilities are single case or nothing", and I think is a very important point. This contrasts with the usual convex approaches in that it does not take the composition of systems as a fundamental operation to be axiomatized. Instead one seeks to characterize the state space of a single system, and *when* one wants to think of separate systems, one does it by decomposing not by composing.

3. The essence of the Born rule, when expressed in terms of SICs is conceptually almost the law of total probability. There is a hidden assumption in the usual Dutch book argument connecting conditional and joint probabilities, that is apparently being surpassed here: It is that "unperformed measurements have no outcomes". Fine, but then why is there any connection at all between the Born rule and old law?

Those are maybe the major components.

Thanks, by the way, for the extensive notes on the title page. Interesting the contrasting reactions I've gotten between you, Lucien, Guido, Rüdiger, and Kiki. You and Kiki are all for the "My Struggles"—enthusiastic about it even. Guido and Rüdiger are offended by it, for some dainty European reason as far as I can tell (but one I don't want to discount, because there are a lot of Europeans in my potential reading audience). And Lucien's first thought when he heard it was "Mein Kampf". It was Lucien's initial reaction (and Guido throwing his two cents in at the same time) that sowed a seed of doubt in me. At the very least, I think I'm definitely keeping the "My"; what I'll do with the subtitles I'm still thinking about.

08-05-08 *Wigner Connectives* (to R. Schack)

Thanks for all the advice. I'll explain in Zurich why I probably won't follow it, but I needed to get a clearer sense of what I might be getting myself into.

Schackcosms fixed as requested.

I'm trusting good discussions in Zurich. I think we really broke ground the last time we were together. Your anti-Zurekian diagram is still at the top of my board. And you should have seen Bill Harper's eyes light up when he understood it. (BTW, it was Harper and Skyrms who laid the first criticism on van Fraassen when he claimed that reflection was a requirement of rationality. They pointed out that it only holds when one judges that recognizing the data is "learning something." I.e., not whacking.)

Below is something I dug up as I was compiling the samizdat. Why I called it a review of general covariance, I'm not completely sure, but it seems to fit now. Linearity of the probability rule—if you take this point of view that actions are defined as sets of likelihoods—arises as a kind of covariance between different agents. It comes about as a kind of intersubjective agreement. I.e., Dutchbook coherence is a one-agent phenomenon, but maybe, just maybe, linearity is a two-agent phenomenon? I.e., I think I'm quarreling with your discomfort with the idea again. [See 23-03-06 note titled "A Review of General Covariance" to G. L. Comer.]

09-05-08 *Keye Bayesian?* (to K. Martin)

My god, you have an interest in Bayesian ideas too? (I just dug up an old paper of yours on `quant-ph`.) How on earth did we not meet for so long? Just do a Google search on "Fuchs quantum Bayesian" and you'll get a few hits.

09-05-08 *Change of Plan* (to S. J. van Enk)

van Enkism 13: *How close were we to writing a paper on counterfactuals?? I do remember having fun making up titles ("Had we found a better title we would have used it" still looks nice!), but I remember almost nothing about the possible contents ...*

So far I found no remarks of mine in your samizdat that I regret: probably you edited them so they were not insulting to anyone. Yes, please tell me I did at least insult one person!

I don't know how close we were, but I think we need to do it. It is a point that has not come up in my other writings. Of course you insulted someone, and of course I was careful not to reprint those words ... One of the entries, by the way, is that very title. I must have written the note because you said it, and I didn't want to forget it. [See 04-04-06 note title "Title" to S. J. van Enk.]

How about this for the real paper: "Had we found a better title we would have used it: The Use of Counterfactuals in Quantum Bayesianism"?

Did you read about our new director here at PI? Ever heard of the guy. BTW, I tried to get 't Hooft to bite on the SIC problem today, but he's a slippery fish. (I explained how useful they'd be as a starting point for his hidden variable considerations.)

09-05-08 *Change of Plan, 2* (to S. J. van Enk)

van Enkism 14: [CAF wrote:]

> "Did you read about our new director here at PI?"

Nope ... does he/she like quantum information??

The more important question is does he like quantum foundations! (My guess is cosmologists rarely do.)

09-05-08 *Change of Plan, 3* (to S. J. van Enk)

van Enkism 15: *While biking back from work I was thinking about counterfactuals: do many-worlders have a different view than Bayesians on this subject??*

I guess it'd be hard to even imagine a counterfactual in a deterministic world—in a world that is one "unbending unit of fact".

12-05-08 *Foundations Curriculum* (to S. L. Braunstein)

Braunsteinism 5: *If you were to teach a graduate course in foundations of QM what topics would you cover?*

I need to decide between this and a course in quantum information pretty soon, so a quick response would be very much appreciated.

There's just one delay after another with me. You're right when you say, "sounds like you're doing a lot of traveling." Here's something I wrote another friend a couple of days ago:

> I've adopted a truly insane travel schedule again. I leave for seven days in Zurich tomorrow. Next month a week in Paris. 2.5 weeks in Munich in July. A week in Sweden in August. Innsbruck in September. Sydney in November. Jerusalem in December. And I had already been to England, Australia, Oregon, and Texas in the previous months of this year. I probably listened to the Allman Brothers Band too much when I was young.

Let's see if you get the final allusion in that.

Here are the kinds of topics I myself would cover in a quantum foundations course. (Of course keeping in mind that I have little sympathy for hidden-variables, GRW, or many-worlds: I.e., I have an agenda. An agenda which takes as a rallying point something Asher first drove home to me, "Unperformed Measurements Have No Outcomes." Thus quantum foundations, as I see it, is about exploring the truth in that phrase at the same time as *not* giving up on the more basic agenda that world would still be here if we petty humans happened to drop dead tomorrow. That physics is an attempt to say something about the world as it is without us.) Thus, the topics below, roughly in the order I'd weave them together.

1) As warm up, selections from Mermin's book *Boojums All the Way Through*. and/or his Rev. Mod. Phys. **65**, 803 – 815 (1993) paper, "Hidden variables and the two theorems of John Bell."

2) Keeping with that theme some selections from Appleby's paper "The Bell-Kochen-Specker Theorem" `quant-ph/0308114`. Maybe also for fun, go over Asher's 33-ray state-independent proof, and Clifton's 8-ray state-dependent proof (old papers, not on `arXiv`).

That material sets the stage for the slogan, and leaves the tension of "My god, where do we go from here?". Accept action at a distance? Or accept that quantum states are not elements of reality, but more akin to incomplete information? (Leaving aside for the moment, the question of information about what.) At this point I would start to move down the informational track, with a prelude of showing off various of the phenomena of quantum information theory: no-cloning, no-broadcasting, teleportation, entanglement monogamy, superdense coding, such things. And then backtrack, by hitting the students over the head with:

3) Spekkens' toy model, `quant-ph/0401052`. That should clench any doubt that quantum states are analogous to incomplete information.

But information about what? At that point introduce them to two parallel themes (that are not yet married but to some extent flirt with each other):

4) The quantum Jamesian pragmatism of Fuchs `quant-ph/0205039`, the quantum Bayesianism of Caves, Fuchs, and Schack `quant-ph/0404156`, `quant-ph/0608190`.

and

5) The relational ideas of Rovelli `quant-ph/9609002`.

Those are both attempts to speak to the issue of information about what (in a way that is not hidden variables).

You might bolster that with a side tour on Bayesian probability itself:

6) Appleby's two papers are about the best things out there: `quant-ph/0402015` and `quant-ph/0408058`.

But if all those ideas on the right track, how do they imply the mathematical shape of quantum mechanics? Well we haven't figured that out yet, but there have nonetheless been some valiant attempts to derive the shape of the theory recently and they should be reviewed for the insight they might give:

7) Hardy's Five Axioms `quant-ph/0101012` (Hardy has a new version not yet posted that he'd probably share with you).

8) The convex sets work of Barnum, Barrett, Leifer, and Wilce: `arXiv:0707.0620`, `arXiv:0803.1264`, `quant-ph/0611295`, `arXiv:0712.2265`.

I'd guess you're at a whole course by now. But if you still have time, and want to leave on a positive note, maybe explore what all this might mean for the one-way model of quantum computation. Honestly, I think that's a grand playground for this kind of point of view in quantum foundations: For there it's obvious that by kicking the cat (state), you really do set the world in motion.

Hope all of this is of some value to your thinking.

12-05-08 *Fascination with Words* (to W. G. Demopoulos)

Can you explain in simple English and give an example or two of what Carnap meant by a "functor"? The term came up at PI's wine and cheese Friday as I joked that I'd like to see quantum measurement outcomes not as indicative of properties of the system, or even indicative of a relation between the system and agent, but rather as a functor of the two objects (system + agent). Then I mumbled some things about the sexual interpretation of QM, and finally admitted that I had no idea what a functor is, but just really liked the sound of the word.

On the other hand, just now I read this in wiki:

> Carnap used the term "functor" to stand in relation to functions analogously as predicates stand in relation to properties. [See Carnap, *The Logical Syntax of Language*, p. 13–14, 1937, Routledge & Kegan Paul.] For Carnap then, unlike modern category theory's use of the term, a functor is a linguistic item.

which intrigues me.

Greetings from Zurich. I just arrived a couple of hours ago, and the spirit of Pauli already seems palpable.

12-05-08 *Fascination with Words, 2* (to W. G. Demopoulos)

Demopoulosism 34: *A functor, for Carnap, is just a functional expression—an expression for a function. So this is a case where Wiki is a reliable guide to the truth.*

You may be a distinguished, honored professor, but you don't read instructions very well! Now I'm more confused than before. Trouble is I have no training in philosophy. Thus, what you've written appears to me to contradict wiki. Probably because I don't really know what "functional expression" is, nor do I really know what "predicate" is. If you could draw up a couple of examples, that'd probably really help me.

Bill's Reply

Let me try to keep it simple; I can give you the long answer when we get together.

The linguistic expression

x is even

is used to express a property of integers. Upon substitution of a numeral name or other singular term for the variable, the result is either a true or a false sentence.

But the linguistic expression

x + y

is used to express a function from pairs of numbers to numbers; upon substitution for the variables, the result is a singular term which picks out a particular number:

x is even/x+y :: predicate/functor.

And by implication, predicates go with properties, functors with functions.

I'll be curious to know if this settles your perplexity, which I suspect is not at the level of words.

I don't recall what a category theorist means by 'functor' but I think it's a *special* kind of function, not a general term with the same meaning as 'function.'

12-05-08 *Fascination with Words, 3* (to W. G. Demopoulos)

That helps quite a bit. I'll keep thinking. I like the word so much, I really do want to use it! Homework challenge for you: find a place where a functor arises in your thoughts on effects.

13-05-08 *Incendiary Stuff* (to C. Misak)

Thanks for the abstract. It'll be good to start a dialog with you. But watch out, the charge of postmodernism is incendiary stuff! It is true, that I think quantum mechanics indicates a certain malleability to reality—that nature can be sculpted to some extent—that is indeed a description I like. But it's a far cry from that to the more extreme idea that reality is just a conversation.

See Sections 4 and 5 in the attached pseudo-paper. A reality that gave no resistance to our whims (or conversations) wouldn't be of much use, I would think.

I'll get your abstract into the PI schedule.

Greetings from Zurich, in case I haven't already sent them!

13-05-08 *More on Malleability* (to C. Misak)

This is secondary material – certainly I hope you'll read the stuff in the last note I sent you before touching this. But while I'm bombarding your email box, I thought I'd go all out.

You can find the aspects of William James that I take seriously here in the attached, starting at item 237. Also, in the Menand item 302, you'll see some of the strains of pragmatism I like best. Schiller in 411. The pieces of Rorty I toy with taking seriously start at 395. But you should never lose sight that I am an experimentalist in thought (part of the nature of being a physicist). Please resist lumping me in with a set school.

I guess your abstract made me sensitive; the last thing I need in this serious effort to get quantum mechanics straight is a misplaced charge of postmodernism. It is bad advertising.

13-05-08 *Misak Tuesday* (to J. E. Sipe)

These are interesting thoughts indeed! I've never thought about things like this. What a place for them to hit me, here at the home of Pauli! (I'm in Zurich at the moment.)

The meeting has not been forgotten; it's just been put into the planning of next year. Next week I will start discussing it with Misak. You might be amused by her abstract. Here it is:

> Some theoretical physicists, Chris Fuchs among them, take quantum mechanics to go hand in hand with an anti-representationalist accounts of truth and reality such as that offered by the American pragmatists — William James, Charles Peirce, Richard Rorty, etc. On this view, scientific theories are instruments, rather than mirrors of the real world. In this talk, I'll suggest that if the quantum physicist is to team up with the pragmatist, he'd do best to join not with James and Rorty, who see the world as radically plastic or malleable. He would do best to join with the founder of pragmatism, Peirce, who argued that a regulative assumption of inquiry is that there is a right or determinate answer to the question at hand. It may look as if the anti-representationalist quantum theorist will be unhappy with this suggestion, but I'll argue that this would be a mistake. The trail of the human serpent, as James said, is over everything but, as Peirce saw, this does not toss us into the sea of post-modern arbitrariness, where there is nothing to say about what is true and what is real.

I love the way she talked about "some theoretical physicists" in the plural!

John's Preply

> Sorry I'll miss the talk on pragmatism; it sounds great. But I'm waiting to hear the announcement for that great workshop you'll be running on pragmatism! ☺
>
> A quick thought: I was musing about that workshop and how one of the goals is to confront the the idea of a block universe with a more pragmatic one. That suggests looking for particular instances where 'block universe thinking' and your 'reach out and touch someone thinking' give one different perspectives or different strategies for dealing with various issues. Just for fun, here's a kind of sci-fi issue: Consider the idea of time travel. The usual objections or difficulties in thinking about it is that you might be able to go back in time and inadvertently kill your grandfather, and then how could it be that you would have been there to do that, and so on and so on. These difficulties seem to me to follow from at least implicitly thinking in a 'block universe' way, with the past and present and future all carved out in the block. It's that that seems to lead to the kind of contradictory situations that one might be able to get into were time travel possible. But if one abandons the block universe view completely, and doesn't think of space and time in this way at all, are the problems of time travel so severe? I'm not asking for a technical solution here, of course, but a discussion involving the concepts.
>
> Grist for a philosopher's mill. How is the pragmatic analysis of the possibility of time travel different from the block universe analysis?
>
> If you don't think this is too stupid, you might ask Cheryl.

14-05-08 *Many Thanks for Those Papers* (to C. Misak)

Misakism 3: *Now that I've read the papers you sent yesterday, I've got a much better set of things to say. You really are a Peircean, not a Jamesian or a Rortian. And that's a good thing!*

My guess is that I'm a nuance that's taken elements from all three. And those elements are likely not consistent ... but they strive to become so in a greater unity motivated by quantum foundational considerations. In any case, I'm glad you seem to have enjoyed what you read.

See you Tuesday.

15-05-08 *1:30 AM Note – Decompressing the Day* (to D. M. Appleby)

A very short note. I believe I made some inroads today with the talk. I think it went quite well. Ben Toner called it "a beautiful talk". Mauro got very excited as usual, and reprimanded me (as usual) for talking about things not yet published (not because he cares about my career, I think, but because he momentarily wants to get his students working on the stuff). Reinhard Werner was attentive, and that was flattering enough—I respect Reinhard a lot. Mathias Christandl really liked the stuff on modified coherence. Howard Barnum tolerated it kindly, even though he surely understood all this stuff long ago. Časlav Brukner was pretty happy, though he pointed out that I did not mention about how he and Anton where the first to make a big deal of the quadratic entropy in quantum mechanics—I really should have; the ellipsis wasn't intentional, but I felt very bad. Alex Wilce said he much better understood the foundational importance of SICs and my obsession with them after listening today; and wanted to get the summer students in his REU working on the project. So I was very happy in general. Gisin was dismissive as usual, but I did not expect less. I had an edifying conversation with him. One thing he emphasized was how wrong he thinks my attitude is that one should take the single system as basic in an axiomatization of QM (rather than giving composition rules like Hardy and everyone else). My point was that tensor products should be derived from decomposition, rather than composition. Gisin said I would miss entanglement that way. I explained that I would not, could not. And I explained how the move was much more in line with your dictum, "Probabilities are single case or nothing"; it is a Bayesian move demanded almost by consistency itself. He said, "Well, Jauch and Piron could get the tensor product from their approach too, but then it took out the mystery of entanglement. Of entanglement, all they could say was 'so what?'." And all I could say was, "Exactly!" "You cling to a mystery; whereas I want to get enough understanding to move to the next stage."

One highlight of the day was meeting Ernst Specker. We talked on the bus, and then shuffled very slowly across the campus. He is 88 and an amazing man. He explained to me how the Kochen-Specker theorem (which he had first published by himself five years before the usually cited joint paper) arose from a theological question. At the time, he really wanted to know whether God could know what the world would have been like if Hitler were never born. He had all kinds of insight to share with me in that hour I had with him, and I loved it. He dismissed the nullification of Meyer as not understanding what real numbers are really about (I didn't completely understand him, but the best I could surmise he thought Meyer was committing a category error). The thing he wanted to emphasize is how often we are caught up in thinking we have a good grasp of reality. The way he viewed it, almost all of physics and our usual discourse is just of "surface phenomena." He said we just have no clue of how much more there is to the world than that. In his lecture, he was very funny, but very serious. He said we should always strive to see the world from the perspective of the things around us: For instance, try very hard to imagine the world as it "appears" to a flag wrapped around a flagpole. I think he was very serious on that point, actually. Wonderful man from what I could tell.

OK, not such a short note, but a grand day. Tomorrow, I recover from these too many beers, and get back to work on the grant proposal.

Thanks for all the help getting me here.

16-05-08 *2:35 Happy Blues* (to R. Schack)

I know you're sound asleep at the moment (it's 2:45 AM), and that you probably won't read your email until the weekend is over.

But I thought I'd give you a progress report. I still can't see how to get the triple product constraint, but I have been able to tell this much: The constraint that the probabilities lie on a sphere is not sufficient to insure that the modified coherence formula be nonnegative. Here's a simple example of two probability vectors which will make the quantity go negative:

$$\begin{aligned} p &= (0, x, y, y, ..., y) \\ q &= (x, 0, y, y, ..., y) \end{aligned}$$

Fulfilling the proper constraints:

$$\begin{aligned} x + (d^2 - 2)y &= 1 \\ x^2 + (d^2 - 2)y^2 &= \frac{2}{d(d+1)} \end{aligned}$$

one finds that the Born rule quantity

$$d(d+1)\sum_i p(i)q(i) - 1$$

already goes negative at $d = 3$.

That is very good. Because I think it now much more likely that we really will need the extra triple-product constraint to keep things from going negative.

I hope you have a good trip back to London in four hours.

17-05-08 *Springtime in the Air* (to G. Musser)

Yes, definitely desirable and soon. My writing cap is on again, in fact. I was stirred by John Wheeler's recent death and had started to compose a note to you the day after. It would be wonderful if I could combine a story on quantum Bayesianism with a story of the "law without law" and "it from bit" of John Wheeler.

I'm in Zurich, and traveling back to Canada tomorrow; fighting a deadline to get a grant proposal in by Wednesday (which I absolutely have to get out the door); and sparring with a pragmatist Tuesday who likely will say some bad things about me. See: [`http://pirsa.org/08050041/`, possibly?]. (It might be a cup of tea that'll interest you, when it's broadcast on the web starting Wednesday; follow the link on the page I just gave you.)

I'll get back in touch with you Wednesday. Thanks for the amazing stamina you've shown in trying to get me to write. It is very flattering.

19-05-08 *Plurals, for Your Reference* (to C. H. Bennett)

Bennettism 33: *Umlauting the vowel and appending an -e is one of the commonest German plural patterns, as in Ansatz ⇒ Ansätze or Fuchs ⇒ Füchse.*

I've never been pluralized before. Thanks for letting me know how to do it!

20-05-08 *SICs at PI* (to H. B. Dang)

I thought I'd keep you up to date on my activities. Attached is a proposal that I just sent off to ONR. If you dig around, you'll find your name mentioned in the proposal briefly. If by wild chance I get the money, you would have the first shot at it, if you want it. That would free you from having to do anything with quantum crypto, and you could devote yourself fully to foundations (ahem, the quantum information theory of SICs).

Schack and I made great, great progress last week in Zurich. I believe we are on the verge of having something I would be willing to call "the fundamental equation of quantum theory." It's turning into quite a beautiful story, but the work is not complete yet.

21-05-08 *John Wheeler* (to S. K. Stoll)

Thanks; I wish I could be there to hear it. When John died, my collaborator Rüdiger Schack was visiting, and it was funny how, spontaneously, all week long I would keep coming back to stories of him or some aspect of his thought. He's a big part of my mind. I didn't know you knew that.

I hope all is well with you.

21-05-08 *Determinacy, Determinates and Determinable* (to J. R. Brown)

It was good meeting you yesterday. I was able to dig up the correspondence I had with Demopoulos about the terms above. Sorry my memory was so frazzled last night. You can see what he meant by going to text pages 596 and 601, page numbers at the bottom of the pages (or pages 619 and 624, respectively, by the raw pdf page count on the top) of the following file: `http://www.perimeterinstitute.ca/personal/cfuchs/nSamizdat-2.pdf`. At least my memory had served me that W. E. Johnson was the right character. [In the present document, see 03-02-07 note "Bill's Thoughts on QL and QI Frameworks" and 04-02-07 note "The Painful Ambiguity of Language," both to W. G. Demopoulos.]

The document I link you to is currently under construction, so I apologize for its present lack of an introduction and its incomplete index. (And I apologize if the page numbers have changed by the time you take a look at it; in which case, just use the search tool to search on "determinacy," etc.) I'm somewhat infamous for publishing my foundational emails; this will be a new collection of them, posted officially relatively soon.

Jim's Reply

> Thanks for the passages from Demopoulos. The idea that we should chop up the world in a very different way (different from objects with properties and the probability

of specific instances) is somewhat radical, but may well be right. Certainly worth considering, at the very least.

It turns out I have a copy of Johnson's Logic, though until now I never read it. The determinable-determinate distinction comes up when he's trying to distinguish "Plato is a man" from "Red is a colour". Grammatically they are the same, but (he rightly claims) they are quite different logically. In a type hierarchy it is easy to see: "Plato" is an individual object, "is a man" and "is red" are first-order properties of objects, "is a colour", is a second-order property, ie, a property of properties. For Johnson, a determinable is like a second-order property and a determinate is a first-order property. Eg, Mary (individual) has the property weight (determinable) and the magnitude of her weight (determinable) is 60 Kg. I presume the QM analog would be: An electron (individual) has observable momentum (determinable) and the eigenvalue is p (determinate). This might turn out to be useful terminology. It is certainly better than the standard "observable."

I'm attaching an invitation to Dubrovnik next April when we're doing physics as a topic. There will be lots of people, including many you know. The place is stunningly beautiful and the conference lots of fun. Try hard to make it.

22-05-08 *Struggles with the Block Universe* (to C. Misak)

Misakism 4: *Many thanks for the invitation Chris. I had a great time and learned much!*

No, thank you for coming! Meeting you has made me wish we could get a serious study group going about these things—too bad you're (I'm) so far away. (By the way, my knowledge of Chauncey Wright came from Philip Wiener's book, "Evolution and the Founders of Pragmatism"; have you seen that one? It might be good material for your present study.)

I'm really angered that I seem to have lost the notes I took at your talk. There were a few things I wanted to reply to. I guess I'll just have to listen to your talk again eventually, and take it from there.

But there is at least one issue that stayed in my mind from the lunch conversation that I can potentially reply to. It is that I got the impression you were dubious of mixing Peircean tychism and Bayesian probability into the same pot. Don't let it be so! (If it is so.) They're perfectly compatible, and not getting confused on the subject, as many fans of Peirce are (like Abner Shimony), is the first step to making progress.

Here's a place to read a little bit about the way to think of it. [. . .]

22-05-08 *Contextuality* (to R. W. Spekkens)

Spekkensism 42: *Speaking of the "recent resurgence of interest in [contextuality] in quantum information and quantum foundations communities," I forgot to tell you about the QIP application of contextuality that Ben Toner and I have finally nailed down: parity-oblivious multiplexing. See* `http://arxiv.org/abs/0805.1463`*.*

Your new results sound juicy. I'm surprised: I didn't realize you were an experimentalist. Watch Cheryl Misak's talk on PIRSA [see `http://pirsa.org/08050041/`]:

American Pragmatism and the Construction of the Universe

> Some theoretical physicists, Chris Fuchs among them, take quantum mechanics to go hand in hand with an anti-representationalist account of truth and reality such as that offered by the American pragmatists — William James, Charles Peirce, Richard Rorty, etc. On this view, scientific theories are instruments, rather than mirrors of the real world. In this talk, I'll suggest that if the quantum physicist is to team up with the pragmatist, he'd do best to join not with James and Rorty, who see the world as radically plastic or malleable. He would do best to join with the founder of pragmatism, Peirce, who argued that a regulative assumption of inquiry is that there is a right or determinate answer to the question at hand. It may look as if the anti-representationalist quantum theorist will be unhappy with this suggestion, but I'll argue that this would be a mistake. The trail of the human serpent, as James said, is over everything but, as Peirce saw, this does not toss us into the sea of post-modern arbitrariness, where there is nothing to say about what is true and what is real.

It was quite a good talk. But she made me sound plumb danged like a philosopher. (And that surprised me too.)

22-05-08 *Unstoppable Forces, Immovable Objects* (to H. R. Brown)

Barnumism 17: *Before she left Cheryl [Misak] told me how much she enjoyed the visit to PI yesterday; you must be pleased with the outcome. And thanks for responding to my criticisms (again) with such good grace yesterday!*

Your criticisms are a pleasure, precisely because they're much needed. They are reminders that I don't have as adequate or as pithy of answers for you as I would like to have.

This question of why update probabilities when one's eyes are closed is a good one. I understand your point well. If one supposes ontic variables (hidden or otherwise) underwriting the results of quantum measurement outcomes, then one has an immediate story for why one is updating one's probabilities (for measurement outcomes, that is) when one's eyes are closed and time flows by: One's degrees of belief should change, because one is supposing the ontic variables to be changing by some objective dynamics.

But we quantum Bayesians presumably have no recourse to such a story, as we reject hidden variables Bohm-style, as well the objective wave functions Everett-style. Our probabilities are probabilities *directly* about experience—directly about the consequences of an agent's interaction with a system external to himself. In the vernacular, probabilities directly about measurement outcomes. So, the point is, you surmise, why would we ever write $p_0(h)$ now, and $p_1(h)$ later, when learn no new data in the meantime?

However, as Marcus Appleby emphatically replied (when he was last visiting and we were discussing your point): one writes $p_0(h) \to p_1(h)$, *precisely* because one does believe SOMETHING is changing. And I have to agree with that. The only question is what is changing? What do we q Bayesians believe is changing with the flow of time?

This is where my answer becomes inadequate, even by my own lights. An agent in this quantum setting changes his probabilities because he believes something integral between himself and the system is changing. But to break it down into a change of variables internal and a change of variables external I will not do; that would be a step backward from our point of view.

I would love to have a more precise answer for you, but I do not have it presently. And when I do have it, I won't only have it for you, but the whole research program will have moved forward significantly by the understanding it'll bring. So, I welcome the question, but one final point on it:

Not having an answer to one isolated question is not a blemish on the program in my eyes. It rather means the program is alive, in contrast to the usual way I view the Everettian program as dead: New PHYSICS will come of it. It has to; it's forced to. Physicists are not born into the world with all the answers. Rather the lucky ones are born with a good nose that'll lead them in directions of progress.

The bit of progress we have made in the last few years is that we now understand much better how to view quantum states in purely probabilistic terms (purely Bayesian or subjectivistic terms, I would even say). And it hangs together with a formal coherence that surprised even us. That, we see as an overpowering clue that we're on the right track. Here's the way, Rob Spekkens put it very eloquently (with regard to his particular approach) in his original toy-theory paper:

> Because the theory is, by construction, local and non-contextual, it does not reproduce quantum theory. Nonetheless, a wide variety of quantum phenomena have analogues within the toy theory that admit simple and intuitive explanations. ... The diversity and quality of these analogies provides compelling evidence for the view that quantum states are states of knowledge rather than states of reality, and that maximal knowledge is incomplete knowledge. A consideration of the phenomena that the toy theory fails to reproduce, notably, violations of Bell inequalities and the existence of a Kochen-Specker theorem, provides clues for how to proceed with a research program wherein the quantum state being a state of knowledge is the idea upon which one never compromises.

The point is, we know which idea NOT TO COMPROMISE on anymore, and we let that partially lead the way to new physics. Your great question is part of that process.

Now to another issue. It is an important psychological question, I think, as to the roots of why we don't see eye-to-eye. I look 1) to the sheer number of phenomena in quantum information theory (from no-cloning to teleportation to correlation monogamy to 25 other things) that come about immediately for any kind of incomplete knowledge (i.e., without any regard to quantum issues), and 2) to the formal near equivalence of quantum theory and probability theory simpliciter. Those two things together lead me down this research path.

For point number 2), SICs make it particularly obvious. See the attached file, which contains the core of the scientific part from the proposal I just wrote for ONR—it is the best introduction I have at the moment. In that language, the Born rule is nothing other than a mathematically minor variation of the law of total probability. And unitary evolution? Well, it is exactly the same thing—formally, the same expression! Look at the last two equations on page 5 and the first equation on page 6:

> Let us describe a unitary evolution $\rho \longrightarrow U\rho U^\dagger$ in these terms. In terms of probabilities, this is just a transfer from an initial probability distribution $p(i)$ to a final one $q(j)$. What is amazing is the way the formula, to within a sharpening factor and a renormalization, looks exactly like a classical stochastic evolution:
>
> $$q(j) = (d+1)\sum_i p(i)t(j|i) - \frac{1}{d}\ ,$$
>
> where the $t(j|i)$ are matrix elements of a doubly-stochastic transfer matrix, which itself is a SIC representation of the unitary operator U:
>
> $$t(j|i) = \frac{1}{d}\mathrm{tr}\Big(\Pi_j U \Pi_i U^\dagger\Big)\ .$$
>
> In other words, aside from the universal sharpening factor $(d+1)$ and the renormalization $1/d$—both of which are some kind of "quantum magic" independent of the particular

unitary U—a unitary evolution in this language is mathematically identical to a noisy classical channel.

Now, the SIC measurement is only there for the representation, but what we are generally interested in are the probabilities of outcomes for some *actual* measurement, perhaps a measurement of the computational basis at the conclusion of a quantum computation. For instance, suppose the measurement of real consideration is a von Neumann measurement consisting of d outcomes characterized by an orthornormal basis $|j\rangle$. Then the usual calculational tool for quantum probabilities, the Born rule, turns into a mathematically minor variation of the *classical* law of total probability! To see this, let $p(i)$ represent the probabilities of the imagined measurement as before, and let $Q(j)$ represent the probability of outcome j in the measurement that will actually be performed. Furthermore, given an outcome i for the imagined measurement, let $T(j|i)$ represent the probability of an outcome j in the actual measurement, but now thought of as occurring immediately after the imagined one. Then,

$$Q(j) = (d+1) \sum_i p(i)\, T(j|i) - 1 \; .$$

In fact, aside from the differing normalization factor (a 1 instead of a $1/d$), this formula is mathematically identical to the one that represents unitary evolution itself.

My physicist's sense says that points 1) and 2) cannot be coincidence. Your philosopher's sense, as far as I can tell, says that it can be NOTHING BUT a coincidence. Thus you lob back the challenge to me, "But what of the intricate structure of the Schrödinger equation?"

And I have an answer to that: The Schrödinger equation is simply our method for setting the conditional probabilities of the last equation of page 5. In character, in fundamentals, it is a method of no great conceptual distinction from Ed Jaynes' introduction of the maximum entropy principle for setting prior probability assignments in statistical mechanical problems. That, I already feel as an adequate answer. But my relations with you are such as to lead me to be believe that you'll think I'm simply not getting the point.

So, I wonder why *you* don't get the point? And you wonder why *I* don't get the point!?! And with that, I start to speculate that perhaps there is something so deeply ingrained in our individual worldviews that it is blocking translation between the two of us. That is the psychological point.

In any case, all I can say is there's work to be done, and I have not dismissed your question!

I hope you won't mind, but I plan to forward this note to Marcus Appleby, Rüdiger Schack, and Rob Spekkens (by the end of the day), as it should impinge upon their own thinking.

23-05-08 *From Waterloo* (to M. Pérez-Suárez)

You will have discovered that I'm not the email man I used to be: It takes me forever to reply to things now. ...

Lately I have been more excited about SICs than ever. I'm writing a paper at the moment on why they're so very special. I will be sure to send it your way when it's done. If you're interested in seeing some of my recent talks, you can go here: `http://pirsa.org/`. Just do a search on my last name. Another you might find interesting is Cheryl Misak's comparing and contrasting some of the things I've written with C. S. Peirce's writings. Schack by the way, has had some interesting developments in analyzing quantum random number generators from a Bayesian perspective. You might write to him for the latest.

27-05-08 *The Best Time* (to R. Renner & O. C. O. Dahlsten)

Sometimes it takes a while for the things on my mind to come out on paper. I want to tell you guys how much I enjoyed your conference, how much I learned, and how much I was taken with the city of Zurich. Despite my spending so much time locked in my room writing a grant application (which had to be turned in on the day of my return), the week in Zurich turned out to be the best conference of the preceding year for me. Rüdiger Schack and I broke an impasse in our q-Bayesian program while there, and we now have the glimmer of something we think is going to be very, very fruitful. And my moments with Specker were priceless—it was a once in a lifetime chance. So thank you both again. The conference was simply fantastic.

28-05-08 *Unstoppable Forces, Immovable Objects, 2* (to W. G. Demopoulos)

Let me send you this note I wrote to Harvey last week for two reasons. [Sentence parsed as, "Let me send you (this note I wrote to Harvey last week) for two reasons."] The first is because the attached document lays out the formalism I showed you on the board yesterday (though, unfortunately, it is buried in the middle of a grant proposal). Second, it dawned on me overnight, that Harvey, once he's thought about it enough, will surely make the same point with you that he continually makes with me.

The criticism would be this: If every property intrinsic to a particle is eternal and timeless from your point of view, then why would we ever write down dynamical (time evolving) probabilities for effects? What is changing if not the particle itself? That would be his question. Further explication below. [See 22-05-08 note titled "Unstoppable Forces, Immovable Objects" to Harvey R. Brown.]

I got to page 5 of your paper last night; I'll try to come back to the rest of it over the weekend. I can say this much right now: I wish I could see the force of your argument for determinacy better; it still seems elusive to me.

29-05-08 *Unstoppable Forces, Immovable Objects and their Points of Contact* (to H. R. Brown)

Would you give me a reference (or, better, a copy) of your paper with Guido, where you take issue with the EPR criterion of reality?

29-05-08 *Determinacy, Determinates and Determinable, 2* (to W. G. Demopoulos)

Demopoulosism 35: *I copied the Specker paper and put it in the mail today. It's very short and very elementary, but it shows that he had the main theorem before 1960. There are a number of interesting things about it, not least his implicit general understanding of the significance of the theorem as having to do with prediction, things I'd forgotten. Oh and I forgot to say that Allen [Stairs] did the translation.*

Regarding your remark, the title of Specker's talk at the meeting I attended was "Infuturabilia and Quantum Logic." Looking on the web, you won't find any entries on this strange word, but if you look up "futurabilia" you will find plenty. Particularly you'll find things about Leibniz's discussion of God's knowledge of counterfactuals. Kind of fun.

29-05-08 *Determinacy, Determinates and Determinable, 3* (to W. G. Demopoulos)

Demopoulosism 36: *Regarding Harvey's question, no doubt the particle is changing; but (I hope I'm not being too glib here) isn't the point of the effects framework precisely this: we can ignore how the particle changes, how it evolves dynamically, and still recover the phenomena—still recover the effects particles produce in various controlled settings.*

You're not being glib. But also I don't think you are helping yourself by talking that way. To say, "we can ignore how the particle changes" is, linguistically at least, pretty much on the verge of invoking hidden variable imagery. Something much better is called for, I would say, and that is why Harvey's question is a good experimental playground.

29-05-08 *Infuturabilia* (to E. Specker)

It was very good meeting you on the bus before your talk at the "Information Primitives and Laws of Nature" conference a couple of weeks ago. It was also very nice walking with you across the campus. I hope you remember me. Your "colorability" results (as in your construction with Simon Kochen) have long interested me, and I well believe they are the key conceptual component of quantum mechanics.

Thus I wonder if you would entertain an email conversation with me? To some extent I have become something of a historian for my small community within physics—the field of quantum information—and I enjoy recording stories on the origins of this and that all around. An example of some I have recorded can be found here: `http://www.perimeterinstitute.ca/personal/cfuchs/SamizdatSE.pdf`.

In that vein, would you record some of what you told me when we met? Would you tell me again about what was on your mind when you first started thinking about (what we in my field call) Kochen-Specker constructions? What were the years? Were you initially thinking about quantum mechanics, or rather theology? I believe I understood from you that these things were on your mind well before you had met Si Kochen—but I want to get all the facts straight.

If you will share this history with me it would be much appreciated. I learn in many ways—some by logical thought, but some by simply compiling history. (In my own way, I too have been concerned with infuturabilia for a long time; see this collection of thoughts in particular `http://www.perimeterinstitute.ca/personal/cfuchs/nSamizdat-2.pdf`.)

E. Specker's Reply, "Futurabilia"

> Thank you for your mail — I shall try to answer your questions as far as possible, but I need some time, for instance I have no idea when the seminar of Gonseth and Pauli was held. In the mean time you have perhaps a look at my article "Was is ein Beweis", published in a book *Grenzen des Wissens*, where there is a reference to the notion of "double truth" of Ibn Rushed. I hope that you understand German. By the way, we had in Cornell a friend named Wolfgang Fuchs. We liked to discuss in German — and not, as an other emigrè called it, American baby talk. If you do not understand the article, please let me know and I shall stick to English.

30-05-08 *Futurabilia* (to E. Specker)

Thank you much for your note. I look forward to your more detailed reply. I apologize, but I don't speak a word of German. Unfortunately, my ancestors came to the United States (Texas actually) in the 1870s–1880s, so that by the time I stuck my head into the world, there was only English around me. So, I know that this will make it more difficult on you (and you don't deserve that at 88), but German would be completely lost on me.

I am intrigued by your mention of Gonseth and Pauli, and wonder how they fit into your story. Did these two people influence your thinking about infuturabilia? I looked in my own database of Pauli'an things, and found these two items having something to do with Gonseth, but otherwise, I don't know who Gonseth was.

> F. Gonseth, "Remarque sur l'idée de complémentarité," Dialectica **2**, 413–420 (1948). Wolfgang Pauli writes of this article in his introduction to the special issue of Dialectica:
>
> > Many of the articles mention possible applications of the idea of complementarity outside physics, as for instance to questions connected with biology or psychology. I shall not discuss these questions in this introductory survey but wish to draw the reader's attention to the interesting attempts of Gonseth to formulate the idea of complementarity so generally that no explicit references is made anymore to physics in [the] proper sense. This is, of course, only possible by the use of a language to which the physicists are not accustomed, which uses expressions like "horizons of reality," "profound horizon" and "apparent horizon," "events of a certain horizon." The word "phenomenon," however, is used in this article strictly in the above mentioned sense given to it by Bohr. To the "profound horizon" of Gonseth belong the symbolic objects to which conventional attributes can not be assigned in an unambiguous way, while the "traces" of Gonseth are identical with the "phenomena" in our sense. I wish again to stress here the circumstance that the free choice of the observer can produce either the one or the other of two "traces" and that every phenomenon or "trace" is accompanied by an unpredictable and irreversible change in the "profound horizon."
>
> W. Pauli, "Theory and Experiment," Dialectica **6**, 141–142 (1952). Translated in Ref. `\cite{Pauli94}`, pp. 125–126.
>
> > F. Gonseth's dualistic standpoint in regard to the "Dialogue between Experiment and Theory" appears to me to be a special case of the more general relation of internal (psychical) and external (physical). In the situation of *cognition* we are concerned with the relation of the cognizant to the known. The purely empiricist standpoint, which seeks to reduce every "explanation" to a "description" (albeit a general and conceptual one) leaves out of account the fact that in every case the setting up of a concept or system of concepts (and hence also a law of nature) is a *psychical reality* of decisive importance.

30-05-08 *Answers and Stories* (to O. J. E. Maroney)

I'm curious to know whether I answered the question you wanted me to answer yesterday? Or was I off on a tangent on another subject?

Funny story, I don't know if I ever told you. Do you know of how much of a big deal Ed Jaynes made of the original rejection of his first MaxEnt paper? He framed the referee report to show and put it on the wall in his office to show students how inane referees can be. Well, as it turns out, Landauer's first erasure paper was rejected too. It put a great smile on my face when I learned that Jaynes was the referee. If you want, sometime I'll show you the referee report (which I don't think I'm allowed to distribute yet). [See 26-10-04 note "More 'More on Landauer'" to W. T. Grandy, Jr.]

If you're interested in lunch, come get me on your way up.

02-06-08 *Unstoppable Forces, Immovable Objects, 3* (to W. G. Demopoulos)

Demopoulosism 37: *As for instrumentalism, there is certainly this difference: an instrumentalist will refrain from saying that a theory is true—it's merely instrumental for getting predictions. But I think QM gives the true description of the algebraic structure of effects, just as CM sought to give the true description of the algebraic structure of propositions. So in this respect I still think of my view as realist. But it's also realist in a more mundane sense insofar as it holds that the reality of the micro world is an observer independent one; it therefore coincides with the realism of Einstein, which was rejected by Born and others.*

First quick comment. I think you're being too hard on Born. In an important and probably never cited essay, he made it clear that he believed in the same kind of man-independent reality that Einstein believed in. Born was not simply positivist. In the essay (I wish I could remember where I read it), he identified the man-independent stuff with the symmetries quantum theory was built on top of. That is a position, I think, not unlike Carl Caves's that John Sipe tries to capture in the essay I sent you.

I will try to remember the source.

Other comments later as they bubble into existence.

02-06-08 *My Christmas Present?, 2* (to S. T. Flammia)

[See 27-12-06 note "My Christmas Present?" to G. L. Comer, S. J. van Enk, and J. W. Nicholson.] Apparently my reputation has somewhat recovered since that time. Google brings up only two pages of hits now, whereas apparently then it brought up three.

It seems that the CSIQM page is indeed gone now; I guess even porn doesn't help sell some subjects.

02-06-08 *Emailing: 453566c* (to G. L. Comer)

Comerism 19: *What does it mean that the Information is always conserved in Quantum Mechanics? It's in the short "Theoretical Physics" piece in the attached file.*

As far as I can tell, it really means nothing—it is just something that people like to say without thinking very deeply. Information is not a fluid, like phlogiston, with a conservation law. Information is not a fluid.

03-06-08 *Dow Commercial* (to me)

"It is a world that responds to our touch."

04-06-08 *Hammerhead* (to G. L. Comer)

Comerism 20: *There is a number 7 in one of your [SIC] equations in the proposal. Now, doesn't that imply something wrong? I mean, I've never seen a 7 before in a fundamental equation. 8, π, e, are good numbers. But 7?*

I've got a funny story about the 7. I first presented the result at an APS meeting a couple years ago. Charlie Bennett was in the audience and asked, "Is that a 7?" I said, "Yep, it's really a 7." Charlie said, "Well then, it's the first 7 I've ever seen in quantum information." And what else would you expect from a truly fundamental equation?! Indeed it is a 7, and well checked many times by myself and independently by my students. In fact, just the other day by the latest, Ryan Morris, who first found a 6 instead … but then ultimately found a 7.

05-06-08 *Death of Auchentoshan* (to J. W. Nicholson)

Funny that you wrote me this morning. I was just going to write you, to tell you of the demise of the lovely bottle of Auchentoshan you brought me in Dublin. The poor old fellow passed away peacefully about 10:30 yesterday evening. He'll be missed.

Yes, the new Lazarides money was a bit of a shock last night. We knew there was going to be a big announcement, but we didn't know about what. I suspect the money will be used to bolster our expansion plans: Somehow (architectural nightmare) the office space in the building is going to be doubled, add a new bigger lecture hall, double the size of the Bistro, etc. The announcement was made just before Bill Phillips's public lecture—I'm really annoyed that I forgot about it, not because of the announcement, but because I bet it was a heck of a lecture: "Time and Einstein in the 21st Century: The coolest stuff in the universe".

I talked to Lazarides briefly after my own public lecture thing (panel discussion); he had dinner with the group of us, and hung out till midnight. It was funny, kind of like Jon Waskan once described his meeting with Bill Clinton, how he almost melted when he shook his hand. In my own case, I had this overwhelming feeling of gratitude—uncontrollably, somehow the first thing out of my mouth when I had him alone was, "Thank you for this place!" He said, "Physicists are a really good investment; you get a really good return on very little money."

Sciencewise, I'm very happy at the moment. Rüdiger and I have made some serious inroads toward squeezing Hilbert space out of a single inequality. If we make it all the way, this will be the best scientific work I've ever done. I just hope the IF isn't too big of one.

If I discover that Philips mentioned your name in his lecture (when I view it on PIRSA), I'll let you know!

09-06-08 *Pauli Understood Entanglement* (to R. Blume-Kohout)

Points all well taken, of course. The moral is I should have titled my note "Pauli had an inkling of entanglement," which is certainly no insult for a 1927 thought.

Robin's Preply

I presume you mean:

> Now it should of course be emphasized that such reductions first of all are not necessary when all the measuring instruments are included in the system. In order to be able to describe the results of observation theoretically at all, one must ask what can be said about one part of the total system on its own. And then one sees as a matter of course the complete solution—that the omission of the instruments of observation in many cases (not always, of course) may formally be replaced by such discontinuous reductions.

Yah?

I started to write a long analysis, then realized I don't have time to think that deeply! So I'll content myself to observe that Pauli obviously *did* have a grasp on some good stuff ... and then I'll dig at the end bit a little.

He writes ("as a matter of course") that the solution is to replace "omission of the instruments of observation" with "discontinuous reductions" ... while noting that this can only be done some of the time. Now, granted that the first part of his letter implies at least that he understood that it's *possible* to describe the supersystem unitarily ... and that such a description doesn't say anything useful about "the results of observation" ... is there really any content in this last bit? He seems to be saying that the process of disregarding the apparatus is, sometimes, equivalent to collapse. This is a rather unhelpful statement because of the "many cases (not always, of course)" ambiguity. Furthermore, it seems to be Copenhagen ("Shut up and collapse") beyond that ... and finally it seems to conflict with our idea that you represent "omission" of a subsystem by partial tracing.

Perhaps a better way to put that is that we represent omission *either* by partial tracing *or* by collapse, but Pauli provides no guidance on which to use.

Anyway, this vague last sentence makes me wonder how to interpret the earlier sentences. I am not sure what he means by "such reductions first of all are not necessary when all the measuring instruments are included in the system". The best way (IMHO) to interpret that is in a relative-state framework – i.e., that we can describe the joint state as being in an eigenstate of the "One system knowing about the other one" observable, and therefore can confidently answer questions like "Does the observer know about the system?" even if we can't answer questions like "So, what does she know?" But I'm not sure if I should interpret Pauli this way!

25-06-08 (to K. Brading)

By interesting coincidence I discovered that our meeting the other night was our third meeting ... not our second. This memory of mine is becoming so horrible! To see what I mean, download [my samizdat] and search on "Katherine Brading".

Well, anyway, it was great meeting you for real this time: Now you'll last in my memory until there really is none left of it. I wish it had worked out that we had talked earlier in the week.

In the document linked, there are also some tidbits about Poincaré that might interest you. Particularly, I thinking about de Finetti's giving Poincaré credit for coming to within a hair of full-blown Bayesianism (and being de Finetti's greatest influence). And also Poincaré's discussion of Boutroux's philosophy.

Hope you met up in London with your family easily enough. Take care, and I hope to see you again without a lapse of four years.

25-06-08 *Darn!* (to H. C. von Baeyer)

Likewise for me, it was great having you a that meeting: It was nice seeing a mind of sense floating in that sea of contrariety. I wish you could come to PI; the time with Marcus is going to be grand. And as I told him recently, I fear you need a booster shot of Fierz.

Attached is a copy of Bitbol's talk, in case you wanted to review it again. I so wish you could have been there for Rovelli's talk. It struck much deeper, it seemed to me, than his papers on "relational quantum mechanics". I took a long walk with him after the meeting, and felt that he is seriously searching ... even if he over-cautiously fears the agent's introduction into physics. Anyway, I like that in a person.

I'll keep you up-to-date as I respond to others about the meeting with some relevant points. But at the moment, I must go be the MC for the HirotaFest!

03-07-08 *Painful Choices of Language* (to A. Stairs)

Stairsism 1: *Good to hear from you. I'd like very much to work out a way to come to Perimeter, though let me toss in a couple of qualifications.*

The first is that I'm very much more a philosopher than a philosopher of physics. By that I mean my technical skills and knowledge are shockingly limited. (I could easily embarrass myself by elaborating...) So caveat sponsor*.*

In all seriousness, it is almost never the case that a philosopher of physics interests me. The technical skills that you speak of, as far as I can tell, are almost always wasted because of deeper wrong-headednesses that have nothing to do with physics per se. ... Thus maybe why I'm attracted to you.

03-07-08 *PIPPO!* (to P. G. L. Mana)

It should not be my business to pry, but I think you should exercise more control with PIPPO. I am sympathetic to his quantity of self-respect, but there are limits necessary within any civilization—one can only go so far and still expect to maintain an orderly and positive life for all citizens. No one living being can be so singled out at the expense of others.

Concerning the carrion "collapse," I do not know when the word was introduced, but von Neumann made a distinction between Type I and Type II evolutions for quantum states already in his 1932 book. Of course, if one changes the word from "collapse" to "conditionalize" (in the sense of a subjectivistic approach to probability), I myself think we are talking about something completely innocuous.

07-07-08 *Philip Goyal and the Information-Geometric Reconstruction of QM* (to C. H. Bennett)

Bennettism 34: *Does this guy's stuff have anything to do with your goals?*

Unfortunately, no. Philip often says the word "Bayesian" like I do, but that's where the resemblance ends. Look harder, and you'll see that he's proposing that quantum theory is a kind of statistical inference theory about a hidden variable. Roughly, whenever a quantum measurement is performed, two outcomes happen instead of one; it is just that one is hidden from us, and we can't tell which of the two we have. My own program (for instance the flavor you saw with the SICs the other day) is pretty anti-hidden variable.

And by the way, I do not write things really big to compensate for the weakness of my own ideas. I write really big because I assume some in my audience are near-sighted ...

08-07-08 *Two Places to Read* (to A. S. Holevo)

It dawned on me to maybe follow up on one of our lunchtime conversations. With regard to what criterion was used for (imperfect) teleportation in the Kimble experiment, you can go here: `http://arxiv.org/abs/quant-ph/9910030`. With regard to our discussion on how the details of an "instrument" are "washed out" when we consider the state update on the far half of an entangled state, you can look here: `http://arxiv.org/abs/quant-ph/0205039`. The relevant part is the discussion around Eqs. (98)–(101).

I hope you had a safe flight back to Moscow.

08-07-08 *Wednesday Instead* (to R. Schack)

I won't be able to call you this morning after all: I've got this damned talk to give at IQC, which I'm still preparing for.

Appleby and I had another long discussion on the ueberungleichung yesterday. The origin of these α_{ijk} is (remains) just damned confusing. One thing valuable that came though is that maybe ueber is not the best prefix. We toyed with the idea that "Ur" might be better. Can you tell us the precise meaning of "Ur"? Urungleichung, does it work?

09-07-08 *Wednesday Instead, 2* (to R. Schack)

Schackcosm 107: *Wednesday OK. Urungleichung is a much better term. Ueberungleichung has been a joke and shouldn't become the official name.*

Ur, as a prefix, means original or primitive (it is also a noun meaning aurochs). It is a very powerful prefix. Here are a few examples:

> *Ursprung = Ur leap = origin*
> *Ursache = Ur thing = cause*
> *Urbewohner = Ur inhabitants = first inhabitants, aborigines*
> *Urknall = Ur bang = big bang*

Beautiful! Urungleichung it is!

09-07-08 *SIC It Will Be* (to C. H. Bennett)

Bennettism 35:

> [Chris said:] When you were visiting, you seemed to naturally pronounce "sic" as "seek". Is that based on a grammatical rule I can look up? Is everyone else wrong when they pronounce it "sick"?

See attached for my pronunciation of sic*. I assumed you were using it in the sense of the Latin textual annotation, not as an abbreviation for symmetric informationally complete, or any of the other meanings for* sic*. According to my dictionary, even the Latin word may be pronounced like sick in English, but I studied Latin in high school, so I pronounce it like* seek*. By the way, the noun corresponding to* pronounce *is* pronunciation*, not* pronounciation *(sic). Don't ask me how the second* o *got lost.*

Thanks! That settles it.

09-07-08 *Life/Etc.* (to D. R. Terno)

Appleby, Schack, and I are working quite hard to "SICken" the axioms of quantum mechanics, and I think we're making some very nice progress. I have *hope* now that the formal structure of quantum mechanics may be pulled out of essentially a single inequality. It would be the greatest of all my dreams. Pulling all of (the formal structure of) quantum mechanics out of a quantification of the idea that "unperformed measurements have no outcomes". It would be nice to be able to say this with some confidence at Asher's summer school.

09-07-08 *HirotaFest Picture* (to O. Hirota, A. S. Holevo, & the invitees)

Thank you all again for coming to PI last week. It was a fantastic time.

Charlie Bennett's conference photo has now been posted on the web. You can find it by going here: `http://www.perimeterinstitute.ca/images/conferences/hirota_fullsize.jpg`.

09-07-08 *Tables of Contents* (to S. Gharibian & L. Sheridan)

Thanks for the interest.

You can find a better, more careful version of my teleportation example here: [See 25-10-05 note "GOBs, Bobs, Steering & Teleportation" to H. Halvorson and B. C. van Fraassen.] In any case, in the talk version, I was careful to say that when Alice checks the parity, she then randomizes the coins (i.e., she shuffles them so that Charlie no longer knows which is which). Thus from Charlie's perspective, he now knows nothing about the coin in the original box he gave Alice, and would write down a 50-50 distribution for heads/tails in it. It is in that sense that Charlie's original state is "destroyed" for his original coin.

About your second question, my own formalism was just quantum mechanics rewritten. Thus, there is everything in it that there is in quantum mechanics, including Kochen-Specker phenomena and Bell-inequality violations. What I said "must break" is some feature of Spekkens's toy model. As presently written (in terms of epistemic states for local hidden variables), it cannot accommodate these kinds of phenomena. In my own case, it is my belief that my rewrite of the formalism is such that it helps pinpoint the essential difference between the classical and quantum worldviews: It is that "unperformed experiments have no outcomes" (as Asher Peres would say). Something new, that was not there before, comes out of each and every quantum mechanical measurement. That is, even at this very low level of things, there is something analogous to birth in the world. If that is an example of something you would call an "inherent disconnect" between the classical and quantum worlds, then, yes, I believe there is such. It was only that I think SICs help massage the formalism into a form that makes this the clearest yet (by giving the formalism a more direct comparison to classical Dutch book arguments).

But do these damned SICs exist generally? That's the real moneymaker of a question.

09-07-08 *The History* (to G. Gutoski)

Thanks for your comments yesterday. In case you're still curious about some of the prehistory about these lines of thought, let me refer you to the Brassard section of `quant-ph/0105039`.

The idea that the existence of QKD might be a key part of the heart of quantum mechanics is an older one, exhibited for instance in the 6 July 1998 letter to Rolf Landauer titled "Evolution and Physics". But the idea that the nonexistence of bit commitment might also be a potential ingredient in QM was born over a bottle of single-malt scotch with Gilles. I'm still very proud of the allegory I created to go with it. Let me particularly direct you to that. It's in the 23 January 2000 letter to Gilles titled "I See Why No Bit Commitment!" See that and the note "Fuchsian Genesis" it refers to.

I hope I provided some entertainment and some food for thought for your group yesterday.

14-07-08 *Harper, Fuchs, and James* (to R. Blume-Kohout)

I read the Berlinski essay. I didn't much like it actually, or maybe more to the point, him. There was something about the writing that made me feel he's pretty arrogant. As you suspected, I guess, there were indeed points I'm sympathetic to (about "things not seen" and about $M + x$), but then he clouded things up with too much about faith in God (Gods?) for my taste.

You can find my own favorite rebuttal of Clifford here: `http://www.perimeterinstitute.ca/personal/cfuchs/nSamizdat-2.pdf`. Do a search on the phrase "Pragmatism versus Positivism" to get to the right spot. (It'll take you to text page 138 in the present build.) Also there are a couple of other tidbits on Clifford if you search on his name.

14-07-08 *Wheeler Scholars* (to W. P. Schleich, B. W. Schumacher & W. K. Wootters)

I've had a little correspondence with Michael Brooks at *New Scientist*, and he told me about how he bought a copy of Wheeler's booklet *Frontiers of Time* from a mail order place and was pleased to find a little inscription by John in it. It is dedicated to a "Ruth" and dated 3 May 1986. See attached photo.

The question is, who is the mysterious Ruth? Do any of you have an idea?

Wolfgang's Reply

> Many thanks for your email concerning the mysterious "Ruth". This is indeed an intriguing problem. I did call up one of Wheeler's old secretaries, Emily Benett. She did have some interesting information but not concerning "Ruth". She had no idea who she might have been.

However, from the date of that dedication, May 1986, I got some ideas. First of all, the dedication was written during the time when I was in Austin. I remember that exactly at this time John had his heart operation. From the dedication it sounds as if it was a nurse who took care of him in the hospital in Houston. This theory would also explain why the book was resold. Anybody in physics would have recognized the value of such a dedication and would have not sold the book.

I have tried to get in touch with one of his daughters, Allison, but she did not pick up the phone. Most likely they are in Maine on the island right now.

By the way, the only Ruth that I associate with America is Dr. Ruth Westheimer. But I seriously doubt that John would have written such a dedication to her despite the fact that she seems to be very much into "creating islands of time". I wonder if she is still alive.

Bill's Reply

Adrienne suggested that Ruth might be his secretary at High Island. He certainly had a longtime secretary there, and I see that Ruth Bentley is thanked along with his Austin secretary Zelda Davis in the preface of the book *Quantum Theory and Measurement*.

15-07-08 *Paris on the Way to Munich* (to H. C. von Baeyer)

Thank you very much. I reduced the font and the line spacing, and I printed it [your manuscript on the Parisian parks through the eyes of a physicist]! Now I have something to read on our flight to Munich Tuesday. (The family and are staying with Kiki's parents for 18 days ... though I'm taking a desk at the Max Planck in Garching and also slipping off to Freiburg for three days.) I will stay conscious of the absence of Lili's drawings, and be surprised again when I see the final product.

This morning, I found a nice new representation of density operators in terms of SICs. It's embarrassingly simple, but somehow I hadn't noticed it before. Appleby, Schack, and I are working away to try to derive the structure of quantum state space almost solely from the "urungleichung". I think I may have told you about the hope while at the philosophy meeting last month. Everyday, the problem yields a little more. But unfortunately so far, little really means little (it is no hyperbole). Thank God for the integral!

I keep promising more: Eventually you'll get it.

16-07-08 *Title/Abstract for FPP-5* (to A. Y. Khrennikov & G. Adenier)

In case I didn't already send you a title and abstract for FPP-5, let me send you the one below. It's the tweak of a tweak of an earlier abstract (which I may or may not have sent you), and I like it better.

> Charting the Shape of Hilbert Space, or SICkening Axioms of Quantum Mechanics
>
> Abstract: As physicists, we have become accustomed to the idea that a theory's content is always most transparent when written in coordinate-free language. But sometimes the choice of a good coordinate system is very useful for settling deep conceptual issues.

This is particularly so for an information-oriented or Bayesian approach to quantum foundations: One good coordinate system may (eventually!) be worth more than a hundred blue-in-the-face arguments. This talk will motivate and chronicle the search for one such class of coordinate systems—the so-called Symmetric Informationally Complete measurements—which has caught the attention of a handful of us at PI, a handful of our visitors, and a handful of other colleagues around the world. Finally, I will turn the tables and discuss how one might hope to get the formal content of quantum mechanics out of the very existence of such a coordinate system.

18-07-08 *Is Probability 1 Probably Certain?* (to N. D. Mermin)

Merminition 169: *I thought as authorities on $P = 1$ you would like the exchange reported by the AP in this morning's Ithaca Journal.*

> Congressman Gallegly R-Calif:
>
> > Had we not [tortured people] would the probability of another
> > attack not only be a probability but a certainty?
>
> Former Attorney General Ashcroft
>
> > It could well have been.

Funny to hear from you today: Marcus Appleby and I were just having a conversation about you last night! And subject was Mermin, subjectivity, and his dual attractions and distastes of the concept.

But that was a break from other matters. We've been making great progress this week in understanding the "shape of Hilbert space." By that I mean, what density operator space looks like when represented as a subset of the probability simplex. There is serious hope that we can reduce everything to the satisfaction of a single inequality between pairs of probability distributions. This is a program of study Rüdiger and I started a couple of months back and it has continued to surprise us evermore ... by looking ever more right. And the inequality, where does it come from? A direct (but quantitative) expression of the idea that "unperformed measurements have no outcomes." Why the particular quantification (where do the constants come from), I don't know: But it all seems to hang together.

18-07-08 *"Experience", with quotes and without* (to H. J. Bernstein)

Bernsteinism 4: *OK so how come you are not a Whiteheadian? Those throbs of experience which constitute Whiteheadian events (at least as Shimon Malin describes them) are the closest idea I have ever encountered to your famous "Zing!"—attributes of the interaction of quantum stuff with real world observers addicted to classical answers through the force of "white man's" European post Renaissance history, power, hegemony etc etc.*

love out of the blue, herb B

You brightened my evening Wednesday. "Throbs of experience"—I love the phrase, and hadn't made note of it before. It's a deep phrase, isn't it? The quantum measurement mysteries teach us that "experience" can't be ignored as a component of things. But the lessons of the Copernican revolution also teach us that we shouldn't hoard "experience" only for ourselves—"ourselves" being the agents of which the present quantum formalism takes as the localized centers of the universe.

Who knows, maybe I am a Whiteheadian. But I am so slow. Whitehead himself (as he explains at the beginning of *Process and Reality*) takes his starting point in William James and Henri Bergson. That's where I myself am at the moment, but I also recognize that it's only the beginning of a road.

I'm glad you came out of the blue.

21-06-08 *Strawson Quote?* (to me)

From Huw Price at breakfast in Sydney:

> "If you prise off language from the world, you prise off the facts, but you don't prise off the objects." — (or something like that), P. Strawson.

Also look at Ryle – "The Concept of Mind" – relevant to the "a implies b" debate.

28-07-08 *Small Calculation* (to J. I. Cirac)

I think the attached partially answers your question. This is at least one sense in which randomly chosen states are always different from SIC states, even asymptotically.

I enjoyed the style of the questions you were asking today. It was a good dose for me because I do need to think about these things more.

d^2 Random States

Recall the function K I defined in the talk (now specialized to pure states):

$$K = \sum_{i \neq j} |\langle\psi_i|\psi_j\rangle|^4 \,. \tag{83}$$

One has that the states $|\psi_i\rangle$ form a SIC if and only if

$$K = \frac{d^2(d-1)}{d+1} \,. \tag{84}$$

This was the value I exhibited today; I'll leave the proof aside.

Let us compare this quantity with the value that obtains on average if the d^2 states are not SIC, but instead pulled out of a hat according to the unitarily invariant measure. The key ingredient is the value of the integral (which I looked up in one of my papers, and is of course much older and well known):

$$\int |\langle\psi|\phi\rangle|^4 d\Omega_\phi = \frac{2}{d(d+1)} \,. \tag{85}$$

Then

$$\begin{aligned}
\langle K\rangle &= \int\!\!\int \sum_{i\neq j} |\langle\psi_i|\psi_j\rangle|^4 d\Omega_{\psi_i} d\Omega_{\psi_j} && (86)\\
&= (d^4 - d^2)\int |\langle\psi|\phi\rangle|^4 d\Omega_\phi && (87)\\
&= 2d(d-1) \,. && (88)
\end{aligned}$$

The point is, asymptotically min K goes as d^2, whereas $\langle K\rangle$ goes as $2d^2$.

30-07-08 *The Lost Pauli Letter* (to H. Atmanspacher)

Just so I don't forget: Please send me the coordinates of that letter from Pauli to Jung that you told me about today. (The one that Jung published somewhere, but did not appear in the Pauli-Jung correspondence.)

Also, don't forget about the letters to Fierz that you were going to select: Ones on neutral language and neutral monism.

30-07-08 *Seeking Peirce?* (to R. W. Spekkens)

Spekkensism 43: *The collected papers of Charles Sanders Peirce, vols. I – VI. This doesn't happen to be something that you desperately need, does it? They're selling here second hand for 45 GBP for the lot.*

That shows how much Peirce is valued in the UK! If they're in good shape, and it is really *only* 45 GBP for the whole lot (rather than the individuals), then *indeed* get them!!! I would repay you in money, kindness, and brotherly love.

I just looked in my records: Vol 8 alone of the collected papers of Bertrand Russell cost me 20 GBP! (The only reason I bought that one is because he has correspondence in that one concerning pragmatism.)

You are a saint for bringing this to my attention.

03-08-08 *European Tour* (to H. C. von Baeyer)

Good morning. I'm writing you as I take a morning train from Freiburg to Munich, having spent two days with Harald Atmanspacher talking of Pauli, neutral monism, and panpsychism. Actually, we started at his very pleasant home in the beautiful Swiss village of Amden (over Lake Walensee).

Finally I get a chance to write you properly. As I had promised, your *Swing Under the Eiffel Tower* was a companion to me on my flight over. I very much enjoyed it and got a better sense of some of the things I will see and do when Emma and I are in Paris next Spring. (I don't know that I've ever shown you pictures of Emma, by the way. Attached are two: One at the piano just before our leaving Canada, and one taken her first morning in Munich!) I came away from my reading with a sense of envy for your years in Paris, and envying your ability to look at things with a physicist's eye. I think you pulled it off well in your text, mingling these two aspects of your life, neither of which I really have. Frankly, or I should say honestly, I learned some physics from it. Too bad I couldn't have seen Lili's illustrations at the same time as my first reading.

If I didn't think it would only cause more trouble in our relationship, I would send the first two paragraphs in your Introduction to my mother-in-law:

> With this book I return to a question that has been rattling around in the lumber room of my brain for thirty years. Although I have rarely asked it explicitly, the answer informs all of my writing, which the French, with barbed Gallic poignancy, would characterize as *vulgarisation de la science*. The question is this: How does a physicist see the world? As all of us go about our daily tasks, our perceptions of what we see and feel are molded by our professional knowledge in ways we are hardly aware of. Artists, for example, see things in terms of colors and shapes, engineers notice structure, biologists pay attention to plants and animal, and musicians to the

> cacophony of the soundscape they are immersed in. The interest of mathematicians is drawn to numerical and geometric patterns, and that of historians to the traces of the past that are encoded in the way things are arranged in the present. It is said that dogs experience their surroundings as a panorama of smells — in the same way people see primarily that to which they are most sensitive. Accordingly, we physicists perceive the world in the light of the laws of nature that are indelibly etched in our brains. What exactly does that imply about our relationship to the universe? How does it shape our perceptions? In what way do physicists think differently from other people? Many of our non-scientific friends would like to understand what makes us tick, but most of them haven't a clue.
>
> I will try to describe some of the images and associations that flit through my mind as I wander through my daily life. I hasten to admit, though, that generally I am not thinking about physics at all, but about the things everybody else is thinking about too. Today's grocery list, my daughter's dental appointment, the news from Iraq, and the itch on the back of my neck jostle each other in the mundane meanderings of my thoughts — normal human concerns. So my world is infused with meaning not so much by what I *think* as by what I *know* about physics. Newton's laws and Maxwell's equations go with me wherever I go; though they are normally hidden from view, they are powerful in their influence on my world view. I don't think about physics most of the time, but I am aware of it throughout my waking hours. Physics provides the spectacles, as it were, through which I see the world.

They are perfect. She tells me over and over how I need to learn to relax and enjoy life—which of course only means that I do not walk through life in the same way she does. I never think of myself as particularly unhappy—certainly at least when I'm traveling away from the construction at my house!—*except* when I'm being told how unhappy I am. (I unfortunately really blew up at her Sunday morning when she pointed out to me for the hundredth time in only five days how much of life I'm missing. How much of life I'm missing?!) When she sees me as wanting some quiet time to think, or to write, she sees no relaxation in it at all. When she sees me pull out a pad to sketch an equation, then of course that must mean miserable work. ... But I digress.

I'll record some things from your draft that caught my eye while reading.

Les Tuileries. This was my favorite chapter. It struck my sensibilities, I suppose, because of my meanderings in the last two years into the issue of Wigner's friend. Einstein taught us that we each "carry" our own proper time. What does quantum mechanics teach us? In part, I think it teaches us to recognize in a concrete way that we each carry our own "experience". Each "I" is the one who has it; no one else does. The lesson is that there is a public part to the world, but there is also a private part to the world. You say, "[R]elative to the park, I am indeed in motion. But relative to myself, which is to say measured in a reference frame that is attached to my own body, and has its origin at my navel, I am always securely at rest, while the park recedes backward at walking speed. Both these claims, that I am moving relative to one reference frame and stationary relative to another, are correct ..." In quantum mechanics, something like this goes too, though in the opposite direction for its particulars: It's in the agent's own frame where the "motion" so to speak occurs—for that's where the experience is that quantum mechanics gives us the tools for gambling upon.

Some things to read in this regard, in case you're interested. First pick up the latest version of *My Struggles with the Block Universe*. Thereafter, do a search on

1. "Wigner's friend"

2. “Rivers of Nows”

3. “Wootters’ Preply” (that’s actually a note Bill wrote, and probably played some inspiration for my own thoughts)

4. and finally have a look at the quotes of William James in the frontispiece of the document.

In this chapter of yours, I was reminded of how much I would have liked you to have heard Rovelli’s talk in Paris. I thought it was very deep, and certainly within reach of (both from and to) the cluster of ideas mentioned above. I think he misses a lot by trying so hard to never refer to agents and states of belief, but on the other hand, he gives hints of having grasped the personal nature of “experience” (he calls it the “relativity of facts”) in a deeper fashion than I had hitherto.

Parc Monceau. I found your challenge in this chapter inspiring:

> [T]hings can’t go on this way. In 1926, when Erwin Schrödinger was inventing his version of the quantum theory, he wrote to a friend: ‘Physics does not consist only of atomic research, science does not consist only of physics, and life does not consist only of science. The aim of atomic research is to fit our empirical knowledge concerning it into our other thinking.’ We have ignored that wisdom, and remained locked in our secret garden. It’s time we invited the people in. I am confident that in the twenty-first century we will finally heed Schrödinger’s advice, and bring quantum mechanics into the world picture of ordinary people. Creating a more accurate and suggestive atomic logo would be a good start! ...
>
> If I were as rich as the Duke of Chartres, I would sponsor an international competition for the design of a modern atomic logo. The jury would include writers, painters, sculptors, physicists, chemists, and teachers. Somewhere, I feel, there must be a mind creative enough to come close to translating the well-understood mathematical language of quantum mechanics into visual terms ...

I will be your publicist, as well as taking my own shots at entry! First though, a few thoughts, as the challenge simmers in my brain. It’s not quite a public slogan yet, or an image that can be drawn on paper, but it is starting to strike me that perhaps the driving idea behind quantum mechanics might just come down to a single inequality. Schack, Appleby, and I have been calling it the “urungleichung”. And it, to my mind, finally starts to give an image to Hilbert space. It is something like a very symmetric spider web stretched over a sphere.

Let me tell you a little bit about it for the fun of it (and for practice). The story goes back to three transparencies I used in Paris last month. Why should I believe Asher Peres’s phrase, “Unperformed measurements have no outcomes”? And how might I turn it into a quantitative statement? Until recently, I believed that the real essence of Asher’s slogan was in the Kochen-Specker theorem and, better, a variation of Allen Stairs’ use of it (which Carl, Rüdiger, and I review in our last paper together). But now I hope/believe it can be traced back to a deeper level, or at least to a deeper quantitative statement in overtly Bayesian terms.

In a separate email, I’ll send you scans of three of my transparencies, and a little LaTeX document besides (some working notes from my collaboration with Rüdiger and Marcus). The essence of the story is in the diagram. It asks us to compare an apple and an orange. “What probability we should assign for the outcomes of the lower right measurement device *if* we’re going to take our quantum system directly to it.” –Versus– “What probability we should assign for the outcomes of the lower right measurement device *if* we first send the quantum system through the measurement device in the sky.” Apple versus orange. Well, we know how to calculate the orange in terms of the given data in the diagram. We make use of the “law of total probability”, which has a perfectly sound Bayesian derivation in terms of de Finettian coherence for *conditional bets*. But how to calculate the apple? There are no conditional bets in this scenario. A Bayesian not steeped in quantum mechanics would say, "Well then, there's no reason to be probabilistically coherent with any conditional betting. The probabilities in apple are stand-alone entities; they are priors in the proper sense, tied logically to nothing else." That "apple DOES NOT EQUAL orange" is a raw statement that unperformed measurements have no outcomes—unperformed SIC measurements at least. This, any Bayesian who has understood de Finetti's Dutch-book derivation of the connection between conditional and joint probabilities should appreciate.

But quantum mechanics says something that surprises even the well-prepared Bayesian. Though it certainly re-enforces the raw statement above, in the end it *does* let us compare the apple to the orange: For there is a precise relation between the two. Not equality; but seemingly a simple linear relation. Who ordered that?!?!?1

Well, I do not know. But that simple relation seems to contain within it much, if not all, of the formal structure of quantum mechanics. Particularly, by demanding that apple be between 0 and 1, one is forced to constraints on the probabilities for the outcomes of the SIC-in-the-sky measurement. We do not yet know whether the resulting space of allowed probabilities is completely equivalent to the standard quantum mechanical set, but it certainly shares many features with it. And we are guardedly optimistic that it will eventually yield the whole structure. The Introduction to the LaTeXed notes defines the problem more precisely than I have done so here and lays out the tools for getting to the image I spoke of previously.

Coming back to your challenge and the diaphanous web. We start by constructing the extreme points of the convex set it will specify. The inequality says that they will lie on the surface of a d^2 dimensional sphere of a specific radius. Now, we get the rest of the state-space structure by removing points from the sphere. Go to any valid point, the urungleichung tells us, and its antipode will not be in the set. Moreover, a spherical region surrounding the antipode must go too: It must be excised from the original sphere. The result of all this pruning, if our hope turns out to be correct, is a diaphanous manifold of dimension $2(d-1)$ living at the intersection of all these excisions.

Maybe not an emotive image yet. But one that, in some deep way, carries the meaning of quantum mechanics.

But going back to your chapter: Is the phrase "put paid" a typo? Or rather an English phrase that I do not know?

Parc Montsouris. This passage struck me:

> Great revolutionaries don't stop at half measures if they can go all the way. For Newton this meant an almost unimaginable widening of the scope of his new-found law. Not only Earth, Sun, and planets attract objects in their vicinity, he conjectured, but all objects, no matter how large or small, attract all other objects, no matter how far distant. It was a proposition of almost reckless boldness, and it changed the way we perceive the world.

For you are right: That was indeed an amazingly bold move—and I had not appreciated that before. Put in that light, one looks at Newton in awe.

Jardin du Luxembourg. Of course, I was flattered to find my name in this chapter. It teaches me it is good to hobnob with good writers! But how does one translate "Chris Fuchs (rhymes with books)" into French?! On my trip to Amden from Munich the other day, I passed through a town Buchs, and was quite surprised when the conductor announced it (just before I had looked out the window). Finally I learned another German word rhyming with my name!

Contentwise, I liked the paragraph on Zeilinger's phrase "the two freedoms". For I think I agree at some level that the secret of quantum mechanics is to be found in the tension between the two freedoms. I have certainly said things along those lines too at selected times in my life. (Where, by the way, does Zeilinger write of the "two freedoms"; I'd like to get the exact flavors of how he says it.) But also, I think the formulation leaves something out. Certainly at least in my own previous versions. For I imagine there is something truly autonomous in the outcomes of quantum measurement. The agent and the system supply the raw materials so to speak (like parents), but the event thereafter is a life of its own. This is why I have been moved at times to call this view the "sexual interpretation" of quantum theory. (Speaking of flavors, you might want to do a search on that phrase too in link.)

Parc des Buttes Chaumont. It's a funny thing, these multiverse and literal-landscape worldviews. At the surface, the arguments behind them must be nonsense—no deeper or more scientific than the story I tell of the priest in the section titled "Cash Value" (17-11-05 note to H. Halvorson). At the level these guys speak of, we experience one world, but, the argument goes, this world can only make sense (or even exist at all) if it is literally one among many. Yet so many of our colleagues are ready to accept such a statement out of hand, feeling that they are driven to it by science itself.

Parc George Brassens. There are two typos in the penultimate paragraph: "fields are the as essential" and "power of the basic idea not been compromised".

I hope you are enjoying your summer in the parks of Paris! It wouldn't do to stop your time in them now that your book is finished!

Hans's Reply

> "Fuchs se prononce comme foucs." Unfortunately fou means crazy.

11-08-08 *Too Exhausted* (to K. Martin)

Martinism 1: *By the time I convinced the security guy at PI to give me a key to my room, I was also tired . . .*

Did you know that in the room I am in they have some books under the tv for casual reading – one of them is a book that you wrote!

No, I did not know that. I had always wondered what happened to the two copies I sent to PI years ago. I have noted that they are not in the library catalog. But it might just be someone's personal copy that they didn't care to keep. There's not a dedication on the first or second page to someone, is there?

11-08-08 *The Two Freedoms* (to H. C. von Baeyer)

That paper? Actually I'm quite familiar with that one: I liked it very, very much. Here's what I have quoted in my Pauli'an Resource file about it:

> **From:** A. Zeilinger, "On the Interpretation and Philosophical Foundation of Quantum Mechanics," in *Vastakohtien todellisuus, Juhlakirja Professori K. V. Laurikaisen 80-vuotispäivänä*, edited by U. Ketvel, A. Airola, R. Hämäläinen, S. Laurema, S. Liukkonen, K. Rainio and J. Rastas (Helsinki University Press, Helsinki, 1996), pp. 167–178.

When investigating various interpretations of quantum mechanics one notices that each interpretation contains an element which escapes a complete and full description. This element is always associated with the stochasticity of the individual event in the quantum measurement process. It appears that the implications of this limit to any description of the world has not been sufficiently appreciated with notable exceptions of, for example, Heisenberg, Pauli and Wheeler. If we assume that a deeper foundation of quantum mechanics is possible, the question arises which features such a philosophical foundation might have. It is suggested that the objective randomness of the individual quantum event is a necessity of a description of the world in view of the significant influence the observer in quantum mechanics has. It is also suggested that the austerity of the Copenhagen interpretation should serve as a guiding principle in a search for deeper understanding.

But I too don't recall a discussion of the "two freedoms" there. Could it instead have been in the little one page thing he published in *Nature* a couple of years ago?

Hans's Reply

In my frustration I googled "the two freedoms zeilinger" and the first entry hit paydirt:

`http://www.signandsight.com/features/614.html`.

11-08-08 *The Two Freedoms Found* (to H. C. von Baeyer)

Cool! Our emails just crossed each other in mid air! Synchronicity! Synchronicity! I'm not lying your note arrived just as I had hit "send" on mine!

13-08-08 *Reflection* (to V. Hardy)

At the end of our conversation outside the restaurant last night, I sensed that I had crossed the line of acceptable teasing. However, even if the line would not have been crossed, I find this morning that I very much regret the things I said. Birth is to be respected, not feared, and my behavior was no better than a schoolboy's in a playground. In honesty—without the teasing now—Dina's assessment strikes me as about right. But more importantly, and the thing I think one should keep in mind through these months up to the moment, is the flipside. I remember how Charlie Bennett's wife, Theo, put it once: "The births of my three children were the three most intense moments of my life. I was, and have never been since, so alive." It is something men never feel, except in the abstract, and in this way, I know that women's lives are more complete than ours can ever hope to be.

Just wanted to say that …

13-08-08 *The Train* (to K. Martin)

Your note did take me back to the South, and brought to mind those Hank Williams words:

Hear that lonesome whippoorwill
He sounds too blue to fly

The midnight train is whining low
I'm so lonesome I could cry

Notes for my (some future day) write-up of the Christian-Snyder morning coin toss story are below. [See 14-12-07 note "No Subject" to C. Snyder.]

14-08-08 *Physical Theories as Women* (to G. L. Comer)

If you haven't seen this before, have a look: "Physical Theories as Women," by Simon Dedeo, `http://www.mcsweeneys.net/links/lists/physical.html`. I love the description of quantum mechanics particularly:

> Quantum mechanics is the girl you meet at the poetry reading. Everyone thinks she's really interesting and people you don't know are obsessed about her. You go out. It turns out that she's pretty complicated and has some issues. Later, after you've broken up, you wonder if her aura of mystery is actually just confusion.

No wonder I've never been able to get her off my mind.

14-08-08 *Possible Collaboration?* (to T. Duncan)

Duncanism 3: *I've been taking some time this summer to reflect ... kind of connecting the dots to see the theme that drives and underlies my work, so that the next phase will stay on track and help develop this core theme further. I've started using the phrase "Looking for meaning in the modern scientific universe" to describe what I see myself doing. Everything I find myself working on ties somehow to the question, "Is there a perspective or world view one can hold which satisfies the longing for meaning/purpose to our lives that we feel, which is also accurate as far as we can tell (i.e. consistent with all of our current scientific understanding of the world)?" For some reason I still feel rather squeamish about revealing this theme for my research to other physicists ... afraid I won't be understood or won't be taken seriously, perhaps? But from some of our conversations, and rereading your collection of papers and notes, I suspect it's a line of thinking you might share or at least be sympathetic to. Anyway I may have an opportunity to build a more formal collaboration around this theme, so I wanted to share a bit of what I'm thinking and see if you'd like to be involved in the discussions or collaboration in some way.*

A few months ago I submitted a proposal for a research program and book on the theme of "looking for meaning in the modern universe" to the U of Chicago Arete Wisdom Initiative. In the end my proposal wasn't funded, but I was told by the review panel that it was important work and my proposal made it quite far in the process. They encouraged me to submit the proposal directly to the Templeton Foundation. So I'm in the process of reworking and possibly broadening the proposal to submit to Templeton. I've attached a very rough draft of the letter of intent. Please take a look when you have a chance and let me know if you have thoughts, and if it looks like something you'd want to be involved in.

Thanks. I'll look at the proposal, and try to write you with any thoughts soon. There's not a chance you'll be at the Växjö meeting at the end of next week, is there? ...

Actually this is very interesting. Plus I have always been impressed by your thoughts in this regard. Let me think for a few days about how I might fit in. What were the sorts of things you were envisioning for my role?

15-08-08 *Free Will and Renouvier* (to R. Schack)

Attached is the latest version of my quote collection. The thing to do is just search on the term Renouvier (just to make sure you miss nothing). But in particular, that will eventually take you to page 101, Logue's discussion. Then, starting on page 105, you will find Long's discussion. Funny coincidence that they are back to back. Then there is some discussion by Menand on pages 111 and 112. You can find a list of Renouvier's original works on page 158.

Now about Free Will more broadly, you can do a search on that term too. I myself like James's discussions on pages 67-68 and 78-79.

Hope this helps.

W. Logue, *Charles Renouvier: Philosopher of Liberty*, **(Louisiana State University Press, Baton Rouge, 1993):**

> The discussion of political freedom and human rights had become a major theme in Western thought only beginning in the seventeenth century, while the theological and philosophical problem of the freedom of the will, whether limited to the question of salvation or more generally understood, had a long history in Western thought, had indeed been one of the perennial big questions of philosophy.[135] The question of the relations between this freedom of the will and the more concrete issues of political freedom and individual rights had rarely been examined, if only because political and individual freedom were rarely issues before modern times. But even when they became issues, few saw any need to connect these practical questions with the abstruse debates of philosophy.
>
> Unreflective opinion had two choices: Either there was no connection between free will and public freedom, or there was some direct but not very clear connection between the two. The former attitude, common from the beginning of the nineteenth century, enabled thinkers to be simultaneously defenders of political freedom and exponents of deterministic and materialistic philosophies that denied free will. This was a secular counterpart of the traditional Christian attitude that emphasized free will for reasons of practical morality but could not reconcile it with the theological determinism of an all-powerful, all-knowing God.[136] Few thought that there was any serious conflict, and still fewer imagined that the diffusion of deterministic philosophies would serve to undermine the cause of political and individual liberty.
>
> Renouvier was, I think, the first, at least the first major philosopher, to see clearly into this danger and to devote himself to drawing attention to it while proposing a remedy. The development of his neocriticist philosophy was itself a response to what he had come to see as the anti-liberty forces dominant in nineteenth-century thought. Under the influences of discussions with his friend Jules Lequier, he became convinced of the reality of human free will and its central importance for the understanding of everything else.[137] This conviction came to Renouvier while he was still deeply under the

[135] *Deuxieme essai*, xiv-xv. Free will was a problem in religion before becoming one in philosophy but a problem most Christians avoided simply by believing in free will and predestination simultaneously. Greek philosophy, the first to give this question nonreligious consideration, was inclined to psychological determinism, though there were, Renouvier believed, some defenders of freedom—Aristotle, Pyrrhus, Epicurus (*Esquisse*, I, 227-28, 238, 240-43).

[136] Esquisse, I, 249-50; see also I, 248-51.

[137] Renouvier's account of his "conversion" to free will is in the last part of Vol. II of the *Esquisse*. Lionel Dauriac ("Les Moments de la philosophie de Charles Renouvier," *Bulletin de la société francaise de philosophie*, IV [1904], 23) defined the high point of Lequier's influence—the writing of the *Deuxième essai*—as one of four "moments" in Renouvier's philosophical development.

influence of his first contact with the Saint-Simonians. He experienced, not an overnight liberation from their deterministic viewpoint, but a more gradual readjustment of his views, which became a complete detachment from them only after 1851. Perhaps the failure of the socialist movements in 1848, rooted as they were in the would-be scientific philosophies of the preceding three decades, finally persuaded him of the dangers of rejecting free will.[138] Alienated from political life during the Second Empire, he would spend nearly two decades in the construction and elaboration of his philosophy of liberty, establishing its foundations and exploring its consequences.

Renouvier was aware that for a long time the question had been of mainly religious significance: whether man's salvation depended on free will or on predestination.[139] This debate had reached its peak, in both vehemence and subtlety, in the famous exchange between Erasmus and Luther in the sixteenth century. The emergence of a secular debate over free will was a result of the rise of the scientific worldview in the seventeenth century. The ascendancy of the idea that the world was governed by invariable laws, taking the role previously occupied by an all-powerful, all-knowing God, seemed to leave less and less room for the view that man was somehow an exception to the general rule. The most heroic task for the modern philosopher was to find a means of validating science and free will simultaneously, and the most heroic effort of the eighteenth century was that of Immanuel Kant. But for many in the next century, it seemed that Kant had saved free will only at the cost of making it irrelevant.[140] Fichte tried to rescue Kantian philosophy from this unhappy outcome, but in the general opinion ... his effort led to the fairyland of absolute idealism, denying reality to the material world.[141]

Against the rising tide of determinism, Renouvier would try to show that Kant could be the launching pad for a defense of free will that would maintain its practical relevance and demonstrate its compatibility with natural science, properly understood. He did not claim to be presenting any new arguments in favor of free will; he felt they were in any case unnecessary.[142] Renouvier's reasons for coming to the defense of free will were partly shared with Kant and partly his own. As we have seen in the previous chapter, the shared part was the most familiar: a concern for the connection between free will and moral behavior. Free will was for Kant the essential basis of *practical reason*; without it, the whole idea of moral obligation ceased to have meaning. For Renouvier, this consideration remained central. Without moral responsibility, man would not be distinct from the rest of the animal kingdom, and the whole of civilization would be meaningless. But this was not the sole basis for his concern with free will, and this additional concern moved Renouvier beyond Kant and Fichte, bringing him closer to our own time.[143]

[138]Mouy (*Idée de progrès*, 43) argues that the disappointments of 1848 played a key role in shaping Renouvier's idea of liberty. For Renouvier, free will came to be seen as the ultimate basis of political liberty (*Deuxième essai*, 551). See *Histoire*, IV, 431, and especially *Esquisse*, II, 382, and *Deuxième essai*, 371*n*1.

[139]Renouvier saw free will as one of the basic concepts of both philosophy and Christian doctrine (*Histoire*, IV, 277).

[140]What does it matter to man if he has freedom in the world of the noumena if his world of phenomena is entirely determined? Renouvier later felt that Kant held on to free will solely for the sake of morals while not really believing in it (*Quatrième essai*, 35–36).

[141]Renouvier praised Fichte as a defender of freedom and criticized him as a mystic (*Quatrième essai*, 46).

[142]Renouvier was concerned to establish a rationalist and not an empiricist view of science. He saw free will as perhaps the main issue dividing the rationalists and empiricists (*Histoire*, IV, 262). He indicated that there had been no new arguments in favor of free will since Kant and Rousseau (*Esquisse*, I, 280).

[143]Renouvier saw Kant's German disciples as having abandoned liberty for determinism, optimism, and pantheism

It is not just the moral aspect of civilization that hangs on the reality of free will, in Renouvier's opinion, but the whole of our intellectual life. Free will is also the foundation on which philosophy and the natural sciences rest.[144] Without free will, our ability to know anything, whether about man or about nature, is fatally undermined. Scientists do not need to believe in free will, and as he knew, they prefer to avoid this sort of question. In practice, they can legitimately do so because in their narrow spheres of inquiry they have developed techniques of investigation that work even when the scientist is unconscious of the fundamental assumptions on which his method rests. But without free will, the certainty of scientific truths becomes illusory; a consistent determinism must lead to a profound skepticism.[145] Renouvier would never despair of convincing the scientists that just as our concepts of right and wrong depend on free will, so do our concepts of true and false. Indeed, without free will, we could not even talk sensibly about things being true or false.

If, as he pointed out, I hold such and such a view to be true and I am determined by forces outside my control to hold this view, the person who disagrees with me is equally determined by outside forces in his position. If these mutually contradictory positions are equally necessary, what grounds can we have for the certainty that either view is the correct one?[146] If our belief that our ideas are determined is itself determined, so is the other person's belief in free will determined. Under these conditions how could it make any sense to speak of one view as "right" and the other as "wrong"? If, on the other hand, our choices are free, I may freely choose to believe in free will or in spite of the apparent contradiction, to believe in universal determinism. Of the four possible positions revealed by this analysis, the only one that can serve as a foundation for a rational certainty in the truth of our beliefs is to freely believe in freedom.[147] But as Renouvier insists, this means that we must give up any pretension to the absolute certainty of our beliefs.[148] The truth of free will cannot be proved so that no rational person can doubt it. It is a relative truth, like all our other truths, but more important because it plants a relativism at the very core of our thought.[149]

Scientists, Renouvier thought, should have no difficulty understanding and accepting this because science is built on an awareness of the conditional character of our knowl-

(*Histoire*, IV, 467).

[144]See *Deuxième essai*, 227.

[145]*Histoire*, IV, 399; *Deuxième essai*, 327.

[146]*Histoire*, IV, 399; *Deuxième essai*, 306–307 (according to Hamelin, *Système de Renouvier*, 242). Necessity destroys truth: "If everything is necessary, error is necessary just as much as truth is, and their claims to validity are comparable" (*Deuxième essai*, 327). For a restatement of his argument that freedom is essential to the certainty of our knowledge, see *Esquisse*, II, 270–74; see also, *Science de la morale*, II, 377.

[147]The four are (1) we are determined to believe in freedom; (2) we are determined to believe in determinism; (3) we freely believe in determinism; (4) we freely believe in freedom. See *Deuxième essai*, 478; *Histoire*, IV, 399; Hamelin, *Système de Renouvier*, 273–74.

[148]"Certitude is not and cannot be an absolute. It is, as is too often forgotten, a condition and an action of man: not an action or a condition where he grasps directly that which cannot be directly grasped—that is to say, facts and laws which are outside or higher than present experience—but rather where he places his conscience such as it is and as he supports it. Properly speaking, there is no certitude; there are only men who are certain" (*Deuxième essai*, 390). For Renouvier's battle against the idea of evident truths, see *Histoire*, IV, 75, 261; certitude is a sort of "personal contract," "a real contract that a man makes with himself" (Lacroix, *Vocation personnelle*, 114).

[149]*Deuxième essai*, 309–10 (according to Hamelin, *Système de Renouvier*, 242). There were, however, "great probabilities in its [free will's] favor" (*Deuxième essai*, 475). "It ought to be a universally accepted maxim that *everything that is in the mind is relative to the mind*" (*Deuxième essai*, 390). Philosophy needs to take into account the existence of disagreement among philosophers (*ibid.*, 414). Renouvier's approach to the existence of these disagreements is one of the distinctive features of his philosophy.

edge, an openness to the discovery of new truths and the abandonment of old ones.[150] In fact, he had to admit, many scientists were still under the sway of older metaphysical conceptions of truth, except in the conduct of their personal research, and were unaware of any inconsistency in their position.[151] Some who were aware were evidently afraid that to admit that an act of belief was at the base of scientific knowledge would risk undermining the claim of science to objectivity and, even worse, open the way to the proliferation of pseudoscientific beliefs.[152] In reality, pseudoscientific beliefs were already proliferating under the aegis of the belief in determinism. Without a critical analysis of the nature and limits of scientific knowledge, however, our intellectual life is subject to a constant abuse of the name and prestige of science.

The abuse of science takes many forms: the application of research methods to fields where they do not apply, the application of particular concepts to areas other than those where they originated, the confusion of "Science" with the operations of particular sciences. One of the main intellectual trends of the nineteenth century, which Renouvier called *scientisme*, usually rendered as "scientism" in English, was the product of this abuse. Renouvier's relativism does not justify believing in whatever we want to believe.[153] It insists on submitting our opinions to every possible test of logic, experiment, and experience. But we have to admit that our logic, the hypotheses on which our experiments are based, the schemas of thought by which we interpret our experience, all rest ultimately on acts of belief and not on absolute certainties.[154]

If free will is thus essential to both morals and science, just what does he mean by it? Over the centuries, most of the debate over free will has failed to advance our understanding because of the lack of agreement about what is meant by the term. I cannot solve that problem, but I think we will see that Renouvier's view makes the issue more comprehensible.

Free will, for Renouvier, is a capacity possessed by human beings, and only by human beings, that enables them to choose whether to accept one idea or another, whether to perform one act or a different one. It is thus a rejection of the doctrine that holds that all events, mental or physical, are absolutely determined and cannot be other than what they are.[155] Free will is also a rejection of the doctrine of chance, for it is an active power and not the "liberty of indifference" so belabored by determinists.[156] Chance is also hostile to liberty, since it denies man a real power of decision.

The existence of free will requires a measure of indetermination in the universe but could not exist if nature were essentially indeterminate.[157] Our acts of free will are the

[150] On the use of hypotheses in science, see *Premier essai*, 200.

[151] Renouvier credited the English empiricists, following Hume, with freeing science from the metaphysical concept of cause (*Histoire*, IV, 273).

[152] This is the concern of Parodi (*Du positivisme à l'idéalisme*, 184–85), who finds in Renouvier a dangerous fideism. So does Brunschwicg (*Progrès de la conscience*, 625). For Renouvier's praise of Boutroux's argument that the contingency of the laws of nature is not a threat to science, see *Histoire*, IV, 673–74.

[153] Dauriac ("Moments de la philosophie," 30–32) strongly makes this point. It would be interesting to compare Renouvier's conclusion on this point with the similar view expressed by Richard Rorty, coming from a rather different direction.

[154] *Histoire*, IV, 692.

[155] See definition of free will in *Histoire*, IV, 337; on liberty as choice, see *Deuxième essai*, 466; on real alternatives, see *ibid.*, 339. Renouvier is rejecting a causal necessity, not analytic necessity, as in the syllogisms of logical operations (*Premier essai*, 232–36).

[156] *Deuxième essai*, 330–34, 336, 337; Hamelin, *Système de Renouvier*, 242–43,249.

[157] "Liberty does not require the complete indetermination of particular future events, even of those that are directly connected to it" (*Deuxième essai*, 459); see also *ibid.*, 357; Hamelin, *Système de Renouvier*, 244.

> beginnings of chains of consequences and would have no meaning if their consequences were not subject to cause and effect. "Free acts are not effects without causes; their cause is man, the ensemble and fullness of his functions. They are not isolated, but are always closely attached to the preceding condition of the passions and of knowledge. *A posteriori* they seem henceforth indissoluble parts of an order of facts, although a different order was possible *a priori*."[158] The laws that permit us to say this is followed by that do not admit of an infinite regression into the past, according to Renouvier. Therefore, every series of phenomena—and indeed the existence of any phenomena—must have a beginning that we cannot explain in terms of antecedents.[159]
>
> The act of creation of the universe is thus replicated (in a much smaller way!) in every act of free will. Every act of free will is the creation of a new series of phenomena, a series that would not otherwise have existed.[160] These new chains of cause and effect are not simply the product of the intersection of existing but independent series, as A.-A. Cournot argued, for such intersections, though they appear random from the point of view of any one of the colliding series, would be necessary from a higher viewpoint.[161] They must be new beginnings, arising from a conjuncture in which, given the antecedents, more than one consequence was possible: "ambiguous futures," Renouvier called them.[162] Free will is the capacity to opt for one or another of those futures.

and

> Renouvier's assault on the optimistic doctrine of inevitable progress was carried out with both philosophical and historical arguments. The philosophical arguments were probably the most conclusive for him, but he understood that it is possible to differ over philosophical positions. What he found especially difficult to understand was how anyone could look at human history and still believe in continuous and automatic progress. The great system builders were also great oversimplifiers: "Hegel and Comte, as well as Bossuet and Vico, treat history the way Eudoxus and Ptolemy treated astronomy, with their ideal spheres." Rather than looking at all of history, most empirical arguments for progress lean heavily on the history of Western science or in more recent years the advance of material comforts or life expectancy. The progress of the sciences in the past has also favored growth of the illusion that science will in the future be able to solve all our problems.
>
> In the nineteenth century there were also some who argued the reality of moral improvement as well as an intellectual advance, and especially the superiority of the nineteenth century over its predecessors. Renouvier's measure of progress was the level of individual freedom, certainly a good measure from which to criticize the belief in

[162] *Deuxième essai*, 210. "The real indetermination of various phenomena envisaged in the future" (*Premier essai*, 240). "[A determinist] would renounce everything called reflection and reason, for these functions do not work without the consciousness of a *representative self-motivation*, which is itself linked to an awareness of the *real ambiguity of future conditions* before it takes action" (*Histoire*, IV, 769). See also *Troisième essai*, xlvii; Hamelin, *Système de Renouvier*, 230.

inevitable progress but not an easy one to apply in any precise way. Unlike many of his contemporaries, Renouvier was not convinced that individual freedom had made great strides in the nineteenth century, but what worried him most was the illusion that the gains made were secure and that further expansion was certain.

The principal reason why there could be (and had been occasionally) progress was the same reason there could be no inevitable, necessary progress: free will. Even if, as Renouvier admitted, most of the decisions men make are psychologically, socially, or otherwise determined, the presence of even a few free acts prevents any long-term necessary process of development. Free will also makes possible not just failure to progress but also regression, and he found enough historical examples to support his conclusion. Modern optimism about progress, he observed, took root in the eighteenth century, but its most celebrated advocate, Condorcet, did not consider it absolutely inevitable, nor did he hold regression impossible. The domination of historical determinist views in the nineteenth century seemed to Renouvier an abusive extension or corruption of more realistic eighteenth-century views. In philosophy, the main culprit was Hegel, though most of the main schools were also guilty.

W. H. Long, *The Philosophy of Charles Renouvier and Its Influence on William James*, **Ph. D. thesis, Harvard University, 1927:**

In 1834, at the age of nineteen, Renouvier entered l'École Polytechnique in Paris ... Here at the École he met two fellow-pupils, Felix Ravaisson and Jules Lequier, destined to contribute significantly to the life of Renouvier. Ravaisson, in his *Rapport sur la philosophie francaise au XIXe siecle*, was one of the first to recognize the neo-criticist as one of the great thinkers of the age. Jules Lequier, an original mind but too sensitive of imperfection to produce published works, was a direct influence in developing in Renouvier that psychological and ethical voluntarism which came to have such a dominant role in his thought, and hence indirectly also an important influence in the thought of William James.

Jules Lequier was born on January 30, 1814, at Quintin (Côtes-du-Nord), and, having studied at various colleges, entered 1'École polytechnique in 1834. Having remained here for two years, the young man entered military service. In 1838 occurred the death of his father, inspiring in the son an impassioned sense of the problem of life and of reality. Resigning from military service, he gave himself up to an intense study of philosophy, passing through a critical spiritual and mental struggle, winning at last a faith in freedom and the divine destiny of man. Strangely enough, Lequier remained a loyal Roman Catholic through life—"la faiblease de ce grand esprit," in Renouvier's words. He was in spirit, however, protestant, insisting upon the authority of the primitive tradition rather than the unique Roman point of view.

It was an unfortunate loss to the world when Lequier, modern Pascal, burned most of his manuscripts. His sensitive spirit was too keen to imperfection, and too restless to achieve the ideal formulation of his thought, to allow him to produce written work. At his death, in 1862, there remained only some few scattered collections of notes, the major portion of which Renouvier, faithful friend and loyal to the name of one whom he called his master, published in 1865 under the title of *La recherche d'une primière vérité, fragments posthumes de Jules Lequier*. Renouvier's loyalty and devotion is quite striking, for he acknowledges in practically all of his works his indebtedness to his friend, and reaffirmed on his death-bed this debt to the mind which had stimulated in him the voluntaristic point of view in speculation.

For example, a noteworthy statement by Renouvier in the introduction of his *Manuel de la Philosophie Ancienne*, written in 1844, is of value in the history of pragmatic voluntarism. He writes that

> Il est surtout une chose que je ne dois poing négliger de dire: de longs entretiens sur les questions fondamentales de la métaphysique avec un ami qu'il n'est pas temps encore de nommer, et qui en a fait depuis plusieurs années l'objet habituel, de ses réflexions, ont imprimé quelquefois sur mes idées les traces des siennes. Ces communications mutuelles ont été, malgré les différences profondes qui nous séparent, favorisées par un accord frappant dans quelques-uns des principes de la haute logique. Accoutumé, comme il l'était lui-même, à donner une grande place à la croyance dans les fondements de la science, j'ai mis à profit des analyses sur la foi; sur la liberté, sur l'intervention de l'idée de liberté dans celles du savoir et de la certitude, qui sont, pour lui, le résultat d'études sérieuses et de méditations suivies, et qui joueront un rôle important dans ses travaux: la publication n'en tant pas prochaine, c'était une raison de plus pour constater ice que les vues generales qui les dominent lui sont tout à fait personnelles.

Elsewhere Renouvier writes concerning the influence of Lequier upon his doctrines of freedom, certitude, and belief, that he owed to his friend and master,

> tout ce qui concerne d'une manière essentielle, dans mon livre, l'établissement de la liberté et de ses rapports avec la certitude, à un philosophe, M. Jules Lequier .... Il ne dépend pas de moi de donner ... satisfaction à sa mémoire. Je peux du moins reconnaître, encore qu'il soit difficile de l'exprimer en termes vraiment suffisants, l'incomparable obligation que j'ai contractée envers l'homme qui a fait tomber un certain jour l'écaille de mes yeux, qui m'a montré la faiblesse des doctrines dont j'étais l'adhérent, même involontaire, et m'a apris ce que c'est que liberté, ce que c'est que certitude, et qu'un agent moral est tenu moralement de *se faire* des convictions touchant des vérités, dont les penseurs rationalistes ont la mauvaise habitude de mettre la preuve sur le compte de l'évidence et de la nécessité.

For Lequier, in Renouvier's words, a man's philosophy centers around a master thought and an active faith. The true Odyssey of the human mind, according to Lequier, must begin with the Cartesian search for a first verity, for certitude. Certitude requires evidence. What, then, is evidence? "Impossible, évident, légitime, que de rapports mal démêles!" ejaculates this remarkable seeker for truth. What is evidence? That which "est impossible de douter avec bonne foi." But there is apparent and false evidence as well as true. Hence the Cartesian methodical doubt is the only true method; for true evidence and apparence [sic] are not identical. For unknown errors may creep into the most apparent truths. What, first of all, shall we say of the pretended separation of belief and science? What shall determine our choice when the head and the heart, science and belief, are in conflict? "J'aviserai, je verrai: je sacrifierai l'une à l'autre," writes this modern Pascal. "Tu dis vrai, mais je ne veux pas t'entendre; ne l'ai-je pas dit souvent? Ou plutôt je dirai à ma raison: Tu dis vrai et je le voie, mais je ne te crois pas, et m'aidant de ne te croire pas pour m'empêcher de voir que mon coeur me trompe, je trouve que tu as tort et que c'est mon coeur qui a raison. Je préfère la sagesse de mon coeur qui m'élève et me satisfait, à ta lumière qui ne me montre que mon abaissement et mon désespoir. Quand tu affirmes que ce qu'il affirme est évidemment faux pourquoi te croirais-je, puisqu'il affirme que ce que tu affirmes est faussement évident?

"Mais il serait mieux que ma raison et mon coeur eussent raison ensemble."

The search for a first verity, avoiding the snares of prestige and false evidence, ends in a vicious circle, since first truths are begged.

> Les vérités primitives ne peuvent s'établir par l'évidence puisque l'évidence est déductive.

To escape the vicious circle and its accompanying doubt requires an act of will:

> Franchir ce cercle vicieux c'est posséder en quelque façon, c'est créer, c'est faire que ce qui n'était pas soit; c'est faire en moi la lumière, mais la faire en effet ... Agir, c'est commencer. Je le franchis donc en agissant, ce cercle vicieux, dans mon effort qui se produit lui-même; cet effort qui l'instant d'avant n'était pas et qui tout à coup devenant, par lui-même à lui-même sa cause, est, c'est-a-dire s'est produit, s'est fait de rien. C'est là vouloir.

Thus knowledge begins with free act, and destroys the illusory necessity.

Lequier's own spiritual history in similar to that of William James, and it is in fact the former whose doctrine brings the latter out of his slough of despond. The striking mental regeneration of Lequier is so interesting in the history of American pragmatism that it is worthy of quotation. From the whole of the remarkable memoire of this young men seeking freedom the following item is given:

> Une seule, une seule idée, partout reverberée, un seul soileil aux rayons uniformes: Cela que j'ai fait était nécessaire, Ceci que je pense est nécessaire, L'absolue nécessité pour quoi que ce soit d'être à l'instant et de la manière qu'il est, avec cette conséquence formidable: le bien et la mai confondus égaux, fruits nés de la méme sève sur la même tige. A cette idée, qui révolta tout mon être, je poussai un cri de détresse et d'effroi: la feuille échappa de mes mains, et comme si j'eusse touché l'arbre de la science, je baissai la tête en pleurant.
>
> Soudain je la relevai. Ressaisissant la foi en ma liberté par ma liberté même, sans raisonnement, sans hésitations, sans autre gage de l'excellence de ma nature que ce témoignage intérieur que se rendait mon âme créé à l'image de Dieu et capable de lui résister, puisqu'elle devait lui obéir, je venais de me dire, dans la sécurité d'une certitude superbe: Cela n'est pas, je suis libre.
>
> Et la chimère de la nécessité s'était évanouie, pareille à ces fantômes formes pendant la nuit d'un jeu de l'ombre et des lueurs du foyer, qui tiennent immobile de peur sous leurs yeux flamboyants, l'enfant, réveillé en sursaut, encore à demi perdu dans un songe: complice du prestige, il ignore qu'il l'entretient lui-même par la fixité du point de vue, mais sitôt qu'il s'en doute, il le dissipe d'un regard au premier mouvement qu'il ose faire.

Thus by an act of will Lequier asserted his freedom and renounced the power of fate and necessity.

True, Lequier insists, it is impossible to demonstrate freedom; but at the same time it is impossible to demonstrate necessity. In this situation the individual has the right to affirm freedom as a postulate of life, and this affirmed truth receives a new dignity and value, namely in being freely chosen by the individual in a moral act. In the absence of proof there arises a definite dilemma and challenge:

To affirm Necessity necessarily; or

To affirm Necessity freely; or

To affirm Freedom necessarily; or

To affirm Freedom freely.

In this alternative of freedom and necessity, Lequier bids us choose "entre l'une et l'autre, avec l'une ou avec l'autre." He preferred to, choose freedom freely; "j'embrasse le certitude," he declares, "dont je suis l'auteur." And in this he finds the first verity which he sought, namely, "freedom the positive condition of knowledge, and the means to knowledge."

It is thus shown that Lequier was a determining factor in Renouvier's theory of belief, certitude, and freedom, end hence, as it will be shown, the immediate source of William James' "will to believe" doctrine, and his theory of freedom, is to be traced to this little-known modern Pascal, Jules Lequier.

L. Menand, *The Metaphysical Club*, (HarperCollins, London, 2001):

In his own way, and despite Holmes's distaste, William James was a bettabilitarian, too. But he did believe in free will—what would it mean to bet, after all, if we were not free to choose the stakes? He was repelled by Wright's reduction of the world to pure phenomena—he thought Wright made the universe into a "Nulliverse" and he regarded the abyss Wright insisted on placing between facts and values as a fiction. James thought that Wright's decision to separate science from metaphysics was itself a metaphysical choice—that Wright's disapproval of talk about values was just an expression of Wright's own values. Wright was a positivist because positivism suited his character: moral neutrality was his way of dealing with the world—and that, in James's view, is what all beliefs are anyway, "scientific" or otherwise.

Wright was a regular visitor to the James family home in Cambridge long before 1872, and in any case William James did not need the Metaphysical Club to reach his conclusion about the nature of beliefs. He had already arrived there by experimentation on what was always his favorite human subject, himself. When he was living in Germany in the late 1860s, he had got caught up in the speculative frenzy about free will and determinism inspired by Buckle's book. As usual, he found merits on both sides. "I'm swamped in an empirical philosophy," he wrote to Tom Ward shortly after getting back to Cambridge in 1869; "—I feel that we are Nature through and through, that we are *wholly* conditioned, that not a wiggle of our will happens save as the result of physical laws, and yet notwithstanding we are en rapport with reason .... It is not that we are all nature *but* some point which is reason, but that all is Nature *and* all is reason too."

After he took his M.D. from Harvard, in June 1869, James collapsed. He descended into a deep depression, exacerbated by back pains, eye trouble, and various other complaints. His diary for the winter of 1869–70 is a record of misery and self-loathing. Then in the spring, after reading the second installment, published in 1859, of a three-part work called the *Essais de critique générale* by the French philosopher Charles Renouvier, he had a breakthrough.

Renouvier was a French Protestant from a family active in liberal politics, but he had quit political life after the rise of the Second Empire, in 1848, to devote himself to the construction of a philosophical defense of freedom. Renouvier's argument was that "the doctrine of necessity" is incoherent, since if all beliefs are determined, we have no way of knowing whether the belief that all beliefs are determined is correct, and no way of explaining why one person believes in determinism while another person does not. The only noncontradictory position, Renouvier held, is to believe that we freely believe, and therefore to believe in free will. Even so, we cannot be absolutely certain of the truth of this belief, or of anything else. "Certainty is not and cannot be absolute," he wrote in the second *Essai*. "It is ... a condition and an action of human beings .... Properly speaking, there is no certainty; there are only people who are certain."

This was, in effect, Wright without the nihilism, and it was entirely appealing to James. "I think that yesterday was a crisis in my life," he wrote in his diary on April 30, 1870.

> I finished the first part of Renouvier's 2nd Essays and see no reason why his definition of free will—the sustaining of a thought *because I choose to* when I might have other thoughts—need be the definition of an illusion. At any rate I will assume for the present—until next year—that it is no illusion. My first act of free will shall be to believe in free will .... Hitherto, when I have felt like taking a free initiative, like daring to act originally, without carefully waiting for contemplation of the external world to determine all for me, suicide seemed the most manly form to put my daring into; now, I will go a step further with my will, not only act with it, but believe as well; believe in my individual reality and creative power.

As bold as this resolution sounds, it did not release James from his depression. He seems to have been incapacitated by psychosomatic disorders—in particular, an inability to use his eyes for reading or writing—for another eighteen months, and he suffered chronically from depression, eyestrain, and insomnia all his life. Henry's mention of the formation of the Metaphysical Club in January 1872 is one of the first signs, after the diary entry about Renouvier, written a year and a half earlier, that William was socially active again.

Still, James believed that Renouvier had cured him, and he sent him thanks. "I must not lose this opportunity of telling you of the admiration and gratitude which have been excited in me by the reading of your *Essais*," he wrote to Renouvier in the fall of 1872. "Thanks to you I possess for the first time an intelligible and reasonable conception of freedom .... I can say that through that philosophy I am beginning to experience a rebirth of the moral life; and I assure you, sir, that this is no small thing." Renouvier had taught James two things: first, that philosophy is not a path to certainty, only a method of coping, and second, that what makes beliefs true is not logic but results. To James, this meant that human beings are active agents-that they get a vote—in the evolving constitution of the universe: when we choose a belief and act on it, we change the way things are.

18-08-08 *SICs and Partial Orders* (to K. Martin)

Thanks for sending your tutorial. This looks like good stuff. I very much like this idea of a partial order on the probability simplex, and I would like to think about it more. Seeing your example about Grover's algorithm the other day convinces me that there's nothing intrinsically bad about building a partial order on the density operators by introducing a fixed BASIS and then relying on a well-known order on the simplex. Introducing a SIC is doing the same conceptual thing, but the SIC has the added bonus of being informationally complete. Thus all density operators become comparable under it.

Maybe one interesting technical question that could be considered is what properties of the partial order are preserved when one changes from one SIC to another. Maybe it's not the case that everything blows to the wind, but at least some features are preserved.

In any case, it was really good meeting you. And how grateful I am that you're interested in this passion of mine. I genuinely do think that a lot of stuff (even revolutionary stuff) will come out of the study of SICs.

20-08-08 *Want to See a Glacier?* (to D. Gottesman)

Having now gone to Bristol, Sydney, Eugene, Zurich (twice), Paris, and Garching already this year, and leaving again for Sweden next week, I woke up two nights ago with the severe pain of a broken travel bone. I decided I just can't take it anymore. Not for a while at least.

Thus I wonder if you'd be interested in taking my place at this meeting:

> `http://www.uibk.ac.at/th-physik/qics-obergurgl2008/`.

It would be nice for PI to have some representation there, and I think it is a meeting (and a subject) you would enjoy in any case.

If you're interested, let me know, and when I tell the organizers I'm out, I'll ask them to consider transferring the invitation to you. (To be honest, it'd be a very good deal for them.)

20-08-08 *Progress* (to E. G. Cavalcanti)

Cavalcanti-ism 1: *By the way, the argument I gave in Vienna, now that I remembered, was along these lines:*

Suppose you believe that (i) A quantum state is just an encapsulation of your subjective degrees of belief; (ii) The lesson of Kochen-Specker and Bell's theorems are that there are no objective facts to further specify your degrees of belief even in principle, at least in the cases where you assign a pure state to a situation; and (iii) You are no more central to the universe than any other agent.

Then considering a Wigner's friend scenario, assumptions (i) and (ii) imply that before you look into the box where your friend is measuring a quantum system, you cannot assign a reality to the measurement outcome of your friend. However, assumption (iii) makes you believe that your friend <u>*can*</u> *assign a definite outcome, whichever it is. That implies that as far as you are concerned, before you open the box that event of your friend measuring the system never happened. But you believe that relative to your friend it did happen. You conclude that the very existence of 'events' is relative to the observer. The world is not made of a collection of events aspersed in space-time, with well-defined causal relations between each pair of events, and between each event and each observer.*

To reinforce that view, you can devise two situations: in one you open the box and ask your friend "Did you see any outcome before I opened the box?". Of course she'll say your opening the box had no influence on that, and by assumption (iii) you'll believe her. So you do the same experiment, but now you perform a transformation that takes all the contents of the box, including your friend, back to its initial state, a little time after you presume the measurement has been done. The fact that the evolution was fully reversible is evidence of the fact that your friend was still in a coherent entangled state with the measurement apparatus, and therefore by (ii) you believe there's no objective fact of the matter relative to you as to which outcome she observed, and since you coherently reversed the interaction, there never will be. Yet, you still believe that relative to her own previous position as an observer inside the box, she must have observed something before you reversed the whole thing. But that observation is forever outside any causal relation with you or even your current time-reversed friend. In other words, that event is in a sense not in the same space-time as you are now, if by definition every event in a space-time have <u>*some*</u> *causal relation with every other event.*

The only way out of this conclusion, it seems to me, is to accept a hidden-variable interpretation in which there <u>*are*</u> *objective matters of fact about events, we just don't know what they are, or extreme solipsism. But I would agree with you if you say that the alternative above sounds much more exciting.*

It took me a long time, but at least I've made a little progress. I finally read the nice set of notes you sent me. I will work on a response during my flight(s!) to Sweden. But I think you'll be there so we can discuss things anyway.

My main qualm is with what you call solipsism at the end. I instead would call it extreme pluralism. It'll be fun talking again.

22-08-08 *Possible Collaboration?, 2* **(to T. Duncan)**

The role you foresee for me is something I can decently fulfill. As you say, we can bat around ideas—maybe I can become more involved if there are some concrete ideas worth pursuing. I love the way you quote William James's "Sentiment of Rationality". Maybe the right call is his essay on man's strenuous nature. I tell my daughter every day that she can change the world—one can suspect that the world is malleable, as the classical pragmatists did. But that is only reinforced by quantum mechanics—that idea is what drives me. So there is plenty of room to talk.

22-08-08 *The Two Freedoms Found, 2* (to H. C. von Baeyer)

Thanks for that. I read the interview a couple or three days ago, and both enjoyed it and grit my teeth too (at the choice of some phrasings). Getting caught up on email.

... Well I started that much of a note to you earlier (about five days ago) and never finished. But now I'm off to Sweden for one of Andrei's crazy conferences. But it unites Schack, Appleby, and me together for a while and there are some other interesting people there too (Bengtsson, Cabello, Larsson).

My key grit was with the word "property". I think it is dangerous business to say that it is a particle's properties that are teleported. See *My Struggles* starting at the section "Qubit and Teleportation Are Words".

But there was other good stuff in the interview that was really good stuff too. I should come back to an exposition of the positive things.

Let's talk soon again about the Pauli-Fierz project. Have you given it any further thought? Any progress? Or has it been forgotten for the meantime. I'll try to write some words in Sweden (particularly if I see a reply from you).

22-08-08 *Invite!* (to H. Mabuchi)

Thanks for letting me off the hook.

Mabuchism 5: *I'm thinking we should have another go at trying to pitch some kind of Perimeter-Stanford quantum foundations thing ...*

Actually I would like that very much. My grant writing skills are much better than they used to be. And I have a feeling Rob would be keen too. Do you have a time frame on which we should think about working something up?

You tell me you can do an experiment that can map out the weirdities of my extended Bloch sphere, and I'll be out to Stanford soon after Christmas. Actually "Bloch sphere" is in a way a misnomer: We now understand it's much more like a spider web sitting on a sphere. A whole lot of spherical caps are missing, and the states really reside at the intersections (the webbing).

Onward to Sweden; I am just about to land at JFK along the way.

25-08-08 *Quotes* (to A. Plotnitsky)

Please don't forget to send me the quotes from your talk today.

Arkady's Reply

> On one hand, the definition of the state of a physical system, as ordinarily understood [i.e. in classical physics], claims the elimination of all external disturbances. But in that case, according to the quantum postulate [of Planck], any observation will be impossible, and, above all, the concepts of space and time lose their immediate sense. On the other hand, if in order to make observation possible we permit certain interactions with suitable agencies of measurement, not belonging to the system, an unambiguous definition of the state of the system is naturally no longer possible, and there could be no question of causality in the ordinary sense of the word. The very nature of the quantum theory thus forces us to regard *the space-time co-ordination and the claim*

of causality, the union of which characterizes the classical theories, as complementary but exclusive features of the description, symbolizing the idealization of observation and definition respectively.

— Niels Bohr (1927), *PWNB* 1, pp. 54–55 (emphasis added)

02-09-08 *Real Lasers* (to J. W. Nicholson)

Learning that one of my high-school acquaintances is now involved in this:

> `http://www.thequantumalliance.com/`
> [[at the time the site had some kind of "laser product" for bio-feedback]]

I couldn't help but forward it on to you. Now that's real cutting-edge laser work, isn't it?

03-09-08 *Two (Important!) Things* (to C. Rovelli)

I have been meaning to write you ever since departing Paris, but the usual malaise in writing came about as soon as I left—too much sociality takes a toll on my correspondence. The reason I wanted to write you is because after meeting you, listening to your talk, and listening to the lunchtime conversation you had with Si Kochen, I felt a rather deep connection between several aspects of our individual (i.e., your and my) takes on quantum mechanics. Even the common imagery we both seem to use struck me as a surprise. What particularly intrigues me is the way we've come at this from different directions, but both end up on a radical thought: That even facts (particularly quantum outcomes) are relative. The two directions—and they certainly seem to be distinct—are 1) for you, relationalism more generally, and 2) for me, an understanding of quantum states in terms of Bayesian probabilities. I would not have initially thought of those roads as traveling to the same point, but there is something to think on here. Whereas you speak of "relative facts", we speak of "facts for the agent", but at least in some aspects they are surely the same thing.

I would be flattered if you would read some of my poetry on the idea before we meet and discuss these things again. Particularly, I want to advertise to you the new compilation I'm putting together as a point of departure. You can pick it up here: [See this samizdat, but with updated page numbers.] I hope that you'll find parts of it entertaining and thought provoking. Of interest for the present purposes, you might read a bit around where I discuss this phrase "fact for the agent" (and see how it compares or contrasts with what you are striving for). Here are some points of entry:

1) Page 687, starting at "Replies to Referee 4"

2) Page 650, starting at "Our Professor"

3) Page 646, starting at "My Two Cents"

4) Page 714, starting at "Facts-in-Themselves"

5) Page 716, starting at "Anti-Algebra, the Reprise"

Also, maybe my correspondence with Bas van Fraassen about what I was perceiving as the difference and similarities between my view and yours: See pages 550–557. Also points to Rüdiger Schack on the same (and Wigner's friend), pages 559–564.

That's one important thing. Now, to the next question. When *shall* we discuss these things again? When we parted in Paris, you said pretty firmly (and I don't believe I am making this up), "I will see you in September." Yet, our conference coordinator has not heard from you yet. Please do write and say you're coming. And particularly, because I would like to ask a further thing of you: Would you give the general PI Colloquium that week in fact? The talk you gave in Paris, from my point of view, would be perfect for it—mostly because it would open up to the wider PI community this difficult idea that we're trying to get at, but also because it was a simply beautiful talk.

Will you be around tomorrow or Friday? I would very much like to call and talk about this (Lee gave me your number): A colloquium from you would be great for PI.

03-09-08 *Er Er* (to D. M. Appleby)

Applebyism 21: *A conference on multiverses I could cheerfully miss. It is strange: I am not a Bohmian, but the Bohm theory never annoys me. Quite the contrary. I don't believe it, but I think it is an interesting hypothesis. I also enjoy talking to Bohmians—Owen is just the latest in a long list. But when it comes to multiverses I feel strong aversion. It strikes me as, not so much a theory, more an intellectual disease. Perhaps even a moral and spiritual disease: for if you think that everything happens it seems to me that you cannot help ending up with the belief that nothing really matters. Everett et al. trivialize the world, and perhaps for that reason I don't think I can even enjoy talking to an Everettian. At least, I can't think of an occasion when I ever have.*

Regarding your first paragraph. There was an interesting passage in the conversation where Hilary Greaves had David Albert draw a tree structure on the board, and then David Albert started to explain the idea of an "indexical fact" to Paul Davies. Davies, said something like, "So some branches are lit up because they contain rational agents; but some branches aren't lit at all." Albert protested about the idea of some branches being lit up by the presence of an agent—i.e., that that's not what he was getting at. But the funny thing was that Hilary, who was sitting beside me, went further. I overhead her say to herself, "Yeah, that *would* be crazy." I think that fares well with your assessment below.

03-09-08 *Your Old Thesis* (to G. Valente)

Could you send me a copy of the thesis you wrote after studying in Oxford. I don't have a copy of the final thesis, and recently I bought the Musil book—I'd like to review what you said about him (or which quote you used of his) in connection with QM.

Giovanni's Reply

> Glad to hear from you! Funny that you write to me because I'm in Paris at the moment… and I just got an unexpected e-mail from that Croatian guy who wrote his thesis in Oxford on your work five years ago…
>
> Unfortunately, I don't have a file with my master thesis anymore. It got lost when my old PC collapsed. I may have a disk where I saved the file at home in Italy and I certainly have a paper copy of the work there, but there's nothing I can send you right now. In any case, I recall that I made a reference to Musil only in the introduction, starting out by quoting the passage below which is taken from the section "If there is a sense of reality, there must also be a sense of possibility" (it's one of the first in the

book). According to my original quantum reading, it conveys the idea that the world is under construction, as a pragmatist would put it; that the realists (e.g. Ghirardi, Albert, Maudlin, etc.), who interpret the quantum state as a state of reality, would regard the possibilists (e.g. Chris Fuchs), who interpret the quantum state as a state of belief, as dreamers or troublemakers...; that all we're given is a bunch of possibilities, namely a set of probabilities, but the latter are of course determined by reality, namely by the outcomes of measurements. I think at the end I even joked that, in connection with the Bayesian interpretation of QM, in quantum theory we're really dealing with "systems without qualities", as we can't say anything about them before a measurement.

I'm sure you'll enjoy the book. Perhaps it'll awaken the deep Mitteleuropean spirit that harbours in your soul. I myself was thinking of reading it again soon.

From *The Man without Qualities* by Robert Musil:

> To pass freely through open doors, it is necessary to respect the fact that they have solid frames. This principle, by which the old professor had lived, is simply a requisite of the sense of reality. But if there is a sense of reality, and no one will doubt that it has its justifications for existing, then there must also be something we can call a sense of possibility.
>
> Whoever has it does not say, for instance: Here this or that has happened, will happen, must happen; but he invents: Here this or that might, could, or ought to happen. If he is told that something is the way it is, he will think: Well, it could probably just as well be otherwise. So the sense of possibility could be defined outright as the ability to conceive of everything there might be just as well, and to attach no more importance to what is than to what is not. The consequences of so creative a disposition can be remarkable, and may, regrettably, often make what people admire seem wrong, and what is taboo permissible, or, also, make both a matter of indifference. Such possibilists are said to inhabit a more delicate medium, a hazy medium of mist, fantasy, daydreams, and the subjunctive mood. Children who show this tendency are dealt with firmly and warned that such persons are cranks, dreamers, weaklings, know-it-alls, or troublemakers.
>
> Such fools are also called idealists by those who wish to praise them. But all this clearly applies only to their weak subspecies, those who cannot comprehend reality or who, in their melancholic condition, avoid it. These are people in whom the lack of a sense of reality is a real deficiency. But the possible includes not only the fantasies of people with weak nerves but also the as yet unawakened intentions of God. A possible experience or truth is not the same as an actual experience or truth minus its "reality value" but has—according to its partisans, at least—something quite divine about it, a fire, a soaring, a readiness to build and a conscious utopianism that does not shrink from reality but sees it as a project, something yet to be invented. After all, the earth is not that old, and was apparently never so ready as now to give birth to its full potential.
>
> To try to readily distinguish the realists from the possibilists, just think of a specific sum of money. Whatever possibilities inhere in, say, a thousand dollars are surely there independently of their belonging or not belonging to someone; that the money belongs to a Mr. Me or a Mr. Thee adds no more to it than it would to a rose or a woman. But a fool will tuck the money away

in his sack, say the realists, while a capable man will make it work for him. Even the beauty of a woman is undeniably enhanced or diminished by the man who possesses her. It is reality that awakens possibilities, and nothing would be more perverse than to deny it. Even so, it will always be the same possibilities, in sum or on the average, that go on repeating themselves until a man comes along who does not value the actuality above idea. It is he who first gives the new possibilities their meaning, their direction, and he awakens them.

But such a man is far from being a simple proposition. Since his ideas, to the extent that they are not idle fantasies, are nothing but realities as yet unborn, he, too, naturally has a sense of reality; but it is a sense of possible reality, and arrives at its goal much more slowly than most people's sense of their real possibilities. He wants the forest, as it were, and the others the trees, and forest is hard to define, while trees represent so many cords of wood of a definable quality. Putting it another and perhaps better way, the man with an ordinary sense of reality is like a fish that nibbles at the hook but is unaware of the line, while the man with that sense of realty which can also be called a sense of possibility trawls a line through the water and has no idea whether there's any bait on it. His extraordinary indifference to the life snapping at the bait is matched by the risk he runs of doing utterly eccentric things. An impractical man—which he not only seems to be but really is—will always be unreliable and unpredictable in his dealings with others. He will engage in actions that mean something else to him that to others, but he is at peace with himself about everything as long as he can make it all come together in a fine idea. Today he is still far from being consistent. He is quite capable of regarding a crime that brings harm to another person merely as a lapse to be blamed not on the criminal but on the society that produced the criminal. But it remains doubtful whether he would accept a slap in the face with the same detachment, or take it impersonally as one takes the bite of a dog. The chances are that he would first hit back and then on reflection decide that he shouldn't have. Moreover, if someone were to take away his beloved, it is most unlikely that he would today be quite ready to discount the reality of his loss and find compensation in some surprising new reaction. At present this development still has some way to go and affects the individual person as a weakness as much as a strength.

And since the possession of qualities assumes a certain pleasure in their reality, we can see how a man who cannot summon up a sense of reality even in relation to himself may suddenly, one day, come to see himself as a man without qualities.

04-09-08 *My Own Update* (to D. M. Appleby)

I'll read your longer note in detail tomorrow. One quick point, I used the full phrase "rational agent" in my stories because that was the phrase bandied about in the Greaves/Albert discussion. But I myself don't know what rational is or should mean. The key part of it for me, the part that played any role in my mind at all, is "agent"—by definition, "that which activates."

04-09-08 *Need Students* (to H. C. von Baeyer)

I have just learned that I got a US grant with enough funding to support 2 graduate students fully at U Waterloo through 4 years each. It's of no great use however for good Canadian students, as they will already have their own NSERC funding. Thus I figure it's most wisely spent on really good non-Canadians who want to be up here in the Mecca of quantum info/foundations. So, I'm writing to see if you have any good students that might be interested? The work I'm hoping to emphasize is, of course, "How come the quantum?", tackled from a quantum-information/Bayesian perspective.

Any leads you can give me would be most appreciated.

08-09-08 *Progress, 2* (to E. G. Cavalcanti)

That was helpful. But, OK, I give up on trying to reply to you: Too many things that I unfortunately *have to* write are getting in my way, and in any case, I will see you soon enough.

See you at *The Clock and the Quantum*.

Eric's Preply

> I guess I didn't express myself very well in those end remarks. I should have said that the argument *seems to lead* to the conclusion that either there are hidden variables or to an extreme solipsism. But when I say I agree with you that the "alternative above" sounds more exciting, I mean exactly the alternative which your research program is trying to find, the alternative which we hope will arise out of realising the full significance of the remark from Pauli, that the observer cannot be separated from the things it observes.
>
> Extreme pluralism is probably a better name for that worldview. However, I also have the strong hunch that this pluralism is of a form which is so beautifully symmetric that one cannot avoid the feeling of an unity behind the different perspectives or worldviews. The reason why we seem to be able to glimpse an order, a pattern behind these different perspectives is probably because behind the apparent pluralism stands an unifying simplicity. I think the search for the basis of this unification is the next step after the recognition of the pluralism.

09-09-08 *Rationalizing Agent* (to D. M. Appleby)

I've now read both of your notes on the subject. The short answer is, yes I do agree with you. I like the way you put this:

Applebyism 22 : *If the word "rational" is understood in that way then I don't believe a rational agent is capable of lighting up anything. Not even itself.*

The point is, the light—the will—comes first (or at least has a significant priority I think). Not only do we see something like this in alchemistic strains of thought, but it is a good piece of James and Dewey's psychology.

All this talk of rationality and where it stands in relation to the light, reminds me of something very different. G. H. Mead's discussion of causality in light of true indeterminism. I'll paste in a passage below about that. [See A. E. Murphy quote in the 23-09-03 note to Steve Savitt, titled "The Trivial Nontrivial."] Maybe you'll see why my mind loosely jumps between the subjects.

Anyway, reflecting on the two issues simultaneously led to the title of this note. "Rational agent" doesn't seem right indeed. But put "rationalizing agent" in its place, and it seems to ring of a little truth.

09-09-08 *Panpsychism* (to D. M. Appleby)

Applebyism 23: *Which brings me back to the term "rational agent". The word to which I take particular exception here is, not "rational", but "agent" (I do object to "rational", for the reasons I gave before, but I object even more to "agent"). To my mind this is an example of the "impersonal expressed in the passive voice". It should be "rational person" (or "rationalizing person"). Or "rational human", in all his or her laughing, crying, breathing, shitting, infinitely layered, ineffable totality.*

Reasoning is something that people *do. Not boxes, with an operating system.*

I continue to like "agent" over "person" or "human" because I think that is the relevant piece of the equation. However, in my case, I don't think it's because there is a Cartesian deep inside me that's trying to re-emerge, but rather a Copernican. That by learning about myself—my position—I learn something about everything else's position. Here's the way I put it to Sipe once. The relevant part is the last item. It is partially, though perhaps not completely, relevant to my discussion with you.

1. When I posit a physical system about which I will speak (by assigning it a Hilbert space, etc.), I am doing that in an almost naïve realistic way. I.e., the $\mathcal{H}$ I write down, represents a piece of the world that is out there independently of me.

2. When I assign a dimension d to that Hilbert space, I am hypothesizing an inherent *property* of that system. I might be right, or I might be wrong, but d is something I hypothesize of it, even if only provisionally. Realism again.

3. When I draw a quantum state out of the space of operators defined by $\mathcal{H}$, however, I am expressing a bundle of my expectations. These are not properties inherent in the system. They are subjective expectations that I bring into the picture (presumably because they have served me well in the past, or at least done me no harm). If I were to conceptually delete myself from the picture, these expectations would disappear with me. To that extent, the view might sound a little like—or at least be confused with—idealism (but that's only if one—as Howard Wiseman often does—forgets elements 1 and 2 above and one of the further elements below.)

4. The subject matter of those expectations, i.e., what they are about, refers both to me and the system I posit. They are MY expectations for the consequences (for ME) of MY interactions with the system. That, you might think is a kind of operationalism: For if I were to conceptually delete myself from the picture, those interactions would disappear too.

5. On the other hand, the reason we use the formal structure of quantum mechanics to bundle our expectations, to manipulate and update them, to do all that we do with them, is to better cope with the world. It is a means to help our species to survive and propagate. That is a kind of instrumentalism. That part of quantum mechanics is a tool like a hammer; it can be used to fix a lot of things, or simply as an aid to help defend ourselves.

6. Still one can never forget the ultimately uncontrollable nature of each quantum measurement outcome—and through Kochen-Specker, at least the way I view it, the non-pre-existence of those "outcomes". That smacks of realism in the oldest, most time-honored way. The world surprises us and is not a creation of our whims and fancies. Back to realism ... but the twist is quantum mechanics, as used by each individual user, only refers to the outcomes HE helps generate. (That smacks of alchemy ... dangerous to say so, but I call it like it is.)

7. Nevertheless, having learned a little from Copernicus, it seems we should ultimately try to abstract away from these personal encounters with the world (having learned what we could from the formalism concerned with gambling on them). If a tiny little system and I create something new in the world when we get together—i.e., we give rise to a birth or new fact—so must it be likely, it seems to me, that any two things give rise to a birth when they get together. That is "F-theory" or the "sexual interpretation of quantum mechanics" ... but you'll have to wait for the movie if you question me any further on that ...

09-09-08 *Panagentism* (to D. M. Appleby)

Just playing with titles. This might have been better for the last note.

10-09-08 *Easier Answers* (to D. B. L. Baker)

Bakerism 4: *Are you planning on staying long? What's your job like?*

I plan to stay forever if I can. This is the most fantastic job ever for the likes of someone like me. I make good money, and the intellectual freedom is wonderful. It gives me hope that I really will solve the problems of quantum mechanics before my days are up. And the work environment is like nothing I've ever seen: good coffee out for us continuously, muffins in the morning, cakes in the afternoon, wine and cheese every Friday afternoon. You can take a virtual tour of the place here `http://www.perimeterinstitute.ca/en/About/Facilities/Facilities_Overview/` and you can see our wine list here `http://www.perimeterinstitute.ca/en/Outreach/Black_Hole_Bistro/Black_Hole_Bistro_Overview/`. So, it's just an amazing place to be at every day.

10-09-08 *Your Old Thesis, 2* (to G. Valente)

Thanks a million for the quote. Yes, everything is going OK here, and Appleby, Schack, and I are on the tail of something big we think: A nice derivation of finite dimensional quantum state-space structure from a single inequality. Or, at least that's what we hope.

Good luck with all these academic things you're doing! Geesh, a degree in physics to complement your degrees in philosophy. Very impressive.

One technical point on what you said:

Valente-ism 5: *I think at the end I even joked that, in connection with the Bayesian interpretation of QM, in quantum theory we're really dealing with "systems without qualities", as we can't say anything about them before a measurement.*

I would say that you can't say anything particular about them *after* a measurement either.

10-09-08 *Really Weird and Not-So Weird Stuff* (to M. D. Sanders)

Sandersism 2: *OK, don't laugh at me, but I am curious if you think the CERN particle accelerator is BS or it might actually reveal something,* http://public.web.cern.ch/Public/Welcome.html*. I read a few of your latest papers (*http://www.pitp.ca/personal/cfuchs/nSamizdat-2.pdf*) indicating that you think the next development is just a matter of viewing things differently, ("Likewise, I'll bet the next big step in physics will only require that we see something right here in front of us.") so I wonder if you think that this CERN BS will actually change anything.*

I didn't go too deep cuz it is like 800 pages, but I tried. I also wonder about the skeptics that think the world will end when it fires up. (Sounds like Star Trek followers, but I don't know.) I don't believe it, but it makes me wonder how crazy people are.

*Anyway, if you have time I would like your opinion. I understand if you think this is stupid based upon where you are . . . you don't have to go too deep, just let me know if you think it will reveal anything or if you think it is a huge waste of money. Also, I'm curious if you are at the pajama party ☺ (*http://ohmyafly.wordpress.com/2008/09/08/largest-hadron-collider-pajama-party/*)?*

Sorry, but you are the only one I know close to this stuff . . .

The really weird stuff is that you were digging around through my notes. Now, that's an old friend! I hope you don't think less of me now! But did you see my TV debut: http://pirsa.org/07120048/. Losing a little hair on top, aren't I? My first comment is lame, but if you have the patience to wait, I get better. (Yeah, right!?)

Now to the not-so weird stuff:

1) Safety of LHC. Here's something to read, and it strikes me as decently authoritative:

   http://en.wikipedia.org/wiki/Safety_of_the_Large_Hadron_Collider.

   I think there's nothing to worry about whatsoever. For me personally, the most conclusive piece of evidence is this. At peak the LHC will be producing 14 TeV collisions (7 TeV each beam), but events like that happen in the upper atmosphere all the time, from cosmic rays slamming into us. The only difference with the LHC is that we'll be able to make the collisions on demand and in the presence of a good detector. Furthermore, the energies of the LHC are really nothing on that scale: Cosmic rays have been recorded not with a measly 14 TeV, but with 10^8 TeV. See:

   http://en.wikipedia.org/wiki/Cosmic_ray
   or
   http://en.wikipedia.org/wiki/Ultra-high-energy_cosmic_ray.

   So, even if these wackos like Rössler were by accident right about black-hole production, etc., (and they're not), then we'd already have black holes flowing through the earth all the time.

2) Cost of the LHC. Estimates run up to $10 billion. I'm pretty sure most of that money is European, though I would like to know what the US contribution is. In my own opinion, it's worth it. For one thing, a key point of the "standard model" of particle physics, the Higgs particle, keeps not being seen. Why does the rest of the model work if this particular major prediction of it keeps hiding? That's more than a 25 year mystery (I first heard of it in 1983), and if the LHC doesn't find it, it'll finally put the nail in the coffin. Secondly, there's the infrastructure for physics as a whole that CERN brings with it. Throughout the world, it helps keep physics education going, and as you can imagine, I'm all for that. To put the costs

in perspective, note that the Iraq war has been costing us $8 to $12 billion A MONTH since 2003. See for instance:

`http://en.wikipedia.org/wiki/Financial_cost_of_the_Iraq_War`.

You can bet your bottom dollar I would trade two months of the war to solve a 25 year old mystery in physics.

3) Efficacy of LHC. It remains true that I believe every word of what I said before: "I'll bet the next big step in physics will only require that we see something right here in front of us. It'll be something no big multi-billion dollar particle accelerator will be needed for. We just have to figure out how to take note of it." But by big step, I mean a REALLY BIG step—the stuff that has historically happened only every two to three hundred years, and can't be planned for beforehand. I think here particularly on Galileo's noticing that any two masses (regardless of their sizes and weights) accelerate toward the ground at the same rate. It is the key insight that ultimately underpinned Einstein's theory of gravitation (containing the essence of his "principle of equivalence"), which in turn led us to predict a load of things, from black holes to the big bang itself. Well, that fundamental phenomenon was right there for anyone to see and take note of in any of the previous 2,000 years of civilization. But no one did. No one had simply said, "Wow, two different rocks, two different metals, two anythings, dropped at the same time always hit the ground simultaneously. I wonder what the significance of that is?" It's observations like that that make the true revolutions in physics. And the LHC is not in that category—that's what I was alluding to. However, I don't belittle little steps in physics either.

   There is clearly something really big brewing on the horizon of physics. Where is all the "missing mass" and "dark energy" in the universe? See

   `http://en.wikipedia.org/wiki/Missing_mass`.

   Is it really just unseen "stuff", or do we have something more basic wrong in our calculations? Why is the universe's expansion accelerating rather than decelerating? These are bigger questions (potentially revolutionary), and the LHC's answers to smaller questions may give us guidance there. At the very least, they may say, "Give up with your usual ways of thinking. Look instead for something that's probably right in front of you."

4) No, I wasn't at the pajama party! I'm too old for that. The last time I was at CERN, I don't even think rap music had been invented yet.

I hope that was of some help.

15-09-08 *PanSICism* (to D. M. Appleby)

What is the new idea for SIC existence?

15-09-08 *Israel December* (to A. Wilce)

Wilce-ism 6: *PS – how did Victor Colussi's week at PI turn out?*

We loved him, had a lot of fun with him. He got a chance to see two old geezers in experimental math mode. While he was here, we were finding an obscene number of new properties for quantum state space when written in SIC language, all by Marcus doing numerical testing as the questions arose. Of course, we didn't have an idea how to prove anything at the time (we have now), but we really opened up a good vein in the mine while he was here. I hope that helped excite him about science.

16-09-08 *What Titles Could Not Be* (to J. Ismael)

I don't think we have your title and abstract yet for The Clock and the Quantum. Could I pressure you to send that in very, very soon?

From a 3 May 1998 note titled "Quantum Probabilities" to Jenann Ismael

> I have just read your nice paper "What Chances Could Not Be" (Brit. J. Phil. Sci. 1996). In particular, I am quite enthusiastic about your closing discussion on how quantum mechanical probabilities may be construed as solely epistemic in character. Have you developed this line of thought further in print? If so, I would very much like a reference to your follow-up articles.
>
> Carlton Caves and I have discussed what I think is a very similar point of view in: C. M. Caves and C. A. Fuchs, "Quantum information: How much information in a state vector?" in *The Dilemma of Einstein, Podolsky and Rosen – 60 Years Later (An International Symposium in Honour of Nathan Rosen – Haifa, March 1995)*, edited by A. Mann and M. Revzen, Annals of The Israel Physical Society, vol. 12, pp. 226–257, 1996. Also available at the Los Alamos World Wide Web E-print Archive `http://xxx.lanl.gov/abs/quant-ph/9601025`. (See, in particular, the discussion of Section 5.)
>
> Presently, we're in the process of writing a paper solely devoted to the idea, and I would like our bibliography to be as complete as possible. (This is how I ran across your paper in the first place.)
>
> Thank you for your help.

17-09-08 *PanSICism* (to P. W. Shor)

I hope you'll be able to come to the SIC workshop that Steve Flammia and I are putting together. I'd really like to see this problem knocked out, and think that an intense workshop with friends (a little talking time, a lot more time at the chalkboard instead) might help shake something loose.

I'm keeping my fingers crossed …

17-09-08 *Seeking Spekkens?* (to R. W. Spekkens)

Spekkensism 44: *How was the contextuality session in Växjö?*

The contextuality session seemed to be enjoyed by everyone participating, but all of the rest of the audience (the ones usually riveted about Bell inequality discussions) slept through most of it. I was a little disappointed that there weren't more conceptual discussions. Mostly there was focus on technicalities, etc.

22-09-08 *Threat of Double Secret Probation* (to A. Kent, A. Steinberg, and W. G. Unruh)

You three are our last hold-outs for supplying titles for your talks at the Clock and Quantum conference next week. It really would be nice to get them posted on the webpage for anyone making a last minute decision about coming. Here's the present schedule:

`http://www.perimeterinstitute.ca/conferences/clock-and-quantum`.

Think of me as Dean Wormer. I really need those titles (and abstracts would be nice too).

24-09-08 *Friends of the Tensor Product* (to S. Abramsky, H. Barnum, B. Coecke, K. Martin, A. Wilce and others)

At the beginning of the summer, my next-door neighbor Keith Rowe, an emeritus professor at University of Waterloo, died after a battle with cancer. Keith was a category theorist, with a love for his children and Canadian football. At the reception for his funeral, I believe I spied a paper titled, "Tensor Products of Categories," but I have not been able to find a trace of it since—maybe I am mistaken. On the other hand, at the end of the summer, Keith's wife Rosemary, came back from her summer stay in their cottage and showed me the papers listed below. I thought I might share the titles with you as a small tribute to him. If any of them look to be potentially useful in your own research (particularly the one that may not have been published), I can get you a copy the next time I see you.

- K. A. Rowe, "Images in Topoi," Canad. Math. Bull. **20** (1977), 471–478.
- K. A. Rowe, "Nuclearity," Canad. Math. Bull. **31** (1988), 227–235.
- D. A. Higgs and K. A. Rowe, "Nuclearity in the Category of Complete Semilattices," J. Pure App. Alg. **57** (1989), 67–78.
- K. A. Rowe, "All Tensor Products are Coequalizers," preprint, don't know if it was published. My summary: "Let E be a category equipped with a bifunctor. In most examples, the bifunctor will be an actual tensor product with special properties such as symmetry or associativity, but we make no such assumptions. We demonstrate that under very mild conditions, every tensor product of algebras with respect to a certain type of monad on E is a coequalizer in the category of algebras."

Samson's Reply

I wrote a paper a few years back, on 'nuclear and trace ideals in tensor *-categories', with Prakash Panangaden and Rick Blute, for which the Higgs-Rowe paper was a very important reference.

Nuclear and trace ideals in tensored *-categories
S. Abramsky, R. Blute and P. Panangaden
In *J. Pure and Applied Algebra*, Vol. 143, pages 3–47, 1999.

24-09-08 *Two Examples* (to R. Healey)

Attached are two examples making the logically pristine point that frequency data *alone* (nor any empirical data, for that matter) *never* determine future probability assignments. I.e., one must feed in a (prior) probability to obtain a (posterior) probability. Of course, this is just the subjective Bayesian point. But it is always nice to be reminded just how simple and uncomplicated that ultimate point is.

In the file `t.pdf` look pages 12-17 (of the total 55). In the file `s.pdf`, look at pages 25-28 (of the total 47). The latter has the example I just showed you in the stair well.

A really good discussion of this point—I think—can be found in Appleby's pedagogical paper: `http://arxiv.org/abs/quant-ph/0402015`.

As I've tried to convey to you before though, I *do not* believe that: Though probabilities are always subjective, the quantum world leaves no empirical mark. Rather it leaves its mark elsewhere than in telling us how to *set* probabilities. I believe it leaves its mark in giving us additional rules to live by beyond Dutch book coherence (when gambling upon the results of our interactions with the external world). In particular, there is a way to look at the Born rule that shows it not as a rule for *setting* probabilities, but rather as a rule for normatively *relating* probabilities. The subjective component of the prior never disappears; instead the world makes it empirical mark in encouraging us to tie our assignments together in stricter ways than de Finetti and Ramsey had envisaged.

We'll get down to business tomorrow.

26-09-08 *Keynes and Zabell Quotes* (to R. Healey)

Two quotes I had wanted to send you earlier in the week, but forgot to.

Here is a the Keynes quote on Ramsey:

> The application of these ideas [regarding formal logic] to the logic of probability is very fruitful. Ramsey argues, as against the view which I had put forward, that probability is concerned not with objective relations between propositions but (in some sense) with degrees of belief, and he succeeds in showing that the calculus of probabilities simply amounts to a set of rules for ensuring that the system of degrees of belief which we hold shall be a *consistent* system. Thus the calculus of probabilities belongs to formal logic. But the basis of our degrees of belief—or the *a priori*, as they used to be called—is part of our human outfit, perhaps given us merely by natural selection, analogous to our perceptions and our memories rather than to formal logic.

And a long quote by Sandy Zabell, from "Ramsey, Truth, and Probability":

> The key point is that previous attempts to explain induction had attempted to model the process by a unique description of prior beliefs [[references]], or by a very narrow range of possibilities [[references]]. De Finetti realized that because probability is a logic of consistency, one can never—*at a given instance of time*—uniquely dictate the partial beliefs of an individual; at most one can demand consistency. The essence of inductive behavior, in contrast, lies not in the specific beliefs that an individual entertains at any given point in time, but the manner in which those beliefs evolve over time. [[In this way it is exactly like classical logic: One is not judged as irrational for starting with the incorrect truth value for some proposition in one's considerations; one is judged irrational only if one makes an incorrect inference in the proof process.—CAF]] Let us pause briefly over this point.

I change my mind slowly; you do so with rapidity; you think I am pigheaded, I think you are rash. But neither of us is of necessity irrational. Disagreement is possible even if we share the same information; we may simply be viewing it in a different light. This is what happens every time the members of a jury disagree on a verdict. Of course it can be argued that the members of the jury do not share the same body of facts: each brings to the trial the sum total of his life experiences, and on juror tries to persuade another in part by drawing upon those experiences and thus enlarging the background information of their fellow jurors. It is the credibilist view of probability that if you knew what I knew, and I knew what you knew, then you and I would—or at least should—agree.

Such a metaphysical stance may well be, as I. J. Good says, "mentally healthy". But it is an article of faith of no real practical importance. None of us can fully grasp the totality of our own past history, experience, and information, let alone anyone else's. The goal is impossible: our information cannot be so encapsulated.

27-09-08 *The Old Jenann* (to R. Healey)

From, J. Ismael, "What Chances Could Not Be," Brit. J. Phil. Sci. **47**, 79–91 (1996):

> There is one possibility which I have refrained from mentioning because it amounts to the denial that there is anything properly called chance, insofar as it is distinct from any species of subjective probability. What I have in mind is the view that chance is just epistemic probability of a particular sort: consider two systems A and B, which differ with respect to the probability pertaining to A of some future event type (say a collapse into a state ψ at t). A either will or will not collapse into ψ at t, B either will or will not collapse into ψ at t, and there is nothing we can now ascertain about either system (e.g. no measurement we can perform) which will decide the case for certain. The occurrence of e is, however, differently correlated with facts about A and B which we *can* determine and with respect to which they differ, e.g. e-type events occur to $l/2$ of systems relevantly like A and only $l/4$ of those like B. This means that we can place A and B in ensembles of systems—as alike to them as we can presently ascertain—in which the frequency of e-type events is $l/2$ and $l/4$, respectively, and this is what the probabilities refer to. The difference between systems with different biographies of probabilities (so long as these assign non-maximal probabilities [i.e. $0 < pr < l$] to the same set of events), is not a difference in the properties of those systems but a difference in what we know about them.
>
> Something about so interpreting probabilities in quantum mechanics has struck physicists as objectionably subjective. Wrongly so, in my opinion. The epistemic probability of a proposition p can be (and often is) represented as a relation between p and a given agent, but can just as well be represented as a relation between p and a set of propositions, those representing the body of information possessed by the agent in question. The t-chance of e on A can be defined as the probability of e relative to the propositions which describe A's state at t or its pre-t history, i.e. as the personal probability of an agent who has no foreknowledge but is perfectly apprised of A's history and the laws which govern its evolution. There is nothing scientifically disreputable [about] chances so construed, indeed it is not unlikely that many physicists have been operating with such a conception without distinguishing it carefully from the view that the t-chances pertaining to A describe objective properties of A such as mass, spin, and

the like. The difference between the two views is just the difference there is in general between the view that some 'parameter' P is a redescription of those in another set $\{P_1, ..., P_n\}$, and the view that P is ontologically distinct from [them] but happens to covary with $\{P_1, ..., P_n\}$. In either case, fixing the values of $P_1, ..., P_n$ fixes the value of P in all physically possible worlds, but the value of P varies independently of those of $P_1, ..., P_n$ in the set of *metaphysically* possible worlds only in the latter case. The value of P fails to supervene on those of $P_1, ..., P_n$ *iff* P is ontologically distinct from $\{P_1, ..., P_n\}$.

Interpreted objectively, quantum probabilities describe properties ontologically independent of the system's other properties and partially characterize its intrinsic state, and it must be (metaphysically) possible for two systems—otherwise alike—to differ with respect to their chances. Interpreted epistemically, the intrinsic state of a system at t is imperfectly correlated with aspects of its post-t state (the events to which it assigns non-maximal probabilities). In this case, the probabilities reflect only uncertainty about the future of the system based on knowledge of its present state (excluding, of course, the chances), and it is impossible for two systems—otherwise intrinsically alike at t—to differ with respect to the t-chances pertaining to each. This view seems to me completely adequate to the role of probabilities in physics (though it would take a much longer paper to show this), and—of all those described—the most natural.

29-09-08 *Tumulka's Reply To You* (to W. G. Unruh)

I got a kick out of your exchange with Tumulka yesterday—particularly, the part where you proposed your universal 7-second-in-the-barrier theory. Roderich's reply that his theory has equations, whereas yours has none, makes all the difference—that that is what makes his a *scientific* theory—took me back a few years to a report I once wrote. I'll place it below in case you might enjoy it. Also a little further commentary below it too. [See 17-11-05 note "Cash Value" to H. Halvorson.]

01-10-08 *Taking Up for Spekkens (this time)* (to W. C. Myrvold)

From the abstract:

> The diversity and quality of these analogies is taken as evidence for the view that quantum states are states of incomplete knowledge rather than states of reality. A consideration of the phenomena that the toy theory fails to reproduce, notably, violations of Bell inequalities and the existence of a Kochen-Specker theorem, provides clues for how to proceed with this research program.

From a section in near the end:

> Contextuality and nonlocality. The Kochen-Specker theorem [28, 30] and Bell's theorem [31] state that any hidden variable theory that is local or noncontextual cannot reproduce all the predictions of quantum theory. The toy theory is, by construction, a local and noncontextual hidden variable theory. Thus, it cannot possibly capture all of quantum theory. In the face of these no-go theorems, a proponent of the epistemic view is forced to accept alternative possibilities for the nature of the ontic states to which our knowledge pertains in quantum theory. It is here that the novel conceptual

> ingredients are required. Note that since nonlocality is an instance of contextuality [57], the latter can be considered as the more fundamental of the two phenomena. Indeed, if quantum theory can be derived from a principle asserting that maximal information is incomplete and some other conceptual ingredient, then contextuality may be our best clue as to what this other conceptual ingredient must be.

From the concluding section:

> A principle stating that maximal knowledge is incomplete knowledge is likely to serve as a foundational principle in a simple axiomatization of quantum theory. This is the claim that we argue is made plausible by the strength of the analogy between the toy theory and quantum theory. Nonetheless, this principle is insufficient for deriving quantum theory. It is intriguing to speculate that we are lacking just one additional conceptual ingredient, just one extra principle about reality, from which all the phenomena of quantum theory, including contextuality and nonlocality, might be derived. To find a plausible candidate for a second such principle, it may be useful to adopt a similar strategy to the one used here to argue for the first principle: do not attempt to derive all of quantum theory, but rather focus on the more modest goal of reproducing a variety of quantum phenomena, even if only qualitatively and in the context of some incomplete and unphysical theory. In particular, attempt to reproduce those phenomena that the toy theory fails to reproduce. Armed with a conceptual innovation that captures the essence of the missing quantum phenomena, a path to quantum theory might suggest itself.

05-10-08 *Titles* (to R. Schack)

Just in from mowing the lawn. I want to record these titles before I forget them. More in a few days.

- Quantum Bayesian Quantum Certainty Is Not a Moore Sentence
- How a Quantum Bayesian Sees Decoherence and Einselection: Van Fraassen Reflection Turned Backwards

06-10-08 *Kent Peacock* (to A. Kent)

Speaking of double-slit toy models, see: `http://arxiv.org/abs/0209082`, the attachment, and the proposal below. Any interest in having this guy out?

On the double-slit, I also checked out Jammer today to see if I could see anything on historical toy models. Not too enlightening, but it did lead me to a tidbit that sounds a little bit like something I might have said. So, all in all, this exercise has been good for me, even if not you!

06-10-08 *SICkening Quantum Mechanics* (to P. W. Shor)

I wonder if I can push you for an answer on the SIC meeting we're having here Oct 26-30. We sure hope you can come, but will understand if you cannot. So far, the confirmed participants are (besides Flammia and myself):

D. Marcus Appleby
Ingemar Bengtsson
Howard Barnum
Markus Grassl
David Gross
Andrew Scott
Lane Hughston
Martin Roetteler

I'm also trying hard to John Conway and Simon Kochen here. Roger Penrose has also recently taken an interest in the problem. I think there's progress to be had if we can just put our minds together for a little while.

06-10-08 *Penrose* (to D. M. Appleby)

Applebyism 24: *If I now believe that the wave-function is non-physical that is in large part* because *I spent so long thinking about Bohm. (The philosophy teacher at my place of work has a quote pinned to the wall of his classroom: "the mark of an educated mind is the ability to entertain propositions without believing them". In other words, a readiness to explore the consequences of an hypothesis without being first convinced of its truth.) Taken in that spirit I think the Bohm theory is extremely valuable (and let me also say that my impression is that Bohm himself took his theory in precisely that spirit).*

You and Wayne Myrvold both made similar points to me. And I accept your arguments.

06-10-08 *Rethinking* (to M. Hemmo)

I want to open up and tell you about a struggle I'm having. As all the travels I've committed to for this year have unfolded (and ones climbed into the middle unexpectedly), I'm afraid I've become more and more broken. It's come to the point where I can hardly stomach the idea of another trip abroad. Basically, one trip abroad each month is killing me—professionally, family-wise, everything.

Yet, this meeting of yours "The Probable and the Improbable: The Meaning and Role of Probability in the Foundations of Contemporary Physics" *subject-wise* is one of the most important ones of the year for me and this Bayesian research program Caves, Schack, Appleby and I have been trying to put together. The idea of not giving our research some representation in Jerusalem is, thus, killing me almost as badly as the thought of traveling again.

So, I'd like to explore the following with you. Would you consider trading me out with Rüdiger Schack as a representative of our research program? I have asked him if he would give a broad talk, particularly addressing the criticisms we've received over the years (from yourself and others), and emphasizing the kind of ontology that goes with our quantum Bayesian stance (something not usually emphasized elsewhere). He has said that he would do that, and that he would be very pleased to go to Jerusalem if it is possible. I think he would be great for the meeting, and Itamar, and all the participants. And I keep my fingers crossed that you will consider this proposition.

I await what you have to say.

06-10-08 *SIC States* (to S. Abramsky and Y. J. Ng)

Thanks for giving me an opportunity to describe my beloved "SICs" at lunch the other day. Here are two things you can read that'll give you a little further introduction to the subject (particularly the aspects of it we discussed at lunch).

1. The proof that SICs are as close as one can get to an orthonormal basis on the cone of positive operators: `http://arxiv.org/abs/0707.2071`.

2. The proof that SICs are maximally sensitive to eavesdropping: `http://arxiv.org/abs/quant-ph/0404122`. To put things more into the context of your axiomatization, Samson, of orthogonal bases, it would be better to have a result proving that SICs form a "least clonable" set of states, but at the moment I don't have that. Though I suspect it is true—for I would guess that any spherical two-design is a least clonable set. Still, maybe this will be enough to get you thinking on the idea.

Finally, let me attach some of the unpublished stuff I was telling you about—namely, how SICs give a particularly clean way to think of the Born rule as simple modification to the law of total probability. The attached document comes from a grant proposal I wrote recently, but I hope to get those equations into an actual paper soon. Anyway, the words there will, I hope, also convey some feeling for the big picture of my foundations program.

Samson, I guess I will see you in New Orleans next week. Thank you both again for coming to *The Clock and the Quantum*. I hope you enjoyed it roundly.

06-10-08 *SIC Invitees* (to S. T. Flammia)

I've updated the Google document. And also nudged one last time Shor, Conway, and Kochen. I think if they can't come, we keep it a small intimate meeting and be done with it.

I also got Roger Penrose fairly interested in the problem last week. He worked out dimension 2, 3, 4 solutions in his head during Harvey Brown's talk. (Same method, as far as I can tell, as Lane Hughston's … though he made his work in $d = 4$, and the last I heard Lane hadn't.) He said the problem related to something he never quite solved in his PhD thesis. Funny. I encouraged him to come too, but he said he had too many other obligations.

06-10-08 *SIC Invitees, 2* (to S. T. Flammia)

Flammia-ism 3: *Wow, Penrose worked out the $d = 4$ solution in his head?!? I'm impressed. I'd be interested to know what other problems it relates to.*

OK, I updated it again, after hearing from Shor.

Unfortunately, I didn't understand anything he said either about his thesis or $d = 4$. One question, though, did arise that I can get my head around. Do we know that we can't construct a SIC on two qubits purely of tensor product states? Of course one can't tensor two SICs and get a new SIC, but that's a different question. The only demand here is that each SIC element simply be a product state of any variety.

Also, there appears to be a dangerous bug in this Google document thing. I can look at the documents of another Chris Fuchs out there, one at NDSU (wherever that is).

06-10-08 *A December Visit* (to K. A. Peacock)

Yesterday, I read your paper "Aristotle's Sea Battle and the Kochen-Specker Theorem," and enjoyed it very much. By my reckoning, what you write is still at the stage of an "idea for an idea", but it is a good idea for an idea! It'd be great to see how to give it some firm substance. I myself tend to believe as well that the ultimate import of KS is that it indicates that the universe isn't a block. I'll attach a document that says as much. [See "Delirium Quantum" `arXiv:0906.1968v1`.] Surely you won't like aspects of it, but perhaps the first and the last sections will tickle you nonetheless. You might also get a kick out of perusing a document I'm presently putting together titled "My Struggles with the Block Universe". Do a search on the terms "block" and "Kochen", and it should take you to the right places.

07-10-08 *Rethinking, 2* (to M. Hemmo)

Thank you so much. And I hope that Itamar will not be too hurt. I feel absolutely bad, but everything I told you yesterday is true, and I don't feel that I will be able to pull myself across the ocean again in December. In fact, my wife just reminded me that my second daughter's birthday is Dec 17, and I had forgotten.

So again thank you for going easy on me. And thank you very much for allowing Rüdiger the opportunity to represent our work and be an ear for any difficulties with it that might be sounded at the meeting.

07-10-08 *Kauffman's Email* (to L. Smolin)

Don't forget to send me Kaufman's email address. I'll send him an invitation to give a foundations seminar.

I should tell you a funny story. A couple months ago, while I was in Austria, I got a note from Rob Spekkens in Cambridge saying that he had run across a nice set of all six volumes of the collected papers of C. S. Peirce, and he offered to buy them for me. When he told me the price, I was floored: The whole set (hardcover) was only 45 pounds! In contrast, I looked in the index I've made of my home library and found that I had paid 20 quid for Vol 8 *alone* of the collected papers of Bertrand Russell (when I myself was in Cambridge last). When I wrote back to Rob accepting the offer, I noted that the bargain he found reveals just how much the Brits value American pragmatism!

I think the Kauffman will be a lot of fun, particularly if he gets good and radical.

07-10-08 *SICkening Quantum Mechanics* (to S. T. Flammia)

Well, we came close. See Kochen's note below: "I couldn't come, but John thought he might be able to make it. Today he told me that he has to stay in Princeton for family reasons."

If you give no objection, I think I'll close the ranks now. We'll have a meeting of:

D. Marcus Appleby
Ingemar Bengtsson
Howard Barnum
Steve Flammia
Chris Fuchs

Markus Grassl
David Gross
Andrew Scott
Lane Hughston
Martin Roetteler

and any locals who might want to show up.

08-10-08 *Another Title* (to R. Schack)

- Reviving Feynman's 'Only Mystery' of Quantum Mechanics in Bayesian Terms

09-10-08 *REU Pestering* (to L. O. Clark)

I liked Mark and Meg's work[163], but it is true that in the end I was not able to use much of it. To be honest, the most important thing I got from it was learning about Seth Sullivant's work (Ref 2 in the report):

> "Statistical Models are Algebraic Varieties,"
> `http://www.math.harvard.edu/~seths/lecture1.pdf`.

That work puts the SIC representation of quantum states into a nice context—the set of quantum states corresponds to a statistical manifold associated with an intriguing quadratic variety. It was invaluable for me to learn that. If you think you can turn it into a publication for other purposes, go for it! It'd be great for them.

10-10-08 *Block U Alternative* (to T. Duncan)

Duncanism 4: *What about "contingent universe" as a name for the alternative to the block universe?*

I think I like that better than "open universe," which is the only competitive term that I think I've noticed before. ... Well actually, John Wheeler used the phrase "participatory universe" and surely he was contrasting it to (the ideas underlying) the block universe.

> [T]he universe is wild—game flavored as a hawk's wing.
>
> — Benjamin Paul Blood

Todd's Reply

Yes, I also like contingent better than open, especially since open has a geometrical/GR meaning. Malleable universe is also not bad, in the spirit of your Pauli Project notes. The definition of contingent that made me latch onto it was "possible but not certain to occur," from `http://wordnetweb.princeton.edu/perl/webwn?s=contingent`.

[163]Maegen Demko and Mark Layer.

10-10-08 *Block U Alternative, 2* (to T. Duncan)

This one goes too far, but inspired by looking in wiki definitions: "alchemical universe". Thinking in particular of definition 3: "Of or pertaining to the creation of something special out of a common material."

14-10-08 *New Orleans Books* (to H. Barnum)

By the way, at least there's excellent book shopping here in the French Quarter. So, maybe not all of the trip is a waste. I just picked up these (recording mostly for my own record):

1. Jonathan Arac and Barbara Johnson, *Consequences of Theory*, PB, $5.00.
2. Justus Buchler, *Metaphysics of Natural Complexes*, PB, $12.50.
3. James A. Connor, *Kepler's Witch*, HC, $9.00.
4. Christopher Norris, *Derrida*, PB, 8.00.
5. Harald Ofstad, *An Inquiry into the Freedom of Decision*, HC, $18.00.
6. Joachim Schulte, *Wittgenstein*, PB, 6.00.

I also found a two volume set of Lotze's *Microscosmus*, 1885 edition. Thinking hard about that one, but it's $100 and they wouldn't bargain down.

15-10-08 *Guilty, but Committed* (to S. Capelin)

I must plead guilty. I got an upgrade on my flights yesterday and found that I essentially slept the whole way here. Then upon landing, I couldn't resist the idea of reading Wittgenstein in a New Orleans oyster house, while eating fried catfish and hushpuppies. Finally, I fell completely weak and went shopping at the used bookshops in hopes of finding a new gem to tingle my philosophy (record below). [See 14-10-08 note "New Orleans Books" to H. Barnum.]

But, I will do my dead level best to hammer you something out tonight. So please don't give up on me ... but don't get too angry with me either! All of these things are important for the grand scheme I have in mind.

16-10-08 *Aaronson's Book Proposal* (to S. Capelin)

Every other Christmas or so for the last few years, I have inevitably included one of chef Jamie Oliver's cookbooks in my wife's melange of presents. I suppose I do this because we enjoy his shows on television, and when gift time comes, it's an easy idea. I suspect that's the case for a lot of other husbands out there as well, but probably more importantly, it may also hold for thousands of women who reward themselves from time to time with the purchase of another of Oliver's books. Reading over Scott Aaronson's manuscript reminds me of the happy times I have had reading his blog, and leads me to wonder whether this, at least in small part, might be the business model destined for the present book. A blog is not the same as a syndicated television show, of course, but it is a wide and ever-renewing vehicle of attention nonetheless. Certainly, for those of us in the field of quantum information, Scott is as close as we have to a "Naked Chef."

I like this book. I like it a lot. Reading parts of it have made me feel young again. And parts of it reminded me of speech patterns I used to speak in—"a polynomial shitload," "a problem called DUH," "The-Mojo-All-Along Theorem"—but have gotten out of the habit of, presumably because of the culture around me that scientific writing should be above that. I love David Mermin's and Nielsen and Chuang's books on quantum computing, but neither have made me spontaneously laugh out loud like this one. To the extent that pleasures like this open the thought receptors, I count its method a success. And there are so many tidbits of wisdom in it—from the mathematical to the philosophical to the social[164]—even I was surprised by what I found myself thinking about as I absorbed Scott's thought style.

Which leads me to what I view as the greatest intellectual strength of this book—the ebb and flow of topics, and the unique way Scott presents them flowing them into one another. What one learns from this book that one will not learn from any other book yet in print is that quantum computing is a very *big*, very *deep* subject. The thoughts surrounding it are not narrow and specialized, but rather have very much to contribute theoretical physics as a whole. Scott gives a sense in this book that one really might tie this vast landscape together—that one really might one day put all these subjects (from cosmology to free will to quantum foundations to the foundations of mathematics) in service of each other. Having this in print would be a valuable service to the physics community.

But the presentation of the book clearly needs work, and this is where I have the hardest time pinpointing what I feel. When I first started reviewing this manuscript, I thought "Oh no!" One chapter, two chapters, and the beginning of the third were consumed, and despite my predisposition for not wanting to think it, I thought things were a bit silly. How would one get into a book like this? Slowly and imperceptibly initially, however, I did indeed get into it. Once I started to take the discussions at Scott's pace and Scott's way, and to think about the questions for the non-lazy, I found that my thinking the exposition silly and flippant simply disappeared—the stuff I was reading pretty much flowed into me without resistance. That very much impressed me. But I also know that I gave it probably more of a college try than a new reader would—I have seen Scott lecture, and I have read his blog, and felt that there must be something of substance here. So I plodded on until the tractor beam took hold, but maybe not everyone else would.

How to smooth this rough and risky (risky for sales) edge off, I don't know: I'm not the author; I'm not the editor. But I do very much think this book should be out there.

23-10-08 *SIC Conference – Titles and Abstracts* (to L. P. Hughston)

We'll miss you!

I talked to Roger Penrose about the SIC-existence problem when he was here a couple weeks back for a quantum foundations conference. The first exchange on it was cute. I briefly described the problem to him before the start of a talk. At the end of the talk, he tapped me on the shoulder and said, "Well, I can see it works in $n = 2$, 3 and 4." As far as I could tell, his $n = 3$ solution sounded pretty much the same as your own. When it got to $n = 4$, I didn't understand him as well. But the main cute thing was, it seems he did it all in his head in those 45 minutes. To the extent that he got a chance to think about it later, I think most of his thought was devoted to seeing if he could recover his $n = 3$ solution from his $n = 4$ solution by an appropriate projection. I think things there were less conclusive then.

[164]Here's an example of the social that tickled my fancy: "In my view, probability theory is yet another example where mathematicians immediately go to infinite-dimensional spaces, in order to solve the problem of having a nontrivial problem to solve!"

24-10-08 *P.S.* (to A. M. Steinberg)

Steinbergism 1: *By the way, I'm also still curious to hear why my suggestion about a Bayes-like rule for noisy projectors fails! (As for the more general discussion of what probability "means" and what valid gambling strategies are, maybe that will await a pub one day.)*

I will. In fact, I plan to put it in my talk on Sunday. I'll send you a link to that after it is posted on `pirsa.org`.

About the second issue, it is not nearly so philosophical as to require a pub. I'll send you the appropriate place in our writings to read about it.

Thanks for the opportunity of interaction with your group today. At Atticus, I got one amazing bargain (all five volumes of *Early Defenders of Pragmatism* for $65.00 total) and two other good books (on pragmatism of course) but not such great bargains.

25-10-08 *Bio and Blurb for TGQI* (to C. M. Caves)

Bio:

Christopher A. Fuchs is currently a Long-Term Visitor at the Perimeter Institute for Theoretical Physics in Waterloo, Canada and an Adjunct Professor at the University of Waterloo. For seven years previous to this, he was a research staff member at Bell Labs, Lucent Technologies in Murray Hill, New Jersey, both in the computer science and the physical science divisions. Fuchs received a PhD in 1996 from the University of New Mexico, under the supervision of Carlton M. Caves. He then held postdoctoral positions at the University of Montréal, Caltech (where he was a Lee A. DuBridge Prize Postdoctoral Fellow), and Los Alamos National Laboratory. His awards include the Albert A. Michelson Prize Lectureship at Case Western Reserve University and an E.T.S. Walton Award from Science Foundation Ireland. He was an associate editor for the journal Quantum Information and Computation from 2000–2008, and the organizer of a dozen international meetings in quantum information and quantum foundations. He is an author of more than 50 scientific papers and two outlandish books of email correspondence with many founders of the field. More information can be found by googling the terms "Fuchs" and "quantum" simultaneously—at the moment, he comes to the top of the heap.

Blurb:

Ten years ago, the field of quantum information was hardly a recognized branch of physics, even by the most forward-looking physics departments. Just ask anyone who was in the job market at the time. But things have changed, and the very existence of the APS Topical Group on Quantum Information is a harbinger of the idea that quantum information not only has a home within physics, but is a school of technique that will have an impact on physics exploration as a whole. By our ways, we can help change the world of physics. In fact, with over 900 members presently, it does not look far-fetched that with an enthusiastic recruitment effort, the GQI could attain APS division status. This would give our field a clout and visibility that should be of great benefit to our fresh graduates and help further infrastructure and funding stability the field is sorely in need of. We should also establish premier awards—paying careful attention to make them significantly competitive and desired—for the best PhD work and research in general. This would bring the best in our field to full view, with all the benefit that entails for everyone. Furthermore we should work hard to lower the gender barrier of physics, and as it seems more women are already attracted to quantum information than many other branches of physics, we have the opportunity to build on an existing base to make a real impact. Finally the GQI can do more to disseminate awareness of the potential of quantum informational techniques for physics problems everywhere, and through the organization of strong specialized conferences and their associated advertisement in departments across the States, we can help make our field a resource for physics that's long here to stay.

05-11-08 *As You Wake Up* (to R. Schack)

Thank god America has finally had some sense! The news of our new president is very good indeed—maybe there is a chance now that our world can move forward, rather than back.

05-11-08 *More Atticus* (to me)

> Moore, Addison W.
>
> *The Collected Writings of Addison W. Moore.* 3 Volumes
>
> Bristol: Thoemmes Pr 2003, 1st Edition, No Jacket, Hardcover, As New Book
>
> Description: After John Dewey, Addison W. Moore was recognized as the chief spokesman for the instrumentalist version of pragmatism. Never before available, this complete collection of Moore's work contains dozens of philosophical articles, essays, book reviews, writings by other philosophers, and reviews of his work, together with his book, *Pragmatism and its Critics* (1910). Vol 1: *Writings, 1896–1910.* Vol. 2: *Pragmatism and Its Critics.* Vol. 3: *Writings*, 1911–1927.

05-11-08 *Slusher Lunch* (to L. Hardy and R. W. Spekkens)

Would either of you be available for an early lunch tomorrow? Dick Slusher, my old manager from Bell Labs (and now a director of a quantum information lab at Georgia Tech), is visiting IQC and giving their colloquium tomorrow. I'm in charge of him from 12:00 to 1:30, and I planned to lunch him at PI and give him a tour. Dick has always had a kind of inchoate interest in quantum foundations, and I thought it'd be fun for him if we could razzle, dazzle him during lunch with some foundationsy things. Dick always wants to know, "how is it relevant for my physics?" I'd really appreciate it if we could give him something to think on, as this is exactly what we should be about. Would a 12:30 lunch work for either of you? I hope you can come. Please let me know if you can, and I'll dig you up at lunch time.

BTW, seeing Wilczek's vision of "the grid" as the ultimate reality was quite revealing to me. Particularly, his use of "quantum fluctuations" made me think he could use a good dose of the quantum foundations mysteries—it might serve him well in these visions of ultimate visions.

06-11-08 *The New Things* (to R. E. Slusher)

I feel like I didn't answer you very adequately last night when you asked if there's been any progress in SIC world. What I wanted to express is that though not much new is known about the existence of these things, we have learned plenty about what quantum mechanics looks like when expressed in terms of them. On the one hand the state space seems to have a really intricate structure, but on the other hand we have hints that all the intricacy may arise from the simple equation I showed you last night.

Unfortunately, I don't have any of this in a completed paper yet. But, I attach three pieces of evidence to show you that I haven't been sitting on my duff. 1) The scientific piece of a grant proposal I wrote (and obtained). It is actually a decent overview of the new simple equations I showed you last night (the expression for unitary evolution and the modification of the law of total probability). 2) The beginnings of a paper on the actual shape of quantum state space. 3) A piece on rederiving that state space, taking the modified law of total probability as an axiom.

I hope you'll find some of this a little enjoyable.

06-11-08 *The Man Who Knew Certainty* (to R. Schack & C. M. Caves)

http://pages.stern.nyu.edu/∼abranden/

06-11-08 *Wilczek World* (to L. Hardy)

Hardyism 3: *I didn't go to Wilczek's talk. I probably should have done "for the cause" but needed a break.*

Yeah, it was funny: I was thinking of the things I had heard about how he was somewhat against PI having involvement in foundations, and at the same time seeing him talk about things that were in bad need of some foundational analysis. The most fundamental stuff he calls, "the grid." As far as I could tell, he means by this that spacetime is filled with a quantum field, continually undergoing "quantum fluctuations". It was the usual particle-physicist speak. But what does this phrase quantum fluctuation mean? The only sense I've ever been able to make of it is that it signifies a quantum state in superposition. The can of worms that's opened up here is precisely the meaning of the wavefunction and the attendant issue of quantum measurement. Maybe it'd be worth my while to read his latest book first, and then try to start up a dialog with him.

07-11-08 *Thoughts on Consciousness* (to T. Duncan)

Duncanism 5: *I've been drafting a paper to organize some thoughts on how to incorporate subjective awareness into our understanding of the natural world. I've attached the latest version in case you have time to take a look . . . critical feedback is most welcome.*

Thanks, I enjoyed that. I particularly liked this image of trying to recover color from a black and white drawing.

Your considerations reminded me of some of the ones in Schrödinger's little book, *Nature and the Greeks*. As I recall, he too held the opinion that any physical model must exclude the idea of subjective experience by its very nature, by its construction. Thus it is no surprise that subjective experience can never be found back in it. But then Copenhagen quantum mechanics perplexed him greatly, for he found subjective experience to be an integral part of the Copenhagen model. How could that be—he thought it must be a confusion in the Copenhageners. I think the book is worthwhile reading and deeply connected to your paper.

Also, I have to admit, I finally printed out "An Ordinary World." I hope to take it to Australia with me next week.

10-11-08 *Interview Questions – The Better Me* (to D. T. Pope)

Pope-ism 1: *What do you think of the many worlds interpretation? (For the purposes of this question, you can take the many worlds interpretation to be the idea that the universe splits into multiple copies whenever a measurement happens.)*

I think that despite all the attention that has been lavished on it by the popular science magazines (and science fiction magazines), the many worlds interpretation has little to no content. You say, "the universe splits into multiple copies whenever a measurement happens," but the whole motivation for the interpretation is to get away from ever making mention of "measurement" at all—the many-worlds interpretation is one species of reaction to the fear that the word "measurement" is too loose and fuzzy and ill-defined to be a significant piece of physical theory.

How does it tackle the problem that the quantum world seems to be making an on-the-fly decision whenever it gives us the outcome of a measurement? It says instead, the quantum world is making these decisions all the time, everywhere and everywhen. But since the quantum formalism gives no mechanism for this, and also hints of no bias for which way these decisions will go, the many worlders postulate instead that the world as a whole branches. It doesn't decide; it just branches. So that for those events in which there are observers around, in one branch the observer sees this outcome, and in the other branch he sees that one.

The trouble I see is that it is just a story. A story that could have been made up, and in fact was made up, before quantum mechanics. There is nothing particular to the quantum formalism about it. Everything that can happen, does happen—you might find that in the longing poetry of a parent who has recently lost a child. Why is my world the way it is? *Because* I am on this particular branch. Which branch? *My* branch. But there's always a better branch where everything is happy again.

Pope-ism 2: *What do you think of the pilot-wave interpretation?*

I think it has had 51 years of a chance but has never made a serious impact on physics (since its formulation in 1957). The de Broglie – Bohm idea was to supplement the equations of standard quantum mechanics for the wave function alone, with equations for where the particles should actually be at all times ... all said *on the condition* that one knows where the particles were initially. But one never knows such. So the pilot-wave theory adds a layer of equations that are never in the end used, outside of giving a warm fuzzy feeling to those inclined to take it. It would be different to me if the addition of those equations gave rise to simplifications in the calculations I need to do as a physicist. Then I would respect them more. But as it is, they just seem to be dangling appendages that have yet to offer any help in our getting to the next stage of physics.

Pope-ism 3: *What do you think of the Copenhagen interpretation? (For the purposes of this question, you can take the Copenhagen interpretation to be the idea that in quantum physics we can only know about the results of measurements. I.e. that it's meaningless talk about what electrons are doing when we're not measuring them.)*

The key idea behind modern variants of the Copenhagen interpretation is that quantum mechanical wave functions represent statistical information, full stop. That is, the wave function is not a property or value or quality *intrinsic* to a quantum system. Instead, when a physicist writes down a wave function, he is writing down his supposed information and nothing more. Information about what? His information about the *results* or *outcomes* of measurement interactions. It is not information about unknown hidden variables or pre-existent properties. Rather, it is his best statistical information on what *will come about* if he interacts with a quantum system this way or that way.

Opponents of the Copenhagen interpretation often present it in a negative light. They see it as an arbitrary injunction to ask no questions about what a quantum system is *really* doing. But I would say it is simply silent on that, recognizing instead an aspect of reality that is much deeper and wholly unexpected before quantum mechanics came onto the scene. It recognizes that in interaction, new things actually do come under the sun. That the big bang is not an isolated far off event, but that little *metaphorical* versions of it are happening all the time. And we have direct knowledge of this; for we see it any time a quantum experiment is done.

There is no story of what electrons are *really* doing simply because there is no completed story of what the universe as a whole is doing anyway. Parts of it are being created on the fly all the time. Quantum wave functions being purely information in character is but a stark recognition of this wonderful property of existence.

Now, how does this contrast with my insults to the many-worlds interpretation? Why would I say these ideas have content when the MWI does not? The recent wealth of discoveries in quantum information has taught us particularly the value of looking at quantum mechanics through information theoretic eyes. Particularly, to do quantum information, we've all discovered the necessity of first going out and purchasing all the textbooks on information theory (written by authors who knew nothing of quantum mechanics). To our great surprise: When one looked at the properties of information written abstractly, one found the properties of quantum wave functions. If it looks like a duck, walks like a duck, honks like a duck … it's probably a duck.

Pope-ism 4: *In the double-slit experiment with electrons, when you put detectors next to each of the slits, the interference pattern disappears. Why is this? (This is for a section on measurement disturbance. If possible, it would be fantastic for you to talk about the idea that measurement at the quantum level is a somewhat disruptive and invasive process. E.g. kind of like kicking something.)*

It is a different experiment. Why would anyone have ever expected its results to be the same as the original one? Aha, only if they had expected the experiment itself—the interaction itself—to be an inconsequential component in the phenomenon under study. But apparently it is not, and that is the lesson of quantum mechanics.

Things like this are encountered all the time in the sphere of psychological study. My wife asks me as we drive down the road, "What do you want for dinner?" I first say, "I have no idea, I'm not hungry." But soon I find myself revising the opinion, feeling the stomach acids start to move in my stomach. If she had not asked me, I might have remained without appetite for a few more hours of driving. But that's psychology. What is interesting is that we now find this phenomenon in our most fundamental physical theory. But that is no reason to think that the phenomenon must then be secondary and that we have been fooled by thinking we had a fundamental theory after all. Instead it is a call to recognize, "It is a world sensitive to our touch."

Pope-ism 5: *How big is the economic impact of quantum physics due to technologies such as computers, iPODs and other familiar electronic devices?*

Quantum computers will be very big. Ten years ago we already knew they would be exciting for what they can do in certain number theoretic problems, like factoring large numbers, and the promise they held for efficiently simulating more exotic physical systems. But make some quantum computing hardware available to hackers and lord knows what we will find can be done with them. I think we have no clue and cannot foresee. All we can do is fulfill this urge to prod matter to do new, exciting things for us.

Pope-ism 6: *In the double-slit experiment with electrons, what happens in between the source and the detector? What are the electrons doing in between the source and the detector and how do they pass through the slits?*

These questions are not the subject matter of quantum mechanics. See above. To think that they should have an answer is to think that the universe is like a book already written.

Pope-ism 7: *How important is quantum physics to physics overall and our understanding of the universe?*

I think we (physicists, mathematicians, computer scientists, philosophers) have taken only the tiniest baby steps toward incorporating the lessons of quantum mechanics into our worldview. I think on this passage of G. K. Chesterton,

> There are some people—and I am one of them—who think that the most practical and important thing about a man is still his view of the universe. We think that for a landlady considering a lodger it is important to know his income, but still more important to know his philosophy. We think that for a general about to fight an enemy it is important to know the enemy's numbers, but still more important to know the enemy's philosophy. We think the question is not whether the theory of the cosmos affects matters, but whether in the long run anything else affects them.

From this point of view, it is imperative to get the story of quantum mechanics straight. What will matter in the end is only how it affects our view of the cosmos.

10-11-08 *Dry Run* (to A. Kent)

Here was a dry run I took for myself before the interview with Damian that you egged me on about. [See 10-11-08 note "Interview Questions – The Better Me" to D. T. Pope.] Of course, I didn't repeat anything written below (my mind doesn't seem to work that way)—so the dry run was really a personal run. I suspect you'll agree with very little of what I write here, but maybe that's why I send it to you. I hate being in the limelight like this; I find it physically painful really. So, I send part of the pain on to you.

11-11-08 *Deleuzean Difference* (to S. Diamond)

It was good meeting you the other day, when we were all talking with Stu Kauffman.

I wanted to follow up on what I had asked about Deleuze and "difference". Reading the Wikipedia article on Deleuze this morning, I came across this description of his metaphysics:

> Deleuze's main philosophical project in his early works (i.e., those prior to his collaborations with Guattari) can be baldly summarized as a systematic inversion of the traditional metaphysical relationship between identity and difference. Traditionally, difference is seen as derivative from identity: e.g., to say that "X is different from Y" assumes some X and Y with at least relatively stable identities. To the contrary, Deleuze claims that all identities are effects of difference. Identities are not logically or metaphysically prior to difference, Deleuze argues, "given that there exist differences of nature between things of the same genus." That is, not only are no two things ever the

> same, the categories we use to identify individuals in the first place derive from differences. Apparent identities such as "X" are composed of endless series of differences, where "X" = "the difference between x and x'", and "x" = "the difference between…", and so forth. Difference goes all the way down. To confront reality honestly, Deleuze claims, we must grasp beings exactly as they are, and concepts of identity (forms, categories, resemblances, unities of apperception, predicates, etc.) fail to attain difference in itself. "If philosophy has a positive and direct relation to things, it is only insofar as philosophy claims to grasp the thing itself, according to what it is, in its difference from everything it is not, in other words, in its internal difference."

I suppose reading something like this once before was the source (in the dark recesses of my mind) that led of my query. The Deleuzean idea must have caught my eye because of my own thoughts on how best to interpret what is happening in the quantum mechanical measurement process. Attached is a little artsy piece of mine that lays that out a little more. [See `http://arxiv.org/abs/0906.1968`.] Sections 1 and 3.2 to 3.4 give some sense of what I'm talking about.

In any case, meeting you has brought Deleuze back onto my radar screen. I'm packing up his book *Bergsonism*, which has been unread on my shelf, to take with me on a short trip to Australia in a couple of days. Thereafter, I hope to get hold of his book *Difference and Repetition*.

12-11-08 *Quantum Systems Are Cranberries?* (to J. A. Smolin and others)

If I had known the answer would turn out to be this simple, I would have lost interest in the hunt years ago!

`http://www.nytimes.com/2008/11/12/dining/12cran.html?8dpc`

"The Zing Starts Here"

12-11-08 *Slightly Zingier Explanation* (to A. Kent)

See Footnote 10, at the bottom of page 9, of

`http://arxiv.org/abs/quant-ph/0205039`.

12-11-08 *Feynman Comment?* (to N. D. Mermin)

Did you somewhere in print comment on this quote of Feynman:

> We choose to examine a phenomenon which is impossible, *absolutely* impossible, to explain in any classical way, and which has in it the heart of quantum mechanics. In reality, it contains the *only* mystery. We cannot make the mystery go away by "explaining" how it works. We will just *tell* you how it works. In telling you how it works we will have told you about the basic peculiarities of all quantum mechanics.

It is from the first chapter in volume 3 of the Feynman Lectures, and concerns the double slit experiment with individual electrons. It seems like you had a discussion somewhere of how these double slit considerations cannot be nearly as decisive as Bell tests. I'd like to track that down and use some of the material in a paper I'm putting together.

Hope you're well and still thinking about coming to PI for a visit.

12-11-08 *Feynman Comment?, 2* (to N. D. Mermin)

I've looked all through *Boojums* (of which I again have a copy; got it for $8.95 in Madison, NJ as I recall), but haven't found anything.

Merminition 170: *What's the paper about?*

It's about this: [See "Quantum-Bayesian Coherence," `arXiv:0906.2187v1`.] particularly the diagrams on pages 45 and 50 and the magical equation on page 46. It then turns the table and asks whether the magical equation (and its relatives on page 51) might be the fundamental idea behind quantum mechanics.

I'm glad I'm not going to that conference; glad I wasn't even invited. After my eighth (round) trip across an ocean in a year's span (and numerous other side trips in the States), I broke down. I've canceled trips left and right. I'm committed to staying home, home, home, only to break my stride when I take Emma to Paris in April for her 10th birthday.

Keep thinking; I really like to use a relevant quote to bolster this passage of mine:

> Richard Feynman wrote these words for the opening chapter on quantum mechanics in his monumental *Feynman Lectures on Physics*. It was his lead-in for a discussion of the double slit experiment with individual electrons or photons. Imagine if you will, however, someone well-versed in the quantum foundations discussions of the last 25 years—since the Aspect experiment, say—yet surprisingly unaware of when Feynman wrote actually this. What might he conclude Feynman was speaking of? Would it be the double slit experiment? Probably not. To the modern sensibility, a good guess would be that he was speaking of something to do with quantum entanglement or Bell inequality violations.

12-11-08 *Autumn at PI* (to N. D. Mermin)

Merminition 171: *I attach a* `.doc` *file giving the program of the Tempe workshop. No website that I'm aware of.*

Liked that title by Derek Abbott (whoever he is): "What happens when the laws of physics change?"

Give him these quotes by Poincaré. [See note to H. Halvorson, dated 10-03-06, titled "Singularities and Evolutionary Laws."]

12-11-08 *Bergsonism* (to N. D. Mermin)

Merminition 172: *Great stuff. I hadn't seen it before.*

The final paragraph is pertinent to my own remarks:

> No doubt many readers will be dismayed to note that I seem constantly to substitute for the world a system of simple symbols. This is not due simply to a professional habit of a mathematician; the nature of my subject made this approach absolutely necessary. The Bergsonian world has no laws; what can have laws is simply the more or less distorted image which the scientists make of it.

Yeah, it is great stuff. I love how he foresaw the meaning of the big bang.

Merminition 173: *What does he mean by "the Bergsonian world"?*

Something like in my credo to Joy Christian and Lucien Hardy. [See note to them dated 12-02-07, titled "Lord Zanzibar."]

12-11-08 *Boutrouxisme* (to N. D. Mermin)

Funny, you didn't ask about who Boutroux was. I remember the great joy I had one evening when I did a google search on the simultaneous names James, Renouvier, and Boutroux. To my amazement one of the references mentioning all three of these characters was a book by Teddy Roosevelt!

Here's a couple of quotes from the old man himself (Boutroux that is):

- E. Boutroux, *Natural Law in Science and Philosophy*, (David Nutt, London, 1914); translated by F. Rothwell, from E. Boutroux, *De l'Idée de Loi Naturelle dans la Science et la Philosophie Contemporaine*, (Société Français D'Imprimerie et De Librairie, Paris, 1895). This is an early work concerning the idea that nature's laws themselves might be evolutionary and not immutable.

  > The theory upheld in the present work is that no absolute coincidence exists between the laws of nature as science assumes them to be, and the laws of nature as they really are. The former may be compared to laws proclaimed by a legislator and imposed *a priori* upon reality. The latter are harmonies towards which we ascertain that the actions of different beings really tend.

  and

  > That which we call the laws of nature is the sum total of the methods we have discovered for adapting things to the mind, and subjecting them to be moulded by the will.

- E. Boutroux, *The Contingency of the Laws of Nature*, (Open Court, Chicago, 1920); translated by F. Rothwell, from E. Boutroux, *De la Contingence des Lois de la Nature*, (Ballière, Paris, 1874).

12-11-08 *PIAF, Peres School, Etc.* (to D. R. Terno)

Terno-ism 1: *Another matter: are you happy with the tentative titles that I gave to your lectures?*

If you could change the one titled "Non-locality in quantum mechanics" to "The Significance of Entanglement", I'd appreciate that. It'd be more honest to my attitude: I don't like to use the word nonlocality anywhere in relation to quantum mechanics. (For instance, the conclusion I draw from Bell inequality violations is NOT that locality goes by the wayside, but rather that "unperformed measurements have no outcomes".)

13-11-08 *Hanneke's Thesis* (to R. Blume-Kohout and others)

Spurred by Hanneke's tragic death, I printed out her 166 page Master's Thesis to have a copy in my office. (It can be found online at `http://philsci-archive.pitt.edu/archive/00004224/`.) However, I will be traveling to Australia for a week starting tomorrow. Thus if anyone would like to borrow the paper copy for a while, just let me know—there's no sense in cutting down more trees.

I think it would be nice if someone would report on the thesis at one of our Thursday foundations group meetings. And given the subject matter, I think it would be particularly nice if Robin would weigh in for at least part of that, telling us what he thinks of the argument.

13-11-08 *Can't Dubrovnik* (to J. R. Brown)

I must apologize, but it is now clear to me that I will not be able to come to the Dubrovnik meeting. The note below, which I paste in, explains what is happening. On April 18, the last day of the Dubrovnik meeting, I will be flying from Toronto to Paris.

However you have built such an expectation of this meeting in my mind that I have come to think it is pretty important to have some representation of our quantum-Bayesian/quantum-pragmatist thoughts there … lest we be forgotten when the history books are written. Thus I wonder if I might convince you to invite two of my strongest and most interesting colleagues in my stead? The two colleagues are Rüdiger Schack and Marcus Appleby (both in the UK). Schack is one of the masterminds of all that we have done in this quantum Bayesian turn, and Appleby is an amazing polymath who has contributed much in the last few years. Here are a couple of representative papers:

> Schack, `http://arxiv.org/abs/quant-ph/0404156`
> and
> Appleby, `http://arxiv.org/abs/quant-ph/0402015`.

Both physicists are very philosophically minded, steeped in knowledge of Wittgensteinian ideas. And I know that Schack has also put significant effort into the classical pragmatists, whereas Appleby has done the same with Hume.

The point is neither would disappoint you. Finally, let me mention this: I gather from a side remark in a note from Chris Timpson that he plans to be at the Dubrovnik meeting. Timpson has recently posted an excellent review and critique of our quantum Bayesian effort: `http://arxiv.org/abs/0804.2047`. It would be very nice if the simultaneous presence of these three would add some real sparks to your conference, and at the same time expose directions of progress for us.

I will keep my fingers crossed …

13-11-08 *Can't Dubrovnik, but Maybe You Can* (to R. Schack & D. M. Appleby)

In my continuing effort to return to an honest living, I have just canceled two trips in April that I had previously promised to undertake. One of them is a meeting in Dubrovnik, Croatia that is historically famous in the philosophical circles. As I understand, the place is truly strikingly beautiful and the food wonderful. My invitation to that meeting (from Jim Brown) and a poster for it are attached.

The reason I'm telling you all this is that when I canceled, I suggested to Jim that he invite you two. The reason is I would like to get some representation there of our quantum Bayesian, pragmatist, Pauli'an, and Wittgensteinian thoughts. Jim had already made me feel that he wanted to develop discussion along these lines, and that this would be a good forum for people to start thinking on these things. Thus I hope he will take the bait and invite you, AND also that you will go and talk on this subject if given the opportunity. I happen to know that Timpson will also be there, so I suggested to Jim that he might want to take the opportunity to generate some intellectual sparks via a session showcasing all three of you.

14-11-08 *Ein Begriffe Again* (to H. C. von Baeyer)

Do you remember the discussion we had on the phrase "ein begriffe", which I thought had turned up in the letter from Pauli to Bohr? What note was that, can you send it to me again? I have finally unearthed the original letters. It looks like Folse probably did transcribe that marginal note incorrectly.

If I don't hear back from you in the next hour, I'll get back to you in a couple days to continue the discussion. I'm on my way to Australia this afternoon, so that'll cause a little delay.

16-11-08 *SICs Exist!* (to D. M. Appleby and S. T. Flammia)

I now know it's unquestionably true! I met one on my way between Sydney Airport and Darling Harbour this afternoon. My taxi driver was a Punjabi SI… wait a minute, he must have meant Sikh not SIC. Aw crap. Back to reality.

26-11-08 *A Draft* (to A. Stairs)

Stairsism 2: *I've attached a draft of what I want to talk about in December. It starts with things I had been thinking about in the talk I gave at Western, but I think you may find that it's actually quite congenial to a good deal of what you want to say.*

That's funny, I already felt pretty damned with this sentence of yours:

> One might protest that this ignores the difference between probability one and truth, but there's not much to be gained by following that thought …

26-11-08 *Appreciation* (to A. Plotnitsky)

I fear I haven't yet expressed adequately how much I appreciated your visit. So, let me take this opportunity before signing off for Thanksgiving. I got loads out of our discussions, and today's discussion particularly. I hope you will believe me; I don't always show it in my face. Conversations with you inevitably teach me how to say things and think things in ways quite different than I am accustomed to, and that is a currency in itself. Your insights today, I felt were particularly keen, and I'm working to incorporate your ways of thinking into my mathematical developments. I want to get back to this concept of efficacity and develop it much further, as I have always felt that dimension d to some extent quantifies it. You helped me a see a clearer relation with d and the SICs today, and for that I'm grateful.

All my best for a safe trip home, and please give my best regards to Paula.

07-03-08 *Why Things Fall* (to N. C. Menicucci)

I was misremembering the Wootters result. What he tried to explain was why things fall, if we take gravitational time dilation as given. See:

`http://www.springerlink.com/content/g7863165m0w47665/fulltext.pdf`

29-11-08 *A Colleague* (to R. W. Spekkens)

Well reasoned. Particularly, I had not thought of this angle on it:

Spekkensism 45: *Nonetheless, he would undoubtedly benefit from spending some time here. Given that he seems keen to pursue foundations, and will ultimately be a representative of our field wherever he goes, it is probably a good idea for us to invite him.*

Strange thing, I go up and I go down on him. The more I analyze it, though, the more it seems to be a Necker cube phenomenon, rather than something objective about him. When I think of the science, I'm very down on him. When I think of the human behind these vague (almost surely non-productive) ideas, a human full of feelings with a wife and child, a different kind of instinct kicks in with me. Probably the only difference between him and any of a dozen other questionable thinkers who write me is that I've met him in person a few times. That associates a human struggle with the quack idea, and I find it hard to ignore.

01-12-08 *Prolegomenon* (to H. C. von Baeyer)

Thanks for sending your draft on Pauli's journey inward. I enjoyed reading it very much, and—you're going to curse me for this—found myself hoping that it is really just a prolegomenon to a more extensive project. It was very good indeed, and I think the writing will serve the purpose of pulling public interest into the man. Why did you struggle with it all year? Can you pinpoint what the difficulty was?

I caught a very small number of typos. Here they are: [. . .]

Now a question: In note 28, I didn't understand why you brought up the 137 story. Did it connect to something in the text that I missed?

I enjoyed the Fierz quote on page 16 very much.

Another question. What does "Gewissen" in note 3 refer to?

By the way, thanks for forcing me to look up "retorts". My reading of "retort" in the Heisenberg quote,

> The alchemist in his laboratory is constantly involved in nature's course, in such wise that the real or supposed chemical reactions in the retort are mystically identified with the psychic processes in himself, and are called by the same names.

had always been as "response" or "answer back"—clearly not satisfactory, but that's what I was thinking. I never thought of chemical vessel!! (Shows what I know of chemistry.)

Really, let's talk more about your struggle with writing this. I'd like to be able to peer into your mind a little more.

BTW, Australia is long since past. I got back almost before I went. Still, it took its toll as expected, and I have canceled all other travels until my April Parisian outing. I am going to write and write in the next three months.

01-12-08 *The Slowest Reader on Earth* (to W. G. Demopoulos)

By the way, in preparation of your visit, I finally read the draft you sent me October 28th. Sorry to have taken so long. Not many comments at the moment: Where we agreed before, I think we continue to agree. And where we disagreed before, I think we continue to disagree. Particularly, in your treating measurement devices as NONquantum in the sense of being "unproblematically propositional." I.e., "effects are traces left on systems whose associated propositions are unproblematically determinately true or false."

One point of wonderment to me, however, was this. You say,

> To my knowledge it has never been maintained that the source of the interpretive problem that the Kochen-Specker theorem poses is the propositional framework, the framework that takes propositions belonging to particles as the subject of probability assignments.

I would say this is exactly what my colleagues Peres, Caves, Schack, Appleby, and I have been on about for a quite some years. But maybe I really am missing a subtle (or not so subtle) distinction between your system and ours. We should get this straight, whether I'm missing something.

It'll be great to see you again tomorrow. I only fear that the discussion may be a little too multi-pronged with so many people wanting to see Allen!

02-12-08 *My Sloppy Reading* (to H. C. von Baeyer)

von Baeyerism 27: *Just off the top of my head, did you notice that the page number in the note was 137?*

No, I had not noticed that. Of course, now that you say it, it is glaringly obvious. You might have pity on the other readers similarly blind as me, modifying what you write to something like: "Note the page number. Pauli would have been very pleased by it turning out to be 137. He considered this to be the most important number in physics, and its mystical connotations did not pass him by . . .

von Baeyerism 28: *The idea of entangling the observer with the observation is, of course, nonsense.*

That is right, and somehow I had not noticed that. But also, now that you bring it up, perhaps the definition could use some tuning. You write, "The term referred to the scientific view of the world as seen 'from the outside', as it were, by an observer who neither influences nor is influenced by the world." I wouldn't go so far as to say that the observer is not influenced by the world. That would preclude any (classical) Bayesian from updating his expectations upon the acquisition of data. A significant trouble I always perceived Pauli had with the "ideal E" was its one-sidedness.

Here's one of the formulations I've given the point from time to time (this from 2003):

> Everybody has their favorite speculation about what powers quantum information and computing. Some say it is the superposition principle, some say it is the parallel computation of many worlds, some say it is the mysteries of quantum entanglement, some say it is the exponential growth of computational space due to the tensor product. For my own part though, my favorite speculation is that it is Newton's Third Law: For every action, there is an equal and opposite reaction. Indeed I sometimes wonder if

the very essence of quantum mechanics isn't just this principle, only carried through far more consistently than Newton could have envisioned. That is to say, absolutely NOTHING is exempt from it.

What do I mean by this? What might have been exempt from the principle in the first place? To give an answer, let me note an equivalent formulation of old Newton. For every REACTION, there is an equal and opposite ACTION. Strange sounding, but there's nothing wrong with it, and more importantly, this formulation allows for the possibility of an immediate connection to information theory. In particular, we should not forget how information gathering is represented in the Shannon theory. An agent has gathered information—by the very definition of the process—when something in his environment has caused him to REACT by way of revising a prior expectation $p(h)$ (for some phenomenon) to a posterior expectation $p(h|d)$ (for the same phenomenon).

When information is gathered, it is because we are reacting to the stimulation of something external to us. The great lesson of quantum mechanics may just be that information gathering is physical. Even something so seemingly unimportant to the rest of the universe as the reactions that cause the revisions of our expectations are not exempt from Newton's Third Law. When we react to the world's stimulations upon us, it too must react to our stimulations upon it.

The question is, how might we envision a world with this property—i.e., with such a serious accounting of Newton's law—but in a way that does not make a priori use of the information gathering agent himself? If the question can be answered at all, the task of finding an answer will be some tall order. For never before in science have we encountered a situation where the theorizing scientist is so inextricably bound up with what he is trying to theorize about in the first place.

It's almost a paradoxical situation. On the one hand we'd like to step outside the world and get a clear view of what it looks like without the scientist necessarily in the picture. But on the other hand, to even pose the question we have to imagine an information gathering agent set in the middle of it all. You see, neither Shannon nor any of modern information theory has given us a way to talk about the concept of information gain without first introducing the agent-centered concept of an expectation $p(h)$.

So, how to make progress? What we do know is that we actually are in the middle of the world thinking about it. Maybe our strategy ought to be to use that very vantage point to get as close as we can to the goal. That is, though we may not know what the world looks like without the information gathering agent in it, we certainly do know something about what it looks like with him in: We know, for instance, that he ought to use the formal structure of quantum mechanics when thinking about physical systems. Beyond that, we know of an imaginary world where Newton's Third Law was never taken so seriously: It is the standard world of classical physics and Bayesian probability.

Thus, maybe the thing to do first is to look inward, before looking outward. About ourselves, at the very least, we can ask how has the formal structure of our *behavior* changed since moving from what we thought to be a classical Bayesian world to what we now believe to be a quantum world? In that DIFFERENTIAL—the speculation is—we may just find the cleanest statement yet of what the quantum world is all about. For it is in that differential, that the world without us surely rears its head.

To do this, we must first express quantum mechanics in a way that it can be directly compared to classical Bayesian theory, where the information-gathering agent was detached from the world. That is what this lecture is about ...

Rereading this, I enjoyed how it made a connection to the title of your draft ["Wolfgang Pauli's Journey Inward"].

02-12-08 *Prolegomenon (I'd better not use this word in the subject line, lest I accept it)* (to H. C. von Baeyer)

Well, I hope that is the first step toward accepting it! Really, you could do so much good, and of all the people I've met nominally interested in these matters, you're the only one with the right combination of skills to be able to pull off something of value if you set your mind to it.

I am relieved to find out the reasons for your blockage. Both yin and yang look reparable to me.

The point for me is not that all he was thinking (or hoping) will turn out to be right, but that SOME of what he was thinking is inspirational for a solid technical turn we can make in physics. I have gotten immense technical inspiration from the little bits I know about the Pauli (and Pauli-Fierz) correspondence. I crave more, and I think knowing more will get us to that technical point oh so much faster than if we have to slog our way there with our own less-than-Pauli'an minds.

I really do applaud this article. I thought I had completely lost you. Emma came home with nearly straight A's yesterday (except in "dance" which I didn't care about, and French, which I do care about, but in this case can blame on the teacher and the broken Ontario system for teaching French). I was so proud of her. So I was already on a bit of a high, but your article reinforced the same feeling. I am proud that Pauli'an things are still on your mind.

Hans's Preply

> I have now fixed the typos. Thanks! [Gewissen] is short for a book entitled *Wolfgang Pauli – Das Gewissen der Physik*. I don't have the bibliographic reference, which somehow got erased, here with me.
>
> Your question about my block is very good, and worth talking about.
>
> I had no trouble writing about Pauli's career in physics, up to page 14. I did that early in the summer, and have been polishing it since then.
>
> But then I stopped for two (possibly related) reasons, one literary, and the other psychological.
>
> The literary reason was that there is just too much material: The detached observer, the significance of symbols, archetypes, Fierz, the psycho-physical "neutral language", Kepler .... I couldn't figure out how to organize it all. Just taking one topic after another made it a laundry list, and no matter what I tried after p. 14, it all sounded tedious.
>
> Then I came across the letter in which Pauli sends the dreams, and I had an inspiration. I removed Fierz from the first 14 pages, popped in some ***s and told the story about the trip to Princeton. That provided a turning point, and then I decided to concentrate on just the letters from that period. If the topics I mentioned above came up, fine, if not, not. The neutral language, for example, made it only into one sentence as "common language". The ocean voyage fit perfectly with the metaphor of voyage that I had decided on long before. Now I had a structure!
>
> The other reason for my block is more serious. Crudely put, the question is: Do I believe all this stuff? Res Jost, a famous theorist and colleague of Pauli, did not.

Aldous Huxley did not. My brother Carl, a smart psychologist in Saskatoon, does not. They are all "rationalists". What am I?

The reason I'm taking it seriously is because Pauli is so damn smart. And so were Kepler, Newton, and Goethe, who were also mystics. Well, uncle Fierz comes to the rescue when he says "you know, I can really agree with you *provided* you express the reconciliation of science and mysticism as a goal for the future" (hundreds of years from now, Appleby told me). And lo! when you read Pauli, he says over and over again that he doesn't know how the two will be reconciled. So I'm off the hook! I don't have to believe all this mystical stuff, only that some day it may come back into vogue.

So you see, I had an inner and an outer conflict with this story. Yin and yang.

02-12-08 *Volumes* (to H. C. von Baeyer)

Wild idea. If I were to purchase one or more volumes of Pauli correspondence to have by my side, which would be the most important ones with respect to what I want to learn? I already have a couple of German-English dictionaries. Who knows what a little will power might accomplish.

03-12-08 *Seeking SICs Story* (to E. Goheen)

I hope you can use the whole thing. I spent quite some time in the middle of the night getting all the words just right, so that I might use this as an opportunity to educate the noninitiated in the PI community about the problem. Partly educational, partly entertaining. Story below.

I have to take a guest to breakfast. I'll be back online as of 11:00 if you have any questions.

Seeking SICs: An Intense Workshop on Quantum Frames and Designs

At the heart of quantum mechanics is Hilbert space. But what is at the heart of Hilbert space? Surprisingly, there are still some very basic—indeed, very fundamental—questions about finite dimensional complex vector spaces desperately seeking an answer. The theme of the workshop "Seeking SICs" was one of these questions.

For a Hilbert space of finite dimension d, can one always find a set of d^2 equiangular lines—that is, a set of lines for which the angle between any two is always the same? Such structures are called SICs (pronounced "seeks"), because in another language they can be thought of as "symmetric informationally complete" sets of quantum states. The phrase informationally complete captures the idea that the projection operators onto such a set of lines form a complete basis for the vector space of Hermitian operators, and hence of quantum states. A SIC, however, wouldn't be just any old basis for the space; it would be a nearly magical one. For, fixing a SIC in the background gives a means to express quantum states in a way that maps the whole structure of quantum mechanics into as mild a variation of (classical) probability theory as one can imagine: quantum states themselves become simple probability distributions; unitary evolution becomes, a up to a single constant, classic stochastic evolution; the Born probability rule becomes a simple variation on the classic law of total probability. The list of similarities grows. Thus SICs, if they exist, would be a highly valued commodity in the quantum foundations game. They would give a new, powerful way to rewrite (or dismiss!) many an old conceptual problem.

But do they exist? That's no easy question! The winner of the best intuition for it of all recent PI visitors is Sir Roger Penrose, who could "see" that they exist in $d = 2$, 3, and 4. But for the rest of us it's been a rough slog. After 9 years of toil since the problem first arose, nearly 20 papers, and some involvement from the best minds in quantum information theory (like Peter Shor, William Wootters, and Marcus Appleby), the most that is known either through hand proof, machine proof, or numerical investigation is that they (appear to) exist for all d from 2 to 47. Beyond that, nothing definitive is known ... but most people believe! And that's the fuel that can organize a conference.

The purpose of "Seeking SICs" was to amass as many of the best in the field as we could to have an intense go at it in the companionship and moral support of each other. The venue consisted of 11 organized talks across five days, with the remaining time devoted to informal idea sessions and chalkboard discussions. Several from the local quantum information community joined the meeting from time to time, bringing the total number of participants up to about 20 for some of the days. The meeting, as the name promised, was an intense event. By all accounts it was a success. Several of the participants particularly commented on how surprised they were to learn that so much UNpublished progress had been made since the last major works were posted 3–4 years ago. There was a great flood of information sharing, and perhaps one of the lasting achievements of the conferences was the establishment of a SIC wiki for building a strong online community to work on this problem.

What do we know now that we didn't know at the beginning of the meeting? Well, we now know by machine proof that SICs do indeed exist in $d = 14$ (it was only numerical before), and we know a method that leads to their hand construction in $d = 6$. More than that, we know the community has been reinvigorated and that maybe in the coming months we'll get a proof for the remaining (discrete) infinity of dimensions!

03-12-08 *I Twitter, Therefore I Am* (to A. Stairs)

Funny to learn about twittering from you yesterday nearly at the same time as a discussion about Jungian synchronicity ... and then to find this article in the *Washington Post* this morning: `http://www.washingtonpost.com/wp-dyn/content/article/2008/12/02/AR2008120202935.html?hpid=opinionsbox1`. Then, to read the content of this and find that it has something mildly to do with Zeilinger's view of quantum mechanics. "In the Information Age: Knowing equals Being," so said.

Surely there's a meaningful coincidence in there somewhere!

From a strange hour of the night ...

09-12-08 *Quantum Random Numbers* (to R. Schack & C. M. Caves)

I'm writing to make you both aware of a talk Ben Schumacher gave here at PI last week. It can be found at this site: `http://pirsa.org/08120020/`. The talk is not at all on quantum random number generators, but I took it that the deep idea in it is the same as the one that you two make use of. **"quantum correlations are monogamous"** = **"no inside information"** = **"unperformed measurements have no outcomes"**. Anyway, I think the talk was extremely exciting and helps put your work in a more general context.

Check it out.

10-12-08 *All the Qualifiers* (to R. W. Spekkens)

(Metaphorically) load your paper tray, print out

`http://www.perimeterinstitute.ca/personal/cfuchs/nSamizdat-2.pdf`

and thumb through the document until you get to the pages listed below.

Note all the qualifiers. By my own admission I don't have a completely consistent story yet, but I don't think you can ignore the overwhelming theme. See particularly the last three quotes.

Obsession is my trademark, I suppose.

Funny: One interesting self-psychology thing I learned from this exercise is that I didn't mention "law of thought" even once in the last 130 pages of the document. I wonder what exactly that signifies.

- p. 14, "more a ... than" in:

> But that is precisely why I would call quantum mechanics more a "law of thought" than a "law of nature." Just as Boole did of probability theory. And just as Jaynes did with (classical) statistical mechanics. (In fact, either of you two—i.e., you or Jaynes—might just as well have written your quote above.)
>
> You might say, and I suspect you will say, the distinction I draw between "nature" and "thought" is only a semantic one. But I don't believe that: I think it is precisely in making that distinction clear (and operational) that we have a chance of closing the quantum foundations debate and moving on.
>
> Physical theory is about two things: what is and what we know (or what we believe). It's the process of putting the two things together that gives a prediction in any practical setting. Quantum theory, interestingly, seems to be a nontrivial jumble of those two things. I think that is a rather deep statement about the world, and one that we have not yet come to grips with.

- p. 16, "with a ... side-input":

> Since the overarching belief here is that "quantum mechanics is a law of thought" (with an almost trivial side-input of honest-to-god physics), it strikes me as being in a category much more like relativity. In the words of J. Bub, it is a "framework theory."

- p. 38, "PLUS" (in letter to J. Bub):

> I know I suggested I would write a longer letter soon, but I'm going to wimp out of it again for now. It would concern the main point of distinction I see between us (and also between myself and Pitowsky). Namely, A) that I view a large part of quantum mechanics as merely classical probability theory (which on my view may be an a priori "law of thought") PLUS an extra assumption narrowing down the characteristics of the phenomena to which we happen to be applying it to at the moment, while B) you are more tempted to view quantum mechanics as a *generalization* of classical probability theory (and with it information theory). I know that my view is not fully consistent yet, especially as I have always distrusted mathematical Platonism—which you pointed out to me I am getting oh so close to—but it still feels more right (to me, of course).

- p. 137, "substantial part of":

I think our greatest hint of that comes from quantum mechanics. I would say that what we're learning in a precise way from it is that there is something about the stuff of the world that makes it uncaptureable with a purely physical picture. We find that we cannot even draw a picture of the world without including our beliefs and belief changes as a crucial background in the sketch. (How could we if the world's not completed yet?)

Does that make me an extreme subjectivist? I don't know. Whatever it is though that I should be called, I think this willingness to accept a substantial part of quantum mechanics as simply "law of thought" will keep me from going down a misguided path. I.e., the path of trying to ascribe all the easiest terms in the theory a kind of physical reality independent of our presence as active agents.

- p. 205, "something that is ... not law of thought":

  Here's where I really think you sell yourself short by advertising your system as an extension or generalization of classical probability theory (with classical probability theory as a special case that's gotten by deleting one of the axioms). For I would say that your framework of "states" as vectors and "measurements" as applications of Bayes' rule is *classical probability theory*, full stop. Or, I should just say "*probability theory*, full stop"—for, the word "classical" seems to imply that it is a subject somehow within empirical science (rather than "law of thought" that antecedes science). In showing me that even quantum "measurements" can be viewed legitimately as nothing more than applications of Bayes' rule, you have done me a great service. For you demonstrate to me more clearly than ever that the concept of POVM ought to be put onto the subjective side of the shelf when I tear quantum mechanics into its two components. But your other intriguing axioms—like the simplicity and composite-system axioms—which you think give the possibility of generalizing upon classical probability, I would say are nothing of the sort. Instead, I would say they express just the opposite. These axioms seem to me to say something about what we are positing of nature. They express something that is not subjective and is not "law of thought."

- p. 272, "to the extent that":

  Now, to quantum mechanics. You find something contradictory about my liking both quantum mechanics and Rorty. Here is the way I would put it. Presently at least, I am not inclined to accept quantum mechanics "to be real, an 'intrinsic nature of reality'," except insofar as, or to the extent that, it is a "law of thought," much like simple (Bayesian) probability theory. Instead, I view quantum mechanics to be the first *rigorous* hint we have that there might actually be something to James's vision.

- p. 343, "there is a part that remains":

  Lee Smolin asks me how I could possibly imagine that the linear structure of quantum mechanics will remain when one moves into such a nonlinear regime as that given by the laws of gravity? I say I'm not fazed at all: Most of what he means when he speaks of quantum mechanics as an expression of physics, is for me but a law of thought. A wave function and its evolution are not properties intrinsic to the system for which they are about. Rather, if they are properties of anything at all, they are properties of their user's head—for they capture all his judgments about what might occur if he were to interact with the system of interest.

  The quantum foundational task as I see it is to baldly accept that A LARGE PART of the theory is simply not about a world without observers: It is only about our interface with the world. But there is a part that remains, and that part must be given a firm identification.

For only once we know how to do that will we know how to move forward when it comes to gravity. Only then will we see that almost all of the ways that have hitherto been considered for combining quantum mechanics with general relativity were far too unconstrained: I am willing to bet that they all essentially boil down to sheer speculation.

- p. 445, "branch of decision theory that is contingent upon properties of the world":

  Be warned that by the phrase I don't mean something like a Kantian a priori category, i.e., a position like von Weizsäcker's in his book *The Unity of Nature*. I don't mean something like, "an understanding using the terms of quantum mechanics is the precondition for possible experience." Rather I have started to toy rather strongly with a Darwinian kind of idea: Using the rules of quantum mechanics for manipulating and updating our expectations (i.e., as a "law of thought") is the presently best known means for survival, given that we are immersed in the particular world we are. That is, I want to view quantum theory as a branch of decision theory that is contingent upon properties of the world we live in ... and it is something we locked into only in our most recent turn in evolutionary development.

- p. 488, "retains a trace of":

  When I say that QM is a theory about a very small part of the world, you should literally think of a map of the United States in relation to the rest of the globe. The map of the US is certainly incomplete in the sense that it is obviously not a map of the whole globe. But on the other hand it is as complete as it can be (by definition) as a representation of the US. There are no hidden variables that one can add to the US map that will magically turn into a map of the whole globe after all. The US map is what it is and need be nothing more.

  Does that help any?

  I think a good bit of the problem comes from something that was beat into most of us at an early age. It is this idea: Whatever else it is, quantum theory should be construed as a theory of the world. The formalism and the terms within the formalism somehow reflect what is out there in the world. Thus, if there is more to the world than quantum theory holds out for, the theory must be incomplete. And we should seek to find what will complete it.

  But my tack has been to say that that is a false image or a false expectation. Quantum theory from my view is not so much a law of nature (as the usual view takes), but rather a law of thought. In a slogan: Quantum mechanics is a law of thought. It is a way of plagiarizing George Boole who called probability theory a law of thought. (Look at the first couple of entries in the Rüdiger Schack chapter of *Notes on a Paulian Idea*.) Try to think of it in these terms, and let's see if this helps.

  ... [Long story about probability theory, then continues with:] ... So I say with quantum mechanics. The story is almost one-to-one the same: You just replace probability distributions with quantum states. ... But then you reply, "But there's a difference; quantum theory is a theory of physics, it is not simply a calculus of thought." And I say, "That's where you err." Quantum theory retains a trace of something about the real, physical world but predominantly it is a law of thought that agents should use when navigating in the (real, physical) world. In particular, just like with probability theory, we should not think of quantum theory as incomplete in the usual sense. If it is incomplete in any way, it is only incomplete in the way that the US map is incomplete with respect to the globe: There's a lot more land and ocean out there.

Teasing out (your words) the trace of the physical world in the formalism—i.e., the part of the theory that compels the rest of it as a useful law of thought—is the only way I see to get a solid handle on what quantum mechanics is trying to tell us about nature itself.

With this let me now go back to the US map for one final analogy. I said that there is a sense in which the US map is as complete as it can be. However there is also a sense in which it tells us something about the wider world: If we tabulate the distances between cities, we can't help but notice that the map is probably best drawn on the surface of a globe. I.e., the US already reveals a good guess on the curvature of the world as a whole—it hints that the world is not flat. And that's a great addition to our knowledge! For it tells a would-be Columbus that he can safely go out and explore new territories. Exploring those new territories won't make the US map any more complete, but it still means that there is a great adventure in front of him.

- p. 532, "THIS ... rather than THAT":

  Concerning, "But I did think it was a Law of Thought for you." ... you never cease to shock me .... And you never cease to cause me to strive to try to convey the very simple little idea more effectively! I wonder when I'm gonna finally hit the sweet spot? Quantum THEORY, a law of thought: Yes. Resoundingly yes. But the quantum WORLD—i.e., that situation, that world, that reality, which conditions us to choose THIS law of thought rather than THAT law of thought (in other words some alternative or imaginary law of thought)—is something else entirely. It's the stuff that's here whether there are any law-of-thoughters around or not. That's what I really want to get at; that's what I've always really wanted to get at.

- p. 533, "mostly":

  This talk tried to set the tone of the meeting by demonstrating that much of the content of finite-dimensional quantum mechanics reduces to two simple modifications of Bayesian ideology—1) the setting of a theory of prior probabilities with regard to the outcomes of a single special quantum measurement, and 2) a modification of the standard Bayesian conditionalization rule for updating probabilities in the light of new information. From this perspective, the formal structure of quantum mechanics becomes *mostly* a "law of thought" (in the same sense that George Boole called probability theory a "law of thought") rather than a "law of nature." Where nature still rears its head—i.e., makes its contingently given empirical content known—is through the higher-level set of reasons for why decision-making agents in this world should use *this* law of thought (i.e., quantum mechanics) rather than *that* law of thought (i.e., some foil theory other than quantum mechanics).

- p. 642, "partially tongue in cheek"

  I am in agreement with your last sentence. Attempts like the former effectively erase the empirical content (or contingency) of quantum mechanics, and I just don't see that. When I myself invoke the slogan "Quantum Mechanics is a Law of Thought," I only do it partially tongue in cheek, quickly correcting myself. For if quantum mechanics were *only* law of thought, it would be like one of Kant's a priori categories of the understanding. On the other hand, I come dangerously close to viewing "probability theory" (i.e., the theory of coherent gambling) in such a Kantian kind of way. And, indeed, it is partially because of this that I would not want to view quantum mechanics as a *generalized* probability theory.

10-12-08 *Myrvold's "Chance"* (to R. Schack)

BTW, I had wanted to give you a heads-up about Wayne Myrvold's talk in Jerusalem. He proposes a kind of epistemically based notion of "chance" that to some extent tracks the sort of thing I say below (from a letter to Mermin two years ago):

> With regard to your phase-diagram remark in particular [I.e. "Don't be so quick to dismiss Leggett as an ideologue, just because he takes quantum states to be objective. It's hard to spend decades worrying about the phase diagram of helium-3 without believing that quantum states are objective."], I think it's got to be instructive to try to imagine what a turn-of-the-century physical chemist (trained in the worldview of classical physics) should have thought of the tables of heat capacities and whatnot that he had spent much of his life compiling. What can those numbers represent in the classical worldview? Why would two distinct chemists compile the same tables of numbers if those numbers didn't signify something objective and intrinsic to the chemicals themselves? Well, a Maxwell demon wouldn't compile the same tables. And there is surely a continuum of positions between us and him. What those tables represent is something about the relation between us, the coarseness of our senses, our inabilities to manipulate bulk materials, all kinds of things like that, and the materials themselves. Those numbers are just as much about us ("anyman") as about "it."
>
> Anyway, forgetting about Leggett, how would I convince the classical physical chemist of such a point of view? It would be damned hard (as history has already shown). Instead of skirting so close to such an anti-Copernican idea—that knowledge gained in science is as much about "us" as about "it"—he'd probably spend his life trying to poke holes in the conceptually simple Maxwell demon idea and trying to return his beloved thermodynamical quantities to their pristine objectivity (a place where they'll last forever).

I was shocked! I had never imagined I would agree with Myrvold about nearly anything. Anyway, I thought it was a good talk. I want to see if you have the same reaction, or whether I missed something devastatingly inconsistent between his idea and our program.

When do you leave for Jerusalem? I presume you'll have email contact there for chit-chat about the draft I'm working on. You will take your laptop, won't you?!?

11-12-08 *A Sorry Comrade* (to R. W. Spekkens)

I'm feeling very bad about this, because I've hardly had any interaction with the candidates and feel responsible to do so, but I'm just in too much pain to come in today. [. . .]

At the moment I've got my foot in our lobster pot, surrounded by a bath of warm Epsom salt water, and my laptop on my lap, writing on my "coherence" paper. Digging up things on Feynman for the paper, I came across the following quote from David Mermin in his article "Spooky Actions at a Distance: Mysteries of the Quantum Theory". I figure it might be of use when we finally put together our "roots" article.

> Most physicists, I think it is fair to say, are not bothered. A minority would maintain that this is because the majority simply refuse to think about the problem, but in view of the persistent failure of any new physics to emerge from the puzzle in the half century since Einstein, Podolsky, and Rosen invented it, it is hard to fault their strategy.

12-12-08 *Myrvold's "Chance," 2* (to R. Schack)

Schackcosm 108: *Isn't this more or less the point of Jaynes' approach to thermodynamics and all the semi-objective ways of getting entropy to increase: coarse-graining, mixing interaction with an environment, ignoring all details that are irrelevant for pressure, volume etc? The idea would be to define a standard of ignorance, that any honest and nondeluded person would subscribe to.*

Roughly, but with a slight twist. In place of "ignoring all details" something more like "biologically incapable of." "Ignoring" implies that you could get at these things if you wanted them. With hindsight, surely it is a kernel of thought motivated by your hypersensitivity program.

More in a minute.

12-12-08 *Lunch Break* (to R. Schack)

I'm sitting in my office eating a curried chicken sandwich.

My only worry in what you say below is the phrase "classical deterministic theory" which is usually taken to mean something about time dependence of variables. The crucial distinction is only in that classical variables are assumed to be "determinate" in the sense of possessing a truth value independent of measurement.

12-12-08 *F-Theory* (to R. W. Spekkens)

Spekkensism 46: *Did you realize that the string theorists are studying F-theory?*

I'm sure there are a lot of people named (and a lot of expletives starting with) F.

What a loon they would think of me, if they came across my credo below: [See 12-02-07 note "Lord Zanzibar" to J. Christian and L. Hardy.]

14-12-08 *Our Dismissal* (to C. M. Caves & R. Schack)

Here's a cute dismissal of us. See Footnote 7 in

`http://philsci-archive.pitt.edu/archive/00002839/01/epist_rev.pdf`.

14-12-08 *FPP5* (to G. Adenier)

Attached is my first contribution for the volume; it is a joint paper with Rüdiger Schack titled "Priors in Quantum Bayesian Inference."

I still owe you my paragraphs for the preface. I should definitely be able to get those to you tomorrow, but it will be in the afternoon (my time).

I would also like to have a second contribution to the volume; it is another joint paper with Schack, but I think this paper will be of lasting significance, somewhat like my earlier paper "Quantum Mechanics as Quantum Information (and only a little more)" was in one of your volumes several years ago. But because of that, it is a much more complex affair to write, and I have been working very hard at it. Is there any chance you could hold off until Wednesday for it? I would very much like to have it in the volume—as it is another important manifesto for me—but I understand I must be pushing you to the limit.

15-12-08 *Are You Out There?* (to J.-Å Larsson)

How late will you be out there today reading email and such? I'm about an hour or two away from getting our preface written (OK, I have to admit I just started writing), and I'd like to pass it by you for comment. Guillaume was hoping I'd submit it today.

Just checking. Now, I'm writing away. It shouldn't be hard.

P.S. Great news in SIC world today. Andrew Scott has finally pushed the numerics further: SICs are now known to exist (at least to the 38 significant figures) in dimensions up to $d = 60$! (I placed a space before the exclamation mark so that you wouldn't think I meant 60 factorial.)

15-12-08 *Draft* (to J.-Å Larsson)

Attached is the draft. I feel that a sentence or two could be added about your and Cabello's papers. Could you volunteer that? Also, I surely missed some important papers in the biblio; please add anything you'd like.

I hope the writing style doesn't offend you.

Foreword: Unperformed Experiments Have No Results

> This year in Växjö we thought we would try an experiment—it felt high time for a new result. Much of the foundations discussion of previous years has focussed on EPR-style arguments and the meaning and experimental validity of various Bell inequality violations. Yet, there is another pillar of the quantum foundations puzzle that has hardly received any attention in our great series of meetings: It is the phenomenon first demonstrated by Kochen and Specker, quantum contextuality. Recently there has been a rapid growth of activity aimed toward better understanding this aspect of quantum mechanics, which Asher Peres sloganized by the phrase, "unperformed experiments have no results." Below is a sampling of some important papers on the topic for the reader not yet familiar with the subject.
>
> What is the source of this phenomenon? Does it depend only on high level features of quantum mechanics, or is it deep in the conceptual framework on which the theory rests? Might it, for instance, arise from the way quantum mechanics amends the classic laws of probability? What are the mathematically simplest ways contextuality can be demonstrated? How might the known results be made amenable to experimental tests? These were the sorts of discussions we hoped the session would foster.
>
> There were eight speakers in our special session—D. M. Appleby (Queen Mary U London, United Kingdom), G. Bacciagaluppi (U Sydney, Australia), I. Bengtsson (Stockholm U, Sweden), A. Cabello (U Sevilla, Spain), J. Emerson (U Waterloo, Canada), C. A. Fuchs (Perimeter Institute, Canada), J.-Å. Larsson (Linköpings U, Sweden), and R. Schack (Royal Holloway U London, United Kingdom)—and the talks were of uniformly high quality and all very enlightening. In this volume, seven of the talks are represented with written contributions.[165] Three of the papers are devoted very directly to Kochen-Specker constructions, inequalities derivable from them, and questions of experimental feasibility: I. Bengtsson, "A Kochen-Specker Inequality"; A. Cabello, "Kochen-Specker Meets Experiments"; J.-Å. Larsson, "The Kochen-Specker

[165] The content of J. Emerson's presentation can be found in the paper: C. Ferrie and J. Emerson, "Frame Representations of Quantum Mechanics and the Necessity of Negativity in Quasi-Probability Representations," J. Phys. A **41** 352001 (2008). In relevance to this session, it is connected to the Spekkens reference on negativity below.

Paradox and Great-Circle Descents". G. Bacciagaluppi's paper "Leggett's Theorem without Inequalities" defines a new no-go theorem that quantum mechanics once again violates: the conjunction of parameter independence and a new condition called "conditional parameter independence." The paper by C. A. Fuchs and R. Schack, "Priors in Quantum Bayesian Inference," is meant to be a follow-up on C. M. Caves, C. A. Fuchs, and R. Schack, "Subjective Probability and Quantum Certainty," (Stud. Hist. Phil. Mod. Phys. **38**, 2007, p. 255), where A. Stairs' modification of the Kochen-Specker noncolorability result was developed into an argument that even probability-1 assignments do not signify the pre-existence of measurement values. The paper by D. M. Appleby, "SIC-POVMS and MUBs: Geometrical Relationships in Prime Dimension," though not directly about issues of contextuality, is part of a larger effort to rewrite quantum mechanics in a language that will be much more serviceable to these kinds of questions. Finally, the paper by C. A. Fuchs and R. Schack, "From Quantum Interference to Bayesian Coherence and Back Round Again," is an example of that larger effort: It argues that the essence of Peres's slogan boils down to the fact that the law of total probability is replaced by a modification when considering counterfactual SIC measurements alongside actualized quantum measurements.

We were very happy to have an opportunity to organize this special session in Växjö, where there is a long tradition of delightful, intense, and thought-provoking foundational discussions. As the reader will find, this experiment was one of those well worth performing.

15-12-08 *Bad Foot* (to K. A. Peacock)

Another interesting person for you to talk to is Rafael Sorkin (on the same floor as you). He too believes that part of the lesson of quantum mechanics is that the universe is continually "giving birth."

18-12-08 *Israel* (to R. Schack)

Schackcosm 109: *I think my talk went well. There was a long discussion.*

David Albert interrupted me after 5 seconds with the remark that the mottos "unperformed experiments have no outcomes" and "the concept of probability is unaltered in qm" are hardly controversial. His main objection in the discussion was that the Einstein criterion of reality is like "bachelors are unmarried", i.e. analytic, and can not be disproved by empirical arguments. Hence the Stairs argument shows that locality has to be abandoned.

It may be for an objective notion of probability (though I doubt it even there), but it certainly isn't for a subjective notion. It's amazing that these guys don't even realize the boxes they think in. And they're the ones who are supposed to be the philosophers.

20-12-08 *Friday* (to R. Schack)

Schackcosm 110: *Before you count Wayne as a new ally, be warned that he strongly believes in objective quantum states.*

Oh, don't worry; I know Wayne all too well. I just thought he was clear on this point, and I had wondered whether I was missing something. (My fear of having misheard something comes from the knowing-Wayne-all-too-well-point just mentioned.)

21-12-08 *OK, You Should Be Back Home* (to N. D. Mermin)

OK, you should be back home from Tempe by now. You told me to write you after your return. PI visit, when?

Lucien told me about the meeting. Makes me double glad I wasn't there.

But I wish Carl had been there, so that you two might have had a chance to talk. I sense you haven't thought as much about (the reasons for) quantum mechanics as you ought to have lately. Carl sent me a link to the talk he would have given. (See, it's all about the counterfactuals.) Link below. I'll forward it to you in case you want to peruse it.

Did you see Louisa Gilder's book? (She must have sent you a copy if she sent me a copy.) I don't know how well she did with everyone else's dialog yet, but she certainly got me on the mark. I was very pleased with that. (And pleasantly surprised. Since meeting her briefly three years ago, I had forgotten about her.)

22-12-08 *Nonlocal Boxes and Ehrenfest* (to N. D. Mermin)

Just back in from shoveling snow.

Merminition 174: *Have you ever run across this particular way of presenting history — in terms of highly imaginary conversations based on texts, memoirs, reminiscences?*

The only thing approaching it that I can think of is Susan Haack's article "We Pragmatists." She managed to put together a good conversation between herself, Peirce and Rorty—with P and R's contributions being solely from published stuff.

I haven't read more than a few beginning pages of the book yet. I do know that already at page 7 I didn't like the sentence, "But no one following Bohr, Heisenberg, Pauli, Dirac, or Born dared grasp, measure, or even name the deepest of all puzzles, entanglement. Then along came John Bell." I feel that Pauli, for instance, already had a decent grasp of entanglement in 1927. It's just simply that the lesson of it was taken to be something else than the Einstein-Schrödinger-Bell camp thought it should be, and so it was marginalized in their thought. The lesson wasn't nonlocality for Pauli, but nondetachedness of the observer. And "degree of detachedness" is something he did try to quantify.

Pet peeve of mine recently, with this incessant talk of "nonlocal boxes" everywhere I go. So, I put these lines in my "coherence" paper (the one I'm writing at the moment). Particularly the footnote:

> So, what is it that Bell inequality violations teach us that the double-slit experiment does not? A common, if quick and dirty, answer is that "local realism fails." Unpacking this phrase, one means more precisely the conjunction of two statements: 1) that actions or experiments in one region of spacetime cannot instantaneously affect matters of fact at far away regions of spacetime, and 2) that measured values *pre-exist* the act of measurement, which merely "reads off" the values, rather than enacting or creating them by the process itself. The failure of local realism means the failure of one or the other or both of these statements. This, many would say, is the essential "mystery" of quantum mechanics.
>
> But the mystery, as already emphasized, has two sides. Of the options, it seems the majority of physicists who care about these matters think it is locality (Option 1 above) that goes down the drain with a Bell inequality violation—i.e., that there really are "spooky actions at a distance."[fn] But there is a small minority that thinks the abandonment of Option 2 is the much more sensible conclusion and among these are the *quantum Bayesians*. In a slogan near to that of Asher Peres's, "unperformed measurements have no outcomes."
>
> [fn] Indeed, it flavors almost everything they think of quantum mechanics, including the *interpretation* of the *imaginary* games they use to better understand quantum mechanics itself. Take the recent flurry of work on Popescu-Rohrlich boxes. These are imaginary devices that give rise to greater-than-quantum violations of various Bell inequalities. Importantly, another common name for these devices is the term "nonlocal boxes." Their exact definition comes via the magnitude of a Bell inequality violation—which entails violation of locality or pre-existence of values or both—but the commonly used name opts only to recognize nonlocality. They're not called anti-realism boxes, for instance. The nomenclature is psychologically telling.

By the way, I really could use that reference to your remarks on double-slits. Please continue to search your mind.

Merminition 175: *Did you know that (as she claims) the famous Bohr-Einstein clock-in-the-box exchange was (from Einstein's point of view) not an attack on the energy-time uncertainty relation but an early version of EPR, the point of which Bohr simply missed. I've never seen it presented that way. Haven't had a chance to check out the evidence for that. It surprised me. Is that in Arthur Fine's book? Or Don Howard?*

Well, I do know it morphed into that sometime after the Solvay meeting. I know that from this passage in Max Jammer's article "The EPR Problem In Its Historical Development," in *Symposium on the Foundations of Modern Physics: 50 Years of the Einstein-Podolsky-Rosen Gedankenexperiment*, edited by P. Lahti and P. Mittelstaedt (World Scientific, Singapore, 1985), pp. 129–149, which I have quoted in the original samizdat:

> [W]hat Einstein had in mind is confirmed by a letter which Ehrenfest wrote to Bohr on July 9, 1931. As Ehrenfest reports, Einstein uses the photon-box no longer to disprove the uncertainty relation but "for a totally different purpose." For the machine, which Einstein constructs, emits a projectile; well after this projectile has left, a questioner can ask the machinist, by free choice, to predict by examining the machine alone *either* what value a quantity A *or* what value an even conjugate quantity B would have if measured on the projectile. "The interesting point," continued Ehrenfest, "is that the projectile, while flying around isolated on its own, must be able of satisfying totally different non-commutative predictions without knowing as yet which of these predictions will be made. . . ."

It would be intriguing if this is what Einstein was trying to get at in the first place.[166] On what page of Gilder's book are you referring to? I'd like to read it.

22-12-08 *Nonlocal Boxes and Ehrenfest, 2* (to N. D. Mermin)

I think I found the part in Gilder's book you were talking about. Pages 128–133. The history is going to be fun to read for me, but the commentary I can already feel is going to be quite painful. "They have no states of their own, and, as far as quantum theory is concerned, a measurement performed on one instantly affects its twin." More humbug!

22-12-08 *Reading* (to N. D. Mermin)

Now that I read two more paragraphs down, I see this pisses me off too:

> Bohr's books and papers—full of careful prohibitions about what cannot be contemplated . . . —have become holy writ . . . From the point of view of the history of entanglement, they are not worth one clear sentence from Einstein, Schrödinger, de Broglie, or John Bell, . . .

Harrumph!!

05-01-09 *After-afterthought* (to H. C. von Baeyer)

Applebyism 25: *Another example. You might write down a list of all the things you know about a person. It would never occur to you that the description was complete. Still less would you be inclined to identify the person with your description of them: to suppose that the person, like the description, actually consisted of a string of words. But the classical physicists were inclined to make an assumption rather similar to that.*

[166] [And apparently it was, as I later learned. See Don Howard's presentation on the subject at `http://www.nd.edu/~dhoward1/Early%20History%20of%20Entanglement/sld026.html`.]

With regard to Marcus's quote below and Hans's remark of liking it, surely in some other context I've sent you this Jamesian beauty before. But it is so apt here again, surely it is worthwhile sending to you again!

> Let me give the name of 'vicious abstractionism' to a way of using concepts which may be thus described: We conceive a concrete situation by singling out some salient or important feature in it, and classing it under that; then, instead of adding to its previous characters all the positive consequences which the new way of conceiving it may bring, we proceed to use our concept privatively; reducing the originally rich phenomenon to the naked suggestions of that name abstractly taken, treating it as a case of 'nothing but' that concept, and acting as if all the other characters from out of which the concept is abstracted were expunged. Abstraction, functioning in this way, becomes a means of arrest far more than a means of advance in thought. It mutilates things; it creates difficulties and finds impossibilities; and more than half the trouble that metaphysicians and logicians give themselves over the paradoxes and dialectic puzzles of the universe may, I am convinced, be traced to this relatively simple source. *The viciously privative employment of abstract characters and class names* is, I am persuaded, one of the great original sins of the rationalistic mind.

05-01-09 *What I Really Want Out of a Pauli/Fierz-Correspondence Study* (to H. C. von Baeyer & D. M. Appleby)

My two dear friends!

Of no one else but Schack do I feel such an intellectual kinship—you three are my triumvirate. Thank you both for the great New Year's reading gift of the last couple of days. It's funny how these things work out; it arrived at just the right time for me. For, I was able to put it in juxtaposition with my reading of the latest issue of *William James Studies*. The two together caused me to think very much about how I want to frame the coming year. And it struck me as worthwhile to try to record as clearly as I can at the moment what I am *personally* seeking to get out of a better knowledge of the byways explored by Pauli and Fierz (and potentially Jung). There is no implication in this that this is what you *should* be seeking as well—it is only an effort to tie the strands of my life together a little better.

Here is what it is really all about for me—it is the root of the root and the bud of the bud, as e e cummings put it. A good vehicle for setting up what I want to say is one of Hans's passages:

> Pauli summarily dismissed two extreme attitudes – total separation of science from religion, and complete surrender to mystical experience. The former approach was advocated in our times by the late paleontologist Stephen Jay Gould, who coined the phrase "nonoverlapping magisteria" for the respectful noninterference of the realms of nature and of morality, of what is and what should be. Discussing a book by a German physicist who also believed in the separateness of science and religion, Pauli had once written to Fierz that he was appalled, and continuing:
>
> > "[The book] is a reversion to the 19th century when religion and science lived in separate sections of the human soul – politely exchanging greetings at a distance, while continually reassuring each other that they had nothing to do with each other – and when the soul seemed to reside outside the boundaries of science."

> For Pauli it was obvious that science should be able to deal with the soul, and that the soul in turn can inform science.

in conjunction with one of Marcus's comments thereafter:

> It is certainly true that I attach more weight to the opus than I do to quantum mechanics. That is I am interested in quantum mechanics because I am interested in the opus, rather than the other way round. For Chris it is, perhaps, a little different. Though I don't think it is all that different, actually. It is true that Chris doesn't use the language of souls (at least I can't recall him doing so in my hearing). But he is deeply concerned with, for example, the question of human freedom. He will have to speak for himself, but I believe that for him too his interest in quantum mechanics is secondary to other considerations.

For it is true that I rarely speak of "souls," "religion," or "redemption." These terms are mostly dead terms for me—they don't stir my soul, so to speak—or maybe I simply don't understand them well enough yet to see their ultimate usefulness for what I *do* want to get at. (Much like I have never understood what the search for "elegance" can possibly mean when it comes to forming physical theories, say, as a criterion for string theory: it is a term that is dead to me.) It is maybe in this way, or more carefully, *in this detail*, that I part company from your tentative feelings on the opus.

Nonetheless, there is no doubt that I believe there is a place—a very important place—for humanistic concerns within physics proper. It seems to me it goes to the core of what quantum mechanics is trying to tell us. You'll find the point made over and over in my "Activating Observer" resource-material document, which both of you have versions of. But I thought the point was made very nicely in the *setting of pragmatism more generally* in this article that I was reading at the time your emails arrived—"'The Many and the One' and the Problem of Two Minds Perceiving the Same Thing" by Mark Moller in Vol. 3 of *William James Studies*, posted at `http://williamjamesstudies.org/3.1/moller.html`:

> Each of these claims about reality is crucial to James's attempt to offer an alternative to the metaphysical theories of the absolute idealists. The importance of the claim that reality is continuous and in flux is that it offers an alternative to the absolute idealists' view that the universe is "known by one [infinite] knower in one act, with every feature preserved, and every relation apprehended." This means that for the absolute idealists, the universe is forever fixed so as to make real change impossible. We make no difference in such a universe. We neither improve upon it through our efforts nor make it worse. James rejects this view completely. His aim is to argue for a conception of the universe that allows real change to occur in it and where our efforts have a role in causing it. He goes on in the passage from *The Many and the One* manuscripts quoted above to make his point:
>
>> This picture of the irremediably pluralistic evolution of things, achieving unity by experimental methods, and getting it in different shapes and degrees and in general only as a last result, is what has made me give to my volume the title of *The Many and the One*.
>
> According to James, we, as conscious agents in the universe, have an active role in introducing new content and unity into it. Such a view thus aligns his radical empiricism with his meliorism. In earlier essays, eventually published together as *The Will to Believe* (1897), and in lectures that he gave to teachers, eventually published as *Talks*

> *to Teachers on Psychology* (1899), James took the position against the absolute idealists that the ultimate fate of the universe has yet to be decided. He insisted that it is an open question as to whether evil will triumph over good or the other way around. This, in turn, led him to claim that our choices and actions do make a difference in the universe, and, in fact, a crucial one. They help to decide how "the everlasting battle of the powers of the light with those of darkness" will turn out. This melioristic attitude only makes sense if the universe is malleable to human action, and, thus, it is one of James's aims in developing his metaphysics to explain how this malleability is possible.

The very phrases "our choices and actions do make a difference in the universe" and "this melioristic attitude only makes sense if the universe is malleable to human action" mean outright that there must be room for a humanistic element of some sort within physics itself.

Here's the way I put it to Lucien and Joy Christian when I was in a poetic mood last year:

> My view of the universe is that it is many—that it ultimately cannot be unified, for it is alive and changing and creative in a very deep sense. Moreover, that reality is, to some not-yet well-understood extent, plastic: It can be molded by our actions. Thus, though humanity is quite well a Darwinian accident, now that it is here, it is a significant component of the universe that must be reckoned with.

Finally, it seems worthwhile for me to let James say it himself (from his article "Pragmatism and Humanism"). It captures with his beautiful sweep the romantic thought that really keeps me going from day to day:

> In many familiar objects every one will recognize the human element. We conceive a given reality in this way or in that, to suit our purpose, and the reality passively submits to the conception. You can take the number 27 as the cube of 3, or as the product of 3 and 9, or as 26 *plus* 1, or 100 *minus* 73, or in countless other ways, of which one will be just as true as another. You can take a chess-board as black squares on a white ground, or as white squares on a black ground, and neither conception is a false one.
>
> You can treat the adjoined figure as a star, as two big triangles crossing each other, as a hexagon with legs set up on its angles, as six equal triangles hanging together by their tips, etc. All these treatments are true treatments—the sensible *that* upon the paper resists no one of them. You can say of a line that it runs east, or you can say that it runs west, and the line *per se* accepts both descriptions without rebelling at the inconsistency.
>
> We carve out groups of stars in the heavens, and call them constellations, and the stars patiently suffer us to do so,—*though* if they knew what we were doing, some of them might feel much surprised at the partners we had given them. We name the same constellation diversely, as Charles's Wain, the Great Bear, or the Dipper. None of the names will be false, and one will be as true as another, for all are applicable.
>
> In all these cases we humanly make an *addition* to some sensible reality, and that reality tolerates the addition. All the additions 'agree' with the reality; they fit it, while they build it out. No one of them is false. Which may be treated as the *more* true, depends altogether on the human use of it. If the 27 is a number of dollars which I find in a drawer where I had left 28, it is 28 minus 1. If it is the number of inches in a board which I wish to insert as a shelf into a cupboard 26 inches wide, it is 26 plus 1. If I wish to ennoble the heavens by the constellations I see there, 'Charles's

Wain' would be more true than 'Dipper.' My friend Frederick Myers was humorously indignant that that prodigious star-group should remind us Americans of nothing but a culinary utensil.

What shall we call a *thing* anyhow? It seems quite arbitrary, for we carve out everything, just as we carve out constellations, to suit our human purposes. For me, this whole 'audience' is one thing, which grows now restless, now attentive. I have no use at present for its individual units, so I don't consider them. So of an 'army,' of a 'nation.' But in your own eyes, ladies and gentlemen, to call you 'audience' is an accidental way of taking you. The permanently real things for you are your individual persons. To an anatomist, again, those persons are but organisms, and the real things are the organs. Not the organs, so much as their constituent cells, say the histologists; not the cells, but their molecules, say in turn the chemists.

We break the flux of sensible reality into things, then, at our will. We create the subjects of our true as well as of our false propositions.

We create the predicates also. Many of the predicates of things express only the relations of the things to us and to our feelings. Such predicates of course are human additions. Caesar crossed the Rubicon, and was a menace to Rome's freedom. He is also an American schoolroom pest, made into one by the reaction of our schoolboys on his writings. The added predicate is as true of him as the earlier ones.

You see how naturally one comes to the humanistic principle: you can't weed out the human contribution. Our nouns and adjectives are all humanized heirlooms, and in the theories we build them into, the inner order and arrangement is wholly dictated by human considerations, intellectual consistency being one of them. Mathematics and logic themselves are fermenting with human rearrangements; physics, astronomy and biology follow massive cues of preference. We plunge forward into the field of fresh experience with the beliefs our ancestors and we have made already; these determine what we notice; what we notice determines what we do; what we do again determines what we experience; so from one thing to another, altho the stubborn fact remains that there is a sensible flux, what is *true of it* seems from first to last to be largely a matter of our own creation.

We build the flux out inevitably. The great question is: does it, with our additions, *rise or fall in value*? Are the additions *worthy* or *unworthy*? Suppose a universe composed of seven stars, and nothing else but three human witnesses and their critic. One witness names the stars 'Great Bear'; one calls them 'Charles's Wain'; one calls them the 'Dipper.' Which human addition has made the best universe of the given stellar material? If Frederick Myers were the critic, he would have no hesitation in 'turning down' the American witness.

Lotze has in several places made a deep suggestion. We naïvely assume, he says, a relation between reality and our minds which may be just the opposite of the true one. Reality, we naturally think, stands ready-made and complete, and our intellects supervene with the one simple duty of describing it as it is already. But may not our descriptions, Lotze asks, be themselves important additions to reality? And may not previous reality itself be there, far less for the purpose of reappearing unaltered in our knowledge, than for the very purpose of stimulating our minds to such additions as shall enhance the universe's total value. *'Die Erhöhung des vorgefundenen Daseins'* is a phrase used by Professor Eucken somewhere, which reminds one of this suggestion by the great Lotze.

It is identically our pragmatistic conception. In our cognitive as well as in our active

> life we are creative. We *add*, both to the subject and to the predicate part of reality. The world stands really malleable, waiting to receive its final touches at our hands. Like the kingdom of heaven, it suffers human violence willingly. Man *engenders* truths upon it.
>
> No one can deny that such a role would add both to our dignity and to our responsibility as thinkers. To some of us it proves a most inspiring notion. Signore Papini, the leader of Italian pragmatism, grows fairly dithyrambic over the view that it opens of man's divinely-creative functions.
>
> The import of the difference between pragmatism and rationalism is now in sight throughout its whole extent. The essential contrast is that *for rationalism reality is ready-made and complete from all eternity, while for pragmatism it is still in the making, and awaits part of its complexion from the future.* On the one side the universe is absolutely secure, on the other it is still pursuing its adventures.
>
> We have got into rather deep water with this humanistic view, and it is no wonder that misunderstanding gathers round it. It is accused of being a doctrine of caprice. Mr. Bradley, for example, says that a humanist, if he understood his own doctrine, would have to 'hold any end, however perverted, to be rational, if I insist on it personally, and any idea, however mad, to be the truth if only some one is resolved that he will have it so.' The humanist view of 'reality,' as something resisting, yet malleable, which controls our thinking as an energy that must be taken 'account' of incessantly (tho not necessarily merely *copied*) is evidently a difficult one to introduce to novices. The situation reminds me of one that I have personally gone through. I once wrote an essay on our right to believe, which I unluckily called the *Will* to Believe. All the critics, neglecting the essay, pounced upon the title. Psychologically it was impossible, morally it was iniquitous. The 'will to deceive,' the 'will to make-believe,' were wittily proposed as substitutes for it.
>
> *The alternative between pragmatism and rationalism, in the shape in which we now have it before us, is no longer a question in the theory of knowledge, it concerns the structure of the universe itself.*
>
> On the pragmatist side we have only one edition of the universe, unfinished, growing in all sorts of places, especially in the places where thinking beings are at work.
>
> On the rationalist side we have a universe in many editions, one real one, the infinite folio, or *édition de luxe*, eternally complete; and then the various finite editions, full of false readings, distorted and mutilated each in its own way.

My anti-Platonist tendencies certainly come out in my feeling of agreement with this quote. There is no sympathy in it to the idea that one might be *attuned* with a divine mind privy to "THE way" the universe is constructed—as Marcus, I think, rightly points out, seems to have been Einstein's modus operandi when theorizing. At most, one might be attuned to the content of this other quote of James:

> If you follow the pragmatic method, you cannot look on any [theory] as closing your quest. You must bring out of each [theory] its practical cash-value, set it at work within the stream of your experience. It appears less as a solution, then, than as a program for more work, and more particularly as an indication of the ways in which existing realities may be *changed*.
>
> *Theories thus become instruments, not answers to enigmas, in which we can rest.* We don't lie back upon them, we move forward, and, on occasion, make nature over again by their aid.

Physical theories, by this view, are conceptual means and tools for making change in the world.[167] Can one be attuned to such a thing in the Platonic sense that Marcus explores? Perhaps. But if so, it's not the medieval Platonism Marcus was talking about—it is instead being attuned to how best be an agent of change. (Perhaps the exemplar of this modified Platonism would be Barack Obama instead of Einstein ... so that a pragmatically modified Platonist would look on him and say, "Now, that man is someone who feels the Old One!")

In any case, what's important here is that I genuinely do see a humanistic role in the very maintenance of the universe. And all of this is potentially independent, and certainly broader, than considerations to do with quantum mechanics. The universe is partially powered by the inhuman, to be sure. But it is also partially powered by *belief*—that I do believe full well. And to the extent that religion or religious feeling are sources of belief, they do indeed play a role in the very construction of the universe. However, from this point of view religion is a special case of something much bigger—namely, belief generally.

I'll quote James one last time, so that you get a precise sense of what I mean here, but then I'll get back to the quantum and Pauli/Fierz and tell you way I'm saying all this. From "The Sentiment of Rationality":

> Now, I wish to show what to my knowledge has never been clearly pointed out, that belief (as measured by action) not only does and must continually outstrip scientific evidence, but that there is a certain class of truths of whose reality belief is a factor as well as a confessor; and that as regards this class of truths faith is not only licit and pertinent, but essential and indispensable. The truths cannot become true till our faith has made them so.
>
> Suppose, for example, that I am climbing in the Alps, and have had the ill-luck to work myself into a position from which the only escape is by a terrible leap. Being without similar experience, I have no evidence of my ability to perform it successfully; but hope and confidence in myself make me sure I shall not miss my aim, and nerve my feet to execute what without those subjective emotions would perhaps have been impossible. But suppose that, on the contrary, the emotions of fear and mistrust preponderate; or suppose that, having just read [W. K. Clifford's] *Ethics of Belief*, I feel it would be sinful to act upon an assumption unverified by previous experience—why, then I shall hesitate so long that at last, exhausted and trembling, and launching myself in a moment of despair, I miss my foothold and roll into the abyss. In this case (and it is one of an immense class) the part of wisdom clearly is to believe what one desires; for the belief is one of the indispensable preliminary conditions of the realization of its object. *There are then cases where faith creates its own verification.* Believe, and you shall be right, for you shall save yourself; doubt, and you shall again be right, for you shall perish. The only difference is that to believe is greatly to your advantage.
>
> The future movements of the stars or the facts of past history are determined now once for all, whether I like them or not. They are given irrespective of my wishes,

[167] This is not the dry instrumentalism one incessantly hears of in philosophy of science circles—that an instrumentalist is one who believes a scientific theory is *solely* an instrument for *prediction*. That is the term of insult they usually throw at Bohr, our quantum Bayesianism, and similar efforts: "it is merely instrumentalism," they say. (See Asher Peres's funny story at the beginning of `arXiv:quant-ph/0310010v1`.) But prediction only takes a secondary role here, at best. What's being talked about instead is a far richer concept than those guys—Jeff Bub, Harvey Brown, David Albert, and the like—are even aware of. For this kind of "instrumentalism" (if it should even be called that) the image to associate with a theory is not so much Babbage's analytical engine, but a hammer and a socket set. [[In a first draft of this footnote I had written "Babbage's prediction engine"; unfortunately that was not historically correct (as I just learned), and I couldn't bring myself to change the term purely for literary license.]]

> and in all that concerns truths like these subjective preference should have no part; it can only obscure the judgment. But in every fact into which there enters an element of personal contribution on my part, as soon as this personal contribution demands a certain degree of subjective energy which, in its turn, calls for a certain amount of faith in the result—so that, after all, the future fact is conditioned by my present faith in it—how trebly asinine would it be for me to deny myself the use of the subjective method, the method of belief based on desire!
>
> In every proposition whose bearing is universal (and such are all the propositions of philosophy), the acts of the subject and their consequences throughout eternity should be included in the formula. If M represent the entire world minus the reaction of the thinker upon it, and if $M + x$ represent the absolutely total matter of philosophic propositions (x standing for the thinker's reaction and its results)—what would be a universal truth if the term x were of one complexion, might become egregious error if x altered its character. Let it not be said that x is too infinitesimal a component to change the character of the immense whole in which it lies imbedded. Everything depends on the point of view of the philosophic proposition in question. If we have to define the universe from the point of view of sensibility, the critical material for our judgment lies in the animal kingdom, insignificant as that is, quantitatively considered. The moral definition of the world may depend on phenomena more restricted still in range. In short, many a long phrase may have its sense reversed by the addition of three letters, *n-o-t*; many a monstrous mass have its unstable equilibrium discharged one way or the other by a feather weight that falls.

These, however, are very big things and very big thoughts James is speaking of. And even though they stir my heart, they remain too vague to transform science as a whole (and indeed the world) in the way that I hope we'll one day transform it. I love the sound of what I'm hearing, but at the end of the day, I'm still not completely sure what I *am* hearing. How do I know I'm not simply fooling myself with pretty words? The main point I want to make at this juncture is that these ideas which drive me forward—these still-too-vague ideas—are *supra-* quantum mechanics. It is 19$^{\text{th}}$ century philosophy, not physics.

What now is the role of quantum mechanics within this system of thought I'm laying out? It is that it is a miniature version of these general points. BUT, though it is a miniature version, it is an extremely *precise* version! And that's its ace in the hole, as Hans said of Pauli's discussion with Huxley. Here's where I agree with Marcus,

> Quantum mechanics is important because it is as close to a refutation of the classical world picture as one could hope to get. It is very rare that something gets refuted in science as completely and finally as the classical hypothesis, of the world machine, has been refuted.

Thus, quantum mechanics is a precision laboratory for defining and testing these things *we think we see* on the horizon. When we've got it in quantum mechanics, we know we have it.

This finally is where I can express the value for me of learning more about the Pauli-Fierz and the Pauli-Jung correspondence. There is an amazing amount of development of the metaphysics of a malleable world in the writings of William James and F. C. S. Schiller[168].[169] And lo and

[168] F. C. S. should not be confused with the famous Schiller, namely Friedrich. F. C. S. stands for Ferdinand Canning Scott—a mostly forgotten pragmatist, who was one of the deepest of the lot if you ask me.

[169] And no disrespect intended, but Pauli and Fierz have got nothing on the sheer volume of even James's and Schiller's correspondence on these subjects, much less their published works. Pauli was an amateur in comparison ... as was necessarily the case, being a professional physicist most hours of the day.

behold, in which direction does that development lead? In significant parts at least, it leads in quite the same direction as Pauli's metaphysic. I don't know that I've ever emphasized this to you two. When James, for instance, asks the question, "What are the materials of the universe's composition?," the answer he tries to develop is that they are things *neutral* to the material/mental or physical/psychical distinction. In fact, he saw the material and mental as *complementary*, but exclusive, aspects of the basic stuff. So, you see the similarity.[170]

But James and Schiller knew no quantum mechanics of course. Particularly, they were not privy to this precision development laboratory for their metaphysic that Pauli and Fierz knew so well. Therefore, I need, I crave, to know more of the precise things Pauli and Fierz were talking about for just this reason. The suspicion is that it will inspire us and help us connect the dots between the quantum formalism and the bigger, much richer, and far-from-really-developed idea of a malleable/alchemical world.

Marcus says,

> Quantum mechanics, as it stands now, is little more than a set of calculational procedures. The calculations show that the vision of the world-machine is completely without empirical foundation. However, the mechanical vision of things has not been replaced with any other.

of which I have a minor qualm, but I think he is right in further saying, "The classical vision of things … was deeply wrong about the relation of mind to matter." For I think this neutral stuff that Pauli and James speak of—James called it "pure experience" but I am not completely happy with that term—will indeed be the "shocking" ingredient that will replace the mechanical vision of things. So, it is not that we have not started the process of replacement; it is only that it has been slow going.

Hans, I suspect, has wondered why I place so much emphasis on wanting to know the most, within all of Pauli's non-x-ing writings and correspondence, about the part to do with the idea of detached and nondetached observers (activating observers). It is because, as I see it, a thorough study of what it means for an observer or agent to be nondetached from the phenomena he helps bring about is the very starting point for a development of James and Pauli's neutral-stuff ontology. If we cannot get the activating-observer idea right and understand all its facets, then I feel we have no chance whatsoever of developing a full-blown "neutral monism"[171]. It is the very place to

[170] At this point, I'd definitely encourage you to read the whole of the Moller paper mentioned above. It gives quite a decent summary of the Jamesian metaphysic. Moreover, in it not only will you see a resemblance between James's ideas and Pauli's "neutral language" considerations, but also, in the objections to James's pluralism, you will find some difficulties that we quantum Bayesians (who take an "alchemical view" on quantum measurement) must eventually address.

[171] Neutral monism is what it is sometimes called in the literature, but a much better name for the idea in the Jamesian context would be "neutral pluralism." Until ten seconds after writing this, I thought I was the first person to make up this term. But apparently Ruth Anna Putnam beat me to it (damned the power of this internet; it is the second time it has foiled me today):

> [Putnam writes:] Another key element of James's radical empiricism is his rejection of mind/matter dualism as well as its reduction to either materialism or idealism. In its place, he offers—it is the title of one of his essays—a world of pure experience. In that world consciousness *as an entity* does not exist. But neither is consciousness a function of matter, for matter *as an entity* also does not exist. Ultimately there are only pure experiences (and, perhaps, experienceables—that is a difficult interpretative question), experiences which only in retrospect are *taken* either as part of a stream of thought or as physical objects. Although one is tempted to call this view a neutral monism, it is, in my opinion, more properly thought of as a neutral pluralism—neutral in not favoring either thought or matter, plural because "there is no *general* stuff of which experience at large is made. There are as many stuffs as there are 'natures' in the things experienced … and save for time and space (and, if you

start, for it forces the issue of this new ontology in its very statement. What is an observer if not psychical? What is an activator if not physical? How can we really combine these two aspects of the phenomenon via the help of a Paulian neutral language?

Unfortunately in the technical development of this first step, Marcus and I have hit a great snag by not yet understanding the structure (a.k.a. knowing how to prove the existence of) these damned SICs. The reason I say this is because I see no way forward to a more precise definition of the activating-observer concept than by a kind of "generalized Newton's third law" of the style I wrote you about last month. And I see no way to make progress in that intermediate program without the ability to completely rewrite quantum mechanics (and particularly the Born rule) in terms of SICs. For completeness, let me reproduce that little essay:

> Everybody has their favorite speculation about what powers quantum information and computing. Some say it is the superposition principle, some say it is the parallel computation of many worlds, some say it is the mysteries of quantum entanglement, some say it is the exponential growth of computational space due to the tensor product. For my own part though, my favorite speculation is that it is Newton's Third Law: For every action, there is an equal and opposite reaction. Indeed I sometimes wonder if the very essence of quantum mechanics isn't just this principle, only carried through far more consistently than Newton could have envisioned. That is to say, absolutely *nothing* is exempt from it.
>
> What do I mean by this? What might have been exempt from the principle in the first place? To give an answer, let me note an equivalent formulation of old Newton. For every *reaction*, there is an equal and opposite *action*. Strange sounding, but there's nothing wrong with it, and more importantly, this formulation allows for the possibility of an immediate connection to information theory. In particular, we should not forget how information gathering is represented in the Shannon theory. An agent has gathered information—by the very definition of the process—when something in his environment has caused him to *react* by way of revising a prior expectation $p(h)$ (for some phenomenon) to a posterior expectation $p(h|d)$ (for the same phenomenon).
>
> When information is gathered, it is because we are reacting to the stimulation of something external to us. The great lesson of quantum mechanics may just be that information gathering is physical. Even something so seemingly unimportant to the rest of the universe as the reactions that cause the revisions of our expectations are not exempt from Newton's Third Law. When we react to the world's stimulations upon us, it too must react to our stimulations upon it.
>
> The question is, how might we envision a world with this property—i.e., with such a serious accounting of Newton's law—but in a way that does not make a priori use of the information gathering agent himself? If the question can be answered at all, the task of finding an answer will be some tall order. For never before in science have we encountered a situation where the theorizing scientist is so inextricably bound up with what he is trying to theorize about in the first place.
>
> It's almost a paradoxical situation. On the one hand we'd like to step outside the world and get a clear view of what it looks like without the scientist necessarily in the picture. But on the other hand, to even pose the question we have to imagine an information gathering agent set in the middle of it all. You see, neither Shannon nor any of modern information theory has given us a way to talk about the concept of

like, for 'being') there appears no universal element of which all things are made."

> information gain without first introducing the agent-centered concept of an expectation $p(h)$.
>
> So, how to make progress? What we do know is that we actually are in the middle of the world thinking about it. Maybe our strategy ought to be to use that very vantage point to get as close as we can to the goal. That is, though we may not know what the world looks like without the information gathering agent in it, we certainly do know something about what it looks like with him in: We know, for instance, that he ought to use the formal structure of quantum mechanics when thinking about physical systems. Beyond that, we know of an imaginary world where Newton's Third Law was never taken so seriously: It is the standard world of classical physics and Bayesian probability.
>
> Thus, maybe the thing to do first is to look inward, before looking outward. About ourselves, at the very least, we can ask how has the formal structure of our *behavior* changed since moving from what we thought to be a classical Bayesian world to what we now believe to be a quantum world? In that *differential*—the speculation is—we may just find the cleanest statement yet of what the quantum world is all about. For it is in that differential, that the world without us surely rears its head.
>
> To do this, we must first express quantum mechanics in a way that it can be directly compared to classical Bayesian theory, where the information-gathering agent was detached from the world.

So, you see, there's work to be done all the way down to the SICs, and all the way up to a full-blown ontology of neutral pluralism and a malleable/alchemical reality. In the case of the SICs, I'm actually more confident: That problem is going to be solved if I have to recruit all of Hannibal's army. But in the case of the ontology it's just verbal hints we have presently—there was only so much James, Schiller, Dewey, and others could discern from general premises, without detailed empirical input.[172] Clearly we will have to see our way through in that big task. But Pauli and Fierz are the only two quantum physicists I know of who have already waded these waters to any depth. If I could get hold of what little they may have already strained from the rocks below, it would be invaluable for this effort. And that is what the title of this New Year's note is all about: What I Really Want Out of a Pauli/Fierz-Correspondence Study.

Thank you both for not losing faith that there is something really important here.

Happy New Year!

05-01-09 *Quick Comment* (to D. M. Appleby)

Applebyism 26 :

> [Chris said:] An agent has gathered information—by the very definition of the process—when something in his environment has caused him to REACT by way of revising a prior expectation $p(h)$ (for some phenomenon) to a posterior expectation $p(h|d)$ (for the same phenomenon).

Which is true. But it needs also to be stressed that what the agent acquires is, not something like this "je ejszwjm r cly gwjn c yn vqrg eugl srb xqmdbs" but something like this "a meaningful statement the agent understands".

[172] And only so much patience I have for straining through a set of thoughts framed so far away from direct quantum mechanical considerations.

The Shannon theory completely disregards meanings. This is reasonable enough if you look at it from the narrow perspective of a communications engineer (it is not the engineer's business to read the messages he transmits). But I don't think it is reasonable at all if you look at it from our broader perspective.

That is true. However, the long tail of meaning (like the long tail of a rat trying to hide under the cupboard) is not lost altogether. It is in the setting of the sample space upon which the probabilities are defined. The sample space is not given by nature alone. It is the agent himself who sets it. And that setting reflects the meaning he draws from the various outcomes, and the level of graining with which he decides to take note of nature.

Nonetheless your point on meaning back-reaction is well taken. If I can dig it up, I have a faint memory of Rorty commenting on Derrida that, for Derrida it is almost that what something is named actually modifies what it is.

Just read your note titled "Synchronicity???". Surely there is no need to rush a reply back to me, or even read what I've sent. All shakes out in due time!

05-01-09 *F-Theory, 2* (to R. W. Spekkens)

I sent the attached essay off to Marcus Appleby and Hans Christian a little while ago, and thought you might enjoy it too. Especially as the last two pages of it refer to something you once told me you liked in my melange of ideas. (The rest of it you probably won't like!) Still, it gives a few more hints of the weird ontology that swirls in the back of my head trying to find substance. [See 05-01-09 note titled "What I Really Want Out of a Pauli/Fierz-Correspondence Study."]

Rob's Reply

> You're right – the last two pages of that note did resonate with me. In particular, I like this comment:
>
>> That is, though we may not know what the world looks like without the information gathering agent in it, we certainly do know something about what it looks like with him in: We know, for instance, that he ought to use the formal structure of quantum mechanics when thinking about physical systems. Beyond that, we know of an imaginary world where Newton's Third Law was never taken so seriously: It is the standard world of classical physics and Bayesian probability.
>
> One of the things that I've been exploring in my toy theories is: what happens if we do take Newton's Third law seriously in the imaginary world of classical physics and we model observers as classical systems that are subject to the law? The answer is that, assuming no reliable supply of systems in dispersion-free ensembles (to use von Neumann's terminology), observers necessarily cause a disturbance to one variable whenever they gain information about a complementary variable.
>
> Please see the discussion beginning at time index 40:53 and ending at around 45:00 in my talk at `http://pirsa.org/08020051/`.
>
> Incidentally, there was a piece on religion in today's Guardian which discussed James' views at length. Given the content of the first half of your note, you may want to have a look: `http://www.guardian.co.uk/commentisfree/andrewbrown/2008/nov/07/religion-psychology-william-james`.

06-01-09 *De Raedt about Bell's Theorem* (to D. Kobak)

Kobakism 1: *I've recently discovered the papers of Hans De Raedt from Netherlands (there are plenty of them on* `arXiv`*), whose views on QM seem to be very peculiar. In a series of papers he and his coauthors claim to have constructed local realist "down-to-earth" models, mimicking quantum behaviour in different cases. They call it "event-based computer simulation models" – of more or less everything from double-slit single-photon interference to EPR correlations. As far as I understand these models are not supposed to be hypotheses about the real world, but more something like counterexamples to the common misconceptions.*

This is certainly most interesting by itself, but what I find completely puzzling is that I failed to find any reply to those papers from other people in quantum foundations community, or any discussions of these ideas whatsoever. Either I'm not looking well enough, or these works are constantly left completely unnoticed. This is maybe my first question: have you heard about these papers, and if yes – do you have any opinion about that?

I remember you well from the summer school, and I am flattered that you would think me worthy to try to lead you through these conundrums. I wish we could have kept you in quantum foundations and that you might have come here to study at PI. However with your question, I have had enough experience to know that these things are always the same—they are analogous to the experience a patent clerk feels when he is presented with yet another proposed perpetuum mobile. The poor clerk has the unedifying task of finding where the mistake is hidden.

So, in advance, I'll say I am sorry. I do not have the stomach for this kind of work. However, I will do the dirty trick of cc'ing this note to two friends of mine who have found some pleasure in finding the flaws in these kinds of arguments before—Profs. Larsson and Gill. For instance, they both have published experience tackling the Hess-Philipp objections to Bell and also Accardi's very similar sounding claim to De Raedt's of being able to "simulate" Bell violations. Thus maybe they know this work of De Raedt's already and can give you a quick answer. And if they do not have a quick answer, perhaps they may find it nonetheless a worthy enough windmill to slay.

Good luck to you all and may God save your souls!

06-01-09 *Pauli for the Library?* (to P. Goyal)

Are you still the foundations representative for the library committee?

My colleague Hans Christian von Baeyer is considering coming from time to time as he is working on a new book on the Pauli-Fierz correspondence on quantum foundations. Crucial to that program, however, is that he have access to all 9 volumes of the Pauli correspondence (there are 8 volumes presently in existence, and a final one to be published this year). He has all the volumes at his home department at William & Mary, of course, but for visits to PI he would have to pack them up each and every time. And they're not small books.

So the question is, could we purchase them for the library? They'd certainly be a long-term resource for the institute, as they include Pauli's correspondence with Einstein, Bohr, Schrödinger, Heisenberg, Born, David Bohm, and many, many others.

I'll keep my fingers crossed …

06-01-09 *Pauli for the Library?, 2* (to P. Goyal)

You might enjoy Hans Christian's book, *Information: The New Language of Science*. I thought it was a great (popular, but serious) account of what people are thinking. He was a professor of physics (just retired) at William & Mary, but has also been a writer for many years and has several books (the most recent being on Parisian parks as seen through the eyes of a practicing physicist). At the moment, aside from working on this new book, he's the book review editor at *American Journal of Physics*.

He's perfect for the job of this Pauli-Fierz (and Pauli-Jung) thing: a) he's fluent in English and German, b) he's a seasoned writer, c) he's a serious scholar beside, d) he's had a long interest in Jung's thoughts, e) his father was actually Fierz's best friend in college and a life-long friend thereafter, f) Fierz's twin brother, the psychologist, was Hans Christian's godfather, and g) Hans Christian's own brother is a psychologist. Perfect confluence of events!

Let me attach a little thing for both you and Luca that I wrote yesterday. [See 05-01-09 note titled "What I Really Want Out of a Pauli/Fierz-Correspondence Study" to H. C. von Baeyer and D. M. Appleby.] It's a letter to Hans Christian and Marcus Appleby and lays out my metaphysical side fairly decently (with respect to Hans Christian's project). You might enjoy it for some light early-year reading.

06-01-09 *Pauli Volumes* (to H. C. von Baeyer)

I looked up links between Jung and James yesterday, and was interested to learn that they had actually met in 1909. Jung was much impressed with James. They mostly had conversation on parapsychology, and learned that Jung had apparently read *Varieties of Religious Experience* and the book *Pragmatism* (along with *Principles of Psychology* of course). James in his correspondence with Flournoy only acknowledged meeting "Yung" with "made a very pleasant impression" and didn't say anything further. He did however have something snide to say of his meeting with Freud (Freud and Jung were together for the visit); he said he seemed to be a man "obsessed by fixed ideas".

06-01-09 *One German Sentence* (to H. C. von Baeyer)

By the way, could I ask you to translate the thing Prof. Eucken said in the longer James quote I sent in yesterday's note?

Hans's Reply

> The correct (and this is not negotiable) capitalization is: "Die Erhöhung des vorgefundenen Daseins."
>
> A quick translation is "the enhancement of what is found to exist." I have no idea what it means, beyond what precedes it in the passage.
>
> Erhöhung is a word one might use to describe the enhancement of a sensation by means of a chemical stimulant. It also means intensification. Vorgefunden means "as found" or "pre-existing". Dasein is a typically German fuzzy word meaning "being" or "existence". (It can also mean daily life, but not here.)

06-01-09 *One German Sentence, 2* (to H. C. von Baeyer)

Well, if he could misspell Jung as Yung, I have no doubt he could get German capitalization wrong as well!

Thanks for the translation!

06-01-09 *Causaloid, Meet Psychoid* (to L. Hardy)

Yesterday, I put together a little note to try to spur on Hans Christian von Baeyer in the lonely task of distilling what Pauli and Fierz were on about in their correspondence. (The note is in the attached file, which was actually to both H. C. and Appleby.) [See 05-01-09 note titled "What I Really Want Out of a Pauli/Fierz-Correspondence Study" to H. C. von Baeyer and D. M. Appleby.] Hans has already put together an introductory article on that side of Pauli, and I've been encouraging him to tackle a full-blown book project.

Anyway, in my research for the note, I came across this word, which I had never seen before. So: Causaloid meet psychoid; psychoid, this is causaloid.

> **psychoid** adj. In analytical psychology, soul-like, a term that Carl Gustav Jung (1875–1961) applied to the collective unconscious, which 'cannot be directly perceived or "represented", in contrast to the perceptible psychic phenomena, and on account of its "unrepresentable" nature I have called it "psychoid"' (Collected Works, 8, paragraph 840). [From Greek psyche the soul + -oid indicating likeness or resemblance, from eidos shape or form]

In any case, I thought you might enjoy the note for some light reading in these lazy days of the New Year.

06-01-09 *The Metaphysics of SICs* (to K. Martin)

BTW, for your amusement, attached is a letter I sent to Marcus Appleby and Hans Christian von Baeyer yesterday. [See 05-01-09 note titled "What I Really Want Out of a Pauli/Fierz-Correspondence Study" to H. C. von Baeyer and D. M. Appleby.] Hans Christian has just written an article on the more spiritual side of Wolfgang Pauli, and I've been encouraging him to turn his efforts toward writing a full-blown book. (No ulterior motives here!) This letter is one of the many mortars I've sent to try to soften him up on the idea; and it reveals a good bit on the weird ontology that I think will ultimately be extracted from quantum mechanics. By the last three pages, the letter ties SICs back into the picture. It should be fun reading for you (even if it convinces you I'm insane). You see, we are working on noble things in this project!

06-01-09 *Remember to get Article on Lotze* (to me)

- Otto F. Kraushaar, "Lotze's Influence on the Pragmatism and Practical Philosophy of William James," J. Hist. Ideas **1**, 439–458 (1940).

07-01-09 *De Raedt about Bell's Theorem, 2* (to D. Kobak)

Kobakism 2: *De Raedt's works can well be completely false, but I wouldn't say that they are just crackpot (regarding what Chris said in the beginning about "perpetuum mobile" proposals). The reason I say so is how I learned about those papers: I was told to read them by a prominent solid state physicist, who is interested in quantum foundations as well. He is definitely a very good and very well known theoretical physicist and he was estimating De Raedt very high, as they had chance to work together (on some decoherence issues, not these "quantum simulators" of De Raedt).*

That's why I became interested in those works, and that's why I was surprised to find almost complete lack of responses from the QM foundations community. I have of course seen the comment *by Michael Seevinck and Jan-Åke Larsson on* arXiv*, but then there's a reply to that comment from De Raedt, and a very detailed one, I would say (*http://arxiv.org/abs/0706.2957*). As a result, there's an impression that those papers are just left unanswered, and since they don't seem to be "evidently crackpot", this situation is somewhat puzzling. I'm honestly sorry if all those topics are completely clear and non-interesting for you, but I can't help wishing that there were a detailed and bottom-line answer to De Raedt's writings, if they are really so false.*

What the lack of response reveals is this: That almost all the people who run across a paper like this have the same feeling I did when I saw it—i.e., the analogue of, "yet another perpetuum mobile." Then, they don't respond publicly, or even take the time to work through the paper privately, because they don't see that it is worth their while to do so, or that they do not have a lot of understanding to gain from the exercise.

The reason is new "refutations" of Bell (and all the other related inequalities and no-go theorems, CHSH, GHZ, Hardy's, etc., etc.) crop up almost literally *every* year. And this runs for many years back. De Raedt is by far not an isolated incident. In the mean time, many very good people (Gill, Larsson, Appleby, Mermin, Shimony, Hardy, van Enk, Kent, Seevinck, more) do in fact, from time to time, make the effort to find the flaws in the new argumentation ... AND they *always* find the flaws. I used to be among that industry when I was younger (20 years ago), though I never published. I suspect many other people are like me.

So, the issue is mostly one of age and previous experience. You are still young enough that you have not seen these things come and go for 20 years. Therefore the attitude you exhibit below is completely healthy and to be commended. It is not at all that the refutation of each new argument is obvious (at least not for me). On the contrary, it is often very difficult to ferret out the flaws, and it may take a lot of hard work. But that doesn't make the exercise less like a proposed perpetuum mobile analysis, it makes it very much of the same flavor.

An education in quantum foundations should consist in exactly what you are doing: Questioning well received opinion. But I feel very confident *in this particular case* that if you

a) study very carefully the logic in Bell's argument from some good references (I will list some of my personal favorites below), and

b) very carefully work out for yourself where the De Raedt proposal goes astray (perhaps initially being guided by the remarks Larsson and Gill have already made),

you will come out strengthened from the process, and see more clearly that Bell's reasoning was not arbitrary, but very beautiful instead.

07-01-09 *Some History of the Block Universe* (to D. M. Appleby & H. C. von Baeyer)

I am sorry, this is one paragraph I had not responded to:

Applebyism 27: *I was thinking particularly of what in the notes I call the "classical world-machine". I didn't use the phrase "block-universe" because I had in mind the whole development of classical physics. I don't believe that Newton was thinking in terms of the block-universe: that particular version of the nightmare only comes with relativity. I guess you could say that the block-universe represents the final stage in the evolution of the world-machine. The senescence of the world-machine? The corpse of the world-machine?*

I have no problem with your new term; I quite like it. But I just wanted to point out that historically the "block universe" phrase/imagery did in fact precede relativity by quite a substantial time. I believe the first public appearance of the concept was in William James's 1884 lecture "The Dilemma of Determinism," where he writes:

> What does determinism profess? ... It professes that those parts of the universe already laid down absolutely appoint and decree what the other parts shall be. The future has no ambiguous possibilities hidden in its womb; the part we call the present is compatible with only one totality. Any other future complement than the one fixed from eternity is impossible. The whole is in each and every part, and welds it with the rest into an absolute unity, an iron block, in which there can be no equivocation or shadow of turning.

Later in the essay, he writes:

> The more one thinks of the matter, the more one wonders that so empty and gratuitous a hubbub as this outcry against chance should have found so great an echo in the hearts of men. It is a word which tells us absolutely nothing about what chances, or about the modus operandi of the chancing; and the use of it as a war-cry shows only a temper of intellectual absolutism, a demand that the world shall be a solid block, subject to one control, which temper, which demand, the world may not be bound to gratify at all.

And finally again:

> A mind to whom all time is simultaneously present must see all things under the form of actuality, or under some form to us unknown. If he thinks certain moments as ambiguous in their content while future, he must simultaneously know how the ambiguity will have been decided when they are past. So that none of his mental judgments can possibly be called hypothetical, and his world is one from which chance is excluded. Is not, however, the timeless mind rather a gratuitous fiction? And is not the notion of eternity being given at a stroke to omniscience only just another way of whacking upon us the block-universe, and of denying that possibilities exist? — just the point to be proved. To say that time is an illusory appearance is only a roundabout manner of saying there is no real plurality, and that the frame of things is an absolute unit. Admit plurality, and time may be its form.

In my further records in my computer, I also have this use of the term from his posthumous book *Some Problems of Philosophy*. Here, he asks rhetorically, "If the time-content of the world be not one monistic block of being, ...” Now, the manuscript for that book was certainly written after the discovery of special relativity (though certainly before 1910 when James died), but I am pretty sure he had no knowledge of relativity. Let me quote the passage in detail a) because I can (it’s already in my computer), and b) because it makes some connection to our discussion of religion, and that may be useful in the future. What I found in re-reading this passage is that though talk of the soul doesn’t seem to stir my soul (as I wrote to Hans and you in the previous note), apparently I am to some extent in tune with a moralistic take on things. [Good God, my American upbringing!]

> But pluralism, accepting a universe unfinished, with doors and windows open to possibilities uncontrollable in advance, gives us less religious certainty than monism, with its absolutely closed-in world. It is true that monism’s religious certainty is not rationally based, but is only a faith that ‘sees the All-Good in the All-Real.’ In point of fact, however, monism is usually willing to exert this optimistic faith: its world is certain to be saved, yes, is saved already, unconditionally and from eternity, in spite of all the phenomenal appearances of risk.
>
> A world working out an uncertain destiny, as the phenomenal world appears to be doing, is an intolerable idea to the rationalistic mind.
>
> Pluralism, on the other hand, is neither optimistic nor pessimistic, but melioristic, rather. The world, it thinks, may be saved, on condition that its parts shall do their best. But shipwreck in detail, or even on the whole, is among the open possibilities.
>
> There is thus a practical lack of balance about pluralism, which contrasts with monism’s peace of mind. The one is a more moral, the other a more religious view; and different men usually let this sort of consideration determine their belief.
>
> So far I have sought only to show the respective implications of the rival doctrines without dogmatically deciding which is the more true. It is obvious that pluralism has three great advantages:—
>
> 1. It is more ‘scientific,’ in that it insists that when oneness is predicated, it shall mean definitely ascertainable conjunctive forms. With these the disjunctions ascertainable among things are exactly on a par. The two are co-ordinate aspects of reality. To make the conjunctions more vital and primordial than the separations, monism has to abandon verifiable experience and proclaim a unity that is indescribable.
>
> 2. It agrees more with the moral and dramatic expressiveness of life.
>
> 3. It is not obliged to stand for any particular amount of plurality, for it triumphs over monism if the smallest morsel of disconnectedness is once found undeniably to exist. ‘Ever not quite’ is all it says to monism; while monism is obliged to prove that what pluralism asserts can in no amount whatever possibly be true—an infinitely harder task.
>
> The advantages of monism, in turn, are its natural affinity with a certain kind of religious faith, and the peculiar emotional value of the conception that the world is a unitary fact.
>
> So far has our use of the pragmatic rule brought us towards understanding this dilemma. The reader will by this time feel for himself the essential practical difference which it involves. The word ‘absence’ seems to indicate it. The monistic principle implies that nothing that is can in any way whatever be absent from anything else that is. The pluralistic principle, on the other hand, is quite compatible with some things being absent from operations in which other things find themselves singly or collectively engaged. Which things are absent from which other things, and when,—these of course

> are questions which a pluralistic philosophy can settle only by an exact study of details. The past, the present, and the future in perception, for example, are absent from one another, while in imagination they are present or absent as the case may be. If the time-content of the world be not one monistic block of being, if some part, at least, of the future, is added to the past without being virtually one therewith, or implicitly contained therein, then it is absent really as well as phenomenally and may be called an absolute novelty in the world's history in so far forth.
>
> Towards this issue, of the reality or unreality of the novelty that appears, the pragmatic difference between monism and pluralism seems to converge. That we ourselves may be authors of genuine novelty is the thesis of the doctrine of free-will. That genuine novelties can occur means that from the point of view of what is already given, what comes may have to be treated as a matter of *chance*. We are led thus to ask the question: In what manner does new being come? Is it through and through the consequence of older being or is it matter of chance so far as older being goes?—which is the same thing as asking: Is it original, in the strict sense of the word?

BUT WAIT!!! BULLETIN!!! I love the power of the internet! I just discovered that James used the block universe idea as early as 1882. This is a lower bound that I had not known of before! Moreover this passage is funny to boot; it comes from an article titled, "On Some Hegelisms." Here it is:

> Why may not the world be a sort of republican banquet of this sort, where all the qualities of being respect one another's personal sacredness, yet sit at the common table of space and time?
>
> To me this view seems deeply probable. Things cohere, but the act of cohesion itself implies but few conditions, and leaves the rest of their qualifications indeterminate. . . .
>
> [I]f we stipulate only a partial community of partially independent powers, we see perfectly why no one part controls the whole view, but each detail must come and be actually given, before, in any special sense, it can be said to be determined at all. This is the moral view, the view that gives to other powers the same freedom it would have itself,—not the ridiculous 'freedom to do right,' which in my mouth can only mean the freedom to do as *I* think right, but the freedom to do as *they* think right, or wrong either. After all, what accounts do the nethermost bounds of the universe owe to me? By what insatiate conceit and lust of intellectual despotism do I arrogate the right to know their secrets, and from my philosophic throne to play the only airs they shall march to, as if I were the Lord's anointed? Is not my knowing them at all a gift and not a right? And shall it be given before they are given? *Data! gifts!* something to be thankful for! It is a gift that we can approach things at all, and, by means of the time and space of which our minds and they partake, alter our actions so as to meet them.
>
> There are 'bounds of ord'nance' set for all things, where they must pause or rue it. 'Facts' are the bounds of human knowledge, set for it, not by it.
>
> Now, to a mind like Hegel's such pusillanimous twaddle sounds simply loathsome. Bounds that we can't overpass! Data! facts that say, "Hands off, till we are given"! possibilities we can't control! a banquet of which we merely share! Heavens, this is intolerable; such a world is no world for a philosopher to have to do with. He must have all or nothing. If the world cannot be rational in my sense, in the sense of unconditional surrender, I refuse to grant that it is rational at all. It is pure incoherence, a chaos, a nulliverse, to whose haphazard sway I will not truckle. But, no! this is not the world.

The world is philosophy's own,—a single block, of which, if she once get her teeth on any part, the whole shall inevitably become her prey and feed her all-devouring theoretic maw. Naught shall be but the necessities she creates and impossibilities; freedom shall mean freedom to obey her will; ideal and actual shall be one: she, and I as her champion, will be satisfied on no lower terms.

Near the end of the article, there's still one more use of the term:

> In the universe of Hegel the absolute block whose parts have no loose play, the pure plethora of necessary being with the oxygen of possibility all suffocated out of its lungs there can be neither good nor bad, but one dead level of mere fate.

Now I've got the fire in me to try to really figure out the first time the phrase was used either in correspondence or print. I never imagined I would actually use any of the early volumes of *The Correspondence of William James*, so I only accumulated Vols. 7–12 for my library. But that only delves back to 1890. It's time to go book shopping again!

08-01-09 *Fuchs-Graaf Inequality* (to A. Uhlmann)

Uhlmannism 1: *Mike Hellmund and I just sent a short paper to the archive, No.* `08120906`*, extending an inequality of you and Graaf to arbitrary dimensions. You have used the inequality for an entanglement of assistance estimate. But this we could not do in higher dimensions yet.*

It is so good to hear from you, though I must apologize for taking so long to respond. The holidays were unusually extensive this year.

That is a nice result of yours. I will try to tuck it away in the bookshelf of my mind. Particularly lately I have been wondering about the "significance" of low order trace powers. For instance, suppose A is a Hermitian matrix. Then one can characterize when A is a rank-1 projection in the following way. A is a rank-1 projection if and only if $\mathrm{tr}A^2 = \mathrm{tr}A^3 = 1$. One need not consider higher trace powers (and consequently higher order elementary symmetric functions). The statement comes about trivially mathematically, but I keep wondering about whether there is any deep information theoretic significance to it (for the purpose of quantum foundations, that is).

Here is a more technical question on my mind. I wonder if you have any insight. Let us have a d-dimensional Hilbert space, and let us *suppose* a SIC exists. That is, suppose there is a set of d^2 rank-1 projections P_i such that $\mathrm{tr}(P_iP_j) = 1/(d+1)$. If you are not familiar with the concept, see the attached paper. Now here's the question:

> Let A be a Hermitian matrix such that
>
> 1) $\mathrm{tr}A = 1$,
> 2) $\mathrm{tr}A^2 = 1$, and
> 3) $0 \le \mathrm{tr}(AP_i) \le 1$, for all $i = 1, ..., d^2$.
>
> Is there an interesting characterization of the further conditions required to ensure that $\mathrm{tr}A^3 = 1$ (and hence we have a rank-1 projection)?

I hope you are doing well. How is your health? What is your age now? It has been many years since we have seen each other.

08-01-09 *My Book Selections* (to Cambridge University Press)

Simon Capelin instructed me to select a few "Cambridge books to the value of about US$200" and contact you in remuneration for a report I wrote for him. See note below.

After a few hours at your website (it was a lot of fun!), I came to the following four selections:

- *William James and the Metaphysics of Experience*
  David C. Lamberth
  (Hardback) ISBN: 052158163X
  99.00 USD

- *The Divided Self of William James*
  Richard M. Gale
  (Paperback) ISBN: 0521037786
  39.99 USD

- *Wittgenstein and William James*
  Russell B. Goodman
  (Paperback) ISBN: 0521038871
  37.99 USD

- *The Dappled World*
  Nancy Cartwright
  (Paperback) ISBN: 0521644119
  34.99 USD

The total for these four comes to 211.97 USD. I hope that this is an appropriate amount.

09-01-09 *That Pragmatism/Science Conference* (to C. Smeenk)

Thanks for bringing that to my attention. I just wrote the note below to one of the organizers. I don't know about the organization behind it (the "Center for Inquiry Transnational"), but their "VP of Research" is John Shook. He has like a gazillion volumes on classical pragmatism that he's edited (great collections of old papers pro and con). I have literally 20 volumes on my bookshelf, and he has at least one proper book *Dewey's Empirical Theory of Knowledge and Reality*. (I know that because I have it on my shelf as well; apparently I picked it up in brand new condition for $6.98, while the list price is $49.95.)

Is there any chance that you and/or Wayne might go to the conference?

09-01-09 *Wild Chance – James Correspondence* (to C. Misak)

I'm wracking my brain over who I know that might be remotely interested in obtaining a good price on some volumes of *The Correspondence of William James*. I think the chances are slim that you'll be interested, but I'll ask anyway.

My dilemma is this: I presently own volumes 7–12, but have been thinking I really should back-fill volumes 1–6 (particularly as I've realized I'm missing some crucial years when James was starting to rebel from the block universe idea; I've lower bounded the phrase "block universe" to 1880–1882, but want to know if it goes further back). So, I want to get vols 1–6. But these volumes generally cost in the \$70–90 US range per volume + shipping, etc. On the other hand, Amazon.com has a special package for all 12 volumes that works out to \$33US/vol.

On wild chance would you have any interest in buying the top half of the volumes while I buy the bottom half?

Just an idea! But if you have no interest, do have an idea of anyone else who might? Or any other ideas in general?

09-01-09 *Wild Chance – James Correspondence, 2* (to C. Smeenk, W. C. Myrvold, D. Fraser, and S. Dea)

I just wrote the letter below to Cheryl Misak, but as I figured she wasn't a taker (already has them all nearby). So I'm widening the net now. Please see note below. \$33/volume new really is a fantastic price (except for volumes 1 and 12, for some reason, which crop up here and there for lower); see `http://www.abebooks.com/servlet/SearchResults?an=Skrupskelis&sts=t&tn=Correspondence+of+William+James&x=86&y=13`.

Is there any chance any of you would be interested in the top half of James's correspondence, i.e., 1890–1910? There's a significant number of letters to and from C. S. Peirce in there. Supposing you're not interested, do you know anyone who might be?

09-01-09 *Pragmatism Library* (to S. Dea)

By the way, if you ever need anything for short loan, I'm building up quite a pragmatism library at home. Just let me know. Attached is my present book list.

To that, I've also got a few things on the way. CUP owed me for some reviewing I did for them, so I've just gotten them to send:

- *William James and the Metaphysics of Experience*
  David C. Lamberth
  (Hardback) ISBN: 052158163X; 99.00 USD

- *The Divided Self of William James*
  Richard M. Gale
  (Paperback) ISBN: 0521037786; 39.99 USD

- *Wittgenstein and William James*
  Russell B. Goodman
  (Paperback) ISBN: 0521038871; 37.99 USD

- *The Dappled World*
  Nancy Cartwright
  (Paperback) ISBN: 0521644119; 34.99 USD

And then I went on a purchasing binge with Atticus and have these on the way:

- Herman J. Saatkamp, Jr. ed.
  Rorty & Pragmatism: The Philosopher Responds to His Critics
  Norman, Oklahoma, U.S.A.: Vanderbilt Univ Pr 1995, 1st Edition Fine Hardcover Fine.
  Price: USD 14.00

- Hodgson, Shadworth H.
  The Metaphysic of Experience, 4 Volumes
  Bristol: Thoemmes 2000, 1st Edition No Jacket Hardcover.
  Price: USD 90.00

- Wright, Chauncey (1830–1875)
  The Evolutionary Philosophy of Chauncey Wright. (3 Volumes)
  Chicago, Illinois, U.S.A.: Thoemmes Pr 2000, 1st Edition No Jacket Hardcover.
  Price: USD 90.00

Finally, I've got John Shook's annotated bibliography of pragmatism, 1898–1940, coming too. (It's got over 4,000 references in it.)

09-01-09 *New Propositions* (to S. Capelin)

It's a long time since I've gotten in contact with you, particularly with regard to your nice note below. But the new year is here, and it is time to come up for some air. I have several things I'd like to discuss with you. I'll number them individually.

1) I finally took up your kind offer of "about US$200" in CUP books in payment of the Aaronson review. I sent the attached note to Laura Clark but have not heard back from her yet. [See 08-01-09 note "My Book Selections" to Cambridge University Press.] Might I ask you to confirm that she got the note?

2) With regard to "My Struggles with the Block Universe" you will see from the running compilation on my web page that it has not developed too much since you last saw it. When I was most committed to developing the document last year and working at it fanatically, my stride was broken by an emergency grant proposal I had to write, and there is something about getting a fanatical stride broken: I never quite returned to the project. It's a bit like a horse tripping in a race, as opposed to tripping in a quiet pasture.

Still, I will return to it. I have every intention of posting a big—overabundantly complete—version of it on `arXiv.org` before the summer is here. And after that I would very much like to pursue publishing an abridged version of it with someone, maybe CUP if you're still interested. In the meantime, however, I'd like to field two more immediate proposals with you ... that are in fact more likely to be sounder business propositions for CUP anyway.

3) The first has to do with the fact that I never ended up following through with Springer on their proposal to publish my *Notes on a Paulian Idea*. A bit before I first met you, they wrote me (23 May 2008):

> Should we not receive any response from you in the coming 6 weeks, we will consider the project stopped and the contract Null & Void.

I never replied, and I think I am happier for it. Particularly, I am free of them, and the more I think about it and have gotten to know the things you have published, the more I am intrigued by the idea that CUP is the right home for the document anyway. Only last week did I learn that you published Mermin's *Boojums* as well as his more recent books.

So, well before thinking about *My Struggles*, what would you think of publishing *Notes on a Paulian Idea*? You have seen Mermin's foreword to it, and my previous self-compilation of praise on it (oh those mirrors!)—I sent you that last June—but let me show off two more recent comments, one from a young author, and one from an old one. I guess what they suggested to me is that the book really might be of broader readership than I had contemplated when Springer first said "yes" so long ago. [I.e., I think I really am ready to publish it now and want it done right.]

The first is praise from Louisa Gilder who wrote this in the acknowledgments of her new book *The Age of Entanglement*:

> Thanks also to Steve Weinstein, who gave me *The Shaky Game*; and especially to Andrew Whitaker, for writing the beautiful *Einstein, Bohr, and the Quantum Dilemma*, and to Chris Fuchs for his wonderful samizdat, *Notes on a Paulian Idea*—these two books sat on my desk rather than on the shelf.

And she accompanied the book she sent me with a personal letter saying,

> Three years ago you gave me your samizdat and it has been my constant desk-side companion ever since. My copy is now dog-eared, bookmarked, further indexed, and underlined everywhere and yet I'm still finding wonderful unexplored sections (just recently I read your letters to Henry Folse for the 1st time, culminating in the great story about Ben Schumacher and Star Wars!) ...
>
> P.S. Have you ever read the tiny book *84 Charing Cross Road*? It has exactly nothing to do with quantum information theory (it is a series of letters between a book lover in N.Y.C. and a bookseller in London) but somehow it feels to me like a companion volume to *Notes on a Paulian Idea*—that atmosphere of erudite but unsolemn enthusiasm, whether for books or P.O.V.M.s, is very satisfying and so vital.

The second praise came from Hans Christian von Baeyer. You must have seen his many books popularizing physics, or perhaps know him. One New Year's Eve, after probably too much wine, he wrote me the very sweet letter in the second attachment. [See H. C. von Baeyer's preply to my 03-01-07 note "New Year's Alchemy".]

So there: Between these quotes and the ones I had sent you previously, I think I can do no more salesmanship. If you want the book, you can have it, and I would say on very short order: I think little more needs to be done in further preparation of it than my adding a good subject index. The presently best indexed version can be found at my website in case you would like to re-peruse it.

4) This leads me to another project that I would like to pursue in short order—something I dreamed up only recently—and I wonder whether CUP might have an interest in it? Asher Peres was a very dear friend of mine, and recently I gave some lectures in Sydney in his honor at the first Asher Peres International (summer) School of Physics. My lectures were titled "Quantum Foundations, Asher Peres Style," and the associated transparencies can be found here

`http://www.perimeterinstitute.ca/personal/cfuchs/Peres%20School%201-110.pdf`

in case you want to peruse them too (though they won't be of much use without lecture recordings).

Anyway, in preparation for those lectures, I reread several of his foundational papers, and I was transported back to my youth in physics. I had simply forgotten how influential those papers were on me. And, indeed, how wonderfully written and concise and forcefully argued they all were. They lay the foundation for a vision of quantum mechanics that is diametrically opposite to the vision of it in Oxford (the vision of David Deutsch, Simon Saunders, Harvey Brown, Jeremy Butterfield, David Wallace, and Artur Ekert), and it struck me: What better place to have those papers republished than Cambridge! I think one could easily make a nice volume of his papers, and the result would get beautiful reviews from the likes of David Mermin, Abner Shimony, Ben Schumacher, and others. (Do you recall Mermin's fantastic review of Peres' book?) I think I counted that Asher had some 70 foundational papers, and we could pick and choose the very best and most influential on the community. The running theme in most every one of them is the idea that "Quantum States Do Not Exist" (a phrase of mine, but you'll find his precise quote on page 5 of my lecture; unbeknownst to me, his was the precursor to my own)—and he explores every aspect of that idea in these papers. I made that the theme of my lectures, and I propose to make it the title of the book. I would write an appropriate introduction explaining the far-influences of Asher's thought (and how it is still developing in pockets of the world) and put Asher, the man, in context with respect to the development of quantum information and the quantum information community. Attached is the piece on him I wrote for his memorial volumes of *Foundations of Physics*; it may give a sense of my writing style with respect to an introduction for the book. I would very much like to tribute Asher in this new way—giving him a new chance to influence the world of quantum foundations the way he influenced me.

That's my four topics. I hope I didn't write you too much to read in one go.

And I hope all is well for you and your family in this new year.

11-01-09 *More on Pauli* (to D. M. Appleby & H. C. von Baeyer)

Boy you sure make it hard for me to feel literary! I thought I was simply being clever with my choice of words—i.e., that talk of the soul doesn't stir my soul! It wasn't an accident. Nonetheless, you have many good points; I liked the soul vs. mind analysis.

We should start thinking about when the two of you might converge on PI again. When do you plan to come next, Marcus? Will you come for your school's Spring break?

It is fantastic what precipitated out of this New Year's discussion of ours. I've been reading voraciously again. I think I'm actually going through a second pragmatic awakening, of the force of the one Matthew Donald's prod set alight nearly 10 years ago. A whole new set of pieces have fallen into place. This time it's not about the theory of truth, but about pure experience. A quantum measurement is pure experience! (In the technical sense.) It is an example of the neutral stuff Pauli was seeking to describe. I hope to give you both an extended report in the coming week.

Marcus's Preply, 11-01-09

> I'll start (and, I fear, possibly finish) with some thoughts provoked by these passages from Hans's notes
>
>> Gieser's section ends: "Science as a discipline must in turn realize that science created by man always includes statements about man. The object of science will therefore always be man himself and his totality; in him is the ethical conflict between good and evil, in him is spirit and matter."
>
> and
>
>> That's the thing that eternally amazes me. How can the cynical modern materialists get around the fact that since time immemorial most of humanity has been religious?
>
> and this from Chris's
>
>> For it is true that I rarely speak of "souls," "religion," or "redemption." These terms are mostly dead terms for me—they don't stir my soul, so to speak—or maybe I simply don't understand them well enough yet to see their ultimate usefulness for what I *do* want to get at. (Much like I have never understood what the search for "elegance" can possibly mean when it

> comes to forming physical theories, say, as a criterion for string theory: it is a term that is dead to me.) It is maybe in this way, or more carefully, *in this detail*, that I part company from your tentative feelings on the opus.
>
> *Nonetheless*, there is no doubt that I believe there is a place—a very important place—for humanistic concerns within physics proper. It seems to me it goes to the core of what quantum mechanics is trying to tell us.

(I could have quoted much more from Chris in this connection, but I won't because cutting and pasting from Acrobat is a pain).

Indeed. As I hope I made clear in my last notes I don't think there is any *essential* difference between Chris and myself. It is just that he tends to focus strongly on the question of freedom while I tend to cast my net a bit wider. For instance, I talk of souls whereas he doesn't.

Why do I talk of "souls"? I used to have a conscience about using this word because I felt I didn't know what it means. And I still don't know what it means: if someone were to ask me what exactly I hope to convey by the word "soul" which I could not equally well convey by the word "mind" I would struggle. Struggle badly, in fact. Nevertheless, I now do use the word, because, although I don't have a very clear idea of what I mean by it, I am very sure that I do mean *something*. Something important.

The word "soul" is a word you simply don't use in respectable scientific discourse. Which is curious because there was a time when the words "soul" and "mind" were regarded as synonymous (if I remember correctly Descartes treats them as synonyms, for instance). But in the contemporary scientific culture it seems that that is no longer the case. The word "mind" is frequently used in the scientific literature; the word "soul" almost never. I suppose one might argue that it isn't used because it is regarded as archaic (in the way that the word "verily" is archaic, for instance). However, I don't think that can be the explanation because the word is in common use outside the world of science. Not only would every scientist understand what Chris means when, in the passage I just quoted, he says "they don't stir my soul". I think that on occasion they would use that phrase themselves. However, they would not do so in a scientific paper. The word seems to be regarded as being somehow "unscientific". The curious thing is that if you asked most scientists what exactly is wrong with the word "soul"—what offensive feature it has got which the word "mind" hasn't—I think they would probably struggle. Indeed, I think they would find it as hard to explain why they *don't* use the word as I find it to explain why I *do*. Nevertheless, they do seem to have a strong feeling that the word is inappropriate when used in a scientific context. This is an observable fact about the psychology of the average scientist. I take it to be evidence that the word has as much meaning for the average scientist as it does for me, even though neither of us can explain quite what the meaning is.

I think the answer to the question "why do I use the word?" may be that I am using it reactively. In avoiding the word "soul" I think the average scientist means to deny something. And whatever it is that he/she wants to deny, I want to affirm.

But, although I can't give an exact definition, perhaps I can give a rough indication. Consider once again the passage from Chris's notes which I just quoted. He begins by saying that the terms "soul", "religion" and "redemption" are dead for him, and then for additional emphasis he says that they "don't stir my soul, so to speak". I can't resist pointing out that there seems to be a contradiction here: for doesn't the fact that Chris uses the phrase "stir my soul" in this way show that the word "soul" is very far from being dead for him? Be that as it may, however. Whatever Chris meant or didn't mean by it, that phrase "they don't stir my soul" gets right to the heart of the matter. I think the word "soul" is an important word because it enables one to say things like this:

It stirs my soul

I felt it in my soul

He put his soul into it

etc. etc. Whatever it is that is conveyed by such phrases cannot be conveyed in mind-language. Just consider:

It stirs my mind

I felt it in my mind

He put his mind into it

So what exactly is the difference between these two groups of phrases? —Part of it is, I think, that the word "mind" is generally used to refer to the cold-blooded, ratiocinative aspects of psychic functioning. There has always been a tendency in modern science to attach overwhelming importance to reason. But in the course of the 400 years that have elapsed since the genesis of modern science in the 17th century the concept of reason has itself become narrower and narrower. The end result is that nowadays the word "mind" tends to convey little more than the idea of an extremely complicated calculating machine. The word "soul", by contrast, conveys a concept which is admittedly more primitive but which is also (it seems to me) richer, and more complete.

For instance when Chris wanted to expand on the idea of a term being "dead" to him he was forced to use the word "soul" rather than the word "mind" because for a calculating machine every term is dead.

I make a point of using the word "soul" because I just flat don't believe that a human being is nothing more than a calculating machine. I should say that I do so with misgivings. For it is, of course, true that the concept of the soul is primitive. It has a distinctly medieval feel to it. So there is a danger of my giving the impression that I am a Luddite, who wants to undo the work of the last five centuries and return to the Middle Ages. Of course, that isn't really the idea at all. My admiration of the 17th century creators of modern science is heartfelt. It is just that I share Pauli's belief that, along with their great achievements, the 17th century thinkers made some serious mistakes. My aim in all of this is only to do what I can to correct those mistakes. However, I do worry that my use of medieval language will obscure that fact.

12-01-09 *Happy Birthday William James* (to H. C. von Baeyer)

Thank you for that fine birthday present for William James. And thank you for teaching me that James's birthday precedes my daughter Emma's [today] by just one day!

I did find the point about thin language interesting. When you and Marcus arrive in Waterloo, perhaps you can help thicken my sauce a bit!

Hans's Preply, "Happy Birthday William James," 11-01-09

Here's a thought I wrote this morning before reading your two contributions.

On Language

In connection with the role of theology and the opus in our study of quantum mechanics I thought it would be useful to hear what Fierz had to say. Contrary to Pauli, who was an atheist by conventional Judeo-Christian standards, Fierz was a Christian, who felt free to interpret scripture in strictly metaphorical ways of his own choosing. Here's what he wrote to Pauli on 11 February 1956:

> ... The old story of paradise — which of course is much older than the creation story — culminates in humans eating from the tree of knowledge and then getting thrown out of the garden of Eden. In my opinion this story does not mean anything sexual, but the sexual just happens to be part of the problem. The story primarily means simply that we have now internalized the apple of *Erkenntnis* (knowledge, discovery, recognition) and that there is no way back.
>
> From this I conclude — for the story is believable and good — that the way to salvation is mediated by *Erkenntnis*. But this *Erkenntnis* is not a revelation. It is work — by the sweat of our brow — thistles and thorns — an *opus*. Besides thistles the field yields fruit, too, and we may enjoy those. But the enjoyment of the fruits of our *Erkenntnis* is not yet an enjoyment of power.
>
> Erkenntnis also implies that opposites are recognized — Adam "recognized" Eve; namely as woman who was the opposite of him, the man.[173]
>
> The discovered opposites will probably have to remain separated, at least for now. That's all right, because, or inasmuch as, they have been truly discovered. In the discovery they are unified insofar as there is someone who can see them both and who is prepared to carry the burden that is thereby put on him — i.e. the cross.
>
> All this sounds a bit theological; but I don't know a better language. The philosophical-conceptual language is too thin for me, too lacking in images, and then I have no idea what I'm talking about.
>
> From *Erkenntnis* I expect salvation (wholeness, well-being). Yes, I mean even from scientific *Erkenntnis* or research (for it has a methodology). This is not a rationalizing point of view. For the object of *Erkenntnis* is precisely the irrational. Internal images and fantasies are just as much objects as the external world. In order to recognize them we need a methodology with which we can operate on them (experiment!). In this methodology I include associations, amplification of images; your [Pauli's] comparison with mythological and other materials, etc.

I thought the bit about language would interest Chris, who's on the other side of the fence.

[173] [Fierz's footnote.] Contra Plotin and other observers: *Erkenntnis* is the the work of *Erkenntnis*, which requires a methodology. Contraries are recognized, i.e. one recognizes that they exist, not that they actually don't exist!

13-01-09 *The Remarkable Theorem* (to A. Uhlmann)

Uhlmannism 2: *Yes, this is an unexpected characterization by Jones and Linden (*`quant-ph/0407117`*) and, if I am right, independently by Patrick Hayden.*

[See 08-01-09 note "Fuchs-Graaf Inequality" to A. Uhlmann for a statement of the characterization.] I am pretty sure that I reported it to Patrick, though my memory may not serve me well. The only independent discoverer (beside Jones and Linden) I know of is Steve Flammia, at the time a student of Carlton Caves. When he first showed Carl the result, Carl didn't believe him. Later I was told about it, and I was shocked: I thought, surely it must be a folk theorem that Caves and I had somehow missed. So, I got in the habit of asking everyone I knew about whether they had ever seen the little theorem. And the interesting thing was that no one had! Here is a list of people I asked about it: Holevo, Leib, Ruskai, Calderbank, Lindblad, Gottesman, John Conway, and many more than that. No one had. So, it wasn't a folk theorem after all, even though the result is almost trivial. Thus, in my presentations, I got in the habit of naming it "the remarkable theorem" and giving profuse credit to Flammia and Jones and Linden for unearthing this beautiful little mushroom.

Uhlmannism 3: *Of course, the set of faithful density operators can be described by a finite set of strict inequalities, you mentioned the elementary symmetric functions.*

That's right; I am aware of this.

Uhlmannism 4: *I do not know. But the manifold of rank one projections has at every of its points an individual tangential hyperplane giving a necessary linear inequality. Therefore, I think, the additional conditions you are looking for cannot be linear if there are finitely many. I am also pessimistic about substituting a degree three polynominal equation by some degree two ones — but this may be a wrong expectation if there are in addition some distinguished linear equations or inequalities.*

Yes, I guess I was *hoping* (no intuition, just hoping) that the inequalities might bring the remaining conditions down to some degree two conditions. I suppose I'm pessimistic too. May I ask you, however, to expand on your remark about a "necessary linear inequality". (I.e., your second sentence in this paragraph.) I don't know what you are saying here.

Uhlmannism 5: *If P_1, P_2, … is a SIC, one perhaps needs some insight of what phases occur in the traces of their products.*

Appleby and I will soon post a very detailed study of the "triple products": I mean $\mathrm{tr}(P_iP_jP_k)$. They have a very remarkable structure.

Uhlmannism 6: *Next month I become 79. Up to now I can be satisfied. Of course, there are always things to be repaired!*

Very good! It is always good to become prime once again!

14-01-09 *The Remarkable Theorem, 2* (to A. Uhlmann)

Uhlmannism 7: *There is a curious convex set, given by the intersection of* $\operatorname{tr}\omega^2 \le 1$ *and* $\operatorname{tr}\omega^3 \le 1$. *This convex set is definitely larger than the state space if dim* > 2. *Do you know whether somebody has looked at it?*

I had contemplated looking at it at the Cambridge workshop on "foils to quantum theory" two summers ago. But then nothing ever materialized of the hope—other things got in the way. I also wanted to look at this convex subset of the probability simplex over d^2 points: The one where $\sum p(i)^2 \le 1$ and $\sum p(i)^3 \le 1$. I don't know that anyone has looked at these things in detail. If you get any results, I would love to hear about them!

15-01-09 *Waterloo Morning* (to D. M. Appleby and Several Others)

Dear old collaborators (in the warm parts of the world),

Don't you wish you were up here in beautiful Waterloo with me this morning? It's −29C outside (−20F for the Americans)! Think of the grand discussions we could have on the quantum on our walk to PI!

15-01-09 *Exchange of the Delusional* (to K. Martin)

Thanks for sending that. I had a great time reading it to my wife last night and trying to get the voices right. Beautiful writing—it felt it must have really captured the circumstances and atmosphere. But don't think for a moment there's no quantum there! I like the way William James put it:

> Taken as it does appear, our universe is to a large extent chaotic. No one single type of connection runs through all the experiences that compose it. If we take space-relations, they fail to connect minds into any regular system. Causes and purposes obtain only among special series of facts. The self-relation seems extremely limited and does not link two different selves together. Prima facie, if you should liken the universe of absolute idealism to an aquarium, a crystal globe in which goldfish are swimming, you would have to compare the empiricist universe to something more like one of those dried human heads with which the Dyaks of Borneo deck their lodges. The skull forms a solid nucleus; but innumerable feathers, leaves, strings, beads, and loose appendices of every description float and dangle from it, and, save that they terminate in it, seem to have nothing to do with one another. Even so my experiences and yours float and dangle, terminating, it is true, in a nucleus of common perception, but for the most part out of sight and irrelevant and unimaginable to one another. This imperfect intimacy, this bare relation of withness between some parts of the sum total of experience and other parts, is the fact that ordinary empiricism over-emphasizes against rationalism, the latter always tending to ignore it unduly. Radical empiricism, on the contrary, is fair to both the unity and the disconnection. It finds no reason for treating either as illusory.

In the vision of the world I hope to construct, there'll always be room for the likes of you, me, and even the phone lady. My experience is a string, yours a bead, and hers a feather. They are no lesser parts of the world than the results of the LHC. And it is quantum mechanics that gives us the most compelling case for that indication!

Attached is a little document I put together for Marcus Appleby and Hans Christian von Baeyer at New Year's. [See 05-01-09 note "What I Really Want Out of a Pauli/Fierz-Correspondence Study" to H. C. von Baeyer and D. M. Appleby.] In other contexts I've been calling it "The Metaphysics of SICs."[174] You think I'm spending all this time just trying to find better descriptions of quantum channels? No, I've got much bigger things in mind!

I hope you enjoy this exchange of the delusional!

17-01-09 *It's Always Einstein* (to P. G. L. Mana)

Manalogue 14: *As for correspondences, I suppose you already have the book 'Letters on Wave Mechanics: Schrödinger, Planck, Einstein, Lorentz'?*

I read that book many years ago. I remember a most amazing letter from Einstein to Schrödinger, soon after S had found his time-independent equation. Einstein misread the draft of the paper and got the equation wrong. So he wrote to Schrödinger a letter saying what he didn't like about the (incorrectly recalled) equation. Then he said, "You will notice that the following equation" (in which case he wrote down the proper Schrödinger equation as if he were the inventor of it) "has all the appropriate properties." Finally he ended the letter by saying, "however I can find no interpretation of this function ψ which is its solution".

Beautiful! Tell me if I'm right with my memory.

19-01-09 *Phishing for Filosophy* (to R. Blume-Kohout)

I never have quick responses to anything … because I never have quick thoughts on anything. The best I can ever muster is to attach an old, partially relevant email, as I will do here. But it was good to juxtapose Fish's article today (which I had not read before your note) with this other one in today's NY Times that I had: `http://www.nytimes.com/2009/01/19/books/19read.html?hp`. The attachment concerns my way of saying the humanities are important to the quantum world, as the quantum world is important to the humanities. (It was a New Year's letter written to Appleby and Hans Christian von Baeyer.) [See 05-01-09 note titled, "What I Really Want Out of a Pauli/Fierz-Correspondence Study."] I'll leave it to you to tell me whether it means I think physics is a liberal art.

20-01-09 *From Pragmatism to Pure Experience* (to M. Bächtold)

Thank you for sending your new email address. I hope you are enjoying your new position and finding it a productive place to think. I can see that you are somewhere in France, but could not figure any more detail than that from your email address. Where are you now?

Thank you for enquiring on the paper. I am in the middle of its construction and hope to have it for you in about a month. It has been very tough going for me—first with the collapse of Bell Labs, then the flood of our home in New Jersey, and then the move to Canada. But all is clear intellectually now, and this paper has become more important than ever for me. In the course of

[174] It is a strange thing that those "other contexts" would be my note to Keye just nine days earlier, in which I had sent him the very same attachment. However, I have a faint memory that I did this on purpose for one reason or another.

developing it, I have greatly clarified my thinking. Particularly, I ended up in a place I had not expected to. What I try to argue now is that in a very serious sense, quantum measurement is an instance of Jamesian "pure experience"—and that quantum mechanics is our laboratory for finally making that notion precise. This is quite a turn for me. My initial attraction to pragmatism had been solely for "theory of truth" reasons: It was a means of making sense of the idea of quantum measurements being generative (i.e., as not simply revealing pre-existent facts), yet, at the same time, allowing that one could be "certain" of a measurement outcome via an initial pure-state assignment. The certainty must be interpreted as subjective Bayesian certainty (i.e., it lives in the realm of ideas), and in any measurement interaction, it can be *made* true or false. So, the "truth" arising from a quantum state assignment is something that comes after the fact—at the conclusion of measurement—and is not something pre-existent with the state itself. (For after all, "quantum states do not exist" as the Bayesian slogan goes.) But that was my initial attraction to the pragmatist line of thought. Where I go now is to understand quantum measurement as an instance of a more general phenomenon—something that is neutral between the physical and the mental (agential would be a better second term). I try to view these "pure experiences" as the active monads of the world, similar to James and similar to John Wheeler with his "elementary acts of observer-participancy" being the building blocks of the world. What I am trying to do in the paper is to show that this is the logical endpoint of my earlier less-radically-empirical pragmatism. And I hope to set up a framework for making these issues much more precise than hitherto possible.

I hope you will like the final result, and that it will have been worth your wait.

21-01-09 *Old Poetry* (to G. L. Comer)

Comerism 21: *Congratulations on your new post! Will you get to meet the head of NSA?*

I'm aiming for the Obama cabinet. I suspect he needs some advice on quantum foundations. ... Though he already shows promise, indeed: He seems to already have good pragmatist credentials. Did you notice the line about our "uncertain destiny" in yesterday's speech?

21-01-09 *More Obagmatism* (to G. L. Comer)

This one from Paul Begala's report of the speech on CNN. (Paul was at the University of Texas just before me, or maybe there was some overlap. He lost against Hank the Hallucination, a cartoon character, when he ran for student-body president.)

> The president closed by quoting the words from Tom Paine that Gen. Washington ordered read aloud at Valley Forge. "Let it be told to the future world," Washington said, "that in the depth of winter, when nothing but hope and virtue could survive ... that the city and the country, alarmed at one common danger, came forth to meet [it]."
>
> The quote shows Obama's belief in unflinching courage, unblinking realism and an unrelenting faith that by coming together we Americans can bend history to our will.

What other philosophy than pragmatism would admit that we "can bend history to our will"?

21-01-09 *Pauli Retally* (to R. W. Spekkens and L. Hardy)

The title's got to give you a giggle.

After Dawn's high number yesterday for these volumes, I decided to look into it myself. The result is attached. A more accurate number is around \$1600 CAD total (or \$1270 US), excluding shipping.

I think Rob is right. Except for Appleby's and my quest for clues toward constructing a "psycho-physically neutral" language (as Pauli called it) for quantum phenomena—which I do very much consider modern research in quantum foundations—this purchase really should be considered more in the line of a resource for the history of physics. I.e., in most anyone's hands but ours, it will be historical reading. And maybe that is not what PI should be in the business of—at least not at such a price premium.

Thus, I want to make the following offer and see how you'll consider it. If PI will pony up half the expenses, I'll cover the other half with my ONR grant. And PI gets a great set of books (however you classify the subject) that it can house forever. Or at least until the inevitable fire that comes to all book collections.

Does that sound reasonable? If so, then I'd like to get to action so that some volumes might be here before Appleby's and von Baeyer's visit Feb 15.

21-01-09 *Pauli Retally, 2* (to H. C. von Baeyer and D. M. Appleby)

Well, I tried (see below), but it seems neither of my senior colleagues in foundations are willing to stand up for a Pauli-correspondence purchase for the PI library. The view of Rob, at least, was that though it may be a resource for the history of physics that is not our business. And when he discovered that the volumes are not translated even, that really pushed him over the edge. Oh you lucky ones at the "liberal arts" institutions; your libraries are so much more tolerant.

I even tried to sweeten the pot by promising to launder half the expenses from Marcus and my (still itinerant) ONR grant. But it was a no go. And somehow I couldn't find myself laundering the full expenses when I honestly feel it should be housed at PI.

Thus before you arrive, I will try to get as many of the volumes as I can by Guelph-Waterloo library loan.

Maybe I should apply for a humanities grant to ease my conscience.

Marcus's Reply

> Compared with the size of the ONR grant \$1270 isn't that much. I wouldn't mind at all if you used the grant to cover the whole cost. Though maybe it ought to be in the possession of someone who can read German (definitely not me!).
>
> I think more hangs on the distinction between "physics" and "history of physics" than meets the eye. In other words the fact that it appears obvious to almost everyone that you can pursue research in "fundamental physics" whilst having, at best, only a very sketchy, journalistic understanding of the "history of physics" shows that almost everyone is looking at physics in a profoundly wrong manner. I think it has to do with objectivism.
>
> The mistake the objectivists make is to misunderstand the relation between (on the one hand) the world and (on the other hand) our thoughts about the world. In particular objectivists tend to identify the conceptual/linguistic/mathematical structures pertaining to our understanding of the object with the object itself (e.g. Everettians identify the state vector of the universe with the universe itself). It is a really weird

mistake when you come to think of it. As if I were to identify the name "Pauli" with the man of whom it was the name and, furthermore, to assume that anyone who challenged that identification was denying the reality of the man himself. But people don't see that it is weird. And that shows that the error is very deep-seated.

The idea that "history of physics" is irrelevant to physics itself is due, I think, to the fact that people are thinking that "history of physics" is to do with us (our ways of understanding), while physics itself they tend to identify with the object (what we are trying to understand). So that makes it look as though "history of physics" and "physics" are two entirely different things.

It is not so, of course. Physics is an intellectual structure, of our own creation. It is true that it has what the philosophers call "intentionality": it points at something different from us. But just as a pointing finger, though it points at something distinct from the body, is itself part of the body; so physics, though it is about things different from us, is still itself part of us.

The fact that physics is specifically *our* intellectual structure means that it is, like us, something organic. And it is fundamental to organic entities that they evolve: in other words, that they have a history. It would never occur to a neurophysiologist that you can try to understand the brain whilst completely ignoring the brain's evolutionary history. The same principle applies (or should apply) to physics which, after all, is a production of the brain. (I was going to say it is a production of the brain at the software level. But I am not sure that is right. One of the differences between brains and computers is that there is not the same clear-cut distinction between software and hardware in the case of the brain. A brain which knows quantum field theory is, probably, physically very different from one which only knows how to make stone axes.)

I am presently trying to understand why some *Mathematica* code is giving me the wrong answer. To do that I am going back over all my working, starting from the beginning. In other words, I am examining the history of how I got to this point. It is surely the natural way to proceed.

Similarly with quantum mechanics. The reason that there is a whole industry devoted to the foundations of quantum mechanics, but no such industry devoted to the foundations of relativity, is that quantum mechanics seems, as judged from the perspective usual among physicists, at least on the face of it, to make no sense (wave function collapse, etc etc). In tackling this problem most people start from the assumption that it only *seems* to make no sense when judged from our usual perspective. However, it is surely no less reasonable to think that there is something wrong with the usual perspective. To track down the error it is surely very reasonable to examine the evolution of that perspective. To look at the history of it, in other words. And it seems to me that such an examination obviously belongs to physics proper.

22-01-09 *Bose-Einstein-Bayes* (to N. C. Menicucci)

Menicuccism 2: *What would you say is the key difference between quantum and classical indistinguishability of particles (e.g., considering bosons/fermions versus classical particles), if any?*

I wish I had a real answer for you, but I don't. The only thing I know is that I still stick by the tenets below. [See 12-03-07 note "More Serendipity" to G. L. Comer.]

23-01-09 *Feynman Comment?, 3* (to N. D. Mermin)

Are you still out there?

Did you ever have any insight in the question below? If you cannot recall any of your own writings, can you recall anyone else's?

I've had an excruciatingly hard time writing this paper, but it is slowly coming together. The upshot is I want to return "interference of probabilities" to the place in quantum foundations where Feynman thought it was. (Though Bayesianified and quantum informationified, of course.) It'll help the drama if I have some quotes of opposition to fight it out with.

You never told me you didn't like the title *Notes on a Paulian Idea* before.

23-01-09 *First Reports on NPI* (to S. Capelin)

Well, Ref B is pretty clearly Scott Aaronson. There's only one lunatic out there who's ever read the whole thing!

24-01-09 *Pauli Retally, 3* (to D. M. Appleby and H. C. von Baeyer)

[Concerning Appleby's reply to "Pauli Retally, 2" . . .] That was indeed an eloquent defense! Would you mind if I forward it to Rob and Lucien? I've given up on the book issue, but I think it's something they should think about for the future.

The reason I've been reluctant to purchase the set solely for ourselves is in significant part the language issue. Putting it in the library and making it available for everybody was the way I had planned to ease my conscience. I mean, ideally I'd like to go through the volumes page for page and catalogue potentially interesting items, but that's most of the use I'd have for them. (Anticipating my only having the patience to scan for significant words, since I don't know the language.) If I felt I was doing more good for the community, I could see doing that. But without PI (as embodied by Rob and Lucien) recognizing some value in the gift, it kind of galls me to give it to them.

02-02-09 *Your PhD Thesis* (to P. G. L. Mana)

Manalogue 15: *During the last few days I've been thinking about our lunch discussion, about what Chiribella said at the panel discussion, and about how you enthusiastically commented on his words. There's much in the current language we use to describe quantum-mechanical phenomena that throws sands on our eyes and precludes us from thinking better, deeper, unbiassedly, and along new paths. Bell criticised the word 'measurement', but there are many, many other words that lurk around in our physical speech and cover our eyes. Yesterday at the group meeting we discussed, at some point, on whether we could do without the concept of particle or of wave in quantum mechanics and quantum field theory. Then, in presenting an experiment (Mach-Zehnder), sentences like 'there is one photon in this mode' came forth. In presenting experiments with such a language we are already committing to an idea, and there is therefore little hope for us to be capable to reinterpret the physics behind them in new ways.*

This is a point that Ed Jaynes made very beautifully somewhere as well, I recall.

Manalogue 16: *Personally, I can speak of any quantum experiment whatever without ever mentioning the word 'particle' even once, and translate what the others say in that particle-less language.*

Similarly for me: the concepts of both particle and wave hold no use in my own understanding of the world.

Manalogue 17 : *Take for example the sentence 'The probability of finding the system in such and such a state', which I hear almost daily.*

You *never* hear that language from me.

Manalogue 18 : *In classical analytical mechanics people speak all the time about the 'evolution of the probability distribution' on phase space. That's nonsense because a probability is timeless; there is not even any updating in the Bayesian sense when we speak about that 'evolution'. And even the term 'updating' is misleading indeed. Bayes' formula simply relates probabilities having different contexts.*

I believe de Finetti put the latter point like this: It is only the following out of our set opinion.

03-02-09 *Title Thoughts* (to S. Capelin)

I'm jumping the gun here, but I'm sober enough to know that if you guys do accept the book, the title at the least will have to be changed. I just wanted to record these thoughts while they're on my mind, and you seem like the appropriate repository for my finding the note again.

- Coming of Age with Quantum Information
- What's Under Quantum Information?
- Quantum Information, Quantum Reality, Quantum Personality

Just playing with words—I know it's got to make connection to a wider audience, but it also has to be true to what the book was intended to be.

Hope you don't mind my bothering you like this.

04-02-09 *Title Thoughts, 2* (to S. Capelin)

Capelinism 1 : *Actually, I like the suggestion that the book should include brief biographical sketches of the people your emails were sent to.*

I do as well. It is a good idea and, I think, it would make for a fun project (to try to say something fun about my old friends).

Capelinism 2 : *Would you be willing to tighten it up a little?*

Potentially. Since the beginning, I have been acutely aware of the repetition factor. I tried very hard to guard against it when I first put the thing together. But the trouble remained that I have variations and variations on the formulations of the ideas I was seeking. Some of them never converged; sometimes the different formulations continued to hold positive aspects that I did not want to throw away. But I will think about the idea of tightening—one thing I fear is that it would be a major undertaking.

Also, there is the comment of Referee A. One of the reasons *I believe* you can dip into the book almost anywhere and pick up the thread is precisely that so much of the book is repetitious, working out variations on variations. After all, it is just notes on an idea.

I didn't like my new titles either much. So I'm glad you're of two minds.

04-02-09 *That Savage* (to R. Schack)

Do you remember a place where L. J. Savage said something *like* "there is a continuous scale between pure coherence and objective probability and the issue is, where does one make the cut? Objectivists go to one extreme, radical personalists go to the other. One may well think there a further normative rules beyond coherence, but when does one stop the process of adding more structure before the abyss of objective probability?"

At least I recall a discussion like that somewhere. I'd like to quote a bit of it for our paper, but cannot find it. Any hints you have would be most useful.

05-02-09 *Savage Morning* (to R. Schack)

By the way, I came across this paper, which I found interesting: L. J. Savage, "Difficulties in the Theory of Personal Probability," *Philosophy of Science* **34**, 305–310 (1967).

The penultimate paragraph harkened back to some of our discussion from the early days of "you're going to tell me a beamsplitter isn't a beamsplitter!":

> The idea of facts known is implicit in the use of the preference theory. For one thing, the person must know what acts are available to him. If, for example, I ask what odds you will give that the fourth toss of this coin will result in heads if the first three do, it is normally implicit not only that you know I will keep my part of the bargain if we bet but also that you will know three heads if you see them. The statistician is forever talking about what reaction would be appropriate to this or that set of data, or givens. Yet, the data never are quite given, because there is always some doubt about what we have actually seen. Of course, in any application, the doubt can be pushed further along. We can replace the event of three heads by the less immediate one of three tallies-for-head recorded, and then take into our analysis the possibility that not every tally is correct. Nonetheless, not only universals but the most concrete and individual propositions are never really quite beyond doubt. Indeed, as you know better than I, such seeming statements of fact must actually be recognized as universals. Is there, then, some avoidable lack of clarity and rigor in our allusion to known facts? It has been argued that since indeed there is no absolute certainty, we should understand by "certainty" only strong relative certainty. This counsel is provocative but does seem more to point up, than to answer, the present question.

I also liked this line from the bottom of page 307 / top page 308:

> Yet, in the very notion of this choice of a framework there are impressive difficulties. Is it good, or even possible, to insist, as this preference theory does, on a usage in which acts are without influence on events and events without influence on well-being?

05-02-09 *The Paulian Idea* (to S. Capelin)

I'm OK with what you say about the title.

But here's another potential idea for the future with regard to the title: Use 'Notes on a Paulian Idea' as a subtitle. *Coming of Age with Quantum Information: Notes on a Paulian Idea*. That would preserve a bit of continuity with the previous edition, but possibly put a more public face on it.

The choice of title came about because reading Pauli particularly turned my conception of quantum mechanics upside down. Not Bohr, not Heisenberg, but Pauli. It was through him that I started to realize that one might have it all: A Copenhagen-style understanding of quantum measurement *without* giving up on reality itself (as so many are apt to accuse me of). [See note titled "The Reality of Wives" [in this volume] to get a sense of the constant defense I'm on.] The beginnings of my transition are documented in the first three pages of the Letters to Greg Comer chapter. Then really, almost all the correspondence throughout built up around the core of Pauli's idea … seen through the lens of quantum information and Bayesianism. The two quotes on page vii are what I consider the essence of the Paulian idea. Nondetached observers, yes, ones who participate in shaping reality, but nonetheless raw reality too—i.e., the world is not a dream or an expression of my fancy. That was the idea that hit me over the head, and it is why I paid homage to it with my title. (Note: Those early letters to Comer were included for completeness; otherwise all correspondence in the book comes from my postdoc period, starting in 1996.)

I would like to deliver the book to you *no later* than June 1. I'm trying my hardest to make this Spring a great house-cleaning exercise.

06-02-09 *Swedes, PDFs, and Experiments* (to R. Laflamme)

Speaking of the geometry of Hilbert space, do you think you could do an experiment like the one in Figure 1 of the attached paper?!?! [See "Quantum-Bayesian Coherence," `arXiv:0906.2187v1`, but Figure 2 instead.] It would be another way to test the Born Rule, and I got the impression you have some interest in that. The first interesting system with regard to these considerations, however, would be a quTRIT. The paper is still under construction. In fact, it is far from complete (many of the main results are not in it yet, sections unfinished, tentative paragraphs, etc.), but the present draft does at least contain the definitions needed to make sense of what I'm talking about. Let me know if you have an interest in learning more. (This is the stuff I'm getting my ONR funding for.)

06-02-09 *4.1 and PI* (to R. Schack)

By the way, this may have been the Savage quote I was thinking of:

> All views of probability are rather intimately connected with one another. For example, any necessary view can be regarded as an extreme personalistic view in which so many criteria of consistency have been invoked that there is no role left for the person's individual judgment. Again, objectivistic views can be regarded as personalistic views according to which comparisons of probability can be made only for very special pairs of events, and then only according to such criteria that all (right-minded) people agree in their comparisons.

It is not nearly as detailed as I remembered, but then again my mind very often fills in a lot of things that were not there originally!

06-02-09 *Something Concrete* (to Å. Ericsson)

It dawned on me that it might be fun to give you something concrete to think about in your off hours as you wait to come to Canada. As you get a chance, have a look at this paper and this presentation:

“Statistical Models are Algebraic Varieties,” by Seth Sullivant

`http://www.math.harvard.edu/~seths/lecture1.pdf`

and

[Something now lost], by Seth Sullivant

`http://www2.warwick.ac.uk/fac/sci/statistics/staff/research_students/zwiernik/wag_june.pdf`

One thing I’d like to explore with you after you arrive and get settled is whether it is fruitful to think of quantum state space as a “statistical model”. And if so, what standard tools we might bring from that area of research to better understand quantum states.

To put this in context, let me attach a paper I’m constructing at the very moment. It is far from complete (many of the main results are not in it yet, sections unfinished, tentative paragraphs, etc.), but the present draft does at least contain the equations you’ll need to make sense of what I’m talking about. Look at equation (30) or alternatively equations (27) and (28). These allow us to think of the set of pure quantum states as an algebraic variety on the probability simplex. By the definition of the links I gave you, quantum state space becomes a “statistical model”. The first question that can be asked then is whether it is a meaningful statistical model? Is it fruitful to think of it that way?

I’m looking forward to your teaching me some geometry!!

07-02-09 *De Raedt Papers* (to C. Ferrie)

Ferrie-ism 1: *Certainly a few of the informal conclusions will drive away some of the more war-torn veterans of Bell’s theorem. But, I really do get the sense that this new paper has some merit in its formal mathematical results. The abstract does not do it justice. The paper, it seems to me, is really about data analysis and the assumptions which go into forming models of the data.*

Sorry, Chris, but it’s my firm belief that your mind is presently darting around some very nasty places. Basically, I think you are charmed by a complicated, but ultimately untenable patent application. I’m alluding to my perpetuum mobiles again. So, I reissue my challenge. With regard to the two attached papers [N. D. Mermin, “Quantum Mysteries for Anyone,” J. Phil. **78**(7), 397–408 (1981); N. D. Mermin, “Bring Home the Atomic World: Quantum Mysteries for Anybody,” Am. J. Phys. **49**(10), 940–943 (1981)]: Pinpoint *exactly* where Mermin makes an unjustified assumption in his analysis. You may use any insights you want from De Raedt *et al.* or Jaynes or anyone else, but stick to the issue. What is wrong with Mermin’s specific argument?

The point here is that (I well believe) there is some very clear thinking going on behind Bell. And papers like De Raedt’s are just so many obfuscations. Stick with a crystal clear argument like Mermin’s and tell me what’s wrong with it.

09-02-09 *Qu* (to O. J. E. Maroney & H. Westman)

I should comment on Owen’s note before walking into the next meeting this afternoon.

Maroneyism 2: *This sounds interesting, but is definitely going to put off the physics side as presented, which would be a shame as the last one got a good mix. [I.e., the last PIAF meeting.] — Is it possible to lump “Perspectivalism” together with “The role of agents” in some way? That might reduce the overall scariness to the physicists of the list.*

My own opinion is, "then too bad for the so-called 'physicists'." It may well just be that the scariness of terms like "agent" is what has kept us in the quantum muddle all these years. The fear of a single little idea: that there is a distinction to be drawn between the objective and subjective, and that quantum theory rather than being exclusively about the one or the other, is about both. So one has to get the distinction clear, or there'll be no progress at all. It's not quite a 12-step program like Alcoholics Anonymous, but recovery has to start somewhere.

There, I said my piece, now I'll go defend it in chamber.

10-02-09 *Quanta Vista* (to R. W. Spekkens, L. Hardy, and H. Westman)

Spekkensism 47: *Hey guys, here's the synopsis:*

> **Quanta Vista: Frame, gauge, context and agent in quantum theory**
>
> Topics:
>
> - Reference frames
> - Relationalism
> - Contextuality
> - Gauge and symmetry
> - Subjective elements in the quantum formalism
>
> *I've slightly modified the topic list. I've replaced "role of the agent" with "Subjective elements in the quantum formalism" to avoid the impression that we're talking about consciousness causing collapse.*

My first quick impressions.

1) I like "subjective elements in the quantum formalism" very much. It captures the issue just right from my perspective.

2) But your fear of agent didn't reach up to the title. In any case, I don't think the title is snappy enough now. Personally, I think you would do better to drop agent from it but *leave* context: "Quanta Vista: Frame, gauge, and context in quantum theory." Sounds physicsy, non-frightening, and captures the matter. With the bullet on subjective elements, I get my cake and can eat it too ... but in a less threatening way.

3) I disagree on throwing out contextuality—more precisely Kochen-Specker—as a subject matter. These are topics the community ought to have a chance to think of in proximity of each other if progress is going to be had. If anything sticks out like a sore thumb, it's consistent histories. I'd say drop that subject this round. I really don't see how it fits.

4) I fear that the philosophers are a bit under-represented this time. Last year we had 7/29. I think we ought to maybe think harder there.

5) I personally would like to bump up Timpson—he's the only philosopher in the standard philosophy-of-physics crowd who really gets the subjective/objective divide. I.e., he's not like most other philosophers of physics who basically just see information as a new kind of fluid. Also, given van Fraassen's paper or papers on Rovelli (one had a title "Rovelli's World") I think it's entirely appropriate to try to recruit him. Though, I think like Rovelli himself, he's unlikely to come.

6) Carlton is spelled Carlton.

I'll have more impressions later. This is becoming a worthwhile exercise.

10-02-09 *Quanta Vista, 2* (to R. W. Spekkens, L. Hardy, and H. Westman)

Spekkensism 48: *Speaking as someone who thinks about each of these things, the connection between frame-dependence, agent-dependence and context-dependence is pretty weak at present.*

I read over the note again and disagree with this even more. Each topic touches on the idea of something "numerically additional" to the quantum system (to use a William Jamesian phrase). Frame, agent, and context all capture this. As well as gauge. It is a unified topic if you look at it this way. They are all about things non-intrinsic.

Spekkensism 49: *I would be very surprised to see many connections drawn between these threads at the meeting.*

Like a good democracy, the only way to set it at work is to set it at work. Give the participants a chance to think about *all* these things in a compact span of time.

10-02-09 *Instance of James* (to R. W. Spekkens)

> Do you wish, like so many of my enemies, to force me to make the truth out of the reality itself? I cannot: the truth is something known, thought or said about the reality, and consequently numerically additional to it.
>
> — from Chap 15 of *The Meaning of Truth*

10-02-09 *Your Thesis* (to J. R. Gustafson)

Hans Christian von Baeyer has told me of your PhD thesis. If you have it in electronic form, may I ask you to email me a copy?

Hans Christian is taking on a project to potentially write a book (or at least some articles) on the Pauli-Fierz correspondence, and will be coming here to the Perimeter Institute to get started on the project next week. And I myself have had a long interest in Pauli (see for instance, my *Notes on a Paulian Idea*, posted at my webpage, which Cambridge U. Press will soon republish).

I think your thesis will be an invaluable resource for our discussions.

John's Reply

> By now I assume you have received the electronic copy of my Ph.D. thesis. I hope you find it helpful.
>
> Your request got me to pick up my thesis again and to think of unfinished business. Since you or Hans Christian von Baeyer are in a better position than I am to follow up on one of the unfinished activities, let me pass on to you that there is one source of Pauli materials likely remaining untapped … the 1300 or so Pauli dreams collected by Jung. Jung published only some of them (see for example Sir Herbert Read, Michael Fordham, and Gerhard Adler, ed., *The Collected Works of C. G. Jung, Vol. 12, Psychology and Alchemy* (London: Routledge & Kegan Paul Publihers, 1953). The rest may still remain in Jung's archives, perhaps in Switzerland. Since Jung excluded many of Pauli's dreams from publication because they might reveal the name of the author, and because Pauli often mentioned in his dreams "physics stuff," I think the unpublished dreams … if

they still exist ... might be excellent resources for deciphering a small part of the mind of Pauli. I thought I might pass this trivia on to you and ask you to forward it to H. C. von Baeyer.

11-02-09 *Invitation to Speak at University of Rochester* (to B. Weslake)

I remember you well. Congratulations on your position in Rochester.

And I'm flattered that you're discussing this Bayesian business. I want to encourage it!

I could give a talk on your March 25 slot if you'd like. The topic would be the attached paper. [See "Quantum-Bayesian Coherence," `arXiv:0906.2187v1`.] *Beware*, it is still under construction. In fact, it is far from complete (many of the main results are not in it yet, sections unfinished, tentative paragraphs, etc.), but it'll give you some sense of the topic. And if you guys are still in ongoing discussions on our Qubayesian point of view, it may help give some sense of the constructive side of the program (which isn't much revealed by my older papers).

I've marked my calendar, but be sure to remind me again anyway as the time draws nearer.

11-02-09 *The Still Way-Incomplete Paper* (to H. C. von Baeyer)

Well I didn't make much more progress on it since last writing you. It still has a long way to go—many of the main results are not in it yet, sections unfinished, tentative paragraphs, etc.—but I wanted to get it to you before your flight nonetheless, in case you might want something small to read.

Particularly with regard to our conversations this coming week, I plan to completely scrap the old ending of the paper and start over (that ending was from the preliminary version sent to a conference proceedings). The new, yet-to-be-written ending will make a transition from Peres to Pauli and have a discussion on the undetached observer.

Anyway, I just wanted to give you some sense of how this all fits together in my mind.

Hans's Reply, "Reaction," 13-02-09

> I'm in Toronto with the three most important volumes, so we'll have plenty of grist. Let the old mill grind!
>
> I read your paper on and between planes and like it very much. Here are a couple of reactions.
>
> Objectivity. This is a very heavily laden word and I wish we could get away from it. Intuitively it is defined mostly by its opposite — subjectivity. I notice that you have started using "personalized" as an alternative, and I'm not sure that's much better. A lot of resistance to the Bayesian view stems from the perception that it is solipsistic, and therefore not "objective."
>
> Pauli thought that q.m., which he believed to be all about information, is objective in the following sense: Once the observer has set up an experiment and has turned on the switch, it proceeds on its own without influence from his feelings or desires — unlike a poem or a work of art. This doesn't say much about the DESCRIPTION of an experiment, but he felt that he had to insist on the objectivity of physics.
>
> Examples. I would love to see some examples of simple phenomena, especially since you start with the double slit, and mock other text-book exercises. Those are

good rhetorical anchors, because all readers are familiar with them, but I would enjoy seeing you return to them and deal with them explicitly in your new language. (here is a reference to a recent paper of yours that might contain examples of descriptions starting with different priors.)

See you soon!

12-02-09 *On the Charge of "Bias"* (to N. D. Mermin)

Referee 1 wrote this:

> The paper is proselytizing a particular point of view, rather than drawing together different sources to provide an unbiased review (i.e. one which would discuss the pros and cons of this idea, and compare it seriously with other interpretations of QM.)

Referee 2 wrote this:

> The authors illustrate their main points with examples and a large number of (text) citations. They do this in such a strong manner that I felt they almost try to inculcate the reader with their viewpoint. In fact, the paper naturally touches on various philosophical aspects (such as the interpretation of quantum states), which are partly lacking a consensus in the scientific community. While the authors, of course, have a right to expose and justify their points of view (and, actually, do this in a very convincing way), I am not sure the style is appropriate for RMP.

With regard to 1, I thought, "Well yeah it's proselytizing, of course. Why should I bother to 'compare it seriously with other interpretations' when the whole point of all my papers is to show that a QBist-style interpretation—even without all the details hammered out—is simply natural, obvious, and should hit the reader over the head."

With regard to 2, I thought, "To justify one's points 'in a very convincing way' is inappropriate for RMP? What would you really want instead?"

Anyway, I expand on these initial thoughts, by quote my old friend Willy James from his lecture "The Types of Philosophic Thinking":

> What distinguishes a philosopher's truth is that it is reasoned. Argument, not supposition, must have put it in his possession. Common men find themselves inheriting their beliefs, they know not how. They jump into them with both feet, and stand there. Philosophers must do more; they must first get reason's license for them; and to the professional philosophic mind the operation of procuring the license is usually a thing of much more pith and moment than any particular beliefs to which the license may give the rights of access. Suppose, for example, that a philosopher believes in what is called free-will. That a common man alongside of him should also share that belief, possessing it by a sort of inborn intuition, does not endear the man to the philosopher at all-he may even be ashamed to be associated with such a man. What interests the philosopher is the particular premises on which the free-will he believes in is established, the sense in which it is taken, the objections it eludes, the difficulties it takes account of, in short the whole form and temper and manner and technical apparatus that goes with the belief in question. A philosopher across the way who should use the same technical apparatus, making the same distinctions, etc., but drawing opposite conclusions and denying free-will entirely, would fascinate the first philosopher far more than would the

> *naïf* co-believer. Their common technical interests would unite them more than their opposite conclusions separate them. Each would feel an essential consanguinity in the other, would think of him, write *at* him, care for his good opinion. The simple-minded believer in free-will would be disregarded by either. Neither as ally nor as opponent would his vote be counted.
>
> In a measure this is doubtless as it should be, but like all professionalism it can go to abusive extremes. The end is after all more than the way, in most things human, and forms and methods may easily frustrate their own purpose. The abuse of technicality is seen in the infrequency with which, in philosophical literature, metaphysical questions are discussed directly and on their own merits. Almost always they are handled as if through a heavy woolen curtain, the veil of previous philosophers' opinions. Alternatives are wrapped in proper names, as if it were indecent for a truth to go naked. The late Professor John Grote of Cambridge has some good remarks about this. 'Thought,' he says, 'is not a professional matter, not something for so-called philosophers only or for professed thinkers. The best philosopher is the man who can think most *simply*. ... I wish that people would consider that thought-and philosophy is no more than good and methodical thought-is a matter *intimate* to them, a portion of their real selves ... that they would *value* what they think, and be interested in it.... In my own opinion,' he goes on, 'there is something depressing in this weight of learning, with nothing that can come into one's mind but one is told, Oh, that is the opinion of such and such a person long ago. ... I can conceive of nothing more noxious for students than to get into the habit of saying to themselves about their ordinary philosophic thought, Oh, somebody must have thought it all before.' Yet this is the habit most encouraged at our seats of learning. You must tie your opinion to Aristotle's or Spinoza's; you must define it by its distance from Kant's; you must refute your rival's view by identifying it with Protagoras's. Thus does all spontaneity of thought, all freshness of conception, get destroyed. Everything you touch is shopworn. The over-technicality and consequent dreariness of the younger disciples at our American universities is appalling. It comes from too much following of German models and manners. Let me fervently express the hope that in this country you will hark back to the more humane English tradition. American students have to regain direct relations with our subject by painful individual effort in later life. Some of us have done so. Some of the younger ones, I fear, never will, so strong are the professional shop-habits already.
>
> In a subject like philosophy it is really fatal to lose connexion with the open air of human nature, and to think in terms of shop-tradition only. In Germany the forms are so professionalized that anybody who has gained a teaching chair and written a book, however distorted and eccentric, has the legal right to figure forever in the history of the subject like a fly in amber. All later comers have the duty of quoting him and measuring their opinions with his opinion. Such are the rules of the professorial game-they think and write from each other and for each other and at each other exclusively. With this exclusion of the open air all true perspective gets lost, extremes and oddities count as much as sanities, and command the same attention; and if by chance any one writes popularly and about results only, with his mind directly focussed on the subject, it is reckoned *oberflächliches zeug* and *ganz unwissenschaftlich*.

Rereading that passage, I think it gets to the point.

13-02-09 *It Wasn't Real Complex* (to R. W. Spekkens, L. Hardy, and R. Blume-Kohout)

Here's what I should have said yesterday. See attached. It's not hard to prove after all that there is no minimal informationally complete POVM for real Hilbert spaces that will give me my infamous diagram.

Suppose I want a map $\Phi : \mathcal{S}(\mathbb{R}^d) \longrightarrow \mathcal{S}(\mathbb{R}^d)$ of this form

$$\Phi(X) = \frac{1}{n}\sum_i \Pi_i X \Pi_i \;, \tag{89}$$

where $\mathcal{S}(\mathbb{R}^d)$ denotes the $\frac{1}{2}d(d+1)$-dimensional space of symmetric operators, the $\Pi_i = |\psi_i\rangle\langle\psi_i|$ are rank-1 projectors, and the set operators $E_i = \frac{1}{n}\Pi_i$ form a minimal informationally complete POVM. Then we must have

$$\frac{1}{n}\sum_{i=1}^{\frac{1}{2}d(d+1)} \Pi_i = I \;, \tag{90}$$

and consequently

$$n = \frac{2}{d+1} \;. \tag{91}$$

Furthermore suppose Φ has this characteristic

$$\Phi(\rho) = \alpha I + \beta\rho \tag{92}$$

for all density operators ρ. To be trace preserving,

$$\alpha d + \beta = 1 \;. \tag{93}$$

These are the properties needed to be able to draw the diagram I always draw and have the Born Rule interpretable as a simple modification of the law of total probability.

The question now is, are there any operators Π_i that can do this for me? Here's a way to see that there generally aren't. Let Φ act on one of the Π_k:

$$\frac{1}{n}\sum_i \Pi_i \Pi_k \Pi_i = \alpha I + \beta \Pi_k \;. \tag{94}$$

Since $\Pi_i\Pi_k\Pi_i = \mathrm{tr}(\Pi_i\Pi_k)\Pi_i$, it follows that we must have

$$(1-\alpha-n\beta)\Pi_k + \sum_{i\neq k}\Big(\mathrm{tr}(\Pi_i\Pi_k) - \alpha\Big)\Pi_i = 0 \;. \tag{95}$$

But the Π_i are linearly independent. Consequently, it is necessary that

$$\alpha + n\beta = 1 \tag{96}$$

and

$$\mathrm{tr}(\Pi_i\Pi_k) = \alpha \qquad \forall i \neq k \;. \tag{97}$$

That is, the E_i must form a SIC-POVM.

For real vector spaces, however, SIC-POVMs generally do not exist.

16-02-09 *The Historical Roots of Our SICs* (to D. M. Appleby and H. C. von Baeyer)

It's entirely appropriate that I came across this passage in the Atmanspacher and Primas article tonight:

> As a consequence of the non-conservation of parity, Pauli discovered a group of transformations relating left- and right-handed neutrinos and antineutrinos—the so-called Pauli group (Pauli 1957). In 1957, he started an initially enthusiastic collaboration with Heisenberg on his nonlinear spinor equation which should provide a unified description of all elementary particles. One reason for Pauli's excitement about this project was that this spinor equation was invariant under the Pauli group.

Pauli 1957: "On the conservation of the lepton charge," Nuovo Cimento **6**, 204–215.

17-02-09 *Historical Question* (to D. Gottesman)

I've got Marcus Appleby and Hans Christian von Baeyer here this week working on identifying the various notions at work in the phrase "detached observer" in the correspondence between Pauli, Fierz, and Bohr, and of course Marcus is always working on SICs. So I was delighted last night when I came across the funny little tidbit below, particularly upon learning that Pauli's interest in his failed "world theory" with Heisenberg centered on its invariance under the group. [See 16-02-09 note "The Historical Roots of Our SICs" to D. M. Appleby and H. C. von Baeyer.]

Anyway, completing the tale in my mind, leads in part to the following historical question. Who invented the phrase "generalized Pauli group"? Was it you? And its first use of the group in quantum information was you? Or Manny Knill? Or still someone else. Presumably it's also called Weyl-Heisenberg group because Weyl and Heisenberg used it. But I wonder if Heisenberg was post-Pauli in this case. (I think Weyl goes back to some discussion in his book on group theory and QM.)

For fun, it'd be nice to compile these facts.

17-02-09 *Dedication* (to A. Y. Khrennikov)

Thanks for all the patience with me in sending in the conference proceedings. In trying to make this one an important paper, I lost sight of my deadlines! So, I turned in what I could for the conference proceedings, and then decided to keep plugging away at the paper making a more complete version of it before posting on the archive. I'm still not finished!! But I did just write a little dedication to you on the front page on the still-incomplete draft. [See "Quantum-Bayesian Coherence," `arXiv:0906.2187v1`.] See footnote 1 in the attached:

> This is a much expanded version of a paper originally appearing as C. A. Fuchs and R. Schack, "From Quantum Interference to Bayesian Coherence and Back Round Again," in *Foundations of Probability and Physics – 5, Växjö, Sweden, 24–27 August 2008*, edited by L. Accardi, G. Adenier, C. A. Fuchs, G. Jaeger, A. Khrennikov, J. Å. Larsson, and S. Stenholm, AIP Conference Proceedings Vol. 1101, (American Institute of Physics, Melville, NY, 2009), pp. 260–279. Per always, we thank Andrei Khrennikov for organizing this wonderful series of meetings, which has been so instrumental in crystalizing our quantum-Bayesian thoughts.

It's heartfelt. These meetings have been very important for my thought. Hopefully I'll get the paper finalized and posted next week.

18-02-09 *Pop Culture* (to D. M. Appleby and H. C. von Baeyer)

"Reality is at the deepest level the response to the observer."

Just heard that on the CBC show "Being Erica" (a story about a woman whose psychologist keeps sending her back in time to revisit her past) in a small discussion about quantum mechanics.

18-02-09 *Saint of the Retort* (to H. C. von Baeyer)

Thanks for this!

Hans's Preply, "Augmented Index Entry," 18-02-09

I have found an important reference to the Detached Observer in Pauli's Kepler Study. Hence the new last item below:
Here is an entry for the (non-existent) subject index of *Wolfgang Pauli: Writings on Physics and Philosophy*, Enz and Meyenn, ed. (Springer 1994).

Detached Observer: pp. 23, 24, 33, 40, 43, 47, 122, 132, 134, 152, 260
Compiled by HvB

PS In 1953 Pauli wrote to Panofsky that he is trying to introduce the term "detached observer" (in English) to physics. Maybe we should give him a posthumous hand.

18-02-09 *Talk* (to A. Wilce)

Wilce-ism 7: *I suppose it's not too early to be thinking about what talk to give. Let me give you some choices, and ask you to tell me what's of most interest:*

(1) I could talk about my paper on formalism and interpretation – basically the same talk I gave in Jerusalem (though I think perhaps Jon has given a similar talk in the last year or so);

(2) I could talk about an axiomatization of QM by way of the characterization of homogeneous self-dual cones (the notes I sent you before Christmas);

(3) I could give a slightly updated version of the talk I gave in Obergurgl (adding some remarks making contact with Lucien's axioms).

Let me know what sounds good.

(1)!! (If it's the one to do with Everett potentially being contentless.)

Alex's Reply

Below are two different abstracts for more-or-less the same talk, emphasizing different aspects thereof. Let me know which one you like better, and I'll send it along to Karen.

Title:
Entanglement and measurement in general probabilistic theories.

Abstract:
Quantum mechanics is a non-classical probability theory, but hardly the most general one imaginable: any compact convex set can serve as the state space for an abstract probabilistic model (classical models corresponding to simplices). From this altitude, one sees that many phenomena commonly regarded as "characteristically quantum" are in fact generically "non-classical". In this talk, I'll show that almost any non-classical probabilistic theory shares with quantum mechanics a notion of entanglement and, with this, a version of the so-called measurement problem. I'll then discuss what's required for an abstract probabilistic theory to admit a somewhat simplified version of Everett's response to this problem – an exercise that turns out to be instructive in several ways.

Title:
Measurement dynamics in general probabilistic theories.

Abstract:
One can view quantum mechanics as a dynamical theory with a familiar mathematical apparatus, but a mysterious probabilistic interpretation, seemingly incompatible with the dynamics. Alternatively, one can view QM as a probabilistic theory with a more or less standard interpretation, but a mysterious formal apparatus, badly under-determined by that interpretation. In this talk, I'll try to take both of these complementary points of view at once, by asking what's required for a general (non-classical) probabilistic theory to support a minimally reasonable measurement dynamics – an exercise that turns out to be instructive in several ways.

19-02-09 *Transcript from "Being Erica"* (to D. M. Appleby and H. C. von Baeyer)

A more accurate transcript from last night's episode . . .

Erica: Here I am trying to relive the perfect day and I can't. Because every time something changes, even if it's a little bit, I freak out.

Dr. Tom: Yeah. (Picking up a leaf from the ground.) Quantum mechanics. You see, we can never know with any kind of certainty how an atom will behave naturally. (Pointing to the leaf.) Because the very instant that we look at an atom we alter it. The very act of looking is never a passive thing. It has an effect. In fact physicists tell us that reality at its deepest level is the response of the observer. You know, it's kind of like you reliving past events.

21-02-09 *PhD Acquired* (to G. Plunk)

Plunkism 7: *I just defended my thesis successfully at UCLA and wanted to announce this to the people who were especially influential along the way. I just wanted to let you know that the path of research that you launched me on in the summer of 2002 has concluded well! I have taken a post-doctoral job at the University of Maryland and expect that I will stay in theoretical physics for the long haul.*

That's excellent news! Congratulations. I hope you like College Park. I'll be there next Friday and Saturday for an APS meeting.

Funny coincidence you would write me now. Just the other day, I started working on a section of the paper (that I'm presently constructing) that makes use of one of your results from our summer together. See Section 5.3, page 23, of the present draft attached. [See "Quantum-Bayesian Coherence," `arXiv:0906.2187v1`.] Too bad the paper's not completed yet, so that I could have replied with an even more forceful "funny coincidence"!

Take care.

22-02-09 *James, Gustafson, and the Urungleichung* (to D. M. Appleby)

Applebyism 28: *I have been reading Gustafson, and the following passage struck me. I am not sure if it bears on this afternoon's discussion, but I feel it might do. Anyway, I thought it worth recording the point before I forgot it.*

On p. 58 Gustafson says this:

Walter Moore, in describing Schrödinger's renunciation of Mach's philosophy, could also have been describing Pauli's:

> There are a number of fairly obvious defects in presentational phenomenalism [positivism]. For instance, it fails to explain the close relationship between mathematical reasoning and theoretical physics; mathematical operations and symbols do not denote empirical sensations, and yet one cannot do science without them. Also, experiments are planned interactions of the scientist with the environment; how can they be explained as mere collections of sensations? Mach fails to explain the enormous predictive power of physical theories; how can it be that [Paul A. M.] Dirac predicts a positive electron and [Carl David] Anderson finds it in a cloud chamber?

Pauli would become fascinated with the deep meaning of mathematical symbols. His "mind's eye" was opened through his explorations of complex numbers, Maxwell's equations, and special-relativity transformations.

I think this is a fair description of the way Pauli felt—i.e. a fair description of the way in which Pauli was definitely not an empiricist (a Platonist even, I think I have seen it said). But be that as it may. The reason I am citing it is not that, but its bearing on what you said about James's belief that relations are part of experience. Could we say that the word "relations", as used by James, includes mathematical relations?

I think James would include mathematical relations as well, insofar or to the extent they are part of experience.

22-02-09 *The Shape of Hilbert Space* (to G. L. Comer)

Comerism 22: *One question: should I prepare for terabytes of musings on a Feynmanian Idea?*

Nope. Just Jamesian ones. I had a new epiphany at the beginning of the year, and I've been gearing up to write a lot again. Wheeler's "elementary quantum phenomenon" IS a modern, precisified version of James's "pure experience"—I get it now after all these years. So I REALLY MUST get *My Struggles with the Block Universe* on the archive this Spring and then start a new chapter. When the real conclusion of the present paper is written (I'm scrapping the old conclusion), it'll allude to some of that.

24-02-09 *Good Thinking* (to R. Schack)

Do you have a complete reference on I. J. Good's article on the number of kinds of Bayesian? It is driving me crazy that I have not been able to find it on the web.

24-02-09 *HCvB and CAF* (to H. C. von Baeyer)

I would be honored to write something with you. I agree with your assessment, only too bad we didn't have it ready to go by mid-December '08! If it remains OK with you, I would expect my participation to be somewhere neutrally (appropriately) between "by me with your help" and "jointly". I.e., you could take the lead, and I would try to be constructive from the side at first, but becoming more involved as more structure starts to arise. Furthermore, as a point of personal policy for me this time around, you would not find me insisting on idiosyncratic terms like "imprimatur," etc! I will be very happy to see something of good substance get out into the airwaves, and I can't really see how to do that without your being at the helm.

Perhaps the only sensitive issue I foresee at the moment is the desire to "tie cautiously into the science/religion debate." You can probably already sense I would want to be very cautious with that. But I also feel that something should be said about the humanistic side of physics—so there is definitely room for negotiation here.

I feel like I will learn a lot with this project. Certainly I learned very, very much from my effort with Asher on the *Physics Today* piece. Somehow in my mind, this will be a bit like that: A great opportunity to crystallize thought.

I hope your cold goes away soon. Marcus and I spent yesterday x'ing and testing things on the computer. We discovered that apparently the conditions arising from the urungleichung also imply $0 \le \mathrm{tr}\rho^3 \le 1$. (We haven't shown it yet; it's only numerical at this stage.) This inequality is still not full quantum state space, but it is a little closer. I.e., another piece of evidence that if we keep squeezing on the urungleichung, eventually the full condition on quantum state space will indeed pop out.

Hans's Preply, "The Detached Observer," 24-02-09

> I am working on the essay for home use that I began at PI. In addition, though, I want to reply to your remark that I should consider publishing something.
>
> An article about the DO at the level of AJP sounds very appropriate. It would be a fine tribute to Pauli 50 years after his death, it would be good PR for Bayesians, and it would tie cautiously into the science/religion debate. It would talk about the classical DO, about Pauli's quantum mechanical NDO, about your effort to define and quantify the NDO in the language of information, and finally about Pauli's unfulfilled dreams of pushing the NDO toward a more neutral language.
>
> Such an article could be written by you, by me with your help, or jointly. Since you are the senior partner in this effort (my grey locks notwithstanding) I would like to ask you to choose among these three options. I am totally happy with each one!
>
> Unfortunately I brought home from Waterloo not Marcus's cold, but the Canadian arctic cold!

4. The non-detached observer in quantum mechanics and the dispute with Bohr
5. The non-detached observer of the future

Nomenclature

According to von Meyenn, the phrase *detached observer* (DO) first appeared in February 1949, in a lecture on complementarity in Zurich.[175] The first mention in the letters seems to be in January 1951.[176] The German version is *losgelšter Beobachter*, which Pauli explicitly translates as *detached observer*.[177] (He also used *abgekapselter Beobachter*,[178] meaning an *encapsulated observer*, and once he wrote the English phrase *loose and untied observer*[179].) Bohr, in German, used *aussenstehender Beobachter*,[180] or *observer standing outside*. In French Pauli liked *observateur détaché*.[181] In the English translation of the essays there are 11 references to DO,[182] in the letters many more. In 1953 Pauli remarks that he has tried several times to introduce the DO into physics.[183] In 1956 he notes that following his dispute with Bohr about the use of the phrase DO neither he nor Bohr ever used it again in print.[184]

It would be useful to find a compelling antonym for DO. Pauli used *non-detached observer*[185] once, and *miteinbezogener Beobachter*[186] several times. The latter adjective can be translated as *involved* or *included (in the description of the phenomenon)*; the term *bezogen* means *related*. Fuchs uses *activating*. Other suggestions include *attached, active, bound, participating, linked, joined, entangled, enmeshed*. In this essay we stick to *non-detached observer* (NDO).

The only antonym I have found is *non-detached observer*[187] (NDO).

Commentaries

Folse[188] comments on the DO, but von Meyenn does not believe that Folse has fully understood Pauli.[189] Gieser devotes five pages to the DO.[190] Enz comments on the DO in his biographical sketch.[191] The editorial apparatus of the letters includes numerous footnotes about the DO.[192]

The classical detached observer

Pauli defined the DO in virtually identical words in his 1949 lecture on Complementarity and his 1952 essay on Kepler,[193] which was published in a book co-authored by Jung: "… [T]here is a basic difference between the observers, or instruments of observation, which must be taken into consideration by modern microphysics, and the detached observer of classical physics. By the latter I mean one who is not necessarily without effect on the system observed but whose influence can always be eliminated by determinable corrections."

The DO serves to characterize classical physics. Einstein claimed: "There is such a thing a the real state of a physical system, which exists objectively, independently of any observation or measurement, and can in principle be described by the modes of expression used in physics."[194] Pauli calls this point of view the *ideal of the detached observer* and points out that it is only one special form of physics. Indeed, "this ideal is now revealed as a special case of more general possibilities of explaining nature."[195]

Heisenberg calls "the idea of an objectively real world, whose smallest parts exist objectively in the same way as stones and tree, independently of whether we observe them or not," the *ontology of materialism*. Pauli prefers to call the same idea the *ideal of the detached observer*, pointing out that the fundamental elements of the real world might be, for example, fields, which don't resemble stones and trees and are not "small."[196]

Fierz uses the DO in his definition of absolute space: "… I believe that absolute space is appropriate for classical physics. The *classical objective real world*, which I like to call *the absolute world* because it is detached from the observer, is located in absolute space. This space is absolute because it is independent of the physical reality that fills it."[197]

The non-detached observer in quantum mechanics and the dispute with Bohr

I will examine the NDO with particular reference to two sources — the essays in which it was first introduced,[198] and the final epistolatory exchange with Bohr.[199] In the case of the Kepler essay, Pauli's tireless exchanges with Panofsky concerning the translation into English bear witness to the pains he took to explain himself precisely. Later, in the Bohr letters, he writes explicitly: "I shall try to make my point logically clear, by defining my concepts, replacing hereby the disputed phrase by other words." Other references in the letters and essays serve as glosses on these two primary sources. An advantage for anglophones is that the essays have been translated, and the Bohr letters were written English.

In passing from the classical DO to the quantum mechanical NDO a complication arises. The context of the DO has two parts depicted as (*system* | *observer*). The context of the NDO, on the other hand, is tripartite: (*system* | *instruments* | *observer*).

[193] [B] p. 40 and p. 260. The latter version is more grammatical.
[194] [B] p. 47.
[195] [A] vol. IV part II p. 149.
[196] [A] vol. IV part III, p. 121.
[197] [A] vol. IV part I p. 383.
[198] Cf. footnote 193
[199] [A] letters [2015] and [2041] from Pauli, [2035] and [2047] from Bohr.

Later in this essay, the first of the two vertical lines will be referred to as the "Pauli cut" and the second one as the "Bohr cut."

The first definition of the NDO read: "In microphysics ... every observation is an interference of indeterminable extent, both with the instruments of observation and with the observed system, and interrupts the causal connection between phenomena preceding and subsequent to it ... In this sense we may say that irrationality presents itself to the modern physicist in the shape of selecting (auswählende) observation." A footnote refers to the technical elaboration of this process in the "reduction of wave packets."

The second definition adds, implicitly, the element of *information*: "In microphysics ... the natural laws are of such a kind that every bit of knowledge gained from a measurement must be paid for by the loss of other, complementary items of knowledge. Every observation, therefore, interferes on an indeterminable scale both with the instruments of observation and with system observed and interrupts the causal connection of the phenomena preceding it with those following it."

24-02-09 *First Consequences of Our Conversation* (to H. C. von Baeyer and D. M. Appleby)

Since our conversations last week, I have not been able to shake the nasty feeling of the complete sterility of what Huw Price, Harvey Brown, Rob Spekkens, Daniel Dennett, and others in that lot think of when they say the word "reality." Marcus's displays of disgust have been quite contagious to me! So I couldn't quite contain myself today as I was improving and polishing my Introduction for the "Coherence" paper. You'll see what I mean if you look at the last paragraph of Section 1, attached. Now I have to hope that the concluding section (not written yet) can live up to the expectations I plant there!

> Finally with Section 7 we close the paper by discussing how our work is still far from done: Hilbert space, from a quantum-Bayesian view, has not yet been derived, only indicated. Nonetheless the progress made here gives us hope that we are inching our way forward to a formal expression of the ontology underlying a quantum-Bayesian vision of quantum mechanics: It really does have to do with the Peres slogan, but tempered with a kind of 'realism' that Peres would probably not have accepted forthrightly. On the other hand, it is not a 'realism' we expect to be immediately accepted by most modern philosophers of science either. (See Footnote 2 and Ref. [50, Sec. 4.1] for a sampling of relevant instances of opposition, and Refs. [63, 64, 65] for the vision more generally.) Part of what must go is the ontology of the block universe [66, 67, 68], as well as the ontology of the 'detached observer' [69, 70]. The 'realism' of the standard vogue is too narrow a concept to be used for our purposes. Reality, the stuff of which the world is made, the stuff that was here before agents and observers, the stuff that prevents us from vanishing in a dream—it strikes us—is more interesting than that.

24-02-09 *Good Thinking* (to W. C. Myrvold)

Do you have a complete reference on I. J. Good's article on the number of kinds of Bayesianism? It is driving me crazy that I have not been able to find it on the web.

Wayne's Reply

Attached:

i) Original publication, as a letter to the editor of *The American Statistician*.

ii) Scan of reprint in *Good Thinking*, which (I think) I got from Branden Fitelson's web site, together with an article in which the categories are explained more fully.

25-02-09 *Undetachedly Denigrating Chance* (to H. C. von Baeyer)

I think the 13 October 1951 letter from Pauli to Fierz is one we'll want to get straight translation-wise. I was apprised of it from Laurikainen's *Beyond the Atom*, pp. 196–197.

Compare Pauli to the three paragraphs below Eq. (1) in the CFS paper `quant-ph/0608190`:

> Within the context of experimental situations with large sample sizes, where Bayesian updating leads to similar posteriors for exchangeable priors, the geometric analogy, combined with the Principal Principle to connect chance with probability, would appear to work quite well. This gives rise to the idea that the Principal Principle accounts for the concept of objective chance in physics. However, from a Bayesian perspective, the introduction of chance is completely unmotivated. More urgently, in those cases where the idea is not already fraught with obvious difficulties, it serves no role that Bayesian probability itself cannot handle.
>
> To illustrate one such difficulty, return to the coin-tossing example discussed above, and assume that there is an objective chance q that a coin-tossing event will produce Heads. As we have seen in the discussion above, the chance cannot be deduced from physical properties of the coin alone, because the probability of Heads also depends on initial conditions and perhaps other factors. An advocate of objective chance is forced to say that the chance is a property of the entire "chance situation," including the initial conditions and any other relevant factors. Yet a sufficiently precise specification of these factors would determine the outcome, leaving no chance at all. The circumstances of successive tosses must be different to give rise to chance, but if chance aspires to objectivity, the circumstances must also be the same. Different, but the same—there is no way out of this conundrum as long as objective and chance are forced to co-exist in a single phrase. Subjective probabilities easily dispense with this conundrum by maintaining the category distinction. The differences between successive trials are differences in the objective facts of the initial conditions; the sameness is an agent's judgment that he cannot discern the differences in initial conditions and thus assigns the same probability to every trial.
>
> But what of probabilities in quantum mechanics? Given the last paragraph, one might well think—and many have thought—there is something different going on in the quantum case. For, in repeating a preparation of a pure state $|\psi\rangle$, aren't all the conditions of preparation the same by definition? Any subsequent probabilities for measurement outcomes will then be determined by applying the Born rule to $|\psi\rangle$. They are not subjective probabilities that come about by an inability to take all circumstances into account. Thus quantum states (and hence quantum "chances") are objective after all, and the Principal Principle is just the kind of thing needed to connect these quantum chances to an agent's subjective probabilities—or so a very beguiling account might run.

(At that stage in his thinking at least) Pauli seems to get round our "different, but same" conundrum by saying the difference is the observer: He ain't detached. No two "identical" experiments are the same, because no two observers are the same. Another way to say it is, there is an extra index around, and that index is the observer himself.

Hans's Reply, "The Same and Not the Same," 26-02-09

I don't have Laurikainen's book. Here's the context. I will of course be happy to refine, expand, and revise as needed.

The same and not the same

[Square brackets enclose my comments.]

From the letter of Pauli to Fierz, dated 13 October 1951, number 1289 of Pauli's Scientific Correspondence:

In part 1 of the letter Pauli, in an irritated tone, corrects Fierz's alleged misunderstandings of general relativity.

In part 2 he refers back to the natural philosophy of the Italian Renaissance. (cf. Atmanspacher, Primas, & Wertenschlag 1995 p. 242 ff). Then:

"The *anima mundi* [world soul], which was also an *anima movens* [motion causing soul] belonged necessarily to the Neoplatonism of the Renaissance (cf. Ficino). Every planet had its individual soul, but how did these relate to each other: spiritually, via the *anima mundi*, of which they are a part. (N.B. I see Mr. Fludd immediately wrinkling his brow at the mention of "part' — so let's say, for his sake: via the *anima mundi*, with which the individual souls are identical, insofar as they belong to the light principle.)

But in the 17th century the *anima mundi* went out of fashion — the idea *paled*. (I would happily learn the attitude of your epigone Henry More and his circle toward this idea — what kind of a Neoplatonism is that, anyhow, *without* the anima mundi?) And exactly through the resulting gap, proportion, geometry, mathematics pushed into the ideas about motion, and pushed toward empiricism, toward measurement. One sees this process clearly not only in Kepler, but also in Galileo. The latter *rejected* not only the Aristotelian-Peripatetic tradition, but also *Neoplatonism*, including the anima mundi, and referred back the *Pythagoreans and to Plato himself.* ("The more ancient is always the new!")

But with this progress (analytic geometry, Newtonian mechanics), space moved up to the Olympus of the Absolute and the relationship between soul and matter became a special problem which vanished in the twilight of "parallelism", just as Venus vanishes in the morning twilight.

But now we seem to be beginning to suffer from the fact that one went too far in the 17th century (cf. my Kepler study) and from then come "revenants" that haunt me during the night, and occasionally also during the day — the way Venus returns as evening star. [Pauli's footnote: I believe that *every* addition to consciousness proceeds in such a way that something which was previously conscious disappears into the unconscious, and returns much later. That's what I want to express with the image of Venus, and also with the maxim: "The more ancient is always the new!"] When something becomes invisible, it still endures and remains effective. General relativity has brought back, in its space-time rippled by matter, the idea attributed to the Peripatetics, of the physical quality of space points (places) — in the transmuted form of the g_{ik} field (even if g.r. couldn't bring back the entire *horror vacui*!)"

Part 3 "Now comes the great crisis of the quantum of action: one has to sacrifice the unique case [or event] and its "meaning", in order to save an objective and rational description of the phenomena. When two observers do the same thing it is really even physically no longer the same thing; in general only the *statistical averages* remain the same. *The physically unique can no longer be detached from the observer* — and therefore slips through the net of physics. The unique case is *occasio* [opportunity, the fleeting moment] and not *causa* [cause, of which there are 32 varieties in philosophy]. I am inclined to see in "occasio" — which includes the observer and his choice of the experimental arrangement — a "revenant" (of course in "transformed form") of the *anima mundi* that was repressed in the 17th century. La donna é mobile [the lady is fickle] — including the *anima mundi* and the *occasio*.

Something has remained open here, which formerly seemed closed, and my hope is that through this gap *new concepts* will penetrate in place of "parallelism", concepts which should be uniformly physical and psychological simultaneously. May a "happier progeny" achieve this."

Part 3 then concludes by saying that the concept of *archetype* does not have the right attributes for this purpose, because it cannot be applied naturally to atomic physics. Maybe *automorphism* will work.

Part 4 praises Fierz's proposal to divide every quaternity into two pairs of opposites: one compensatory labeled + and −, and one complementary labeled p and q. This scheme yields four elements $+p$, $-p$, $+q$ and $-q$.

25-02-09 *Image of Occasio* (to H. C. von Baeyer)

See

`http://web.archive.org/web/20110704222210/http://www.iisg.nl/occasio/occasio-image.php`,

where it is written:

> The image of Occasio is taken from a work by famous Czech philosopher and pedagogue Johan Amos Comenius (Moravia 1592 – Amsterdam 1670), the *Orbis sensualium pictus* (1658). The book contains pictures with text in Latin and the vernacular, and was intended for teaching. Occasio is the Opportunity we must seize before it flies away and vanishes: "*Occasioni (quae, fronte capillata sed vertice calva, ad hoc alata facile elabitur) attendit captatque eam*", or, "She watches Opportunity (which, having a forelock but being bald at the back of its head and being winged, escapes easily) and seizes it." "She" is Prudentia, looking at the past with one of her two faces and at the future with the other. Occasio was chosen by Tjebbe van Tijen as an emblem appropriate for a project aiming to archive such volatile materials as Internet documents. An other image of Occasio can be found at Alciato Emblem 122 (Latin) from the 1621 edition of Andrea Alciato's *Book of Emblems*. See also Prudentia, from *Comenius Orbis Sensualium Pictus* at the Universidad Nacional de Educación a Distancia.

26-02-09 *Undetachedly Denigrating Chance, 2* (to H. C. von Baeyer)

Thanks. Here was Laurikainen's translation of the part of "The same and not the same":

> Now there comes the major crisis of the quantum of action: one has to sacrifice the unique individual and the "sense" of it in order to save an objective and rational description of the phenomena. If two observers do the same thing even physically it is, indeed, really no longer the same: only the *statistical averages* remain, in general, the same. *The physically unique individual is no longer separable from the observer*—and for this reason it goes through the meshes of the net of physics. The individual case is *occasio* and not *causa*. I am inclined to see in this *occasio* which includes within itself the observer and the selection of the experimental procedure which he has hit upon—a revenue of the *anima mundi* which was pushed aside in the seventeenth century (naturally "in an altered form"). La donna è mobile—so are the *anima mundi* and the *occasio*.

Your word revenant is certainly better than his revenue.

I've been Pauli'ing most of the day when not talking to drivers. I'm finding I really enjoy Gieser's book, though I'm only 43 pages into it.

Hans's Reply

> "Unique individual" sounds like a person, which is wrong. The original is "das Einmalige." This word has a sense of being unique in space and time — "something that occurs only once". In relativity it is called an event, and since Pauli has just mentioned GR this might be an appropriate word.

27-02-09 *Vivienne and the Universe* (to L. Hardy and V. Hardy)

How tickled I was this morning to awake in this lonely Washington hotel to find an announcement of Vivienne's birth. And what a name! One that means being alive itself. My thoughts of course wandered to my favorite vision for an ontology of this world we live in—that the big bang is here and now, everywhere, being the sum total of all acts of creation. I hope that one day Vivienne will come to understand how deep her role goes in the vast order of things.

Please let me offer her this little passage from William James to commemorate the occasion:

> Lotze has in several places made a deep suggestion. We naively assume, he says, a relation between reality and our minds which may be just the opposite of the true one. Reality, we naturally think, stands ready-made and complete, and our intellects supervene with the one simple duty of describing it as it is already. But may not our descriptions, Lotze asks, be themselves important additions to reality? And may not previous reality itself be there, far less for the purpose of reappearing unaltered in our knowledge, than for the very purpose of stimulating our minds to such additions as shall enhance the universe's total value. 'Die Erhoehung des vorgefundenen daseins' ['the enhancement of what is found to exist.'] is a phrase used by Professor Eucken somewhere, which reminds one of this suggestion by the great Lotze.

Congratulations to both of you, and congratulations especially to Vivienne!

02-03-09 *Getting Facts Straight* (to D. C. Cassidy)

It was good meeting you Saturday. I was grateful for the accident that brought me to your table! I meant what I said about your book: I loved it. I read it about the same time as Moore's biography of Schrödinger, and there was no comparison.

I'd like to make sure I get the facts straight about von Meyenn. Would you mind saying everything again, but this time in email. A) Is his biography of Pauli actually finished, or is it something he is writing on? More importantly, B) please repeat what you said about the delay in the Briefwechsel project. Is it that Springer lost patience with him? Or simply that they're not foreseeing a sufficient $$ return on the project to go another volume? It frightens me immensely that this project might slip into oblivion: I have a vested interest in this side of Pauli (for various lines of research it might inspire in quantum foundations), and I would like to get oriented on how I might help.

In case you're interested, you might peruse my book *Notes on a Paulian Idea* to see why I believe these more private matters of Pauli can have an impact on the technical side of physics. It's the third item down on my webpage. (It was previously published by a small university press; but I just learned this weekend that Cambridge U. Press will be reissuing it soon with the title *Coming of Age with Quantum Information: Notes on a Paulian Idea*.)

Thanks for your help.

03-03-09 *Dates* (to R. Schack)

Schackcosm 111 : *Very provisionally, would this work: after Växjö, you come to Egham, we drive to Hay-on-Wye, then we both fly to Perimeter, where I stay for two weeks.*

That arrangement sounds perfect from my perspective. We'd have a nice continuous time to really get some things thought out.

Schackcosm 112 : *If I want to find out how James overcame the Miller-Bode objection, i.e., how he solved the problem of two observers, where would I look?*

Here's what Lamberth says in his (excellent) book *William James and the Metaphysics of Experience*:

> When James unveiled his radical empiricism in the 1904-5 *Journal of Philosophy* "series," both the issue of the compounding of consciousness and the related problem of solipsism (or of direct realism and a shared world) were on his mind. "Does Consciousness Exist?" goes straight to the issue of the compounding of consciousness, as well as James's direct epistemological view, while "The Thing and its Relations" and "How Two Minds Can Know One Thing" pursue the philosophical issues that I am construing broadly as having to do with co-consciousness or a shared world. That James himself remained unsatisfied with the position in those articles, however, is clear from the notebooks he kept between 1905 and 1908 on Dickinson Miller's and B. H. Bode's objections to his articles on radical empiricism.

So, those three articles are places for you to start, and they can be found on the web. Unfortunately, I don't yet have the book *Manuscript Essays and Notes* which contains the spoken-of notebook. What I suspect is that this is an issue we're going to have to ultimately work out for ourselves—those old notebooks, when dug up, will only get us so far. Still I'll have them waiting here when you arrive.

05-03-09 *Graduate Openings* (to M. A. Graydon)

All commendable answers. Sorry to pry like that. I'm feeling pretty comfortable with my inclination of decision. I hope you'll join the effort here: I think we can make some great progress getting quantum mechanics sorted out. And I'm quite sympathetic to one of the lines in your statement of interest: What we want in this quantum foundations game is to get at a clear-cut description of the reality underlying quantum mechanics. The quantum-Bayesian approach is an oblique approach (because it takes as its starting point agents and decisions), but it is a firm and careful approach: The ultimate residue will be the reality itself, whatever it is.

I think I have two very good other students lined up as well, along with a postdoc. We could make a great team. I'm going to work to get everyone in the team some desk space at the Perimeter Institute, for much easier interaction.

Attached is a still further improved version of the paper. See Eq. (44) describing unitary time evolution: I hope it'll knock your socks off. [See "Quantum-Bayesian Coherence," `arXiv:0906.2187v1`.]

07-03-09 *The Beautiful Shape* (to D. M. Appleby, cc H. C. von Baeyer)

Thanks for the alternate proof of Tommy. Åsa Ericsson and I discussed Tommy a lot yesterday—she's just moved to Waterloo—and so I forwarded her the note. Hope you don't mind. I'm trying to get her in the thick middle of this problem.

Let me tell you and Hans a story.

Yesterday as I was parking the car, Katie asked me, "What's your favorite color?" "Blue," I said, as if she hadn't already heard the same answer a thousand times before. But then she asked me something she's never asked, "What's your favorite shape?" I was just about to say "ball" when I caught myself. "What a wonderful question Katie! My favorite shape is Hilbert space; I've never told you that." She said, "What does it look like?" I said, "I can't tell you yet, because we're still trying to figure it out. That's what I work on every day at PI." "If you don't know what it looks like, how do you know you like it?" "Because it's a beautiful shape, the most beautiful shape ever. That much we can already tell!" She looked perplexed; I came away delighted.

If Pauli is right, that shape must already be in our archetypes. On this rainy grey Saturday, I think I'll sit down with a book I ran across in DC the other day. The title is *Robert Fludd* and its back cover says, "All Fludd's important plates are collected here for the first time, annotated and explained ..." Maybe that's another way to look for our lovely, but still hidden shape.

09-03-09 *The Beautiful Shape, 2* (to D. M. Appleby, cc H. C. von Baeyer)

Regarding:

Applebyism 29: *I am slightly puzzled, though, because the thoughts in your note (the beauty of the hidden shape, and the idea that it is already there in our archetypes) are, to my way of thinking, decidedly Platonic in character. ... I have had the impression that you didn't wish to go down that path*

It is a bit like the story of Niels Bohr's horseshoe. Upon seeing it hanging over a doorway someone said, "But Niels, I thought you didn't believe horseshoes could bring good luck." Bohr replied, "They say it works even if you don't believe."

Yes, you have read me correctly in the past. Saturday's note was mostly a reflection of my wispy mood of the moment. But you've caused me to reflect. Perhaps my flipping through the Fludd book was more akin to this. With the warmer weather, Kiki has started to dream of what she will do with the porch, whether she'll put rocking chairs on it, a table, what kind of table, where they'll be placed, things like that. But in her inability to act (the weather is not that warm yet), she's lately taken to looking through catalogs for quite long lengths of time. She's not doing it, however, to buy anything—just to get ideas, she says. I think she uses the catalogs mainly to stimulate the right parts of her brain. And now come to think of it, maybe the monkey in me was doing the same. Kiki had been looking at catalogs all afternoon, and at some level I fell in line with her: I reached for the closest thing I had to a catalog.

The book I have is this one: `http://www.amazon.com/Robert-Fludd-Hermetic-Philosopher-Surveyor/dp/0933999690/ref=pd_bbs_sr_2?ie=UTF8&s=books&qid=1236592436&sr=8-2`.

There's all sorts of wonderful pictures in there, even ones with decidedly SICish features: a seven pointed rose, a tetragrammaton, or, say, this one `http://data5.blog.de/media/739/3229739_d0eb33369c_m.jpeg` which evokes in me a whiff of the urungleichung. But as you've told me with the *I Ching*, one cannot force these things. And in my looking, I have the overwhelming feeling that I'm probably forcing these interpretations.

Marcus's Reply

The link to amazon didn't work for some reason. And when I did a search on Amazon for Robert Fludd it came up with a long list (rather to my surprise: I hadn't realized he was so well known). Is the book you are talking about the one by Joscelyn Godwin?

Anyway, Plato. I wanted to write at length, but I have had an enormous number of distractions today. I have done nothing since lunch-time, and I badly want to get back to the calculation I was doing. So I hope you will forgive me if I am a little brief.

But yes, the word "wispy" would describe my own state of mind when I use the word "Platonic". I don't really know, with any exactitude, what I mean by it. Just that there is something there which feels right, and which I feel needs development. Badly needs, in fact. Plato, the man, is not too important really. What is important is that I strongly feel that there is something there (I am not sure what exactly, but something) that matters, and which is being ignored in the current climate. In my mind this is all tied up with our discussions about Pauli. In fact I am pretty sure I have seen Pauli described as a Platonist (though I can't remember by whom).

When we were talking once you said something (again, I can't remember what exactly) which suggested that in your mind Platonism was all tied up with the block universe. I think you were thinking that the Platonic archetypes are something immutable. But immutability is certainly not the point for me. For me the word "Platonism" has no such connotation.

Rather "Platonism" (as I use the word) has to do with the connection between the inner and the outer. The idea of people like Popper is that physics progresses in two stages. First one guesses a hypothesis (Popper uses the word "conjecture"), and then one tests it. Philosophers of science focus on the second stage: testing hypotheses. But to my mind the really interesting, and by far the most important part is the process by which one comes up with the hypothesis in the first place. Testing hypotheses is a non-trivial activity. But it hardly takes genius. Whereas I think it does take genius to think of the hypothesis. At least it does if the hypothesis has any depth to it. If, for example, it is like Faraday's hypothesis of field lines, or Kepler's hypothesis of elliptical orbits.

I should explain that I am using the word "genius" in what I believe is the correct sense, which differs significantly from what has become the usual sense. Nowadays the word "genius" means an extremely intelligent person. But originally it meant something quite different: a guiding or tutelary spirit (according to Wikipedia). I think I have also seen it described as a "fertile spirit". At any rate a genius, in the original sense of the word, is not a person. Genius isn't something anyone can *be*. It is something one can *have* ("have" in the sense one can *have* a daughter, or a father, or a friend) (and just as one can't own a daughter, or a father, or a friend, so one cannot own genius) (if anyone—anyone at all, Einstein and Faraday not excluded—has the temerity to think they own their genius—has the arrogance to identify themselves with their genius—they will surely and deservedly lose it). I think this is a very important distinction. The point is not that Faraday or Einstein were especially intelligent people. Doubtless they were above averagely smart. But I would question whether they were so much more smart than lots of other people, whom no one now remembers. I don't think smartness is the point about someone like Faraday. Rather it is the fact that Faraday was somehow communicating with something in the depths of his soul. And, what is more, something maybe not all that personal to Faraday. Something, in short, for which the word "genius", in the old sense, seems appropriate.

And that is what Platonism means to me. It is the idea that the sources of science are as much internal as external. Science, as practiced by a man like Faraday, isn't just a matter of taking careful note of data coming in through the external senses. It is also, and perhaps even more importantly, a matter of listening to something located deep down in his own inner being.

That is also the point about archetypes, as I understand them. And I feel that you had in mind something similar in the note you sent me about the beautiful shape.

10-03-09 *Vienna Saturday Afternoon (9 years later)* (to Å. Ericsson)

I wanted to say thanks for yesterday, for your commentary on my paper: It will help me improve it. So, please don't stop if you've got a mind to keep going. Attached is the latest version. It still hasn't incorporated most of yesterday's comments, but I hope to address that soon. In any case, it already incorporates a "thanks" to you!

This morning I was looking through my files for stuff on an old summer student, and I ran across the note below from December 2000. Look how excited I was about an idea of mine. In the end, there was a fundamental flaw in the approach I was taking. But notice the similarity between my phrases below and the things I say in Section 3.1 of the present paper. Nearly nine years: I am nothing if not stubborn!

From a letter to Greg Comer dated 2 December 2000

Did I tell you I'm in Vienna? Tomorrow I go to Budapest and then I come back to Vienna until Dec 12. It's been a very busy last few days for me: I've finally done it! I have a fully Bayesian derivation of complete positivity for quantum time evolutions (that's the generalization of unitarity for density matrices, taking into account measurement-disturbance nastiness). This is the best work I've done in six years. As suspected, quantum time evolutions boil down o *nothing* but Bayes' rule in disguise. I've been working furiously to dot the i's and cross the t's and get something written up before I leave here.

So, I may not be writing you email until my return to the States. Keep thinking about those dictionaries: that is a very deep train of thought.

12-03-09 *Cover Art* (to S. Capelin)

Attached is one idea. Maybe a real artist could base something on it. It is a transparency I have used in my talks for years, and is meant literally to convey what I have been calling "The Paulian Idea." It captures the following points:

1. That the quantum state lives in the head of the observer, not in the system being measured. Quantum states are epistemic.
2. That measuring devices should not be considered independent of the measuring agent, but rather are more like prosthetic hands than external pieces of the world.
3. That the quantum system (which is an external piece of the world) is something like an alchemist's "philosopher stone"—its conceptual role is like a catalyst that transforms the alchemist.
4. That the result of a measurement is like a miniature act of creation. These are the sparks depicted as flying between the measuring device (measuring device) and the quantum system.

Anyway, that's one idea, if it is something that can be made tasteful.

Another idea stems from another rhetorical trick I play in my talks. See pages 2, 7, and 9 of `http://www.perimeterinstitute.ca/personal/cfuchs/Peres%20School%201-110.pdf`. I often put a picture of a block down and say, "This is a quantum system." But then I superpose a state vector $|\psi\rangle$ on top of it, and say, "This symbol represents *my* knowledge of it." "No me, in the room? Then no state vector in the room." And then I lift the vector off the block. Then, I say, "But the quantum system remains; it hasn't disappeared, only the state vector." That's another way of putting some of what I said above—it is an essential aspect of The Paulian Idea. That quantum systems exist in a substantive way, even if state vectors do not. So, another idea for cover art would be of a cubical block with a stylistic state vector rising off of it.

That's the two best ideas I have at the moment.

13-03-09 *Graduate Openings, 2* (to M. A. Graydon)

You should make sure you are making the right decision for yourself. Ross Diener was just out here, and we spent a good bit of time together. You two should get together and share notes, dreams, plans. Research is a big step: It's not at all like class work. You write your own questions, and you seek your own answers in byways that no one has ever traveled. In a way, you put your own personality *into* the world itself. Emotion, personality, and science become pretty inextricably entwined. So, take into account the whole package in your thinking.

13-03-09 *The Unfinished Universe* (to M. A. Graydon)

In rereading what I just wrote, I found myself thinking of a passage from William James that I've always liked, and I thought I'd send it too. File attached. [See passage in 05-01-09 note "What I Really Want Out of a Pauli/Fierz-Correspondence Study" to H. C. von Baeyer & D. M. Appleby.] Read it as a metaphor for the group I'd like to assemble. Picking up on the last line in it—"the universe, unfinished, growing in all sorts of places"—I see our "additions" as helping the universe grow in all sorts of places.

23-03-09 *Bayesian Chance* (to W. L. Harper)

I want to cite your Bayesian Chance paper with Chow and Murray in the paper I'm writing at the moment. Has it been published anywhere, or posted anywhere?

I started reading it this morning. It gives me a great foil for some remarks I want to make at the end of my own paper, where I presently have the placeholder: "sketch how to build a fully Bayesian theory of objective indeterminism without invoking objective chance."

26-03-09 *The Varieties of Optimistic Experience* (to A. Ney & B. Weslake)

Thanks again for the conversation yesterday and last night. Particularly, last night, it helped refocus my thoughts on the issue of temperament in science and philosophy. Here's a quote from William James that I've always had some respect for:

> The history of philosophy is to a great extent that of a certain clash of human temperaments. Undignified as such a treatment may seem to some of my colleagues, I shall have to take account of this clash and explain a good many of the divergencies of philosophies by it. Of whatever temperament a professional philosopher is, he tries, when philosophizing, to sink the fact of his temperament. Temperament is no conventionally recognized reason, so he urges impersonal reasons only for his conclusions. Yet his temperament really gives him a stronger bias than any of his more strictly objective premises. It loads the evidence for him one way or the other, making a more sentimental or more hard-hearted view of the universe, just as this fact or that principle would. He *trusts* his temperament. Wanting a universe that suits it, he believes in any representation of the universe that does suit it. He feels men of opposite temper to be out of key with the world's character, and in his heart considers them incompetent and 'not in it,' in the philosophic business, even though they may far excel him in dialectical ability.
>
> Yet in the forum he can make no claim, on the bare ground of his temperament, to superior discernment or authority. There arises thus a certain insincerity in our philosophic discussions: the potentest of all our premises is never mentioned. I am sure it would contribute to clearness if in these lectures we should break this rule and mention it, and I accordingly feel free to do so.

I was acutely aware that there was no time in my talk to explain or to even sketch the things that drive me the most in this quantum-Bayesian quest—it is the pursuit of a malleable world. Let me just point to these papers as a momentary band-aid: `http://arxiv.org/abs/quant-ph/0404156` and `http://arxiv.org/abs/quant-ph/0608190`

Also, let me share the present attachment, which very much addresses the optimism/pessimism issue discussed last night. [See "Delirium Quantum" `arXiv:0906.1968v1`.] It is a conversation I had with Howard Wiseman on the subject: He too labeled quantum Bayesianism a kind of pessimism, and I did my best to lay out what I find "wildly optimistic" in it. Actually, relooking, the whole document is devoted to this issue. See, for instance, the paragraph on page 15 that starts "Doesn't that just make you tingle?" Anyway, it is the potentest of the premises that drive me personally in physics—for instance, the drive that leads me to reformulate quantum mechanics in this way or that—and it is indeed worth declaring forthrightly.

26-03-09 *Review of the Magic Equation* (to C. R. Stroud, Jr., J. H. Eberly, A. Ney, Y. Shapir & B. Weslake)

Thanks for the seeming interested in my talk yesterday; it's much appreciated. However, this morning as I awake, I find myself feeling disappointed that the key idea from near the end—that of taking the "magic" formula as a fundamental axiom of quantum mechanics—didn't have a chance to come across so well. Thus, let me ease my conscience by sharing a draft of a paper I'm presently writing with Schack on the subject. [See "Quantum-Bayesian Coherence," `arXiv:0906.2187v1`.] It is attached. The first five sections of it are stabilized now and should be completely readable. I hope it will give you a much better picture of where I think quantum mechanics comes from.

If you have any constructive or deconstructive comments on the draft, I would love to try to incorporate them into an improved paper.

It was great discussing with you all. Thank you for that and the fine wine and the fine hospitality.

Excerpt of Joe Eberly's Reply

> I agree that it's very attractive to have the possibility of an axiom that can encompass several desiderata at once, including the Born Rule, even if only to 38 decimal places.

26-03-09 *QB Coherence* (to W. G. Demopoulos)

... from a hotel in Rochester. I apologize for taking so long to reply to you. I kept hoping to finish the draft of my paper so that I could send it along in a reply. It hasn't happened; I continue to keep fiddling with the manuscript, and I presently judge myself only about 80% complete.

Still I think it is finally at a stage where it might benefit from your input. Particularly Section 2, of which I am not completely happy with at the moment. Sections 2 and 4 could probably use the most Demopoulizing actually.

Any input you might have would be invaluable.

To answer your other questions. I'd like to stay over when I visit London, if it fits with my other obligations; but I'll tell you definitively as the time draws nearer.

About Smeenk's talk, it was *very*, *very* good. I enjoyed it tremendously and indirectly it connected with several things that I worry about most in my forming view of quantum mechanics.

27-03-09 *New Slogan* (to R. Schack)

QM is only about the clicks you put yourself in a position to see (feel, experience).

27-03-09 *New Slogan, 2* (to R. Schack)

Schackcosm 113: *Ahhh, we need some time to discuss these things. The point is that qm is only about your active experience, right?*

Yep! Sad to think this formulation took so long. It came to me while driving back from Rochester yesterday. It looks like we have two strong supporters in Joe Eberly and Carlos Stroud (both involved in quantum optics, both students of Jaynes). Do you know them?

27-03-09 *Quantum Fiddling and Twiddling* (to N. D. Mermin)

A while back I mentioned a paper to you that I was just starting to construct; I asked whether you could remember where you had remarked on Feynman's "only mystery" of quantum mechanics. Well, I'm still twiddling on the draft. But it is now about 80% complete, and particularly the first 5 sections are pretty stabilized. Still, I'm not completely happy with the introductory section. If you've got the time/interest, might I ask you if you have any constructive feedback for the introduction. No promises that I'd incorporate anything of course, but you've shaken me from my dogmatic slumbers before, and you might again. And you're certainly the best test kitchen I know.

Hope things are going well for you.

I invented a new slogan yesterday: QM is only about the clicks you put yourself in a position to see (feel, experience). You're the second eyes to see it.

28-03-09 *Clicks Happen – (the bumper sticker)* (to N. D. Mermin)

Last night I reported your note to Kiki after we'd had a little wine, and I found myself speaking in quite a mocking voice ... "David's spennnndinggg threeee months in Cooopenhaggggen." That sort of thing. Hearing myself, I realized I was actually childishly jealous! You lucky boy!

Funny, we just had a discussion on the Bohr, Mottelson, Ulfbeck paper in our quantum foundations group meeting the week before last. The consensus was it's damned unclear. But I've said that before in the singular. I got much more from the more poetic Ulfbeck-Bohr paper (the one sans Mottelson). There is an idea in there that I like; that each quantum event is very literally unique.

Yesterday's slogan was meant to imply that stuff happens all the time, everywhere. But when I use quantum mechanics, I'm talking very strictly about the stuff that impinges on ME (and results partially because of ME).

If you do decide to delve into the paper a few days from now, let me know. I'll send you whatever is the latest draft at that point.

I'll think about how to make use of the Bohr archive. Interesting proposition.

30-03-09 *What If?* (to W. G. Demopoulos)

Demopoulosism 38: *Here's a simple idea apropos our conversation about conditionalization: What would be anti-subjectivist about the idea that there is convergence to the same algorithm for assigning subjective probabilities? Of course this has the effect of converging to the same assignment on discovering an outcome, but agreeing to a common algorithm is not the same as agreeing to base our probability assignments on an objective and physical property of things, as I assume an objective chance theorist would hold. The situation is similar to our agreement to rules of inference* *in logic. (Here I'm not talking about logics of events, etc., where there is something like a physical interpretation of what's going on, but of pure logic.)*

I don't think there is anything wrong with converging to the "same algorithm" (Lüders' Rule for instance). Nothing wrong with two agents starting with different state assignments initially, but having a common assignment after viewing a particular piece of data.

01-04-09 *Lunchtime Conversation* (to R. W. Spekkens)

Our lunchtime conversation yesterday has prodded me write a new essay. Hopefully I'll have it generated next week after Marcus is gone. The subject was really all about this slogan I'm trying to polish into something pithy: "QM is only about the clicks you put yourself in a position to see (feel, experience)." It is the very point of a theory from the inside of the world (i.e., if there is no God's eye view, that is what you have). I want to flesh that out and put it in the context of the Norsen argument (which I view as a recalcitrant attempt to view quantum states onticly[200], via the apparatus of the EPR criterion of reality). It will be a good exercise.

05-04-09 *E on Time's Illusion* (to D. M. Appleby)

Here's a quote close to the one you were thinking of. It's from a letter of Einstein's to the son and sister of Michele Besso, 21 March 1955:

> Now he [Besso], too, has just preceded me in his departure from this strange world. This means nothing. To us believing physicists the separation of past, present and future has only the significance of an illusion, albeit a stubborn one.

06-04-09 *Where's ONR?* (to K. Martin)

Hey, have you watched "The DiVincenzo Code" on YouTube? It redeems Oxford Physics in a way. (Nothing can redeem Oxford Philosophy.) Seriously. Get some beers and watch it slowly—I did that in Australia a few months ago—it's a lot of fun.

Isn't it like 4 AM there right now?

06-04-09 *A History-of-Knowledge Thing* (to D. P. DiVincenzo & C. H. Bennett)

A fitting story for John Wheeler. John himself would slide between two formulations, that our quantum measurements here and now determine what we can say of the past, and that our measurements here and now create the past. As far as I can tell he never completely decided between the two very different ideas.

I've always been intrigued by an argument of George Herbert Mead (who by the way was born in South Hadley, MA) that in a world with real indeterminism, the past must indeed be open or malleable, something like John's second formulation. Below is Arthur Murphy's summary of Mead's argument. [See Murphy's quote in 23-09-03 note "The Trivial Nontrivial" to S. Savitt.]

[200] Or ontically? How do you spell it?

Coming back down to earth though, I recall how disappointed I was when I learned that John, though he always gets (and took?) credit for it, did not invent the word "black hole". Someone in an audience called it out after one of his talks on gravitational collapse. This story of Xe-135 might be of a similar type.

David's Preply

> I read with interest some of the stories of Wheeler in the new *Physics Today*. One that really caught my eye was the story that, in a few minutes of work at Hanford, it was Wheeler who realized that Xe-135 was the principal poisoner of nuclear-pile reactions. This is one of the profound engineering insights of the 20th century — it was the lack of this knowledge that may well have blown up Chernobyl.
>
> But then, in browsing a book called *Nuclear Technology*, I see a detailed story attributing this insight to Fermi! (He is rushed by train to Hanford, does some serious thinking, etc.) So, I wonder, what is right? Is this one of these things that can be made to come out either way by those exoplanet residents 65 light years away that are just receiving the first Hanford light?

06-04-09 *Completing the Story of Incompleteness* (to L. Freidel)

Here's the lines from that old paper of mine that I was telling you about:

> There are two issues in this … that are worth disentangling. 1) Rejecting the rigid connection of all nature—that is to say, admitting that the very notion of *separate systems* has any meaning at all—one is led to the conclusion that a quantum state cannot be a complete specification of a system. It must be information, at least in part. This point should be placed in contrast to the other well-known facet of Einstein's thought: namely, 2) an unwillingness to accept such an "incompleteness" as a necessary trait of the physical world.
>
> It is quite important to recognize that the first issue does not entail the second. Einstein had that firmly in mind, but he wanted more. His reason for going the further step was, I think, well justified *at the time*:
>
>> There exists … a simple psychological reason for the fact that this most nearly obvious interpretation is being shunned. For if the statistical quantum theory does not pretend to describe the individual system (and its development in time) completely, it appears unavoidable to look elsewhere for a complete description of the individual system; in doing so it would be clear from the very beginning that the elements of such a description are not contained within the conceptual scheme of the statistical quantum theory. With this one would admit that, in principle, this scheme could not serve as the basis of theoretical physics.
>
> But the world has seen much in the mean time. The last seventeen years have given confirmation after confirmation that the Bell inequality (and several variations of it) are indeed violated by the physical world. The Kochen-Specker no-go theorems have been meticulously clarified to the point where simple textbook pictures can be drawn of them. Incompleteness, it seems, is here to stay: The theory prescribes that no matter how much we know about a quantum system—even when we have *maximal*

information about it—there will always be a statistical residue. There will always be questions that we can ask of a system for which we cannot predict the outcomes. In quantum theory, maximal information is simply not complete information. But neither can it be completed. As Wolfgang Pauli once wrote to Markus Fierz, "The well-known 'incompleteness' of quantum mechanics (Einstein) is certainly an existent fact somehow-somewhere, but certainly cannot be removed by reverting to classical field physics." Nor, I would add, will the mystery of that "existent fact" be removed by attempting to give the quantum state anything resembling an ontological status.

The complete disconnectedness of the quantum-state change rule from anything to do with spacetime considerations is telling us something deep: The quantum state is information. Subjective, incomplete information. Put in the right mindset, this is *not* so intolerable. It is a statement about our world. There is something about the world that keeps us from ever getting more information than can be captured through the formal structure of quantum mechanics. Einstein had wanted us to look further—to find out how the incomplete information could be completed—but perhaps the real question is, "Why can it *not* be completed?"

Indeed I think this is one of the deepest questions we can ask and still hope to answer.

The real question is why can it not be completed? I still like that formulation and still think it has a lot of fruit to bear.

07-04-09 *Quantum Mechanics and Pragmatism* (to M. S. Leifer)

There's nearly as many varieties of pragmatism as there are Bayesians:

- I. J. Good, "46656 Varieties of Bayesians," in I. J. Good, *Good Thinking: The Foundations of Probability and Its Applications*, (University of Minnesota Press, Minneapolis, 1983), pp. 20–21.

07-04-09 *Your Thoughts* (to N. Bao)

You wrote, "My largest concern is with whether or not I am absolutely dead-set sure that I want to do Quantum Information / Quantum Foundations in grad school." It is hard for me to see how that reconciles with what you wrote in your statement of purpose for U. Waterloo: "At this point, I truly believe that quantum information theory is what I want to do for the rest of my life." My guess is you were seduced somewhat by the old-school prestige of Stanford in comparison to U. Waterloo and the self-confidence of the students there. But those things make little impression on me: Great physics is had by great passion. Almost nothing else matters. On the other hand, there is something John Wheeler once said that did make a great impression on me. He was asked by someone in an audience, "What differences do you see between the students at Princeton and the students at University of Texas?" Wheeler replied, "Only that the students of Princeton *know* they're smart." The implication was that the local students just needed more nurturing, but therein stopped the difference. And so it was true: No student at Princeton invented quantum information theory—that came almost exclusively from the University of Texas, with Schumacher, Wootters, Deutsch, and Zurek there at the time. It was the place that mattered, not the prestige of the place. Nor was it the breadth of the place—it was really all about focus and the sense of exploring a true frontier: That brought out the best in everyone involved.

07-04-09 *Question* (to A. Plotnitsky)

Shamefully I'm still working on the SIC paper I told you about. Attached is the present draft; it's still only about 80% complete! [See "Quantum-Bayesian Coherence," `arXiv:0906.2187v1`.] Feel free to cite it however; it will I hope soon be posted on the quant-ph archive. (OH, there was also a very preliminary version in Andrei's conference proceedings; a citation can be found in the footnote on the first page.)

Though it's only about 80% complete, the first five sections are relatively stabilized. Any comments are most welcome!

You can read about Glauber's coherent states here:

> `http://en.wikipedia.org/wiki/Coherent_state`

and find the original references therein. That the coherent states can be used as an informationally complete POVM to give a Bayesian representation of quantum states, can be read about here

> `http://en.wikipedia.org/wiki/Husimi_Q_representation`.

Beware though, that that article calls Q a "quasi-probability" when in fact it is an honest-to-god probability—nothing quasi about it.

08-04-09 *Media Interview for FQXi about Hugh Everett* (to G. Stemp-Morlock)

Thanks. I much appreciate that. Only two changes I'd make to the quote; I'll set them off with brackets:

> "It was a reaction to the Copenhagen interpretation that went in a particular direction, and it was a healthy move because ultimately one does want to get away from thinking about observers as an integral part of quantum mechanics and it does do that," said Fuchs. "But, what price do you pay [for] a view of the world that is not very particular to [that] world?"

Might I also suggest you modify this sentence slightly: "believes it is a contentless interpretation, that is, it doesn't tell us anything beyond the Copenhagen interpretation that could lead to new developments in quantum foundations." In the present formulation, if MWI is contentless, then the only conclusion is that Copenhagen is contentless as well! I'd never agree with that. So I would prefer for you to simply strike the words "beyond the Copenhagen interpretation". For instance, you could make it:

> Christopher Fuchs ... believes it is a contentless interpretation, that is, it doesn't tell us anything that could lead to new developments in quantum foundations.

The main point is that one could make up a many-worlds interpretation of *any* theory. That is, despite all the posturing of the believers, there is nothing particular to quantum mechanics that actually pushes it upon us. That is why I say it is contentless.

I wish I could find the quote of John Wheeler where he says something similar to the latter part of your sentence, i.e., "it doesn't tell us anything that could lead to new developments in quantum foundations." If you want me to look, I can do it when I get to the office.

Good luck with your article.

08-04-09 *Mermin the Epistemicist* (to R. W. Spekkens)

If I read you correctly yesterday, you seemed a little surprised when I said that Mermin ought to be in the epistemic team. I discovered he says it pretty succinctly here:

> `http://arxiv.org/abs/0808.1582`,

starting particularly at the last paragraph on page 2.

09-04-09 *Testing Quantum Certainty* (to R. Schack)

How does that sound for a title for yet another paper we must write this year?

Can you spot the flaw in `http://arxiv.org/abs/quant-ph/0601205` from our perspective? Apparently the only way I'll ever build (true and enduring) respect with my colleague Spekkens is to respond thoroughly to this paper.

By the way, it's an easy (and fun) exercise. I encourage you to try it.

09-04-09 *QBism, Certainty, and Norsen* (to R. Schack)

Between the two files attached is a draft for a draft of a paper responding to Norsen. Let me know what you think. Using him as a foil is, I think, a chance to do our certainty paper much better.

I'd like the new paper to begin with something like this:

> Travis Norsen has recently given a very clear exposition on the underpinnings of the idea that quantum mechanics all on its own implies a violation of Bell Locality, without any need for a hidden variable assumption. The paper has been a great service to the community. However, in making his claim, Norsen made significant and unabashed use of a variant of the EPR criterion of reality. In contrast, the present authors some years ago wrote a not-so-very-clear paper arguing in effect that the EPR criterion of reality is at odds with a personalist Bayesian account of probability, and that holding strictly to the Einstein notion of locality indeed forces its bankruptcy in the quantum context. In this paper, we plan to do the argument much better justice by using the clarity of Norsen's paper as a counterpoint with which we must contend. By sharpening ourselves with respect to Norsen blah blah blah . . .

09-04-09 *Request to Review Manuscript* (to The Physics Teacher)

I'm sorry, I read the first two sentences of this paper—"In 1964 John Bell proved a theorem allowing the experimental test of whether what Einstein derided as "spooky actions at a distance" actually exist. We will see that they do."—and I feel a revulsion. All I can do is reject it. This is such an old issue, such an old mistake, much like the continued proposal of a perpetuum mobile.

What the violation of a Bell inequality demonstrates is that "local realism fails." Unpacking the term local realism, one means more precisely the conjunction of two statements: 1) that actions or experiments in one region of spacetime cannot instantaneously affect matters of fact at far away regions of spacetime, and 2) that measured values pre-exist the act of measurement, which merely "reads off" the values, rather than enacting or creating them by the process itself. The failure of local realism means the failure of one or the other or both of these statements. It does not mean what the author says above. See, for instance:

- S. L. Braunstein and C. M. Caves, "Wringing Out Better Bell Inequalities," Ann. Phys. **202**, 22 (1990).
- N. D. Mermin, "Hidden Variables and Two Theorems of John Bell," Rev. Mod. Phys. **65**, 803 (1993).

for very thorough discussions of this point. Please save the average physics teacher by sending this article back home.

10-04-09 *Testing Quantum Certainty, 2* (to R. Schack)

Schackcosm 114: *The exercise is indeed easy. Unperformed experiments have no results. Even probability 1 predictions are subjective. There is nothing in the world which guarantees the outcome of a probability one measurement. You name it.*

This "Nature IS nonlocal" theme is everywhere at the moment. Have you seen Albert's paper in Scientific American *(February I think)?*

I haven't had the courage to look at it, though everyone wants me to.

Long discussion with Rob yesterday. It seems he's not unsympathetic to "even probability 1 predictions are subjective" most generally, but that the general point may become inoperative in physical theories like quantum mechanics. That is to say, it seems he wants the role of physical theory to be a bridge between belief and fact. Something of that flavor.

10-04-09 *SICing a Symbol* (to H. C. von Baeyer and D. M. Appleby)

Good Good Friday to both of you. I slowly continue my refreshed study of Pauli, and last night, just at midnight, got to Gieser's chapter on *The Reality of the Symbol*. Previous to this, I had never paid much attention to this concept of a "symbol." However, here are some of Gieser's words that quite struck me, and I haven't been able to get them off my mind all night:

> Jung sees a living symbol as the best possible expression of something divined but not yet fully known – something which cannot be represented in a more characteristic way than in the form taken by the symbol. If one says that the cross is a symbol of divine love, then according to Jung one gives a semiotic *explanation* of the cross, which is something quite different from seeing it as a symbol. If on the other hand one believes that the cross is beyond all conceivable explanation, but that it is still the most apt expression of an as yet unknown and incomprehensible fact, then one has a symbolic attitude to the cross. The symbol always consists of a known or rational part and an unknown or irrational part, which is not accessible to reason. The known part of the symbol is represented by its current form while the unknown part opens up to the non-visual aspect of the archetype. The state of tension between known and unknown gives the symbol a numinous character, which lends it a power and attraction. Our fascination with and manipulation of the symbol gradually leads to a discovery of the true characteristics of the object and the symbol increasingly produces real knowledge. In this way the unknown is made conscious and thus the symbol loses its power and attraction and 'dies'.

It's obvious what I thought upon reading this. By these lights, the SICs are surely a symbol for Marcus and me. There's almost a discussion in Gieser's description that Marcus and I had several times over in the last few years. For somehow we felt, long before we could articulate why—long before the urungleichung or anything like that—that the SICs were somehow the "most apt expression" of quantum-state space. There has been a "power and attraction" in these things that neither of us have understood and neither of us have been able to yield to (in our own ways).

I'm quite thankful I read this passage, as I suppose I should be, given that today commemorates the birth of the symbol Gieser uses as her example.

Marcus's Reply

> Yes. Absolutely.
>
> But maybe I would like to add a couple of qualifications. If a symbol is defined to be something that
>
> > consists of a known or rational part and un unknown or irrational part, which is not accessible to reason
>
> then I think that the concept of divine love *also* has a good deal of the symbol about it. I am sure I don't understand what is meant by it. So in that sense it is certainly unknown (at least to me). But at the same time it doesn't mean nothing (at least to me). Religious language like this leaves me perplexed. But it doesn't leave me feeling perplexed in the way I would feel perplexed if someone were to say (or rather write) "oub##4 b12xp".
>
> I had a conversation with Hulya the other night which may be relevant here. She has been reading *Zen and the Art of Motorcycle Maintenance*, and she criticized it on the grounds that it isn't deep (though I should perhaps add that she was at pains to stress that she hasn't got very far into it yet and may change her mind). This led to a discussion as to what counts as deep. We decided that it was best to begin with an example that is the complete opposite of deep. Suppose one were to take a USB stick and put onto it a list of the names and addresses of everyone living in Waterloo. That would strike Hulya and I as totally shallow. The reason is (we decided) that it contains exactly what one consciously chose to put there, no more, and no less. If someone lives in Waterloo then their name and address will be on it, but their telephone number won't be. There is no ambiguity to it at all. But if something is deep there is always a lot of ambiguity.
>
> Of course mere ambiguity is not sufficient. Otherwise one could make any book deep simply by leaving it out in the rain, so that the ink runs, and then getting a dog to chew the pages. It is important also that the ambiguity be suggestive. Of course that is not enough either: for it mustn't be suggestive of just anything but specifically of something that strikes us as — what exactly? Here I find myself at a loss. The best I can do is to say that it must be suggestive of something that strikes us as deep. Which, it may appear, does not get us very far.
>
> Still I think it does get us somewhere. If a book is deep that means (Hulya and I decided) that in some sense it reaches out beyond itself. It actually contains more than the author consciously chose to put in it. A deep book is one that the author themselves might read and re-read and each time discover something new. Just as if they were re-reading a book written by someone else. In short a book is deep if the

supposed author isn't exactly the author at all. At least not completely the author. As if the author had a hidden co-author.

Hardy, in *A Mathematician's Apology*, says something about this. He says that a chess puzzle is shallow because, even if it is a very difficult problem, it is open and shut. Once you have solved it then you have solved it. There is nothing more to do. By contrast Euclid's proof that there are infinitely many primes is deep (according to Hardy). Mathematicians have been coming back to it for thousands of years, and they keep on finding new connections.

I think what I so hate about classical physics (even General Relativity—pace Hans) is that it is built on the idea of what Gieser calls a semiotic explanation. The universe, classically conceived, consists of a great mass of dead facts. You can imagine putting these facts on a cosmic USB stick and what would result would be exactly like a list of the names and addresses of everyone in Waterloo. Ugh!

Quantum mechanics is wonderful because it dispels this nightmare. Classical physicists see the fact that quantum mechanics doesn't permit complete knowledge as a disaster. They couldn't be more wrong. Just because it forbids a complete description (the kind of description which would allow us to reliably predict the result of any experiment) it permits the possibility of depth. It is not a disaster but a liberation.

Which brings me back to Jung and symbols. I profoundly disagree (indeed profoundly dislike) his idea that

> Our fascination with and manipulation of the symbol gradually leads to a discovery of the true characteristics of the object and the symbol increasingly produces real knowledge. In this way the unknown is made conscious and thus the symbol loses its power and attraction and 'dies'.

One sees from this that Jung was classical at heart. As if one were to say that our inability to know position and momentum simultaneously is only temporary. Eventually we will discover Einstein's true theory, and then we can go back to thinking of the universe as an enormous telephone directory.

And, to go back to the point with which I began, I think his concept of symbol is too narrow. As he sees it the cross is symbolic, but divine love not. It seems to me that just about every word in the gospel stories is charged with meaning. Deep meaning. I don't understand them. I am certainly not saying that I am a Christian in any conventional sense (though I probably am in some extremely unconventional sense). But they are shot through with the quality which Jung attributes to a symbol:

> a numinous character, which lends it a power and attraction.

I would say everything in them is symbolic. If one is going to use that word.

But I agree completely about SICs.

Hans's Reply

Dear Marcus, thank you for that excellent and useful gloss on the word symbol. I agree with your critique of the last part of the passage, but I don't know whose words they are. Probably Gieser's, possibly Jung's, but certainly not Pauli's. I can't imagine Pauli talking about "true characteristics of" or "real knowledge about" an object. Or to give up a symbol as dead, after making it the centerpiece of his enterprise. In fact the sentence reminds me of the point that Pauli and you have made often: that most people, even good physicists, remain convinced, or at least hopeful, classical thinkers, and that it will therefore take a long time for the scientific community to switch to a radically new worldview.

Chris's Reply to the Replies

Oh, you guys make me feel guilty! I too had disliked the latter part of Gieser's description, but I decided to keep the whole paragraph for completeness sake. I should have made a comment! ... Please don't think less of me!

11-04-09 *QBism, Certainty, and Norsen, 2* (to R. Schack)

Schackcosm 115: *I have now studied your handwritten notes. I like the parts where you explain why Norsen's argument falls to pieces from a QBism perspective. I am not too sure about your explanation of what locality means from a QBism perspective, though. We had these discussions last year. It looks to me as if locality is built into the QBism formalism from the start, so that it becomes impossible within that formalism to ask, e.g., does nature allow superluminal signalling?*

Indeed, we don't have a very good story of signaling yet, superluminal or otherwise. It dawned on me for the first time this morning that until we can say something intelligible about that we're going to always be exposed to the charge of solipsism. We must understand how to describe "communication" within the QBism framework! I'm a slow learner.

13-04-09 *Easter Pictures and the Beginning of Depth Psychology* (to D. B. L. Baker)

Fantastic pictures, I enjoyed seeing them very much. Made me miss you again old man. Do you still go to church regularly?

Attached is a representative of my own Easter pictures. Sorry, not much better fare at the moment. The girls are on the balcony outside of Katie's room.

I'd like to write you a little essay on "depth" and "deep thoughts" harkening back to our days in high school. I've been thinking about what we found to be "deep" then, when we would discuss this or that, songs of Paul Simon, Rush, The Clash. This has come about because in reading a book about Carl Jung, I came across a definition of "symbol" that struck my fancy, making sense of what I've been doing the last four years. It's not so very different from our thinking about a song over and over. See note below.

The particular example being discussed—a thing I call a SIC (pronounced "seek")—is a certain mathematical structure we've been trying to prove the existence of, on and off since 1999. In the last four years or so, it's turned into a real obsession. You can read about it, if you're interested, in somewhat general terms (which I wrote up for the Navy) in the attached PDF.

I'll also place further down a part of Appleby's reply, which reminded me of our old high school discussions indeed.

14-04-09 *Your Thesis, 2* (to J. R. Gustafson)

I think you should post it, for instance on the quant-ph archive.

In case you're interested, I attach my "Resource Material for a Pauli'an / Wheeler'ish Conception of Nature" file. It's been a long time since I've updated it. For instance, it doesn't have your thesis listed yet, or Gieser's book, etc. But there's plenty there for you to read and think about, if you want to start thinking in these directions again. (And if you find any typos, please let me know!) One of these days, I'm going to finish putting it all together and post it as well.

15-04-09 *Math Question* (to P. Hayden)

Haydenism 1: *Thanks for coming to dinner on Wednesday (and for the grace under pressure at the lecture). We were unfortunately seated at more than a correlation length apart so didn't get a chance to talk. Did you still want to pose that math question?*

I'm just now replying to this note! Let me start out with an apology, not for the sloth here, but for forgetting to say goodbye to you after dinner the other evening! Wine does mysterious things. And let me apologize too for not doing a better job of storytelling. With just a tad of thought, I could have pulled off a relevant (and funny) punch line for the story I did tell. I've been kind of beating myself. I wish I could blame the wine for this one, but truth be told it was only the aging of my synapses.

With regard to the math problem, it was really just a way to lure you in to thinking about technical aspects of my QBism program. Attached is a draft (about 80% complete) of a paper I'm writing at the moment. [See "Quantum-Bayesian Coherence," `arXiv:0906.2187v1`.] Sections 1 to 5 are now relatively stable, so they should at least make some sense at this point. The basic mathematical question is how much of the structure of density operator space is implied simply from having a maximal set with respect to the inequality in (97)

$$\frac{1}{d(d+1)} \le \sum_i p(i)s(i) \le \frac{2}{d(d+1)}\ ? \tag{98}$$

It would have been better to tell about these things at the board, so you wouldn't have to wade through all this nonsense to get to the basic question … but time flies. If you do wade, though, and have any insight, I'm all ears. Else we can talk at the ONR meeting in May.

15-04-09 *The Egocentric Paradigm* (to R. W. Spekkens)

The right-hand column of Lindley's discussion (attached) reminds me of our conversation after the group meeting Thursday.

> The Bayesian, subjectivist, or coherent, paradigm is egocentric. It is a tale of one person contemplating the world and not wishing to be stupid (technically, incoherent). He realizes that to do this his statements of uncertainty must be probabilistic. This is important on its own for it rules out a large class of behavior patterns, like sampling theory statistics, but is it enough? Once I coined the aphorism "Coherence is all." Was I right? It is when we consider two coherent Bayesians that new features arise. Does their egocentric behavior allow them to talk to one another? In one respect it does. Suppose that you and I are both coherent and you tell me that your probability for A, were B to be true, is α, say. How does this knowledge affect my probability for A given B? It is easy for me to do the coherent calculations in terms of my assessments that were A and B both true, you would say α, and that were $\overline{A}$ and B both true, you would say α. For to me α is just data and the likelihood ratio updates my probability in the usual way. A weather forecaster who announces rain whenever it is subsequently dry,

and vice versa, is badly calibrated but very useful. So I can respect your egocentricity; and you, mine.

15-04-09 *My Own Credo on Hidden Variables* (to D. M. Appleby & R. W. Spekkens)

Just to make sure everyone understands my honest position on hidden variables, I paste in an old note (and an old referee report) below. [See 17-11-05 note "Cash Value" to H. Halvorson.] It has similarities to Rob's shape-like remark. I'm certainly not opposed to postulating entities beyond the clicks. But the entities had better have "cash value" to get my attention. And I haven't seen a hidden-variable (or ontic-variable theory if you will) yet that has gotten my attention in that way.

15-04-09 *The Well-Calibrated Bayesian* (to R. Schack)

Schackcosm 116 : *Internet access speed truly awful. Not sure that I'll be able to access Dawid's paper. I expect that I'll be a lot less negative now. I have a worry that this kind of reasoning might lead to a concept of "correct" probability assignments. Well calibrated probabilities are "better" than others. But that might not be so bad in the light of our discussions at IHOP. I would pay more for forecasts from a well-calibrated Bayesian.*

Please remind me of those discussions as well.

In the present case (i.e., with regard to the particular paper I sent you), I was more intrigued by the coherence issues to do with the concept. What he tries to establish in this paper is that any forecaster will expect himself with probability 1 to be well-calibrated. Then he asks, how can that be, since every forecaster surely knows that he is fallible. Second to that, though, I wonder if his calibration might just be arbitrary (and also, as some of the commentators expressed, operationally without content).

About Lindley, I very much like the sound of him, except for this Cromwell's Rule business. It is surely inoperable—same point de Finetti made.

15-04-09 *Marcus on the Symbol 3.5 Years Ago* (to H. C. von Baeyer)

I've been putting together a coffee table book called *The Unpublished Appleby*, and consequently rereading some old notes and paper drafts he's written over the years. Attached is one example. Have a look at the paragraph just preceding Section 5:

> The recognition, that quantum mechanics doesn't supply us with an exact mental replica of the world, may initially be experienced as a disappointment. In the same way, the little boy I mentioned above may feel disappointed when, in spite of repeated attempts, he finds that he is simply unable to get his foot physically into the picture of the shoe. And perhaps his first reaction will be throw the picture away in disgust, as completely useless. However, he will eventually come to realize, with time, and a great deal of mental effort, that the power of a symbol does not depend on its being an exact replica. More than that: he will come to realize that symbols are powerful precisely because they do not replicate their objects.
>
> I believe that progress depends on our relearning that nursery lesson.

So, I guess this symbol talk is nothing new between us! (You see, I'm a very slow learner.)

15-04-09 *Two Letters to Track Down* (to H. C. von Baeyer)

Here are two letters that it might be interesting to look at in more detail: Pauli to Jaffé, Aug. 1954 [1865], PLC IV/2 Pauli to von Franz, 12 Nov. 1953 [1672], PLC IV/2.

I was intrigued by there being in the first a variation of the thing Pauli told Fierz about a "black mass":

> Suddenly I had a remarkable *feeling* experience. The "observation" of microphysics appeared to me to be a kind of black mass and I felt remorse. Remorse with regard to matter, which appeared to me to be a maltreated *living thing*. (Biological implication.) — The practice of this black "mass of measuring" in the external world transforms only *its* condition, not that of the observer. [Translation by Gieser, presumably.]

Second letter apparently says more about the black mass concept.

Hans's Reply

> Chris, [1865] is a very short postcard to Jaffé. It mentions the black mass, as did the long important letter to Fierz [1864] written on the same day.
>
> [1672] to von Franz does not mention the black mass. (It is nevertheless a useful letter because it spells out like none other the significance of the yin/yang in Pauli's thinking.)
>
> So far I have not seen other mentions of the black mass, but I have not searched. This is why volume 9 — online — would come in very handy!

15-04-09 *Some Similarity to Your Mumbles on Probability* (to D. M. Appleby)

See the description of the book below. It seems to have some similarity to an idea I've seen you groping for.

Happy holiday with Hulya.

> *Projective Probability*
>
> James Logue
>
> Description: This book presents a novel theory of probability applicable to general reasoning, science, and the courts. Based on a strongly subjective starting-point, with probabilities viewed simply as the guarded beliefs one can reasonably hold, the theory shows how such beliefs are legitimately "projected" outwards as if they existed in the world independent of our judgements.
>
> Product Details: 192 pages; tables; ISBN13: 978-0-19-823959-8 ISBN10: 0-19-823959-9
>
> About the Author: James Logue, Fellow and Tutor in Philosophy, Somerville College, Oxford; and Lecturer in Philosophy, Oxford University

15-04-09 *QBism, Certainty, and Norsen, 2* (to R. Schack)

By the way, the reason I was re-looking at Dawid originally is because I was thinking of how to respond to Lucien's passages below:

Hardyism 4: *From a mathematical point of view, any interpretation of probability that allows us to help ourselves to the basic mathematical properties of probabilities will suffice. These properties are that probabilities are positive, sum to one over mutually exclusive outcomes, and the validity of Bayes' rule for converting between joint and conditional probabilities. One approach that does this might be called the* best prediction available interpretation. *In this we interpret the probability to be the best prediction available of a theory for the empirical relative frequency (the ratio of times a particular outcome is seen to the total number of times the experiment is repeated when the latter is very large). The best prediction available interpretation asserts that the purpose of a theory is not to actually make exact predictions (i.e. we do not need to say exactly what the empirical relative frequency is for a given denominator) but to rather give the best prediction it can. This approach remains neutral with respect to what might be regarded as the deeper interpretation of probability but is consistent with such deeper interpretations. It is consistent with the idea that probability is a degree of belief as promoted by the Bayesians. It is also consistent with the idea that there is some deeper structure in the world supporting some objective property that might be called a propensity.*

Hardyism 5: *What about a "best prediction available" interpretation for probability. Probability is the best prediction available of a theory for the empirical relative frequency. We do not expect our theory to give a better prediction than this and we are content that nature only agrees so far with the prediction of theories. This is a sort of probability squared approach. Once we let go of the idea that a theory has to predict everything — even probabilistically — we are free to take such an approach. This "best prediction available" works well for the next definition. Best prediction available could be regarded as being like the degrees of belief idea but more radical. Alternatively, we might say that there is structure in the world such that the best prediction available is the prob. This now starts to sound like a propensity approach but where the propensity "resides" in the deeper structure rather than just the object itself. Interesting that the best prediction available approach can be interpreted as both the degrees of belief and the propensity interpretations. It is a sort of withholding commitment approach.*

I wanted to ask him, how would one know if one made the best prediction available? It could only be settled with respect to a prior, and now how do you interpret that prior? Something along those lines. But it should be fleshed out better. How would you respond?

When all is said and done though, I still harbor those old fears of being indefensible to someone like Dawid who writes:

> I have been justly chastised by the discussants for spreading alarm about the health of the body Bayesian. Certainly it has held together more successfully than any other theory of statistical inference, and I am not predicting its imminent demise. But no human creation is completely perfect, and we should not avert our eyes from its deficiencies. In its solipsistic satisfaction with the psychological self-consistency of the schizophrenic statistician, it runs the risk of failing to say anything useful about the world outside.

It probably doesn't help that yet again (after writing up those hand-written notes for Rob), Rob called the position solipsistic.

16-04-09 *QBism, Certainty, and Norsen, 3* (to N. D. Mermin)

I'm not sure I understood either of your remarks concerning page 2 and page 3. Could I ask you to try again? Particularly, I'm lost on this one:

Mermintion 176: *Probably what you mean to say is that only a minority thinks that the (well-known) fact that measured values do not pre-exist the act of measurement, is enough to undermine the view that locality has to abandoned.*

??? Please say it again in a different way.

Not unrelated: Have you seen `quant-ph/0601205v2` by Travis Norsen? Attached are my lecture notes contra that paper. You will find in them an unequaled clarity with respect to my usual writings. Anyway, the page 2 and 3 sentences you commented on were molded by the attitude I take in those lecture notes.

How long are you staying in Copenhagen? And we can't even get you to Waterloo for a minuscule week of conversation!

16-04-09 *QBism, Certainty, and Norsen, 4* (to N. D. Mermin)

Mermintion 177: *We're about to leave for a long weekend in Berlin, so it may be a while before I can reply. I'm surprised that you didn't understand what bothered me. So I guess it's not that you were being careless (as I had assumed) but that there is a real difference in point of view here.*

I am never careless in papers. I am sometimes wrong, but I am never careless.

Indeed!

16-04-09 *QBism, Certainty, and Norsen, 5* (to N. D. Mermin)

Mermintion 178: *I would never have suggested that you were careless in a paper. But I thought you had said that this was a preliminary draft. Why are you up so early in the morning?*

Chronic insomnia. It has gotten particularly acute in Canada.

OK, it's a draft. Mostly I want to understand how you found those few sentences confusing, and I did not understand you at your previous attempt.

Is it that I should change:

> But there is a small minority that thinks the abandonment of condition 2, that measured values pre-exist the act of measurement, is the more warranted conclusion and among these are the quantum Bayesians.

To something more like:

> But there is a small minority that thinks the abandonment of condition 2, that measured values pre-exist the act of measurement, at the same time as the absolute holding fast of condition 1, is the more warranted conclusion and among these are the quantum Bayesians.

Is that the sort of thing you thought needed fixing?

16-04-09 *QBism, Certainty, and Norsen, 6* (to N. D. Mermin)

Mermintion 179: *On page 3 you say*

> But there is a small minority that thinks the abandonment of condition 2, that measured values pre-exist the act of measurement, is the more warranted conclusion [to reach from Bell inequality violations]

This implies that were it not for violations of Bell inequalities, that small minority (along with the majority) would have believed that measured values pre-exist the act of measurement. That's just not so. Practically nobody believed that measured values pre-exist the act of measurement. They didn't believe it before Bell. They didn't believe it before EPR. EP&R were condemned as heretics for suggesting that measured values might pre-exist the act of measurement. It was almost a truism, that values were brought into existence by the act of measurement — that measurement outcomes were a joint manifestation of the system in combination with the process of measurement.

So I would say that what you should have said is

> But there is a small minority that thinks that the non-existence of values that pre-exist the act of measurement is enough to account for Bell inequality violations, without requiring the abandonment of condition 1).

But of course that only makes sense if you do not assert earlier on page 2 that measured values pre-existing the act of measurement is one of the two pillars of local realism. But indeed it is not a pillar. In Bell's original paper (and in EPR) it is a deduction from the EPR reality criterion. In the post-Bell era there are many assumptions much weaker than the EPR reality criterion. For example that joint distributions exist for the outcomes of all the experiments — the one you actually did and the ones you might have done but didn't — without making any commitment to whether such experiments reveal pre-existing values.

Or you can assume the "conditionally independent" form for the joint distributions implicitly used by CHSH and explicitly invoked by Jon Jarrett which I'm told goes all the way back to Reichenbach, though I've never found it there. That's what I was verbally trying to describe in my note to you yesterday.

Hope that helps. I don't think I'm just being perverse. I think most people in the Bell-EPR business will react in the same way I have done.

Time to run. More from Berlin, if we have wireless in the hotel room and I also have insomnia.

You are right, and now I understand. I was leaving too much out by not mentioning the EPR considerations. I will fix this. Good thing it was only a draft!! (I now understand I can still wear the label 'careless' when it comes to a draft.) Have a safe trip to Berlin.

16-04-09 *Gieser's Book, Preliminary and Completed Notes* (to H. C. von Baeyer)

Some things that interested me with the book, along with corresponding page numbers. Don't know whether it'd be of any use to you, but one never knows. Sadly, I've yet to get back to finishing the book. I hope to get back to it soon after returning from Paris. Before Paris, too busy; during Paris, I only want to think about Pure Experience. [Fragment from 09-04-09 note.] ...

OK, I got more active than I thought I would before Paris. Below is my complete set of points of interest with regard to Gieser's book. Strangely, I enjoyed almost the whole book, even though looking back on it now, I don't think I learned anything at all particularly. It's probably all just about acquiring a taste, somewhat like I once did for beer many years ago.

I believe there is at least one typo below from my previous partial compilation, but I haven't been able to re-find it.

I'll answer your questions on von Meyenn later today (or tomorrow morning).

Suzanne Gieser, *The Innermost Kernel: Depth Psychology and Quantum Physics. Wolfgang Pauli's Dialogue with C. G. Jung*

"he aroused the malice of the object" – 20, 21

17-04-09 *Pearls of Bayesianism* (to R. W. Spekkens)

This paper looks quite interesting to me:

`http://ftp.cs.ucla.edu/pub/stat_ser/r284-reprint.pdf`

I'd like to (read it and) discuss it, if you're interested, after I get back from Paris on the 28th. If he is right that "probability theory deals with beliefs about an uncertain, yet static world, while causality deals with [BELIEFS ABOUT] changes that occur in the world itself" (my crucial addition), then I'm half-Bayesian as well.

17-04-09 *Two Quotes Before I Forget* (to R. W. Spekkens)

I copied down two quotes yesterday that bear a little on our discussion last week. Let me record them:

1) From "Subjective Probability and Its Measurement," by J. M. Hampton, P. G. Moore and H. Thomas (J. Roy. Stat. Soc. A **136**, 21–42 (1973)):

> Bruno de Finetti believes there is no need to assume that the probability of some event has a uniquely determinable value. His philosophical view of probability is that it expresses the feeling of an individual and cannot have meaning except in relation to him.

2) From Dennis V. Lindley's comment on A. P. Dawid's article (J. Am. Stat. Assoc. **77**, 611–612 (1982)):

> The Bayesian, subjectivist, or coherent, paradigm is egocentric. It is a tale of one person contemplating the world and not wishing to be stupid (technically, incoherent). He realizes that to do this his statements of uncertainty must be probabilistic. This is important on its own for it rules out a large class of behavior patterns, like sampling-theory statistics, but is it enough? Once I coined the aphorism "Coherence is all." Was I right? It is when we consider two coherent Bayesians that new features arise. Does their egocentric behavior allow them to talk to one another? . . .

Particularly what caught my attention was the descriptor "egocentric," which I decided I like very much. There is a world of difference between "egocentric" (which is an accurate account of my proposed take on QM) and "solipsistic" (which is not).

26-04-09 *Server Config* (to D. M. Appleby)

Applebyism 30: *I am glad you and Emma are enjoying your time in Paris. I know what you mean. Strolling round big cities, with a long history behind them, does indeed give one insights one can get no other way. Just the intangible feel of the place, that one somehow picks up without even setting foot in a museum or gallery or cathedral or whatever. And Paris must be one of the most important foci in the whole of human history. So many of the things around us (the very existence of the United States) depend on events which took place in those few square miles.*

Hope you get well soon! I really liked that phrase "foci of human history"! Maybe that indeed is how the spirit sinks in. (I'm turning on to the word "spirit", by the way, since our soon-after-new-year's discussions; for instance, I now think Hans should use the labels "spirit" and "matter" on his Möbius strip logo.)

28-04-09 *Spirit and Matter* (to D. M. Appleby and H. C. von Baeyer)

Here was the quote I had wanted to send you last night, but I got too lazy to look it up (I was only up briefly from the jetlag).

It comes from the very beginning of William James's article "Does Consciousness Exist" (which I started to read for the third time while in Paris). Previously, I had not noticed any of this, but I suppose our recent discussions set me up for it this time.

> 'Thoughts' and 'things' are names for two sorts of object, which common sense will always find contrasted and will always practically oppose to each other. Philosophy, reflecting on the contrast, has varied in the past in her explanations of it, and may be expected to vary in the future. At first, 'spirit and matter,' 'soul and body,' stood for a pair of equipollent substances quite on a par in weight and interest. But one day Kant undermined the soul and brought in the transcendental ego, and ever since then the bipolar relation has been very much off its balance. The transcendental ego seems nowadays in rationalist quarters to stand for everything, in empiricist quarters for almost nothing. In the hands of such writers as Schuppe, Rehmke, Natorp, Munsterberg – at any rate in his earlier writings, Schubert-Soldern and others, the spiritual principle attenuates itself to a thoroughly ghostly condition, being only a name for the fact that the 'content' of experience is known. It loses personal form and activity – these passing over to the content – and becomes a bare Bewusstheit or Bewusstsein überhaupt of which in its own right absolutely nothing can be said.

28-04-09 *Spirit and Matter, 2* (to D. M. Appleby and H. C. von Baeyer)

Applebyism 31: *How did James answer the question?*

Isn't it a very peculiar question? Suppose someone were to write an article entitled "Does sleep exist?" or "Does perception exist?". Or how about "Does smelling exist?".

They wouldn't do it of course. Or, if they did, no one would publish it. But why not? If one thinks the existence of consciousness is doubtful, then surely the existence of perception is doubtful too. Isn't perceiving something more or less the same as to be conscious of something?

Gassendi's response to the Cartesian "cogito ergo sum" was to argue "I walk therefore I am". How if someone were to write an article entitled "Does walking exist?"

It should be taken in the spirit of de Finetti's provocative remark, "PROBABILITY DOES NOT EXIST." Just a tad further down than my quote, James writes:

> To deny plumply that 'consciousness' exists seems so absurd on the face of it – for undeniably 'thoughts' do exist – that I fear some readers will follow me no farther. Let me then immediately explain that I mean only to deny that the word stands for an entity, but to insist most emphatically that it does stand for a function. There is, I mean, no aboriginal stuff or quality of being, contrasted with that of which material objects are made, out of which our thoughts of them are made; but there is a function in experience which thoughts perform, and for the performance of which this quality of being is invoked. That function is knowing. 'Consciousness' is supposed necessary to explain the fact that things not only are, but get reported, are known. Whoever blots out the notion of consciousness from his list of first principles must still provide in some way for that function's being carried on.

This is the article where James introduces the idea that reality is made of a neutral stuff that is neither thought nor thing. But that thoughts and things are aspects of the neutral stuff (when taken in relation to other patches of the stuff).

07-05-09 *Bell's Inequality* (to B. Dreiss)

Thanks for your thoughtful note. The key to understanding that statement from my old paper with Asher Peres is in focusing on the part: "any objective theory giving experimental predictions identical to those of quantum theory". That means any theory that gives quantum states an objective level of reality, rather than a Bayesian-style significance (as I strongly support), will have this spooky action-at-a-distance character. Bell was correct on that point. Asher and I were putting such extensions of quantum theory in contrast to quantum theory itself.

Attached are a couple of pieces that help clarify this. One is a paper that I am presently constructing (it's about 80% complete) representing the state of the art with respect to our quantum-Bayesian research program. The opening section very much addresses your query, and among other things you'll find a very extensive collection of references there to do with the QBism program more generally. The other two files are copies of some lecture notes I wrote a few weeks back to do with the QBism *rejection* of nonlocality as the lesson to be learned from Bell inequality violations. The lesson instead is that quantum "measurements" are not measurements at all in the historic sense, but *actions* one can take on external systems that elicit *consequences*. Bell inequality violations negate not one bit the reality of those external systems. The external world is there whether you act upon it or not. Bell inequality violations only negate the pre-existent reality of the consequences to those actions: No actions on the external world, no consequence. That is the subject matter of quantum theory, from our take.

Now to Jaynes. You're right, I should have a specific reply to him. Many years ago—about 15!—Carl Caves (certainly a disciple of Jaynes in his own right) explained to me what was wrong with Jaynes's argument, and I haven't looked at that aspect of his work since. Jaynes is certainly one of my heroes, but that doesn't absolve him from making mistakes. I will read his paper carefully again and form a statement on it (and send it to you). But that will probably take me a good few weeks: I've got the present papers to pump out first, and a meeting each week for the next four to travel to!

I was born in Cuero, TX; do you know the town? Where do you live in Australia? I've been flying to the continent about once to twice a year lately, and I'll be in Sydney in December.

07-05-09 *Curious George* (to H. Price)

Lund? Your auto-reply says you're on "research leave". Any interesting enclaves of pragmatism there?

By the way, I gave a joint physics/philosophy colloquium in Rochester last month for Brad Weslake. It was a good time. But I had a funny encounter with him and Alyssa Ney when I mentioned that the term "block universe" originates with William James' 1882 article "On Some Hegelisms" (as far as I can tell). A) They didn't know that, but then B) they assured me that James had the *wrong* definition of a block universe!

07-05-09 *Obsession with a Footnote* (to H. Price)

That's what David Albert would say of my whole philosophy, I'm sure ...

I just haven't been able to get that damned footnote exactly right. Here's the latest attempt:

```
\footnote{See Footnote \ref{Misunderstandings} and Ref.\
\cite[Sec.~4.1]{Timpson08} for a sampling of instances of
opposition to our inchoate ontology, and see Refs.\
```

```
\cite{Nagel89,Dennett04,Price97} for details on the ``view from
nowhere'' / ``view from nowhen'' {\it weltanschauung\/} more
generally.}}
```

I think I'm finally feeling better about this one ... and wanted to share the moment!

08-05-09 *Your Talk at UWO* (to W. C. Myrvold)

Let me just give you the title and abstract from the new paper.

Quantum-Bayesian Coherence

> In a quantum-Bayesian take on quantum mechanics, the Born Rule cannot be interpreted as a rule for setting measurement-outcome probabilities from an objective quantum state. But if not, what is the role of the rule? In this talk, I will argue that it should be seen as an empirical addition to Bayesian reasoning itself. Particularly, I show how to view the Born Rule as a normative rule in addition to usual Dutch-book coherence. It is a rule that takes into account how one should assign probabilities to the consequences of various intended measurements on a physical system, but explicitly in terms of prior probabilities for and conditional probabilities consequent upon the imagined outcomes of a special counterfactual reference measurement. This interpretation is seen particularly clearly by representing quantum states in terms of probabilities for the outcomes of a fixed, fiducial symmetric informationally complete (SIC) measurement. We further explore the extent to which the general form of the new normative rule implies the full state-space structure of quantum mechanics. It seems to get quite far.

Initially the words "objective" and "counterfactual" were italicized, but I figured that would get in your way, and so I stripped it out.

Does that sound OK?

09-05-09 *The Excruciating Hangover* (to O. J. E. Maroney)

Below is the passage from Marcus I was thinking of. It was in the middle of a very lengthy (and not all that coherent) letter he wrote to Rob.

Attached also is a paper I'm writing at the moment. [See "Quantum-Bayesian Coherence," `arXiv:0906.2187v1`.] It still has a good way to go to being completed, but all the advertisements are already in place. Please see the final paragraph on page 7 (ending on page 8) and the two associated footnotes. Like my care to put the Martin Gardiner quote on realism at the beginning of my recent talks, I'll be writing that section with you in mind ... ☺

Excerpt from D. M. Appleby's note to R. W. Spekkens, 14 April 2009:

> I would like to stress that I really meant what I said about finding hidden variables interesting. I have been arguing in this negative way because I felt you were trying to force me in a direction I do not choose to go, and I felt obliged to give some reasons for resisting. But now that I have done so let me be a little more positive.
>
> Perhaps you ought to know that Chris and I do not think entirely alike. To some people, indeed, it seems that we think quite differently. When I was at PI in the summer

I had several lengthy discussions with Owen. At a fairly early stage in those discussions Owen exclaimed, in tones of incredulity, "are you aware that Chris goes around telling people that you are a quantum Bayesian?" It took many many beers, and some truly excruciating hangovers, to convince him that Chris was not misrepresenting me. And perhaps he never was fully convinced. To Chris and I it seems that the differences between us are of very minor importance. But that is not always how it seems to other people.

Anyway one of these minor differences is that, although I do not believe in hidden variables, I do find them interesting. Another difference is our previous intellectual history. Though never a true believer, I was for a long time very close to the hidden variables school of thought, to such an extent that people often assumed that I was a Bohmian. (And perhaps there was a sense in which I really was a Bohmian—for Bohm himself was not a Bohmian in the sense this term has come to have. In particular he didn't believe in hidden variables.) I was also a convinced anti-Copenhagenist. When the paper that Chris wrote with Peres "Quantum Mechanics Needs no Interpretation" first came out my sympathies were all with the critics. But then I actually met Chris, and that brought about a revolution in my thinking.

I should explain what exactly this revolution consisted in. I didn't suddenly decide that the reasons I had previously had for rejecting the Copenhagen Interpretation were invalid. On the contrary all the bad things I used to say about the Copenhagen Interpretation, before I met Chris, I continue to say now. I thought in the past, and I still do think that Bohr is impossibly obscure, and Heisenberg and Pauli not a lot better. I used to think, and I still do think that Bell was absolutely bang on the nail when he described the Copenhagen interpretation as "unprofessionally vague and ambiguous" (I am quoting from memory, and may not have reproduced his words exactly). Chris didn't cause me to see clarity where I had formally seen obscurity. But what he did bring about was a fundamental change in my attitude to that obscurity. Specifically he led me to think that buried in all the obscurity there were the germs of something true. Formerly I had seen the Copenhagen interpretation as dirt, fit only for the bin. But now I see it as soil, in which something good may eventually be got to grow.

12-05-09 *Read Me* (to R. F. Wachter)

Wachterism 1: *I'm looking for a few bullets about research directions in the area of "quantum-classical" computing & communications. Sorry for the vagueness. I could use a few — just what comes to mind as you read this.*

- (In the application of quantum cryptography) Quantum information knows when it has been read. (Or leaves a trail that it has been read.)
- Why is quantum information a better resource for communication channels than classical information?
- What powers quantum information's sensitivity to eavesdropping?
- Quantum communication is what you get when you build the world of components that are inherently sensitive to the touch. If you push, they go further than might have been expected.

Since I have no idea what you need, I don't know if you want questions or answers. Just making things up.

- Need formalism that makes quantum and classical information directly comparable, so that inherent differences are revealed in a direct way.
- Quantum information is sexy.
- *Mechanica Quantica Lex Cogitationis Est* (this is the quantum Bayesian version of *Semper Fi*)
- Quantum information is the way it is because the world is the way it is, but there is still much confusion on exactly what way the quantum world is.
- Quantum information exploits the fantastic creative power of quantum matter.
- The field of quantum information is just applied quantum foundations.

Give me more guidance, and I'll try to make up something more relevant.

- quantum cryptography protocols that are even more sensitive to eavesdropping than present protocols
- better quantum error correction through better understanding of the basic structure of quantum channels
- understanding geometry of quantum-state space is key to understanding the power and potential of quantum information processing

Do you say uncle yet?

12-05-09 *Found It!* (to R. Schack)

I finally found that damned William James quote I'd been wanting to use! It was in his "unpublished" manuscripts (and they apparently are not scanned to the web as so many of his other things are).

> Of every would be describer of the universe one has a right to ask immediately two general questions. The first is: "What are the materials of your universe's composition?" And the second: "In what manner or manners do you represent them to be connected?"

12-05-09 *Figure* (to R. Schack)

Have you looked at the whole paper now? If so, then I guess sit tight for a while.

I find myself completely burned out tonight. The most energy I've been able to muster is to start reading about the Bode-Miller objections, and James's 5 year(!) struggle with them. When it's our turn, we've got to do better! We at least have a leg up on him when it comes to 'certainty'. Strangely, he only seemed to get halfway there in his conception:

> When an event that is not yet actual is nevertheless *certain to occur* in [the] future, it is more than a bare possibility. We speak of its enjoying even now a *virtual or potential existence*.

Hopefully I'll wake up in the middle of the night and do some work on the paper. I still want to add a couple of points in Section 5.2. Add a $d = 3$ discussion to Section 5.5. I want to add another paragraph to 6.1. And then there's the dreaded Section 8. I have a vision that the paper should be 54 pages long.

15-05-09 *Emailing: 459164a* (to G. L. Comer)

At first I thought I was going to hate this article, but then I found that I loved it. I want to print it out when I get back to the office. I particularly like the phrase "their expectations about the consequences of their actions"—because I say that is exactly what a quantum state is.

I read the article (and am writing to you) in the back of a van returning me to Waterloo from the Toronto airport.

Free will in the back of a van ... I haven't done that since high school.

16-05-09 *Measurement Problem and the Reality of Wives* (to R. D. Gill, J. Emerson, A. Plotnitsky, and T. M. Nieuwenhuizen)

Dear Richard, Joseph, Arkady, and Theo,

Thanks for the entertaining banter. I found seven emails in my box when I returned from today's outing to buy hostas and suddenly felt very popular ... that is, *until* I actually read the notes and learned that I'm merely imaginary. Oh well, I guess I have to live with that.

But it reminded me of a story I wrote down for John Preskill several years ago, titled "The Reality of Wives." I reproduce it below for anyone interested. [See 21-07-01 note "The Reality of Wives" to A. J. Landahl & J. Preskill.]

Imaginary wishes,

17-05-09 *Reply to Several Things* (to K. Martin)

Martinism 2: *James told me you had over 50,000 mp3's, is that right? If so, when combined with your email collection and obvious love of books, one can begin to formulate interesting theories about you.*

53,694 to be precise, as of today at least. And 930 books. Finally, here's a number I've never tabulated. (It took me about 20 minutes to do it this morning.) Since May 1997, I apparently have written 31,675 emails. As you suspected, I like to keep lists.

20-05-09 *Measurement Problem and Dates* (to R. Schack)

I'm in London, ON, where I presented our paper to the philosophy dept yesterday. Wayne Myrvold had one point that may call for some modification to our Section 4.2. He complained that we are giving a diachronic reading to the Principal Principle, but that its raw statement (as a requirement on conditional probabilities) is a synchronic one. I think he's at least partially right. He points out that one would only adjust one's updated probability to the conditional if one thinks that being apprised of the value of a chance is actual "learning." I.e., it doesn't so shake up one's world picture that one adjusts for this new knowledge by something other than strict conditioning. That is certainly a technical point that is right in other contexts. On the other hand, I think the reading we gave the PP is the usual one: I.e., that *implicit* in it is the idea that knowing the chance is the pinnacle of knowledge, i.e., implicit in the concept is the diachronic usage of it. I want to go back to Lewis's original statements to see more precisely how he's using it. I hope it doesn't cause me too many annoying acrobatics in recomposing the paragraphs to reflect Wayne's point.

Another thing that must be rewritten somewhat is Section 4.1. When I was in Washington, Patrick Hayden pointed me to a later paper than the one we cite, where nonminimal (but still finite) two-designs are systematically constructed in every finite dimension. I believe they have an exponential number of outcomes though—I've got to get the reference—though that's not all that important. Anyway, we just have to admit straight up that it's the minimal two-designs we like. So, I'm going to shift the argument to emphasize that with larger two-designs, though the urgleichung holds, the priors must then be restricted to a lower dimensional subspace of their defining simplex. That is surely an unpalatable feature.

28-05-09 *PIAF Postdoc at UQ* (to G. J. Milburn)

Thanks for this. I will distribute it appropriately.

By the way, I could stand to get some references from you. Attached is a paper I'm constructing at the moment. [See "Quantum-Bayesian Coherence," `arXiv:0906.2187v1`.] The references I need are for the middle paragraph of page 26, the one starting with "The most telling reason …":

> But the quantum-Bayesian view cannot abide by this. For, the essential point for a quantum-Bayesian is that there is no such thing as *the* quantum state. There are potentially as many states for a given quantum system as there are agents. And that point is not diminished by accepting the addition to coherence described in this paper. Indeed, it is just as with standard (nonquantum) probabilities, where their subjectivity is not diminished by normatively satisfying standard Dutch-book coherence.
>
> The most telling reason for this arises directly from quantum statistical practice. The way one comes to a quantum-state assignment is ineliminably dependent on one's priors. Quantum states are not god-given, but have to be fought for via measurement, updating, calibration, computation, and any number of related pieces of work. The only place quantum states are "given" outright—that is to say, the model on which much of the notion of an objective quantum state arises from in the first place—is in a textbook homework problem. For instance, a textbook exercise might read, "Assume a hydrogen atom in its ground state. Calculate …." But outside the textbook it is not difficult to come up with examples where two agents looking at the same data, differing only in their prior beliefs, will asymptotically update to distinct (even orthogonal) pure quantum-state assignments for the same system. Thus the basis for one's particular quantum-state assignment is always *outside* the formal apparatus of quantum mechanics.

I remember your once expressing very eloquently this point with respect to quantum process tomography. (It may have been at the Konstanz meeting, but it might have been elsewhere as well.) It would be nice to cite some of the nitty-gritty of coming to a particular quantum state assignment (how one must do tomography and calibration and stuff like that). Any suggestions?

Are you here at PI this week? If so, I could also just print this out and give you a copy.

29-05-09 *The Elusive Nature of the Quantum State* (to G. J. Milburn)

John Wheeler used to say, if you really want to get a job done, give it to a busy man! It looks people are using that philosophy in spades with you.

Milburnism 2 : *Your paper looks fascinating. I am not sure if I will get time today to give a considered response to your request, but I should be able to get back to you early next week. Would that be soon enough?*

It surely would. I've still got about five more pages of material to write in it anyway.

BTW, aside from the particular section I asked you the question about, if you want also to get a quick summary of what the paper is about (i.e., without reading the whole thing), just go directly to the figure on page 20. The point of the paper is that the equation

$$q(j) = (d+1)\sum_{i=1}^{d^2} p(i)r(j|i) - \frac{1}{d}\sum_{i=1}^{d^2} r(j|i)$$

holds some chance of being taken as the *single* postulate of quantum mechanics.

02-06-09 *Unprofessionally Vague and Ambiguous* (to D. M. Appleby)

How have things been going the last week? When you can muster the energy and thought, we should discuss your post-Växjö plans.

On an immediate matter: I've heard you use the phrase in the title of this note several times. I know it is something John Bell said, but can you give me the precise coordinates of it. In which essay does it appear. I have his unspeakable book at home, so I should be able to find it if just given a hint.

Using him, will be part of the completion of these paragraphs of mine:

> Of every would be describer of the universe one has a right to ask immediately two general questions. The first is: "What are the materials of your universe's composition?" And the second: "In what manner or manners do you represent them to be connected?"
>
> — William James, 1903–1904

> This paper has focussed on adding a new girder to the developing structure of quantum-Bayesianism ('QBism' hereafter). As such, we have taken much of the previously developed program for the background of the present efforts. If a reader wants to know the core arguments for why we choose a more 'personalist Bayesianism' rather than a so-called 'objective Bayesianism', she should refer to Refs. [17,20,55]. If she wants to know why a subjective, personalist account of certainty is crucial for breaking the impasse set by the EPR criterion of reality, she should refer to Refs. [21,55]. This paper was meant to get a new phase of the program off the ground without dwelling too much on the past.
>
> Still, fearing James' injunction, we know it is our duty to discuss anew one term of this paper that has so far been waived about most uncritically: It is 'measurement.' How can one really understand the proclamation 'Unperformed measurements have no outcomes!' in a deep, soul-satisfying way? Answering this question, we feel, is the first step toward characterizing "the materials of our universe's composition."
>
> Believe it or not, we take our cue from John Bell: Despite our liberal use of the term so far, the word 'measurement' should be banished from fundamental discussions of quantum mechanics.

04-06-09 *Tomorrow. Tonight?* (to K. Martin)

I'm sorry to hear this. [...]

Look, Keye, take care. Write a poem about this experience, and look for whatever insight it gives you on quantum mechanics (remembering that every single experience should be used to give insight on quantum mechanics).

10-06-09 *Typos and Experience* (to N. D. Mermin)

Sadly, I'm still working on that paper I showed you last. I put it on the shelf for a while, and now I'm back to it, bound and determined to get it posted by the end of the week. (There'll be smaller, twin paper after my visit with Rüdiger, titled "Quantum-Bayesian Decoherence" where we show how Zurek's thinking is *exactly* backwards, when seen through Bayesian eyes.)

I was working on Footnote 29 (where I mention you), when I found your typo. I might as well attach the latest version. I reworked the intro after the last comments you sent me. It was indeed crucial that I make explicit the EPR-criterion-of-reality business prior to Bell's argument, and I've done that now. Still, I suspect you won't like the new version either—for one thing, I didn't give any respect to all the alternatives to EPR-criterion that you mentioned.

Have a look at Figure 3 and the long caption; you might enjoy it. I notice that you too have been leaning on the word "experience" lately. At least in the paper that I cite in Fn 29, but also I ran across your *Phys Today* piece a couple days ago. [I wonder too whether you've yet appreciated the beauty of the second equation in the caption to Figure 2. You've never mentioned it if you have.]

Comments are still welcome, but you're probably tired of me.

More on my new views of "experience" below. [It concerns another one of my papers in the works, that one for a collection on "pragmatism and quantum mechanics."]

11-06-09 *The Paulian Idea, Full Frontal* (to R. Schack)

Regarding,

Schackcosm 117: *"From within any part, the future is undetermined" is exactly what a many worlder would say. It suggests that the evolution of the whole is determined, which is not at all what we want to say. Of course you point that out in the footnote. But there you say that there is no whole. Why do we have to take a view on whether there is a whole beyond saying that q.m. isn't about it if it exists? Why do we have to go into this discussion at all? Why not simply point out that from any agent's perspective, there is uncertainty, full stop? I also don't like "treating a part as an agent". We are not treating parts of the universe as agents. Agents are primitives at the moment.*

I think it is better to just write a better footnote, incorporating your remarks into that. The thing is, I do want to "take a view" ... that is the whole point of that and the next paragraph, and the previous two James quotes.

Let me try to finesse it all. Give me another shot. Perhaps "treating a part as" is not the best choice of words, but this whole last part of the discussion was to build toward James's (and Pauli's) "pure experience" ... where agenthood is not primitive, but rather one of two complementary aspects of something neutral.

Did you read the version where I had the Wheeler quote at the end?

11-06-09 *The Paulian Idea, Full Frontal, 2* (to R. Schack)

Did you see my "apologetic" comment on my `quant-ph` posting of "Delirium Quantum":

> Stuffed away in a conference proceedings for years, I finally worked up the nerve to post this because I needed to cite it in a paper with some proper equations. Stay posted.

Funny thing is I just got a letter from the editor of the *NeuroQuantology Journal* saying that they would like to publish the paper!!

Different worlds, different worlds!

11-06-09 *The Paulian Idea, Full Frontal, 3* (to R. Schack)

Schackcosm 118: *I don't understand "But perhaps this republican-banquet vision of the world that so seems to fit with a QBist understanding..." It's not even clear to me from this sentence if the republican-banquet vision is ours or not.*

It is certainly my present vision. I thought I had already declared enough ownership in the sentence: "It is almost as if one can hear in the very formulation of the Born Rule one of William James's many lectures on chance and indeterminism." ... which itself refers to urgleichung stuff a couple of sentences above.

Think like William James: absolute clarity might be the enemy of poetic flow.

12-06-09 *In Defense of a Nomenclature that is Psychologically Rather Mature* (to J. Barrett)

Thanks Jon. Your note actually pushed me over the edge in some way: Before I had always said "anti-realism box" to myself tongue in cheek. But now, knowing that it'd be a pleonasm, I'm starting to take it quite seriously. Actually, it really does capture the idea I was shooting for in Section 8!

BTW, attached is a more extended diatribe on why I don't like to call qm "nonlocal". Rüdiger and I plan to make that into a proper paper later in the year.

Jon's Preply

> "Indeed, it flavors almost everything they think of quantum mechanics, including the interpretation of the imaginary games or toy models they use to better understand quantum mechanics itself. Take the recent flurry of work on Popescu-Rohrlich boxes [5]. These are imaginary devices that give rise to greater-than-quantum violations of various Bell inequalities. Importantly, another common name for these devices is the term 'nonlocal boxes' [6]. Their exact definition comes via the magnitude of a Bell-inequality violation-which entails the non-pre-existence of values or a violation of locality or both-but the commonly used name opts only to recognize nonlocality. They're not called anti-realism boxes, for instance. The nomenclature is psychologically telling."

The phrase "nonlocal box" is made up of two words: "nonlocal" and "box". The second word here is intended to call to mind a "black box" — that is a device or process that admits an input, and produces an output, but whose internal workings are either unfathomed or unfathomable. By this light, the terminology does already recognise the non-preexistence of values as a possible interpretation, and "anti-realism box" would be a pleonasm.

More seriously: the paper looks very interesting and I'm looking forward to a better look. Will either of you be at the Reconstructing Quantum Theory conference at PI in August?

13-06-09 *Reasons for Rewriting Quantum Mechanics* (to A. S. Holevo)

I finally wrote down a paper version of the thoughts that were going through my head the last time I saw you. Let me call your attention to it: `http://arxiv.org/abs/0906.2187`. I hope that, being in paper form now, it will help convince you that what I have in mind is the very antithesis of a hidden-variable program. (I remember well the pain of your remarks at the end of my talk!)

I hope things are going well with you and that maybe we will have a chance to see each other a little when you are in Toronto.

13-06-09 *At Last, At Last!* (to G. M. D'Ariano)

I finally fulfilled the promise I made to you long ago: I finally posted a paper on the foundational significance of SICs. You can find it here: `http://arxiv.org/abs/0906.2187`.

It'll be great seeing you again this week; I'm just on the drive between Waterloo and Toronto on my way to Sweden.

13-06-09 *Still Seeking SICs* (to J. Bub & I. Pitowsky)

I have finally written up the stuff I was telling you about one evening at Bill Demopoulos's party. Since you seemed interested, let me give you a pointer to it: `http://arxiv.org/abs/0906.2187`. I hope maybe it'll give you a little food for thought, and show a little more why I resist thinking of quantum theory as a *generalization* of Bayesian probability theory.

I hope you are both doing well. I'm on my way to Sweden and plan to have a thoughtful midsummer there.

13-06-09 *Discussion Points* (to W. K. Wootters)

I'm so glad you're coming to PI this Fall. Do you yet know when you will arrive? It's going to be a fantastic year here, I deem: Beside you Howard Barnum, Richard Healey, and Steve Bartlett will also come. For different periods of time each, I suppose, though I do know that Howard is coming for a full year. Furthermore, we have another added treat: Marcus Appleby will come for a month-long visit every other month. So, I'm going to be one happy boy ping-ponging between all you guys.

I finally put down on paper my reasons for thinking SICs are important for quantum foundations, and I wonder if you might have an interest. If so, you can find the paper here: `http://arxiv.org/`

abs/0906.2187. Now that I think about it, I should have cited your "probability tables" paper in there, and I can think of exactly where (page 6). I'm sorry about that. It was surely the root of the root of the tree that led me up to this point. I'll fix it in the revised version. One thing is for sure though, I hope my enthusiasm for SICs in that paper is contagious enough that we'll have many long discussions on related items when you visit.

13-06-09 *Update* (to D. M. Appleby)

Thanks. I'll print your notes out and read them on my flight later today. We can discuss in Sweden.

Likewise, would you mind having a read of Section 8 (only section 8, don't worry about the rest) in my: http://arxiv.org/abs/0906.2187. I'd like to discuss some of that with you as well.

The other day when I was digging up Wheeler quotes for the above said Section 8, I ran across a little exchange between Wheeler and Richard Rorty. Wheeler had just given a talk where he explores the idea of taking the "elementary quantum phenomenon" as the fundamental building block of the universe. Rorty's question came afterward. What struck me was how prescient the question was respect to the title of your talk in Växjö. I thought you might enjoy:

> RORTY: What puzzles me is the degree to which the surprisingness of quantum physics is an empirical, and the degree to which it is a philosophical matter. That is, what I don't know enough to grasp is whether the philosophical overlay on science, the nineteenth century philosophical account of the nature of science, was so inadequate in itself that practically anything would make one doubt it. As it happened, quantum phenomena did. But it may have been so faked up that it merely needed a suggestion to collapse in favor of something like a pragmatist understanding of science. But I take it that Professor Wheeler feels that it is quite specific quantum results that simply contradict fundamental empirical theses which had been presupposed by the older theories. So the relation is much more direct.

13-06-09 *From Pragmatism to Pure Experience, 2* (to M. Bächtold)

I apologize again for keeping you waiting so long.

Yes, I am still working on the paper—intellectualistically, even if the writing has come to a temporary standstill. I can quite understand if you have well lost patience with me, but I really want to get this paper written in one form or another. If you need me to drop out, I can do that, but I am trying very hard to pull my quantum Bayesianism into an ontology, and until I get this paper out of my system, I feel it's all going to be clouds to me. I need to write this to clarify things to myself: It is a bit like giving birth. So, I would still like to have a contribution to your volume.

The bad thing is I've gotten all hung up over the Miller-Bode objections. They are as relevant in this context (the quantum context), I am discovering, as they ever were. They turned the skeletal manuscript I told you about below into a kind of scarecrow. Rüdiger Schack and I are going to meet June 18 and spend until July 3 intensely trying to come to a conclusion on this, and I very much hope a baby will be born.

Could you possibly give me until the end of August for a submission? To demonstrate some piece of my good faith that this is topmost on my mind, let me show you another paper much closer to completion (five more pages to go!) that may give you some sense of the one I'm trying to produce for you. The one for you would be an infinitely more philosophical piece (with little to no equations), but it would build off the last paragraph on page 7 / first paragraph of page 8, and particularly all of Section 8 (only 3/4 complete itself). Please read through those parts, even though the punchline is not included yet. The title of Section 8 is a direct allusion to my paper for you. I plan to get the present paper submitted to the archive this week before flying to Sweden Saturday. I just thought the writing there might give you some flavor of what is to come.

What I am aiming for is a pluralistic ontology something like "pure experience." Quantum measurement should be an instance of it. But it is so very painful to get the ideas straight.

I will live with whatever your opinion is.

13-06-09 *Measurements Generate Reality* (to A. Zeilinger)

I finally posted something proper on the foundational import of the representation of quantum states I was speaking of the last time I saw you: It's all about "Unperformed experiments have no outcomes." I hope you will enjoy it, as I know this is our greatest common interest. The paper can be found here `http://arxiv.org/abs/0906.2187`.

I suspect you guys just had a great conference in Vienna.

13-06-09 *Reply* (to H. C. von Baeyer)

von Baeyerism 29: *I have loaded my Kindle with* Pragmatism *for free, and I'm reading it with great pleasure. "Theories thus become instruments, not answers to enigmas, in which we can rest." So no rest for you!*

Good for you! I've always liked the continuation of that line: "We don't lie back upon them, we move forward, and, on occasion, make nature over again by their aid." What a slap in the face to rationalism. A good theory is not a description of what is there, fixed and unchangeable, but a *tool*, not different in kind from a hammer, for actually reshaping nature.

I'm as far as Boston now. I'm looking forward to plenty of insights this week. I don't know how it happens, but I always find being in Sweden shakes loose at least one new QBist thought.

13-06-09 *Abstract to QTRF5* (to I. Bengtsson)

Bengtssonism 2: *If possible I would be delighted to have you in "my" session; I have some premonitions about the contents.*

Your premonition is probably correct. You can find the full story here now: `http://arxiv.org/abs/0906.2187`.

I've just started my long journey to Sweden. I hope we get a good chance to discuss things there. Åsa told me that you may now have more sympathy for a "quantum mechanics within probability theory" (as opposed to "quantum mechanics as a generalization of probability theory") than you once had. I'd like to hear what you're thinking.

13-06-09 *Single-User Theory* (to J. Emerson)

Here's that note I started to construct but never finished. Also included are the attachments to have gone with it. I think at this stage I won't go ahead and finish the note after all. That's because part of the answer was superseded by my recent posting `http://arxiv.org/abs/0906.2187` which includes some of the material from the note below anyway. So, why don't you have a look at Section 1 and Section 8 in the posting, and the notes attached here. Maybe that'll at least give you enough information so that you can say with good reason that you do indeed disagree with "what Fuchs thinks about reality".

— — — — — — — — —

I'll respond quietly (aka, privately) to a couple of points in one of your emails. Happy Victoria Day, by the way. After this note, I'm out to work in the garden again.

Emersonia 1: *By the way, I was a student of Ballentine's and I agree almost entirely with his point of view. I'm not quite sure what Fuchs thinks about reality and I probably would disagree with it.*

If you're not sure what I think, how do you know that you would *probably* disagree with it? ☺

I believe of reality what Martin Gardner believes of it. The first attachment is a quote from him:

> The hypothesis that there is an external world, not dependent on human minds, made of *something*, is so obviously useful and so strongly confirmed by experience down through the ages that we can say without exaggerating that it is better confirmed than any other empirical hypothesis.

As for quantum mechanics, I believe it is the best tool we (each of us) presently have for seeing our way through our *encounters* with that world. Another way to put this particular point: I see quantum mechanics as a single user theory. I can use it, you can use it, she can use it. Any of us. And when any of us uses it, we are using it to better prepare for our own (personal) encounters with the world. We use it to make sure our *beliefs* about the consequences of those encounters are *consistent* with each other. It is a calculus for "consistifying" our beliefs.

Saying this much—but only this much—is not inconsistent with a Ballentine-Emerson program of trying to (or hoping to) complete quantum mechanics. At least as far as I can tell, it is not inconsistent with that program. For it could be that quantum mechanics is a multi-user theory as well, and that I, Chris, am ignoring an extra, rich layer of the theory. For this option to be had, those things that I take to be ostensibly personal encounters with the world, would have to be more public things.

13-06-09 *Once a Solipsist, Always a …* (to H. M. Wiseman)

Our old conversations have been on my mind again lately. (That's a good thing.) Anyway, to honor it, I made an oblique reference to you in my most recent posting `http://arxiv.org/abs/0906.2187`. A little challenge: Let's see if you can find yourself.

Howard's Reply

> A little challenge indeed. How many friends do you have left in Australia? ☺
>
> I don't think I would have said "Rubbish! … It would mean quantum mechanics collapses into a kind of solipsism—a theory that there is only the self." but rather something like "Yes indeed, and this crypto-solipsism is, as I think Einstein saw, why quantum mechanics is not complete, why it does not describe the world in which the

many observers live and make predictions etc, and why we should try to find a theory which does."

However, exactly what I would have said I could only judge after a careful reading of your paper rather than the cursory one needed to meet your challenge. I'll try to provide that sometime soon.

Thanks for the honour.

14-06-09 *Once a Solipsist, Always a . . . , 2* (to H. M. Wiseman)

. . . from a Heathrow lounge . . .

Wisemanism 35 : *How many friends do you have left in Australia?* ☺

Good point!

One point of language: I was a little worried that an Australian would ever use the word "rubbish". Rob Spekkens told me that Terry Rudolph would most certainly say "bullshit". But I could swear I've heard you say "rubbish" before (though I don't actually remember to what).

Howard's Reply

Probably. I'm more polite than Terry.

14-06-09 *Seeking a Home for the SIC'ening Bayesians* (to J. I. Cirac)

Rüdiger Schack and I just posted a rather long paper covering two subjects rather dear to me: 1) what quantum mechanics looks like in terms of symmetric info complete measurements (i.e., what I talked about during my last visit to you), and 2) what this all means for the "quantum Bayesian" interpretation of quantum mechanics that Caves, Schack, Peres, Appleby, etc., and I have been putting together for some time.

Here's a link: `http://arxiv.org/abs/0906.2187`.

May I ask you to have a look at it and give me an opinion on whether you think Rev. Mod. Phys. is an appropriate home for it? It's quite extensively referenced, both on things to do with SICs and things to do with the quantum Bayesians (pro and con). It's definitely partially review article, and no doubt "in depth" as your webpage calls for.

If it is a style of article you think worthwhile, we'll submit it to RMP and see what the referees say. Otherwise, we'll seek another home for it, no problem.

I'm glad to hear you'll be spending a little time at PI. Do you know when you will likely come in the coming year?

16-06-09 *Feeding Quantum Mechanics* (to B. C. van Fraassen)

You once wrote me this (seven years ago actually!):

van Fraassenism 13 : *Now when it comes to theories that give us probabilities, whether absolute or conditional, I'll agree with scientific realists that literally read they say that there are objective probabilities in nature. But accepting such a theory does not involve believing that. Rather it involves appointing the theory as an 'expert' for guidance of our subjective probabilities concerning observable events. The metaphor of 'expert' is cashed out (as by Haim Gaifman) as follows. Suppose* *that I appoint Peter as my expert on snuffboxes. That means for my subjective probability P and Peter's subjective probability q the constraint:*

$$P\Big(A \,|\, q(A) = x\Big) = x$$

with generalizations of this to intervals, odds, conditional probabilities, for statements A that are about snuff boxes.

Thus the issue of whether there are objective probabilities in nature or whether to believe in them is finessed: there are only the theory's probabilistic pronouncements accepted as input and my own subjective probabilities.

That is clearly not how you are approaching it overall. But perhaps there are connections? I'd like to know how the QM probabilities are fed into your subjective probability as a whole – I wonder if it will not be similar. After all, even if a quantum state is read as a compendium of probabilities, and you say something like "this material is in quantum state such and such", your own subjective probability function has a domain much larger than facts pertaining to this material.

I now have a very direct answer for you. (Sorry, sometimes it takes me a while!) If you have a small amount of time, I'd be very flattered if you'd look at my new paper to see what I mean: `http://arxiv.org/abs/0906.2187`. (The key idea is in the figure on page 20.) I hope it gives you some food for thought.

(By the way, it will actually be followed in a month or so with a sibling paper titled "Quantum-Bayesian Decoherence." In that one, we make use of your Reflection Principle to argue that Zurek's decoherence program is just exactly opposite the way a good Bayesian would think about what's going on.)

Hope life in California is treating you well.

16-06-09 *Latter-Day Wheeler* (to W. H. Zurek)

Here's that passage I was thinking of. I was wrong though, it's not from his December 2000 op-ed in the *New York Times*, but rather his 1998 autobiography.

> Many students of chemistry and physics, entering upon their study of quantum mechanics, are told that quantum mechanics shows its essence in waves, or clouds, of probability. A system such as an atom is described by a wave function. This function satisfies the equation that Erwin Schrödinger published in 1926. The electron, in this description, is no longer a nugget of matter located at a point. It is pictured as a wave spread throughout the volume of the atom (or other region of space).
>
> This picture is all right as far as it goes. It properly emphasizes the central role of probability in quantum mechanics. The wave function tells where the electron might be, not where it is. But, to my mind, the Schrödinger wave fails to capture the true essence of quantum mechanics. That essence, as the delayed-choice experiment shows, is *measurement*. A suitable experiment can, in fact, locate an electron at a particular place within the atom. A different experiment can tell how fast the electron is moving. The wave function is not central to what we actually know about an electron or an atom. It only tells us the likelihood that a particular experiment will yield a particular result. It is the experiment that provides the actual information.
>
> Measurement, the act of turning potentiality into actuality, is an act of choice, choice among possible outcomes. After the measurement, there are roads not taken. Before

> the measurement, all roads are possible—one can even say that all roads are being taken at once.

In the *New York Times* pieces, he only says this and doesn't say anything explicit on the wave function:

> My mentor, the Danish physicist Niels Bohr, made his peace with the quantum. His "Copenhagen interpretation" promulgated in 1927 bridged the gap between the strangeness of the quantum world and the ordinariness of the world around us. It is the act of measurement, said Bohr, that transforms the indefiniteness of quantum events into the definiteness of everyday experience.

The last paragraph of the more relevant quote expresses a world of difference between John's view at the time and standard many worlds (of Deutsch, Wallace, and the rest of the Oxford crowd), and one I thought you did good justice expressing in your *Physics Today* piece: Before the measurement "one can say all roads are being taken at once"; "after the measurement there are roads not taken". Most many-worlders—I'm thinking of Tegmark in particular—would probably dismiss that as a literary flourish, one that's not crucial for how John visualized things. The typical many-worlder would say, "Before measurement, all roads at once; after measurement, all roads at once. And anyway, what is this thing called measurement? Let's just get rid of it. To the extent that it's there, it's a messy concept that should be derived and secondary." For Wheeler, as far as I can tell—and I have read everything he's ever written—it held the most central place.

Anyway, I was very proud of your piece with Misner and Thorne, and thought it was just wonderful.

19-06-09 *Your Talks* (to D. M. Appleby)

From Hay-on-Wye; what a fantastic town!! Rüdiger and I have been discussing QBism, and I feel it is just a glorious day for the project. We'll be in the UK for the next three days, then 2 weeks together in Waterloo. I have this feeling really good things are going to happen.

Thanks for sending your talk. I read it last night before bed and definitely enjoyed it.

21-06-09 *Rainy Day Train* (to C. Eriksson)

Thanks for the note. Emma is 10 now, and Katie is 7. Attached is a recent picture of the two of them just after they got out of bed one morning. They're good kids; I'm very proud of them—all the time I tell them they'll "change the world".[201]

Just flying home from London. Between Sweden and now, I went book shopping in a strange little town in rural Wales. They have 35 bookstores, with nearly 3/4 million books between them! (I bought 27 books in point of fact.) A great vacation!

21-06-09 *Renege* (to Y. J. Ng)

It is no problem. I am just flying back home from London. Right after the meeting in Sweden, Rüdiger Schack and I took a little vacation to the town Hay-on-Wye in rural Wales. It's an amazing place: There are 35 second-hand bookshops there! And so I'm coming home with a

[201] Because the world is malleable and "ever not quite".

suitcase stuffed with 27 specimens for my library. Speaking of Rüdiger, you might enjoy our new paper: `http://arxiv.org/abs/0906.2187`. It tells a more complete version of the story I told you during your last visit.

Paul Frampton was at the same meeting that I was in Sweden. It was good seeing him again after all these years.

22-06-09 *More Thoughts* (to D. M. Appleby, H. C. von Baeyer and R. Schack)

1) Reading your note below,

and

2) thinking of the story where Wheeler commands the equations "Now fly!"

and

3) thinking of this quote that I copied into my first samizdat: "I forbade any simulacrum in the temples because the divinity that breathes life into nature cannot be represented."

and finally,

4) thinking of this passage from "my friend" James:

> I am as confident as I am of anything that, in myself, the stream of thinking (which I recognize emphatically as a phenomenon) is only a careless name for what, when scrutinized, reveals itself to consist chiefly of the stream of my breathing. The 'I think' which Kant said must be able to accompany all my objects, is the 'I breathe' which actually does accompany them. There are other internal facts besides breathing (intracephalic muscular adjustments, etc., of which I have said a word in my larger *Psychology*), and these increase the assets of 'consciousness,' so far as the latter is subject to immediate perception; but breath, which was ever the original of 'spirit,' breath moving outwards, between the glottis and the nostrils, is, I am persuaded, the essence out of which philosophers have constructed the entity known to them as consciousness. That entity is fictitious, while thoughts in the concrete are fully real. But thoughts in the concrete are made of the same stuff as things are.

I found myself asking Rüdiger how to say "primal breath" in German. He proposed: urhauch. (Now Marcus, try to pronounce that one!) The neutral stuff fighting it out at the republican banquet, and by way of that making our universe, is urhauch.

Just trying the word on for size.

Marcus's Preply

> I have just been thinking about your friend James.
>
> [. . .]
>
> Anyway, back to James, and pure experience. I take your point about what he meant, and I think perhaps I semi-agree with him. However, I have some significant qualifications.
>
> In the first place I think he chose the wrong name. Instead of "pure experience" it might be better to call it, say, "ur-stuff". Or perhaps "primal-stuff". The trouble with "experience" is that the name isn't really neutral, it seems to me. It is strongly biased on the mind side. Also, "experience" suggests (to me) that what we are talking about is all out on the surface. But I think that what we are talking about is deep: behind or

below what we see is loads of stuff that we can hardly guess at. "Experience" suggests to me a sheet of water only millimeters thick. But I think what we talking about is an ocean, and it goes way way down.

Both aspects go way way down. Not only the external matter aspect (the fact that quantum systems are unpredictable). But also the internal mind aspect.

In this room where I am now writing the principal cause of uncertainty is me (so far as the things I can observe without ancillary apparatus are concerned). I am pretty confident that the book on the table in front of me will still be there in 5 minutes time, unless I decide to move it. I am likewise pretty certain what the clock will read in 5 minutes time, unless I decide to adjust it. But I have no idea what I myself will be thinking/feeling/writing/doing in 5 minutes time. In a very real and immediate sense I am a mystery to myself.

(I would guess I will still be writing this in 5 minutes time, assuming I don't get up to stretch my legs. But what will I be writing? —It is almost as much a mystery to me who is writing it as it is to you who is reading it. The ideas are forming themselves as I write, in a way which, though not independent of my will—is in fact an expression of my will—is nevertheless far from being fully known to me.)

I prefer "ur-stuff" or "primal-stuff" to "pure experience" because I think it conveys this sense of something mysterious, not fully known.

Another objection to "pure experience" is that it doesn't convey the notion of agency. At least it doesn't to me. One just sits there and has experiences, like it or not. Experiencing, as I understand the word, is passive.

It is of course true that if you go into the neurophysiology of it experiencing things turns out to be far from passive. It is highly active, in fact. But I don't think that is in the ordinary language meaning of the word.

Perhaps "ur-stuff" doesn't have the connotation of agency either. But it does at least have the advantage that it doesn't really have any connotations at all, beyond the connotation of something elemental. Or even pre-elemental. It is anyone's guess what an ur-thing might do or feel or be.

****

However, though I prefer "ur-stuff" or "primal-stuff" to "pure experience" I am still not totally happy. The term suggests something structureless. Something, in other words, like a vector (c.f. the slides for my talk) which owes all of its properties to its relations with other vectors, and has no intrinsic properties of its own, considered in isolation. And I don't like that because I think that as soon as you start to think that way you are going to end up with something which is like classical field theory, in as much as it invites the misunderstanding that what is in question is a complete description.

Perhaps I wouldn't be happy with any name at all (c.f. the Tao Te Ching: "it was from the nameless that Heaven and Earth sprang"). But I guess that doesn't get us very far.

At all events I think it is essential that we avoid the error of thinking that any of our terms denote structureless simples.

In this connection I very much liked your response to Bell's criticism of the way the concept of measurement is used in the Copenhagen Interpretation in section 8 of your paper. Bell, of course, wants a complete description of the measurement process, framed in the language of beables (as does Rob and many others). He is wrong about that. Not only is it OK to use terms which aren't defined in the way that Bell would like: it is absolutely essential that we do so.

We need in fact to recognize that it is not only necessary, but actually essential that we use terms which are similar to the terms of ordinary language in as much as there is no attempt to resolve them into atomic or other elemental components. No one thinks it necessary to define the meaning of the word "chair" by giving a detailed description at the atomic level. The word "chair" is defined relative to its human uses, as something one can sit on. Similarly with the word "measurement".

You do that in your latest paper, and I think you are absolutely right.

(I do have a question however. My own inclination is to take a measurement to be any process by which I or someone else acquires information. If I look at the chair opposite me, and see that it is about 6 inches from the window, then that is a measurement I am inclined to say. Similarly, if an astronomer tells me that such-and-such a white dwarf star has such-and-such mass, then that too is a measurement. Moreover I am tempted to say that I have measured the star [as opposed to saying that I have measured the astronomer] [because it is the star that I have acquired information about]. My question is: do you go along with that? And, if not, can you make it a bit clearer what you do count as a measurement?)

****

A quick point about pragmatism. I was meaning to tell you in Växjö that I am not totally unsympathetic to pragmatism.

The reason I believe quantum mechanics—the reason that I have thought it worth spending years of my life trying to understand it better—is that quantum mechanics works. I have always thought (not just now, but back in the days when I was sympathetic to Bohm) that the fact quantum mechanics works means that it must be in some sense true.

So I will agree with James that the concept of "truth" is intimately related to the concept of "what works". I also share James's conviction that we need to get away from the idea that knowing the truth equates to the possession of some kind of map.

My only disagreement is that I feel it can't be right to actually identify truth and "what works". I feel the concepts are logically distinct, and that it is important to keep them that way.

****

One last remark. The thought in my last email (about Wheeler-Feynman) grew out of a conversation I had with David Craig after my talk. A little to my surprise he actually liked the talk. He especially liked the point about the counter-factual element in the classical field concept, and the point that this means a classical field is much more similar to the Bayesian view of the wave-function than is generally realized. I had the impression that I had got to him there. However, he then asked what I would say about the space-time manifold. I think that is a good question. For of course as soon as you start thinking in space-time terms you do find yourself being driven in a block-universe direction. At any rate, I find myself being driven in that direction. The point about Wheeler-Feynman grew out of my attempts to find some way of getting round that difficulty. Trying to find some more appropriate way of thinking about space and time.

23-06-09 *Fragments* (to D. M. Appleby and H. C. von Baeyer)

Let me reply to a couple of your points.
To

Applebyism 32: *I do have a question however. My own inclination is to take a measurement to be any process by which I or someone else acquires information. If I look at the chair opposite me, and see that it is about 6 inches from the window, then that is a measurement I am inclined to say. Similarly, if an astronomer tells me that such-and-such a white dwarf star has such-and-such mass, then that too is a measurement. Moreover I am tempted to say that I have measured the star [as opposed to saying that I have measured the astronomer] [because it is the star that I have acquired information about]. My question is: do you go along with that? And, if not, can you make it a bit clearer what you do count as a measurement?*

and

von Baeyerism 30: *I'm still re-reading Section 8 and appreciate Marcus's question about measurement.*

here is the way I respond.

With every movement and every breath, I take actions upon the world surrounding me: These are actions with potentially unpredictable consequences for my experience, and actions that the rest of the world could not have "foreseen" coming either. With every breath I contribute to the ongoing making of the world. "Quantum measurement" refers to the special cases of this broad idea where one feels comfortable conceptualizing a distinct number of consequences arising from one's actions, imagines one can write down actual numerical expectations (probabilities) for those consequences, and indeed bothers to conceptualize the actions in the first place to some mathematical precision. In other words, "quantum measurement," as an idea, arises only in very controlled and introspective settings. But wash away the numerics and the need for mathematical precision, and it is something happening all the time, everywhere around us.

I like the way Misner, Thorne and Zurek put it in their *Physics Today* piece on John Wheeler last month. It carries at least part of what I was trying to say above (though "relation" sounds so much more static than what I, and I think John himself, was trying to get at). Let me copy it:

> Quantum mechanics in 1976 was the backbone of atomic, nuclear, and condensed-matter physics as well as quantum chemistry. Yet the essence of "the quantum" was a mystery that gripped Wheeler's attention; quantum measurement, he thought, was the crux of the mystery. Why? Because quantum measurement is only a euphemism for the relation between observers—us—and the rest of the physical universe. So quantum measurement, he said, is where "the quantum gets personal."

Getting a more precise handle on this cluster of ideas, I feel, is the next stage of our research. We are long from getting there, but that is the direction to start turning as we make smaller bits of progress.

Applebyism 33: *The Wheeler story and the quote from your samizdat are just so totally appropriate. I love them. (Where did you get the quote in your samizdat from, by the way?—Just to save me the trouble of looking it up).*

I got the quote many years ago (1997) while reading some crazy book by Jean Baudrillard, but I think he himself got it from another source. Let me see if I can find it on the web. ... Well, I didn't. Maybe Baudrillard made it up, but he put quotes around it as if it came from somewhere else.

Applebyism 34: *I am not so sure about the quote from James. I do think that introspection, considered as a route to understanding consciousness, is totally useless. And perhaps that is all that James is trying to say. But I must say that whenever I look into myself, in an effort to find out what consciousness is, I don't notice any particular connection with breathing. I don't notice a connection with anything else, mind you.*

You miss the point of the quote. It is that "knowing," for us, is a bodily function, neither more nor less sacred than breathing itself. It is that Descartes well should have said (at least for the track Descartes was pursuing), "Spiro, ergo sum." But in James's exact passage, Kant was his target. His point was that it is not "subject" that always accompanies "object," but that it is "breath."

24-06-09 *Those Einstein Quotes* (to W. H. Zurek)

Sorry for the delay: Here are those Einstein quotes I said I would send you. It turned out that I only had two of them in my computer in an acceptable form; the third and most important, that from the Schilpp volume, had only been an abridged version I use in my talks from time to time—so I wanted to add all the missing words before sending it on to you. Anyway, everything is collected in the attached `.pdf`.

It was good sparring with you the other day. We should do it more often—it'd certainly lead to more mutual understanding, which would be most useful for me.

Einstein's Personal Argument for the Incompleteness of Quantum Mechanics (a selection)

Einstein, in a letter to Erwin Schrödinger dated 19 June 1935, referring to the EPR paper:

> For reasons of language this [paper] was written by Podolsky after much discussion. Still, it did not come out as well as I had originally wanted; rather the essential thing was, so to speak, smothered by the formalism.

Now, to let Einstein speak for himself. Particularly note in the quotes below Einstein never invokes what has become known as the EPR criterion of reality: "If, without in any way disturbing a system, we can predict with certainty (i.e., with probability equal to unity) the value of a physical quantity, then there exists an element of physical reality corresponding to this physical quantity." [See Arthur Fine's discussion in the Afterword to the Second Edition of his book *The Shaky Game*, where he has taken to calling it snidely the Podolsky Criterion. Fine also makes the point somewhere that these quotes are not atypical; never once after the EPR paper did Einstein use the precise argument of the paper.]

Einstein, in his "Autobiographical Notes" section of the 1949 Schilpp volume (with some translation details modified by Rüdiger Schack):

> If one asks: does a ψ-function of the quantum theory represent a real factual situation in the same sense in which this is the case of a material system of points or of an electromagnetic field, one hesitates to reply with a simple "yes" or "no"; why? What the ψ-function (at a definite time) asserts, is this. What is the probability for finding a definite physical magnitude q (or p) in a definitely given interval, if I measure it

at time t? The probability is here to be viewed as an empirically determinable, and therefore certainly as a "real" quantity which I may determine if I create the same ψ-function very often and perform a q-measurement each time. But what about the single measured value of q? Did the respective individual system have this q-value even before the measurement? To this question there is no definite answer within the framework of the theory, since the measurement is a process which implies a finite disturbance of the system from the outside; it would therefore be thinkable that the system obtains a definite numerical values for q (resp. p) the measured numerical value, only through the measurement itself. For the further discussion I shall assume two physicists, A and B, who represent a different conception with reference to the real situation as described by the ψ-function.

A. The individual system (before the measurement) has a definite value of q (resp. p) for all variables of the system, and more specifically, *that* value which is determined by a measurement of this variable. Proceeding from this conception, he will state: The ψ-function is no exhaustive description of the real situation of the system but an incomplete description; it expresses only what we know on the basis of former measurements concerning the system.

B. The individual system (before the measurement) has no definite value of q (resp. p). The measurement value only arises through the act of measurement in cooperation with the probability which is given to it in view of the ψ-function. Proceeding from this conception, he will (or, at least, he may) explain: the ψ-function is an exhaustive description of the real state of the system.

We now present to these two physicists the following instance: There is to be a system which at time t of our observation consists of two partial systems S_1 and S_2, which at this time are spatially separated and (in the sense of classical physics) are without significant reciprocity. The total system is to be completely described through a known ψ-function ψ_{12} in the sense of quantum mechanics. All quantum theoreticians now agree upon the following: If I make a complete measurement of S_1, I get from the results of the measurement and from ψ_{12} an entirely definite ψ-function ψ_2 of the system S_2. The character of ψ_2 then depends upon *what kind* of measurement I undertake on S_1.

Now it appears to me that one may speak of the real factual situation at S_2. Of this real factual situation, we know to begin with, before the measurement of S_1, even less than we know of a system described by the ψ-function. But on one supposition we should, in my opinion, absolutely hold fast: the real factual situation of the system S_2 is independent of what is done with the system S_1, which is spatially separated from the former. According to the type of measurement which I make of S_1, I get, however, a very different ψ_2 for the second partial system $(\psi_2, \psi_2^1, \ldots)$. Now, however, the real situation of S_2 must be independent of what happens to S_1. For the same real situation of S_2 it is possible therefore to find, according to one's choice, different types of ψ-function. (One can escape from this conclusion only by either assuming that the measurement of S_1 (telepathically) changes the real situation of S_2 or by denying independent real situations as such to things which are spatially separated from each other. Both alternatives appear to me entirely unacceptable.)

If now the physicists, A and B, accept this consideration as valid, then B will have to give up his position that the ψ-function constitutes a complete description of a real factual situation. For in this case it would be impossible that two different types of

ψ-functions could be coordinated with the identical factual situation of S_2.

The statistical character of the present theory would then have to be a necessary consequence of the incompleteness of the description of the systems in quantum mechanics, and there would no longer exist any ground for the supposition that a future basis of physics must be based on statistics.

Einstein in a 1952 letter to Michele Besso:

What relation is there between the "state" ("quantum state") described by a function ψ and a real deterministic situation (that we call the "real state")? Does the quantum state characterize completely (1) or only incompletely (2) a real state?

One cannot respond unambiguously to this question, because each measurement represents a real uncontrollable intervention in the system (Heisenberg). The real state is not therefore something that is immediately accessible to experience, and its appreciation always rests hypothetical. (Comparable to the notion of force in classical mechanics, if one doesn't fix *a priori* the law of motion.) Therefore suppositions (1) and (2) are, in principle, both possible. A decision in favor of one of them can be taken only after an examination and confrontation of the admissibility of their consequences.

I reject (1) because it obliges us to admit that there is a rigid connection between parts of the system separated from each other in space in an arbitrary way (instantaneous action at a distance, which doesn't diminish when the distance increases). Here is the demonstration:

A system S_{12}, with a function ψ_{12}, which is known, is composed of two systems S_1, and S_2, which are very far from each other at the instant t. If one makes a "complete" measurement on S_1, which can be done in different ways (according to whether one measures, for example, the momenta or the coordinates), depending on the result of the measurement and the function ψ_{12}, one can determine by current quantum-theoretical methods, the function ψ_2 of the second system. *This function can assume different forms*, according to the *procedure* of measurement applied to S_1.

But this is in contradiction with (1) *if one excludes action at a distance*. Therefore the measurement on S_1 has no effect on the real state S_2, and therefore assuming (1) no effect on the quantum state of S_2 described by ψ_2.

I am thus forced to pass to the supposition (2) according to which the real state of a system is only described incompletely by the function ψ_{12}.

If one considers the method of the present quantum theory as being in principle definitive, that amounts to renouncing a complete description of real states. One could justify this renunciation if one assumes that there is no law for real states—i.e., that their description would be useless. Otherwise said, that would mean: laws don't apply to things, but only to what observation teaches us about them. (The laws that relate to the temporal succession of this partial knowledge are however entirely deterministic.)

Now, I can't accept that. I think that the statistical character of the present theory is simply conditioned by the choice of an incomplete description.

Einstein in a 1948 letter to Walter Heitler:

[T]hat one conceives of the psi-function only as an incomplete description of a real state of affairs, where the incompleteness of the description is forced by the fact that observation of the state is only able to grasp part of the real factual situation. Then one can at least escape the singular conception that observation (conceived as an act of consciousness) influences the real physical state of things; the change in the psi-function through observation then does not correspond essentially to the change in a real matter of fact but rather to the alteration in *our knowledge* of this matter of fact.

24-06-09 *The Section 8 Interpretation of Agency* (to W. H. Zurek)

And by the way, speaking of the sparring, I really would appreciate it if you'd read through Section 8 of the paper I gave you (Sec 8 only, don't bother with the rest): `http://arxiv.org/abs/0906.2187`. I feel it's the best I've done yet for answering your perennial question, "So what is the observer made of?" My answer has always been, "Well he's made of the same things as you. And that is not greatly distinct in physical kind from what dogs, or amoebas, or even tables and chairs are made of." What goes wrong in your question, from my view, is that it goes backwards. "Agent" refers to a position within quantum theory, not to the detailed architecture of some specific types of quantum systems. Anyway, read my Section 8: I do myself better there.

24-06-09 *(again?)* (to S. Savitt)

Savittism 8: *[T]he quote from Will Durant in your newest paper is terrific. I am stealing that for my metaphysics course. Of course, I also am inclined to think that freedom in an indeterministic universe is also illusory.*

The Jamesian idea (which really goes back to / comes from Renouvier) is that freedom is a more basic concept than either determinism or indeterminism. Freedom is not something that subsists in one or the other kind of universe, but rather an expression of an ultimate kind of (ontological) pluralism, that can allow to some extent for both.

25-06-09 *Review of the Magic Equation, 2* (to C. R. Stroud, Jr., J. H. Eberly, A. Ney, Y. Shapir & B. Weslake)

Getting a note from Andrew Jordan on some APS GQI business reminded me of you all. I finally posted the paper associated with the talk I gave you guys. If you're interested, it's here: `http://arxiv.org/abs/0906.2187`. (I'll give a prize to the first person who finds the instances of "rubbish," "salacious," and "bastardization" in it.)

25-06-09 *Section 2* (to A. Y. Khrennikov)

I meant to tell you before leaving Sweden: Given our discussions on "contextuality", you might want to read my discussion in Section 2 of the paper I gave you. In case you've lost it, you can regain it here: `http://arxiv.org/abs/0906.2187`.

25-06-09 *Down with Unitarity* (to T. Rudolph, cc J. Rau)

I was talking with Jochen Rau the other day, and he told me about a result of his that was quite similar, if not identical, to your old one that any unitary operation can be simulated by a sequence of closely spaced measurements. I figure I should put you two in touch with each other.

(You're both addressed on this email.) If that result still hasn't been pulled out of the drawer, it'd be nice for it to appear out in the external world so more people can discuss it. (I'm also thinking of John Wheeler's words, which I dug up for Wojciech the other day. Read below.)

P.S. Terry, by the way, if you haven't seen this one of mine `http://arxiv.org/abs/0906.2187`, I'll give you a challenge: If you find all the instances of "womb," "rubbish," "salacious," and "bastardization" in it, I'll reward you with the first annual *Chris Fuchs Creepy Word Prize* the next time I see you, to be redeemed at the pub of your choice, either in London or Waterloo. (No cheating; Adobe search tool invalidates challenge.)

Wheeler quote below. [See 16-06-09 note "Latter-Day Wheeler" to W. H. Zurek.]

26-06-09 *Up, Up, and Away!* (to N. D. Mermin)

Rüdiger is here with me for two weeks; we're hard on the trail of what can be meant by "others' experiences" from a quantum-Bayesian view. Our first task is to get the simple idea of "communication" straight. Harder than you might think ... or at least harder than we might think.

26-06-09 *This and That* (to M. Tait)

I had several things I wanted to tell you by email soon after my last visit to London, but now that too much time has passed, I have forgotten most of the things! Sorry about that: But at least I finally write.

Here's a partial list.

1) The philosopher I was trying to remember who interprets Bohr in a very Kantian way is John Honner. The book I read was titled, *The Description of Nature: Niels Bohr and the Philosophy of Quantum Physics*. The main thing I remember is how the guy meticulously discussed something like more than 20 drafts of the Como lecture.

2) I finally posted the paper which I was speaking on at your seminar. You can find it here: `http://arxiv.org/abs/0906.2187`. You might enjoy Section 8 of it, where I turn to more philosophical matters, and lay my heart on the line, so to speak.

3) Attached is a hefty piece of paper, that's far, far from complete, but since you have some interest in these matters, I thought it might be of some use to you as a point of entry into some literature. You might have a look at the Folse entries in particular; he is my personal favorite Bohr interpreter.

Maybe we should get you to PI for some more extensive discussions. Any interest in dropping in for maybe a week or two in the Fall or Spring?

26-06-09 *Laws Workshop* (to S. Weinstein)

You said, women. What about some of these people:
Jane E. Ruby, who wrote:

- J. E. Ruby, "The Origins of Scientific 'Law'," J. Hist. Ideas **47**, 341–359 (1986).

Or Lorraine Daston, who co-edited:

- *Natural Law and Laws of Nature in Early Modern Europe.*

I don't know the people at all, but I do remember enjoying Ruby's article.

Here's another one: I think Cheryl Misak (from U. Toronto) would be excellent. She could talk on C. S. Peirce's conception of evolving laws, for instance. And what about Nancy Cartwright?

Moving away from women, what about Ian Hacking? I think he's always great. What about Shimony?

- A. Shimony, "Can the Fundamental Laws of Nature Be the Results of Evolution?," in *From Physics to Philosophy*, edited by J. Butterfield and C. Pagonis (Cambridge U. Press, Cambridge, 2000), pp. 208–223.

- Y. Balashov, "On the Evolution of Natural Laws," Brit. J. Phil. Sci. **43**, 343–379 (1992).

You see in my mind the ideas of "information theoretic laws" and "law without law" are fundamentally linked. That's how these particular names came to mind.

Arthur Fine?

And maybe from the other side of the fence: How 'bout Daniel Dennett?

Hope that's been of some help.

27-06-09 *Aczél* (to P. G. L. Mana)

Thanks; these references are useful.

Also let me take a moment to mend my evil ways: I was pretty rude, cutting Rüdiger off yesterday. Here is the idea he was trying to express to you, and I got in the way of his expressing it adequately. As Appleby says "probability is single case, or nothing" (see Marcus's paper `http://arxiv.org/abs/quant-ph/0408058`). That is, everything that can said of the meaning of probability applies to the single-case alone—consideration of long sequences of trials adds nothing to our foundational understanding of the subject. Similarly for all meaningful concepts within probability theory, and "expectation" is one of those. It is perfectly meaningful in the single case, and Dutch-book considerations (like in Section 2 of our `http://arxiv.org/abs/0906.2187`) can show that.

Consider a single lottery ticket of the form:

If outcome is 1, pay x_1 dollars.
If outcome is 2, pay x_2 dollars.
If outcome is 3, pay x_3 dollars.
Etc.
If outcome is n, pay x_n dollars.

where the outcomes $i = 1, ...n$ are a mutually exclusive exhaustive set, and place that in contrast to a set of other lottery tickets, n of them, each of the form

If outcome is i, pay 1 dollar.

The amounts one will freely buy or sell the latter tickets for define one's "probabilities" p_i for the events. The question now is at what price should one freely buy or sell the first (conglomerate) lottery ticket above for? The Dutch-book answer is E dollars, where

$$E = \sum_i p_i x_i \ .$$

If an agent buys or sells the lottery ticket for anything other than that amount, then a Dutch-bookie can force him to a *sure* loss of money *in a single trial*. No repetition of trials is needed at all.

And that single case consideration gives meaning to the concept of "expectation."

27-06-09 *Abstracts for Reconstructing Quantum Theory* (to P. Goyal)

Title: Quantum-Bayesian Coherence (or, My Favorite Convex Set)

Abstract: In a quantum-Bayesian delineation of quantum mechanics, the Born Rule cannot be interpreted as a rule for setting measurement-outcome probabilities from an objective quantum state. (A quantum system has potentially as many quantum states as there are agents considering it.) But what then is the role of the rule? In this paper, we argue that it should be seen as an empirical addition to Bayesian reasoning itself. Particularly, we show how to view the Born Rule as a normative rule in addition to usual Dutch-book coherence. It is a rule that takes into account how one should assign probabilities to the outcomes of various intended measurements on a physical system, but explicitly in terms of prior probabilities for and conditional probabilities consequent upon the imagined outcomes of a special counterfactual reference measurement. This interpretation is seen particularly clearly by representing quantum states in terms of probabilities for the outcomes of a fixed, fiducial symmetric informationally complete (SIC) measurement. We further explore the extent to which the general form of the new normative rule implies the full state-space structure of quantum mechanics. It seems to go some way.

Here are three papers associated with the approach:

- `http://arxiv.org/abs/0906.2187`
- `http://arxiv.org/abs/quant-ph/0205039`
- `http://arxiv.org/abs/quant-ph/0404156`

29-06-09 *'Acquiring Information' Is Not the Primary Idea* (to D. M. Appleby)

A short answer to your long letter!

Applebyism 35: *However, there are some points on which I do agree with Bell. One is that I think he was right to insist on the maximum possible degree of clarity and precision, and right* *again when he accused Bohr et al. of falling short of that standard. Hence my question. If the term "quantum measurement" refers to every process by which we acquire information then it is sufficiently sharp for me. But if it only refers to a certain subset of such processes the question arises: which particular subset, defined precisely how?*

I am not expecting you to answer this question here and now. Like I said, I am groping myself, and I appreciate that you are in the same position. I am only saying that this is, as it seems to me, a question which eventually has to be answered.

I thought I had answered that (even to some precision) with my lines:

> With every movement and every breath, I take actions upon the world surrounding me: These are actions with potentially unpredictable consequences for my experience, and actions that the rest of the world could not have "foreseen" coming either. With every breath I contribute to the ongoing making of the world.

At this point let me send you to some pages of my collection: Particularly three notes to Bas van Fraassen: "'Action' instead of 'Measurement'," on pages 550–551, "Questions, Actions, Answers, & Consequences," on pages 553–555, and "Canned Answers," on pages 555–557.

I can do the story of mutual information (in the second note above) better now, thinking of both random variables in terms of the consequences of actions (i.e., experiences), but the present words should be a decent start.

In short, I am answering you with the "refers to every process by which we" you say above; I just protest at the phrase "acquire information."

29-06-09 *Quantum Bayesianism + Book* (to M. Schlosshauer)

In a recent email David Mermin mentioned knowing you, and it caused me to remember how kind you were in Växjö. If I haven't already expressed it, thanks for the interest in QBism. If you have any further, good pointed questions, feel free to send them. The exercise is definitely good for me, whatever this research program ultimately morphs into.

By the way, I recall your questions mostly centered on "certainty." Let me forward you a note I wrote to Appleby this morning, where I address some of that (particularly in the third note to van Fraassen). [See 29-06-09 note to D. M. Appleby titled "'Acquiring Information' Is Not the Primary Idea."]

On another note, Rüdiger and I will soon write a much smaller companion piece to the last paper—this one titled "Quantum-Bayesian Decoherence"—where we try to put decoherence in QBist terms. When the time comes, I'll forward you a draft if you don't mind.

29-06-09 *Off-the-Shelf Ontology vs. the Republican Banquet* (to C. G. Timpson)

I was just talking to Rob Spekkens and he told me he hadn't heard back from you concerning the PIAF meeting in late September. I sure hope you can come! I know that you're supposed to be coming to the Reconstructing Quantum Theory workshop a month earlier, but I feel your insights will be needed even more at the PIAF meeting. Particularly, I would love a proper philosopher to give David Albert the "what for" (old Southern language) if he happens to show up and throws his usual dismissal of anything approaching an epistemic view of quantum states. It would be nice to have a balanced discussion for once. So, please, please, please do come; I so hope you'll find a way to make it happen.

On another note, I finally posted a summary of the things my little team has been working on for the last year. You can find it here if you haven't already seen it: `http://arxiv.org/abs/0906.2187`. I hope you will enjoy it (and see some real progress in it). In my usual way, I've included some footnotes that are bound to cause me to be banned from Oxford. On the more philosophical side, you might jump to Section 8, which can be read independently of the rest of the paper.

Rüdiger and I have quite a palette of things to write up this year, and I'm hopeful that we'll pull it all together. The next paper will be titled "Quantum-Bayesian Decoherence" (you can guess what that will be about), but the one following that will be "Quantum Bayesian Quantum Certainty Is Not a Moore Sentence" ... and you can guess what we'll try to argue there as well!

Anyway, please let me encourage you again to come to PIAF and help set the stage. Help keep me on the run, and maybe we'll both grow from the exercise! (It's in the reciprocity of our names!)

29-06-09 *Unpacking a Little Rhetorical Traction* (to H. M. Wiseman & E. G. Cavalcanti)

Sorry to keep you waiting so long for a reply. It would have come much more quickly if Howard hadn't thrown us for a real loop with his final note: It has been impressively difficult for us to decide whether Howard exists or not! We just didn't know what to answer, and all expediency of reply was lost at that point.

But we've somewhat recovered now. Let me tackle your notes in little spurts.

First and foremost I apologize that our little rhetorical flourish at the beginning of the paper—i.e., our two-paragraph statement on "local realism" designed to get some traction on the intro—would cause so much trouble and consternation. As you surely know, it had very little to do with the paper as a whole (issues to do with locality were not mentioned again). The trouble is localized, we believe, in your not being able to "read off" our intentions when it came to the phrase "reads off" (in quotes in the text). We certainly didn't mean the naive realism that Howard rightly points out would have been the setting up of a straw man. Instead, we meant very much [double quotes being Howard's own words]:

> 'realism' (in the sense of the theorem) = "measurement results are determined by inputs ... plus any number of other 'hidden' variables specified in the past of all measurements" *without recourse to* "the experimenter (who is assumed for this purpose to be outside the description of the physical system)"

Howard is right when he says,

Wisemanism 36: *I don't think Chris and Rüdiger's paper claims that* local causality *can be saved, only that* locality *can be saved. Whether* locality *is a concept worth saving is then a point for discussion.*

We do indeed think locality can be saved. And that is because we reject:

Wisemanism 37: *any agent who is a genuine realist, and who believe[s] he can predict with certainty the result of a measurement, must believe that there is a pre-existing value "out there" in the world. (This is the Bayesian-friendly version.)*

This is the point of our previous paper with Carl, "Subjective Probability and Quantum Certainty". Of course, you are free to define a "genuine realist" any way you like, and by rejecting this sentence we then become nongenuine realists. But realists, we believe we remain.

Attached are a set of notes I wrote up for one of our group meetings here a couple months ago. They represent my response to Norsen's paper "Bell Locality and the Nonlocal Character of Nature" (I keep talking about Eqs. (11) and (12) in that paper). The notes are most certainly tentative and not carefully formulated enough yet, but they represent the skeleton of a paper Rüdiger and I are going to write on the subject before the summer is out. Feel free to look over the notes with this proviso. Maybe they possibly shed some light on what we were thinking when we wrote our little bit of rhetorical traction in the posted paper.

Finally, with regard to,

Wisemanism 38 : *So in summary it seems to me ... that perhaps you don't appreciate the import of Bell's theorem.*

Bell's theorem is absolutely significant to us: Rejecting the EPR criterion of reality, while proposing to hold on to Einstein locality, Bell's theorem causes us to reject the particular definition of 'realism' in the equation above. That's pretty earth-shaking to us: I would never want to think we "minimize Bell's work"; we just take home a different conclusion than the usual one.

Thus ends my first installment. More replies later.

29-06-09 *Disturbing the Solipsist* (to H. M. Wiseman & E. G. Cavalcanti)

Wisemanism 39 : *I disagree with your idea that this formulation shows that QM probabilities have* more structure *than classical probabilities. I think it's just a different structure. I mean if we allow you to use SIC-POVMs as a tool, then surely we should allow a classical probabilist the concept of non-disturbing measurements as a tool. Thus I would argue that in exactly the same way that you have derived constraints on QM probabilities, we can "derive" the "constraint" (which is usually taken for granted but which you disavow) that $p(B) = \sum_A p(B|A)p(A)$ even when A is only a hypothetical event. You seem to argue this is illogical because A may disturb B. But I could equally claim that your SIC-POVM measurement could disturb the quantum system* more than is necessary*. If you are allowed minimally-disturbing SIC-measurements, then in the classical case you have to accept no disturbance.*

We do not argue that the law of total probability, i.e., $p(B) = \sum_A p(B|A)p(A)$, is "illogical". Only that it is a judgment that one may or may not make, when comparing the counterfactual upper path (which necessarily generates the $p(B)$ you mention, via Dutch-book coherence) to the 'factualized' lower one (which generates the probability $q(B)$ we discuss). We certainly don't bar any Bayesian from making the judgment that $q(B) = p(B)$; we only point out that one need not have to make it. In that sense, you are right, quantum theory is just a "different structure" (or rather a different addition to raw Bayesianism) ... *but* I don't believe we claimed anything stronger than that in the paper. Try reading that section again and see if you still find it coming out so overly strong.

Thus ends my second installment. More replies later.

29-06-09 *Forgotten Reason for the Title* (to H. M. Wiseman & E. G. Cavalcanti)

In case you were wondering about the last note's title, it was referring to:

Wisemanism 40: *Thus in the end, the difference comes down to the fact that quantum measurements necessarily induce disturbance (of our probabilities), which is indeed an old lesson in QM that we don't need Bell's theorem for.*

but I had forgotten to mention that.

29-06-09 *Eric's Note* (to E. G. Cavalcanti & H. M. Wiseman)

Thanks for defending me as a "metaphysical realist in the sense that he believes in the existence of a world outside of oneself." Rarely do I have a friend strong enough to tread those waters!

Cavalcanti-ism 2: *Now I think really Chris should say that being a Bayesian does not a priori entail anything about ontology whatsoever, since that is just a statement about epistemology.*

This is certainly true, and I would not have wanted to convey otherwise. This is why I have the attached slide prepared for my talks: It is meant to express that one can equally validly talk of one's Bayesian degrees of belief about "states of pre-existent reality" as one can talk of one's Bayesian degrees of belief about the "consequences of one's actions." Nothing about the *raw* structure of probability theory changes in the move from one subject matter to the other. It just so happens—from our point of view—that quantum mechanics represents a use of the latter type.

But that is Bayesianism per se. It still leaves me room to disagree with this:

Cavalcanti-ism 3: *It is just saying that QM is a theory of epistemology, and that this leaves open the question of ontology.*

And that is because I don't view QM as an expression of raw probability theory. It is *dressed* so to speak with an extra normative assumption concerning how to gamble on factuals in terms of counterfactuals (the urgleichung being one such example), and consequently gives in part a theory of priors (i.e., the convex set of states on the simplex). I imagine the adoption of this dressing as a statement supervening on an ontology yet to be completely fleshed out. So, QM as a theory of decisions still has an essential empirical component.

Cavalcanti-ism 4: *I think Chris seems to want to say something about ontology, and I think he really wants to say something that sounds like a relational ontology. (Whatever that is). Maybe it would be easier if he were explicit about it?*

You don't much (if ever) hear me say things about "relational ontologies" because right now that doesn't seem like the right direction to develop to me. This is one of the reasons I was so intrigued by our first conversation together: You seemed to get that distinction in my thought. You asked something like, "Do two quantum Bayesians live in the same spacetime?," and I answered something (mystical) like, "Only when they interact with each other." More seriously, I am much taken with the image of a "republican banquet" kind of ontology, like that expressed in the two quotes by James and the one by Durant in Section 8.1 of the paper. Relational ontologies, to the extent that anyone has sketched any detail in them to me, always seem to rely on an image of a static, block-world lacking any good notion of struggle and creation. Things just are, though now the things that are are relations between nodes rather than facts residing on nodes. That's not a picture that attracts me much. The other night Rüdiger and I were semi-jokingly saying that the dimension d of a quantum object quantifies how much "will" it has. But, maybe some variant of that will not turn out to be so much of a joke after all.

Thus ends my third installment. Tomorrow comes the difficult one: Whether Howard Wiseman indeed exists.

I bid you good night.

29-06-09 *Relationalism vs. the Republican Banquet* (to C. Rovelli)

Rob Spekkens walked into my office a few minutes ago with some very disappointing news: You won't be coming to our PIAF meeting this year, just as you didn't come last year. I suspect you won't reconsider, but I want you to anyway: If you want the seeds of relationalism you have planted in quantum interpretation to thrive and grow, there is no more fertile ground than here at PI. We really, truly need to hear your voice on the subject. Discussion would proceed so much faster that way. Please do reconsider!

It's funny too that Rob walked in as I had just sent off the note below to a few colleagues who are reading a paper I posted a couple of weeks ago: `http://arxiv.org/abs/0906.2187`. [See 29-06-09 note "Eric's Note" to E. G. Cavalcanti & H. M. Wiseman.] I don't know that you would be interested in the whole thing (the paper), but you might find some amusing things in Sections 8 and 8.1 with regard to the perennial issues. The note below addresses whether the ontology I'm shooting for is a relational one. At the moment, I don't see that it would be, as Eric Cavalcanti had suggested. I'd be curious to get your reaction if you find anything you can pinpoint. And it'd be better if I could finally lure you here to hear it in person!

30-06-09 *A New Name for Some Old Ways of Thinking* (to M. Schlosshauer)

Schlosshauerism 1: *In your note to van Fraassen entitled "Canned Answers," you mention a file* `certainty.pdf`*. Might this be helpful to me too in bringing about further enlightenment?*

I'll do better than that: Let me point you to pages 330–335 of "My Struggles"—you'll find there a couple of notes titled "Utter Rubbish and Internal Consistency" (Parts I and II). The long de Finetti quote is in there, but also I bear my soul and pay penance for the greatest mistake of my Bayesian life. It's a bit embarrassing really ... but maybe there is something to be learned from it.

Schlosshauerism 2: *I believe you know everything you need to know about decoherence, but if there's anything I can help answer or comment on, let me know. Also, if you ever would like a (free) copy of my book on decoherence, I'm happy to have Springer send you one.*

Yes, that would be most helpful for the upcoming project. I would be very proud to have a copy! You can use the address below.

Schlosshauerism 3: *Finally, I'm quite interested in getting into some William James. If you had to choose and recommend just one of his books, which one would it be?*

That's an easy choice. It is the book titled *Pragmatism*. It conveys all the spirit, while leaving aside all the dry technical arguments (of Dewey and Schiller predominantly). Below is a collection my favorite quotes from the book.

Happy reading, and tell me what you think in the end.

W. James, "The Present Dilemma in Philosophy," in his *Pragmatism, a New Name for Some Old Ways of Thinking: Popular Lectures on Philosophy*, (Longmans, Green and Co., New York, 1922).

> For a hundred and fifty years past the progress of science has seemed to mean the enlargement of the material universe and the diminution of man's importance. The result is what one may call the growth of naturalistic or positivistic feeling. Man is no lawgiver to nature, he is an absorber. She it is who stands firm; he it is who must accommodate himself. Let him record truth, inhuman though it be, and submit to it! The romantic spontaneity and courage are gone, the vision is materialistic and depressing. Ideals appear as inert by-products of physiology; what is higher is explained by what is lower and treated forever as a case of 'nothing but'—nothing but something else of a quite inferior sort. You get, in short, a materialistic universe, in which only the tough-minded find themselves congenially at home.

W. James, "What Pragmatism Means," in his *Pragmatism, a New Name for Some Old Ways of Thinking: Popular Lectures on Philosophy*, (Longmans, Green and Co., New York, 1922).

> Metaphysics has usually followed a very primitive kind quest. You know how men have always hankered after unlawful magic, and you know what a great part in magic *words* have always played. If you have his name, the formula of incantation that binds him, you can control the spirit, genie, afrite, or whatever the power may be. Solomon knew the names of all the spirits, and having their names, he held them subject to his will. So the universe has always appeared to the natural mind as a kind of enigma, of which the key must be sought in the shape of some illuminating or power-bringing word or name. That word names the universe's principle, and to possess it is after a fashion to possess the universe itself. 'God,' 'Matter,' 'Reason,' 'the Absolute,' 'Energy,' are so many solving names. You can rest when you have them. You are at the end of your metaphysical quest.
>
> But if you follow the pragmatic method, you cannot look on any such word as closing your quest. You must bring out of each word its practical cash-value, set it at work within the stream of your experience. It appears less as a solution, then, than as a program for more work, and more particularly as an indication of the ways in which existing realities may be *changed*.
>
> *Theories thus become instruments, not answers to enigmas, in which we can rest.* We don't lie back upon them, we move forward, and, on occasion, make nature over again by their aid. Pragmatism unstiffens all our theories, limbers them up and sets each one at work.

W. James, "Some Metaphysical Problems Pragmatically Considered," in his *Pragmatism, a New Name for Some Old Ways of Thinking: Popular Lectures on Philosophy*, (Longmans, Green and Co., New York, 1922).

Let me take up another well-worn controversy, *the free-will problem.* Most persons who believe in what is called their free-will do so after the rationalistic fashion. It is a principle, a positive faculty or virtue added to man, by which his dignity is enigmatically augmented. He ought to believe it for this reason. Determinists, who deny it, who say that individual men originate nothing, but merely transmit to the future the whole push of the past cosmos of which they are so small an expression, diminish man. He is less admirable, stripped of this creative principle. I imagine that more than half of you share our instinctive belief in free-will, and that admiration of it as a principle of dignity has much to do with your fidelity.

But free-will has also been discussed pragmatically, and, strangely enough, the same pragmatic interpretation has been put upon it by both disputants. You know how large a part questions of *accountability* have played in ethical controversy. To hear some persons, one would suppose that all that ethics aims at is a code of merits and demerits. Thus does the old legal and theological leaven, the interest in crime and sin and punishment abide with us. 'Who's to blame? whom can we punish? whom will God punish?—these preoccupations hang like a bad dream over man's religious history.

So both free-will and determinism have been inveighed against and called absurd, because each, in the eyes of its enemies, has seemed to prevent the 'imputability' of good or bad deeds to their authors. Queer antinomy this! Free-will means novelty, the grafting on to the past of something not involved therein. If our acts were predetermined, if we merely transmitted the push of the whole past, the free-willists say, how could we be praised or blamed for anything? We should be 'agents' only, not 'principals,' and where then would be our precious imputability and responsibility?

But where would it be if we *had* free-will? rejoin the determinists. If a 'free' act be a sheer novelty, that comes not *from* me, the previous me, but *ex nihilo*, and simply tacks itself on to me, how can *I*, the previous I, be responsible? How can I have any permanent *character* that will stand still long enough for praise or blame to be awarded? The chaplet of my days tumbles into a cast of disconnected beads as soon as the thread of inner necessity is drawn out by the preposterous indeterminist doctrine. Messrs. Fullerton and McTaggart have recently laid about them doughtily with this argument.

It may be good *ad hominem*, but otherwise it is pitiful. For I ask you, quite apart from other reasons, whether any man, woman or child, with a sense for realities, ought not to be ashamed to plead such principles as either dignity or imputability. Instinct and utility between them can safely be trusted to carry on the social business of punishment and praise. If a man does good acts we shall praise him, if he does bad acts we shall punish him,—anyhow, and quite apart from theories as to whether the acts result from what was previous in him or are novelties in a strict sense. To make our human ethics revolve about the question of 'merit' is a piteous unreality—God alone can know our merits, if we have any. The real ground for supposing free-will is indeed pragmatic, but it has nothing to do with this contemptible right to punish which has made such a noise in past discussions of the subject.

Free-will pragmatically means *novelties in the world*, the right to expect that in its deepest elements as well as in its surface phenomena, the future may not identically repeat and imitate the past. That imitation *en masse* is there, who can deny? The general 'uniformity of nature' is presupposed by every lesser law. But nature may be only approximately uniform; and persons in whom knowledge of the world's past has bred pessimism (or doubts as to the world's good character, which become certainties if that character be supposed eternally fixed) may naturally welcome free-will as a *melioristic* doctrine. It holds up improvement as at least possible; whereas determinism assures us that our whole notion of possibility is born of human ignorance, and that necessity and impossibility between them rule the destinies of the world.

Free-will is thus a general cosmological theory of *promise*, just like the Absolute, God, Spirit or Design. Taken abstractly, no one of these terms has any inner content, none of them gives us any picture, and no one of them would retain the least pragmatic value in a world whose character was obviously perfect from the start. Elation at mere existence, pure cosmic emotion and delight, would, it seems to me, quench all interest in those speculations, if the world were nothing but a lubberland of happiness already. Our interest in religious metaphysics arises in the fact that our empirical future feels to us unsafe, and needs some higher guarantee. If the past and present were purely good, who could wish that the future might possibly not resemble them? Who could desire free-will? Who would not say, with Huxley, 'let me be wound up every day like a watch, to go right fatally, and I ask no better freedom.' 'Freedom' in a world already perfect could only mean freedom to *be worse*, and who could be so insane as to wish that? To be necessarily what it is, to be impossibly aught else, would put the last touch of perfection upon optimism's universe. Surely the only *possibility* that one can rationally claim is the possibility that things may be *better*. That possibility, I need hardly say, is one that, as the actual world goes, we have ample grounds for desiderating.

Free-will thus has no meaning unless it be a doctrine of *relief*. As such, it takes its place with other religious doctrines. Between them, they build up the old wastes and repair the former desolations. Our spirit, shut within this courtyard of sense-experience, is always saying to the intellect upon the tower: 'Watchman, tell us of the night, if it aught of promise bear,' and the intellect gives it then these terms of promise.

Other than this practical significance, the words God, free-will, design, etc., have none. Yet dark tho they be in themselves, or intellectualistically taken, when we bear them into life's thicket with us the darkness *there* grows light about us. If you stop, in dealing with such words, with their definition, thinking that to be an intellectual finality, where are you? Stupidly staring at a pretentious sham! "Deus est Ens, a se, extra et supra omne genus, necessarium, unum, infinite perfectum, simplex, immutabile, immensum, aeternum, intelligens," etc.,—wherein is such a definition really instructive? It means less than nothing, in its pompous robe of adjectives. Pragmatism alone can read a positive meaning into it, and for that she turns her back upon the intellectualist point of view altogether. 'God's in his heaven; all's right with the world!'—*That's* the real heart of your theology, and for that you need no rationalist definitions.

Why shouldn't all of us, rationalists as well as pragmatists, confess this? Pragmatism, so far from keeping her eyes bent on the immediate practical, foreground, as she is accused of doing, dwells just as much upon the world's remotest perspectives.

See then how all these ultimate questions turn, as it were, upon their hinges; and from looking backwards upon principles, upon an *erkenntniss-theoretische Ich*, a God, *a Kausalitätsprinzip*, a Design, a Free-will, taken in themselves, as something august and exalted above facts,—see, I say, how pragmatism shifts the emphasis and looks forward into facts themselves. The really vital question for us all is, What is this world going to be? What is life eventually to make of itself? The centre of gravity of philosophy must therefore alter its place. The earth of things, long thrown into shadow by the glories of the upper ether, must resume its rights. To shift the emphasis in this way means that philosophic questions will fall to be treated by minds of a less abstractionist type than heretofore, minds more scientific and individualistic in their tone yet not irreligious either. It will be an alteration in 'the seat of authority' that reminds one almost of the protestant reformation. And as, to papal minds, protestantism has often seemed a mere mess of anarchy and confusion, such, no doubt, will pragmatism often seem to ultra-rationalist minds in philosophy. It will seem so much sheer trash, philosophically. But life wags on, all the same, and compasses its ends, in protestant countries. I venture to think that philosophic protestantism will compass a not dissimilar prosperity.

W. James, "The One and the Many," in his *Pragmatism, a New Name for Some Old Ways of Thinking: Popular Lectures on Philosophy*, (Longmans, Green and Co., New York, 1922).

It is possible to imagine alternative universes to the one we know, in which the most various grades and types of union should be embodied. Thus the lowest grade of universe would be a world of mere *withness*, of which the parts were only strung together by the conjunction 'and.' Such a universe is even now the collection of our several inner lives. The spaces and times of your imagination, the objects and events of your day-dreams are not only more or less incoherent *inter se*, but are wholly out of definite relation with the similar contents of any one else's mind. Our various reveries now as we sit here compenetrate each other idly without influencing or interfering. They coexist, but in no order and in no receptacle, being the nearest approach to an absolute 'many' that we can conceive. We can not even imagine any reason why they *should* be known all together, and we can imagine even less, if they were known together, how they could be known as one systematic whole.

But add our sensations and bodily actions, and the union mounts to a much higher grade. Our *audita et visa* and our acts fall into those receptacles of time and space in which each event finds its date and place. They form 'things' and are of 'kinds' too, and can be classed. Yet we can imagine a world of things and of kinds in which the causal interactions with which we are so familiar should not exist. Everything there might be inert towards everything else, and refuse to propagate its influence. Or gross mechanical influences might pass, but no chemical action. Such worlds would be far less unified than ours. Again there might be complete physico-chemical interaction, but no minds; or minds, but altogether private ones, with no social life; or social life limited to acquaintance, but no love; or love, but no customs or institutions that should systematize it. No one of these grades of universe would be absolutely irrational or disintegrated, inferior tho it might appear when looked at from the higher grades. For instance, if our minds should ever become 'telepathically' connected, so that we knew immediately, or could under certain conditions know immediately, each what the other was thinking, the world we now live in would appear to the thinkers in that world to have been of an inferior grade.

With the whole of past eternity open for our conjectures to range in, it may be lawful to wonder whether the various kinds of union now realized in the universe that we inhabit may not possibly have been successively evolved after the fashion in which we now see human systems evolving in consequence of human needs. If such an hypothesis were legitimate, total oneness would appear at the end of things rather than at their origin. In other words the notion of the 'Absolute' would have to be replaced by that of the 'Ultimate.' The two notions would have the same content—the maximally unified content of fact, namely—but their time-relations would be positively reversed.

After discussing the unity of the universe in this pragmatic way, you ought to see why I said in my second lecture, borrowing the word from my friend G. Papini, that pragmatism tends to *unstiffen* all our theories. The world's oneness has generally been affirmed abstractly only, and as if any one who questioned it must be an idiot. The temper of monists has been so vehement, as almost at times to be convulsive; and this way of holding a doctrine does not easily go with reasonable discussion and the drawing of distinctions. The theory of the Absolute, in particular, has had to be an article of faith, affirmed dogmatically and exclusively. The One and All, first in the order of being and of knowing, logically necessary itself, and uniting all lesser things in the bonds of mutual necessity, how could it allow of any mitigation of its inner rigidity? The slightest suspicion of pluralism, the minutest wiggle of independence of any one of its parts from the control of the totality would ruin it. Absolute unity brooks no degrees,—as well might you claim absolute purity for a glass of water because it contains but a single little cholera-germ. The independence, however infinitesimal, of a part, however small, would be to the Absolute as fatal as a cholera-germ.

Pluralism on the other hand has no need of this dogmatic rigoristic temper. Provided you grant *some* separation among things, some tremor of independence, some free play of parts on one another, some real novelty or chance, however minute, she is amply satisfied, and will allow you any amount, however great, of real union. How much of union there may be is a question that she thinks can only be decided empirically. The amount may be enormous, colossal; but absolute monism is shattered if, along with all the union, there has to be granted the slightest modicum, the most incipient nascency, or the most residual trace, of a separation that is not 'overcome.'

Pragmatism, pending the final empirical ascertainment of just what the balance of union and disunion among things may be, must obviously range herself upon the pluralistic side. Some day, she admits, even total union, with one knower, one origin, and a universe consolidated in every conceivable way, may turn out to be the most acceptable of all hypotheses. Meanwhile the opposite hypothesis, of a world imperfectly unified still, and perhaps always to remain so, must be sincerely entertained. This latter hypothesis is pluralism's doctrine. Since absolute monism forbids its being even considered seriously, branding it as irrational from the start, it is clear that pragmatism must turn its back on absolute monism, and follow pluralism's more empirical path.

This leaves us with the common-sense world, in which we find things partly joined and partly disjoined.

W. James, "Pragmatism and Common Sense," in his *Pragmatism, a New Name for Some Old Ways of Thinking: Popular Lectures on Philosophy*, (Longmans, Green and Co., New York, 1922).

But the scientific tendency in critical thought, tho inspired at first by purely intellectual motives, has opened an entirely unexpected range of practical utilities to our astonished view. Galileo gave us accurate clocks and accurate artillery-practice; the chemists flood us with new medicines and dye-stuffs; Ampère and Faraday have endowed us with the New York subway and with Marconi telegrams. The hypothetical things that such men have invented, defined as they have defined them, are showing an extraordinary fertility in consequences verifiable by sense. Our logic can deduce from them a consequence due under certain conditions, we can then bring about the conditions, and presto, the consequence is there before our eyes. The scope of the practical control of nature newly put into our hand by scientific ways of thinking vastly exceeds the scope of the old control grounded on common sense. Its rate of increase accelerates so that no one can trace the limit; one may even fear that the *being* of man may be crushed by his own powers, that his fixed nature as an organism may not prove adequate to stand the strain of the ever increasingly tremendous functions, almost divine creative functions, which his intellect will more and more enable him to wield. He may drown in his wealth like a child in a bath-tub, who has turned on the water and who can not turn it off.

and

The most fateful point of difference between being a rationalist and being a pragmatist is now fully in sight. Experience is in mutation, and our psychological ascertainments of truth are in mutation—so much rationalism will allow; but never that either reality itself or truth itself is mutable. Reality stands complete and ready-made from all eternity, rationalism insists, and the agreement of our ideas with it is that unique unanalyzable virtue in them of which she has already told us. As that intrinsic excellence, their truth has nothing to do with our experiences. It adds nothing to the content of experience. It makes no difference to reality itself; it is supervenient, inert, static, a reflexion merely. It doesn't *exist*, it *holds* or *obtains*, it belongs to another dimension from that of either facts or fact-relations, belongs, in short, to the epistemological dimension—and with that big word rationalism closes the discussion.

Thus, just as pragmatism faces forward to the future, so does rationalism here again face backward to a past eternity. True to her inveterate habit, rationalism reverts to 'principles,' and thinks that when an abstraction once is named, we own an oracular solution.

The tremendous pregnancy in the way of consequences for life of this radical difference of outlook will only become apparent in my later lectures.

W. James, "Pragmatism's Conception of Truth," in his *Pragmatism, a New Name for Some Old Ways of Thinking: Popular Lectures on Philosophy*, (Longmans, Green and Co., New York, 1922).

When Clerk-Maxwell was a child it is written that he had a mania for having everything explained to him, and that when people put him off with vague verbal accounts of any phenomenon he would interrupt them impatiently by saying, 'Yes; but I want you to tell me the *particular go* of it!' Had his question been about truth, only a pragmatist could have told him the particular go of it. I believe that our contemporary pragmatists, especially Messrs. Schiller and Dewey, have given the only tenable account of this subject. It is a very ticklish subject, sending subtle rootlets into all kinds of crannies, and hard to treat in the sketchy way that alone befits a public lecture. But the Schiller-Dewey view of truth has been so ferociously attacked by rationalistic philosophers, and so abominably misunderstood, that here, if anywhere, is the point where a clear and simple statement should be made.

I fully expect to see the pragmatist view of truth run through the classic stages of a theory's career. First, you know, a new theory is attacked as absurd; then it is admitted to be true, but obvious and insignificant; finally it is seen to be so important that its adversaries claim that they themselves discovered it. Our doctrine of truth is at present in the first of these three stages, with symptoms of the second stage having begun in certain quarters. I wish that this lecture might help it beyond the first stage in the eyes of many of you.

Truth, as any dictionary will tell you, is a property of certain of our ideas. It means their 'agreement,' as falsity means their disagreement, with 'reality.' Pragmatists and intellectualists both accept this definition as a matter of course. They begin to quarrel only after the question is raised as to what may precisely be meant by the term 'agreement,' and what by the term 'reality,' when reality is taken as something for our ideas to agree with.

In answering these questions the pragmatists are more analytic and painstaking, the intellectualists more offhand and irreflective. The popular notion is that a true idea must copy its reality. Like other popular views, this one follows the analogy of the most usual experience. Our true ideas of sensible things do indeed copy them. Shut your eyes and think of yonder clock on the wall, and you get just such a true picture or copy of its dial. But your idea of its 'works' (unless you are a clockmaker) is much less of a copy, yet it passes muster, for it in no way clashes with the reality. Even though it should shrink to the mere word 'works,' that word still serves you truly; and when you speak of the 'timekeeping function' of the clock, or of its spring's 'elasticity,' it is hard to see exactly what your ideas can copy.

You perceive that there is a problem here. Where our ideas cannot copy definitely their object, what does agreement with that object mean? Some idealists seem to say that they are true whenever they are what God means that we ought to think about that object. Others hold the copy-view all through, and speak as if our ideas possessed truth just in proportion as they approach to being copies of the Absolute's eternal way of thinking.

These views, you see, invite pragmatistic discussion. But the great assumption of the intellectualists is that truth means essentially an inert static relation. When you've got your true idea of anything, there's an end of the matter. You're in possession; you *know*; you have fulfilled your thinking destiny. You are where you ought to be mentally; you have obeyed your categorical imperative; and nothing more need follow on that climax of your rational destiny. Epistemologically you are in stable equilibrium.

Pragmatism, on the other hand, asks its usual question. "Grant an idea or belief to be true," it says, "what concrete difference will its being true make in any one's actual life? How will the truth be realized? What experiences will be different from those which would obtain if the belief were false? What, in short, is the truth's cash-value in experiential terms?"

The moment pragmatism asks this question, it sees the answer: *True ideas are those that we can assimilate, validate, corroborate and verify. False ideas are those that we can not.* That is the practical difference it makes to us to have true ideas; that, therefore, is the meaning of truth, for it is all that truth is known as.

This thesis is what I have to defend. The truth of an idea is not a stagnant property inherent in it. Truth *happens* to an idea. It *becomes* true, is *made* true by events. Its verity *is* in fact an event, a process: the process namely of its verifying itself, its veri-*fication*. Its validity is the process of its valid-*ation*.

W. James, "Pragmatism and Humanism," in his *Pragmatism, a New Name for Some Old Ways of Thinking: Popular Lectures on Philosophy*, (Longmans, Green and Co., New York, 1922).

What hardens the heart of every one I approach with the view of truth sketched in my last lecture is that typical idol of the tribe, the notion of *the* Truth, conceived as the one answer, determinate and complete, to the one fixed enigma which the world is believed to propound. For popular tradition, it is all the better if the answer be oracular, so as itself to awaken wonder as an enigma of the second order, veiling rather than revealing what its profundities are supposed to contain. All the great single-word answers to the world's riddle, such as God, the One, Reason, Law, Spirit, Matter, Nature, Polarity, the Dialectic Process, the Idea, the Self, the Oversoul, draw the admiration that men have lavished on them from this oracular rôle. By amateurs in philosophy and professionals alike, the universe is represented as a queer sort of petrified sphinx whose appeal to men consists in a monotonous challenge to his divining powers. *The* Truth: what a perfect idol of the rationalistic mind! I read in an old letter—from a gifted friend who died too young—these words: "In everything, in science, art, morals and religion, there *must* be one system that is right and *every* other wrong." How characteristic of the enthusiasm of a certain stage of youth! At twenty-one we rise to such a challenge and expect to find the system. It never occurs to most of us even later that the question 'what is *the* truth?' is no real question (being irrelative to all conditions) and that the whole notion of *the* truth is an abstraction from the fact of truths in the plural, a mere useful summarizing phrase like *the* Latin Language or *the* Law.

Common-law judges sometimes talk about the law, and schoolmasters talk about the latin tongue, in a way to make their hearers think they mean entities preexistent to the decisions or to the words and syntax, determining them unequivocally and requiring them to obey. But the slightest exercise of reflexion makes us see that, instead of being principles of this kind, both law and latin are results. Distinctions between the lawful and the unlawful in conduct, or between the correct and incorrect in speech, have grown up incidentally among the interactions of men's experiences in detail; and in no other way do distinctions between the true and the false in belief ever grow up. Truth grafts itself on previous truth, modifying it in the process, just as idiom grafts itself on previous idiom, and law on previous law. Given previous law and a novel case, and the judge will twist them into fresh law. Previous idiom; new slang or metaphor or oddity that hits the public taste;—and presto, a new idiom is made. Previous truth; fresh facts:—and our mind finds a new truth.

All the while, however, we pretend that the eternal is unrolling, that the one previous justice, grammar or truth are simply fulgurating and not being made. But imagine a youth in the courtroom trying cases with his abstract notion of 'the' law, or a censor of speech let loose among the theatres with his idea of 'the' mother-tongue, or a professor setting up to lecture on the actual universe with his rationalistic notion of 'the Truth' with a big T, and what progress do they make? Truth, law, and language fairly boil away from them at the least touch of novel fact. These things *make themselves* as we go. Our rights, wrongs, prohibitions, penalties, words, forms, idioms, beliefs, are so many new creations that add themselves as fast as history proceeds. Far from being antecedent principles that animate the process, law, language, truth are but abstract names for its results.

Laws and languages at any rate are thus seen to be man-made things. Mr. Schiller applies the analogy to beliefs, and proposes the name of 'Humanism' for the doctrine that to an unascertainable extent our truths are man-made products too. Human motives sharpen all our questions, human satisfactions lurk in all our answers, all our formulas have a human twist. This element is so inextricable in the products that Mr. Schiller sometimes seems almost to leave it an open question whether there be anything else. "The world," he says, "is essentially $\upsilon\lambda\eta$, it is what we make it. It is fruitless to define it by what it originally was or by what it is apart from us; it *is* what is made of it. Hence . . . the world is plastic." He adds that we can learn the limits of the plasticity only by trying, and that we ought to start as if it were wholly plastic, acting methodically on that assumption, and stopping only when we are decisively rebuked.

This is Mr. Schiller's butt-end-foremost statement of the humanist position, and it has exposed him to severe attack. I mean to defend the humanist position in this lecture, so I will insinuate a few remarks at this point.

Mr. Schiller admits as emphatically as any one the presence of resisting factors in every actual experience of truth-making, of which the new-made special truth must take account, and with which it has perforce to 'agree.' All our truths are beliefs about 'Reality'; and in any particular belief the reality acts as something independent, as a thing *found*, not manufactured. Let me here recall a bit of my last lecture.

'Reality' is in general what truths have to take account of; and the *first* part of reality from this point of view is the flux of our sensations. Sensations are forced upon us, coming we know not whence. Over their nature, order and quantity we have as good as no control. *They* are neither true nor false; they simply *are*. It is only what we say about them, only the names we give them, our theories of their source and nature and remote relations, that may be true or not.

The *second* part of reality, as something that our beliefs must also obediently take account of is the *relations* that obtain between our sensations or between their copies in our minds. This part falls into two subparts: 1) the relations that are mutable and accidental, as those of date and place; and 2) those that are fixed and essential because they are grounded on the inner natures of their terms. Both sorts of relation are matters of immediate perception. Both are 'facts.' But it is the latter kind of fact that forms the more important subpart of reality for our theories of knowledge. Inner relations namely are 'eternal,' are perceived whenever their sensible terms are compared; and of them our thought—mathematical and logical thought so-called—must eternally take account.

The *third* part of reality, additional to these perceptions (tho largely based upon them), is the *previous truths* of which every new inquiry takes account. This third part is a much less obdurately resisting factor: it often ends by giving way. In speaking of these three portions of reality as at all times controlling our beliefs formation, I am only reminding you of what we heard in our last hour.

Now however fixed these elements of reality may be, we still have a certain freedom in our dealings with them. Take our sensations. *That* they are is undoubtedly beyond our control; but *which* we attend to, note, and make emphatic in our conclusions depends on our own interests; and, according as we lay the emphasis here or there, quite different formulations of truth result. We read the same facts differently. 'Waterloo,' with the same fixed details, spells a 'victory' for an Englishman; for a Frenchman it spells a 'defeat.' So, for an optimist philosopher the universe spells victory, for a pessimist, defeat.

What we say about reality thus depends on the perspective into which we throw it. The *that* of it is its own; but the *what* depends on the *which*; and the which depends on *us*. Both the sensational and the relational parts of reality are dumb; they say absolutely nothing about themselves. We it is who have to speak for them. This dumbness of sensations has led such intellectualists as T. H. Green and Edward Caird to shove them almost beyond the pale of philosophic recognition, but pragmatists refuse to go so far. A sensation is rather like a client who has given his case to a lawyer and then has passively to listen in the courtroom to whatever account of his affairs, pleasant or unpleasant, the lawyer finds it most expedient to give.

Hence, even in the field of sensation, our minds exert a certain arbitrary choice. By our inclusions and omissions we trace the field's extent; by our emphasis we mark its foreground and its background; by our order we read it in this direction or in that. We receive in short the block of marble, but we carve the statue ourselves.

This applies to the 'eternal' parts of reality as well: we shuffle our perceptions of intrinsic relation and arrange them just as freely. We read them in one serial order or another, class them in this way or in that, treat one or the other as more fundamental, until our beliefs about them form those bodies of truth known as logics, geometrics, or arithmetics, in each and all of which the form and order in which the whole is cast is flagrantly man-made.

Thus, to say nothing of the new *facts* which men add to the matter of reality by the acts of their own lives, they have already impressed their mental forms on that whole third of reality which I have called 'previous truths.' Every hour brings its new percepts, its own facts of sensation and relation, to be truly taken account of; but the whole of our *past* dealings with such facts is already funded in the previous truths. It is therefore only the smallest and recentest fraction of the first two parts of reality that comes to us without the human touch, and that fraction has immediately to become humanized in the sense of being squared, assimilated, or in some way adapted, to the humanized mass already there., As a matter of fact we can hardly take in an impression at all, in the absence of a preconception of what impressions there may possibly be.

When we talk of reality 'independent' of human thinking, then, it seems a thing very hard to find. It reduces to the notion of what is just entering into experience and yet to be named, or else to some imagined aboriginal presence in experience, before any belief about the presence had arisen, before any human conception had been applied. It is what is absolutely dumb and evanescent, the merely ideal limit of our minds. We may glimpse it, but we never grasp it; what we grasp is always some substitute for it which previous human thinking has peptonized and cooked for our consumption. If so vulgar an expression were allowed us, we might say that wherever we find it, it has been already *faked*. This is what Mr. Schiller has in mind when he calls independent reality a mere unresisting $\upsilon\lambda\eta$, which is only to be made over by us.

and

In many familiar objects every one will recognize the human element. We conceive a given reality in this way or in that, to suit our purpose, and the reality passively submits to the conception. You can take the number 27 as the cube of 3, or as the product of 3 and 9, or as 26 *plus* 1, or 100 *minus* 73, or in countless other ways, of which one will be just as true as another. You can take a chess-board as black squares on a white ground, or as white squares on a black ground, and neither conception is a false one.

You can treat the adjoined figure as a star, as two big triangles crossing each other, as a hexagon with legs set up on its angles, as six equal triangles hanging together by their tips, etc. All these treatments are true treatments—the sensible *that* upon the paper resists no one of them. You can say of a line that it runs east, or you can say that it runs west, and the line *per se* accepts both descriptions without rebelling at the inconsistency.

We carve out groups of stars in the heavens, and call them constellations, and the stars patiently suffer us to do so,—*though* if they knew what we were doing, some of them might feel much surprised at the partners we had given them. We name the same constellation diversely, as Charles's Wain, the Great Bear, or the Dipper. None of the names will be false, and one will be as true as another, for all are applicable.

In all these cases we humanly make an *addition* to some sensible reality, and that reality tolerates the addition. All the additions 'agree' with the reality; they fit it, while they build it out. No one of them is false. Which may be treated as the *more* true, depends altogether on the human use of it. If the 27 is a number of dollars which I find in a drawer where I had left 28, it is 28 minus 1. If it is the number of inches in a board which I wish to insert as a shelf into a cupboard 26 inches wide, it is 26 plus 1. If I wish to ennoble the heavens by the constellations I see there, 'Charles's Wain' would be more true than 'Dipper.' My friend Frederick Myers was humorously indignant that that prodigious star-group should remind us Americans of nothing but a culinary utensil.

What shall we call a *thing* anyhow? It seems quite arbitrary, for we carve out everything, just as we carve out constellations, to suit our human purposes. For me, this whole 'audience' is one thing, which grows now restless, now attentive. I have no use at present for its individual units, so I don't consider them. So of an 'army,' of a 'nation.' But in your own eyes, ladies and gentlemen, to call you 'audience' is an accidental way of taking you. The permanently real things for you are your individual persons. To an anatomist, again, those persons are but organisms, and the real things are the organs. Not the organs, so much as their constituent cells, say the histologists; not the cells, but their molecules, say in turn the chemists.

We break the flux of sensible reality into things, then, at our will. We create the subjects of our true as well as of our false propositions.

We create the predicates also. Many of the predicates of things express only the relations of the things to us and to our feelings. Such predicates of course are human additions. Caesar crossed the Rubicon, and was a menace to Rome's freedom. He is also an American schoolroom pest, made into one by the reaction of our schoolboys on his writings. The added predicate is as true of him as the earlier ones.

You see how naturally one comes to the humanistic principle: you can't weed out the human contribution. Our nouns and adjectives are all humanized heirlooms, and in the theories we build them into, the inner order and arrangement is wholly dictated by human considerations, intellectual consistency being one of them. Mathematics and logic themselves are fermenting with human rearrangements; physics, astronomy and biology follow massive cues of preference. We plunge forward into the field of fresh experience with the beliefs our ancestors and we have made already; these determine what we notice; what we notice determines what we do; what we do again determines what we experience; so from one thing to another, altho the stubborn fact remains that there is a sensible flux, what is *true of it* seems from first to last to be largely a matter of our own creation.

We build the flux out inevitably. The great question is: does it, with our additions, *rise or fall in value*? Are the additions *worthy* or *unworthy*? Suppose a universe composed of seven stars, and nothing else but three human witnesses and their critic. One witness names the stars 'Great Bear'; one calls them 'Charles's Wain'; one calls them the 'Dipper.' Which human addition has made the best universe of the given stellar material? If Frederick Myers were the critic, he would have no hesitation in 'turning down' the American witness.

Lotze has in several places made a deep suggestion. We naïvely assume, he says, a relation between reality and our minds which may be just the opposite of the true one. Reality, we naturally think, stands ready-made and complete, and our intellects supervene with the one simple duty of describing it as it is already. But may not our descriptions, Lotze asks, be themselves important additions to reality? And may not previous reality itself be there, far less for the purpose of reappearing unaltered in our knowledge, than for the very purpose of stimulating our minds to such additions as shall enhance the universe's total value. *'Die Erhöhung des vorgefundenen Daseins'*[202] is a phrase used by Professor Eucken somewhere, which reminds one of this suggestion by the great Lotze.

It is identically our pragmatistic conception. In our cognitive as well as in our active life we are creative. We *add*, both to the subject and to the predicate part of reality. The world stands really malleable, waiting to receive its final touches at our hands. Like the kingdom of heaven, it suffers human violence willingly. Man *engenders* truths upon it.

No one can deny that such a role would add both to our dignity and to our responsibility as thinkers. To some of us it proves a most inspiring notion. Signore Papini, the leader of Italian pragmatism, grows fairly dithyrambic over the view that it opens of man's divinely-creative functions.

The import of the difference between pragmatism and rationalism is now in sight throughout its whole extent. The essential contrast is that *for rationalism reality is ready-made and complete from all eternity, while for pragmatism it is still in the making, and awaits part of its complexion from the future.* On the one side the universe is absolutely secure, on the other it is

[202] H. C. von Baeyer corrected the capitalization of this from James's original, and translated it as, "the enhancement of what is found to exist."

still pursuing its adventures.

We have got into rather deep water with this humanistic view, and it is no wonder that misunderstanding gathers round it. It is accused of being a doctrine of caprice. Mr. Bradley, for example, says that a humanist, if he understood his own doctrine, would have to 'hold any end, however perverted, to be rational, if I insist on it personally, and any idea, however mad, to be the truth if only some one is resolved that he will have it so.' The humanist view of 'reality,' as something resisting, yet malleable, which controls our thinking as an energy that must be taken 'account' of incessantly (tho not necessarily merely *copied*) is evidently a difficult one to introduce to novices. The situation reminds me of one that I have personally gone through. I once wrote an essay on our right to believe, which I unluckily called the *Will* to Believe. All the critics, neglecting the essay, pounced upon the title. Psychologically it was impossible, morally it was iniquitous. The 'will to deceive,' the 'will to make-believe,' were wittily proposed as substitutes for it.

The alternative between pragmatism and rationalism, in the shape in which we now have it before us, is no longer a question in the theory of knowledge, it concerns the structure of the universe itself.

On the pragmatist side we have only one edition of the universe, unfinished, growing in all sorts of places, especially in the places where thinking beings are at work.

On the rationalist side we have a universe in many editions, one real one, the infinite folio, or *édition de luxe*, eternally complete; and then the various finite editions, full of false readings, distorted and mutilated each in its own way.

W. James, "Pragmatism and Religion," in his *Pragmatism, a New Name for Some Old Ways of Thinking: Popular Lectures on Philosophy*, (Longmans, Green and Co., New York, 1922).

Let us apply this notion to the salvation of the world. What does it pragmatically mean to say that this is possible? It means that some of the conditions of the world's deliverance do actually exist. The more of them there are existent, the fewer preventing conditions you can find, the better-grounded is the salvation's possibility, the more *probable* does the fact of the deliverance become.

So much for our preliminary look at possibility.

Now it would contradict the very spirit of life to say that our minds must be indifferent and neutral in questions like that of the world's salvation. Any one who pretends to be neutral writes himself down here as a fool and a sham. We all do wish to minimize the insecurity of the universe; we are and ought to be unhappy when we regard it as exposed to every enemy and open to every life-destroying draft. Nevertheless there are unhappy men who think the salvation of the world impossible. Theirs is the doctrine known as pessimism.

Optimism in turn would be the doctrine that thinks the world's salvation inevitable.

Midway between the two there stands what may be called the doctrine of meliorism, tho it has hitherto figured less as a doctrine than as an attitude in human affairs. Optimism has always been the regnant *doctrine* in European philosophy. Pessimism was only recently introduced by Schopenhauer and counts few systematic defenders as yet. Meliorism treats salvation as neither necessary nor impossible. It treats it as a possibility, which becomes more and more of a probability the more numerous the actual conditions of salvation become.

It is clear that pragmatism must incline towards meliorism. Some conditions of the world's salvation are actually extant, and she can not possibly close her eyes to this fact: and should the residual conditions come, salvation would become an accomplished reality. Naturally the terms I use here are exceedingly summary. You may interpret the word 'salvation' in any way you like, and make it as diffuse and distributive, or as climacteric and integral a phenomenon as you please.

Take, for example, any one of us in this room with the ideals which he cherishes and is willing to live and work for. Every such ideal realized will be one moment in the world's salvation. But these particular ideals are not bare abstract possibilities. They are grounded, they are *live* possibilities, for we are their live champions and pledges, and if the complementary conditions come and add themselves, our ideals will become actual things. What now are the complementary conditions? They are first such a mixture of things as will in the fullness of time give us a chance, a gap that we can spring into, and, finally, *our act*.

Does our act then *create* the world's salvation so far as it makes room for itself, so far as it leaps into the gap? Does it create, not the whole world's salvation of course, but just so much of this as itself covers of the world's extent?

Here I take the bull by the horns, and in spite of the whole crew of rationalists and monists, of whatever brand they be, I ask *why not?* Our acts, our turning-places, where we seem to ourselves to make ourselves and grow, are the parts of the world to which we are closest, the parts of which our knowledge is the most intimate and complete. Why should we not take them at their facevalue? Why may they not be the actual turning-places and growing-places which they seem to be, of the world—why not the workshop of being, where we catch fact in the making, so that nowhere may the world grow in any other kind of way than this?

Irrational! we are told. How can new being come in local spots and patches which add themselves or stay away at random, independently of the rest? There must be a reason for our acts, and where in the last resort can any reason be looked for save in the material pressure or the logical compulsion of the total nature of the world? There can be but one real agent of growth, or seeming growth, anywhere, and that agent is the integral world itself. It may grow all-over, if growth there be, but that single parts should grow *per se* is irrational.

But if one talks of rationality—and of reasons for things, and insists that they can't just come in spots, what *kind* of a reason can there ultimately be why anything should come at all? Talk of logic and necessity and categories and the absolute and the contents of the whole philosophical machine-shop as you will, the only *real* reason I can think of why anything should ever come is that *some one wishes it to be here*. It is *demanded*,—demanded, it may be, to give relief to no matter how small a fraction of the world's mass. This is *living reason*, and compared with it material causes and logical necessities are spectral things.

In short the only fully rational world would be the world of wishing-caps, the world of telepathy, where every desire is fulfilled instanter, without having to consider or placate surrounding or intermediate powers. This is the Absolute's own world. He calls upon the phenomenal world to be, and it is, exactly as he calls for it, no other condition being required. In our world, the wishes of the individual are only one condition. Other individuals are there with other wishes and they must be propitiated first. So Being grows under all sorts of resistances in this world of the many, and, from compromise to compromise, only gets organized gradually into what may be called secondarily rational shape. We approach the wishing-cap type of organization only in a few departments of life. We want water and we turn a faucet. We want a kodak-picture and we press a button. We want information and we telephone. We want to travel and we buy a ticket. In these and similar cases, we hardly need to do more than the wishing—the world is rationally organized to do the rest.

But this talk of rationality is a parenthesis and a digression. What we were discussing was the idea of a world growing not integrally but piecemeal by the contributions of its several parts. Take the hypothesis seriously and as a live one. Suppose that the world's author put the case to you before creation, saying: "I am going to make a world not certain to be saved, a world the perfection of which shall be conditional merely, the condition being that each several agent does its own 'level best.' I offer you the chance of taking part in such a world. Its safety, you see, is unwarranted. It is a real adventure, with real danger, yet it may win through. It is a social scheme of co-operative work genuinely to be done. Will you join the procession? Will you trust yourself and trust the other agents enough to face the risk?"

Should you in all seriousness, if participation in such a world were proposed to you, feel bound to reject it as not safe enough? Would you say that, rather than be part and parcel of so fundamentally pluralistic and irrational a universe, you preferred to relapse into the slumber of nonentity from which you had been momentarily aroused by the tempter's voice?

Of course if you are normally constituted, you would do nothing of the sort. There is a healthy-minded buoyancy in most of us which such a universe would exactly fit. We would therefore accept the offer—"Top! und Schlag auf Schlag!" It would be just like the world we practically live in; and loyalty to our old nurse Nature would forbid us to say no. The world proposed would seem 'rational' to us in the most living way.

Most of us, I say, would therefore welcome the proposition and add our *fiat* to the *fiat* of the creator.

Max's First Reply

I finally received my copy of *Pragmatism* and have been reading it with much enjoyment ever since. I found myself nodding in agreement many times as I was reading along. I also enjoyed James' prose and choice of words. I like the idea of a world that might be pluralistic at its core, a world whose future is not yet hammered out, a world that is not subsumed into a monistic, eternal, static One. I like the open-minded, non-dogmatic and practical (yet not mundane) nature of the pragmatist approach. Among many things, reading the book has further cemented my ever-growing antipathy to Everett's many worlds. Not a bad outcome, I think, given that I used to be quite partial to this type of interpretation. Well, once I've finished the book, I hope to be able to communicate some more concrete thoughts and comments.

Also, I just re-read your paper "Subjective probability and quantum certainty," and I feel it has helped me in coming to grips with the idea of a purely subjective nature of certainty. I suppose my initial slight unease with this issue had something to do with the question you address toward the end: "Isn't not asking for a further explanation a betrayal of the very purpose of science, namely, never to give up the quest for an explanation?" I think that, for most of us, the idea of "explanation" is usually indeed intuitively linked with notions of causality and (moreover) determinism. And hence the initial discomfort when our feeling of certainty is not further related to some underlying mechanism that "indeed" (as we would then say) ensures an objective basis for our certainty. To some extent, much of the spirit of science may be built on the quest for such a mechanism: we observe patterns, regularities, and want to have them set in stone, in form of mechanistic physical laws, for example. But the upshot of QM may indeed be to look no longer for such mind-soothing tracks to underlie the journey of our experiences.

I'm very curious to see how your thoughts on "decoherence in QBist terms" will evolve. I too have sometimes found myself contemplating the precise role decoherence could assume in such an interpretive framework, and what the particular input of decoherence would be here.

As with similar questions about the implications and views of decoherence in the various interpretations of QM, it is apparent that, on the one hand, decoherence is simply an application of the QM formalism and hence cannot really "solve" any foundational riddles; but also that, on the other hand, decoherence may sharpen or inform or lessen certain worries of foundational relevance. I understand that you believe that decoherence has rather little (if any) input for q-foundations, which is a fair point (though I'd add that its force may also in turn depend on one's interpretive commitments and thinking, and thus on the particular form one chooses to state and rank foundational problems).

Of course, QBism in no way keeps us from applying the full machinery of decoherence analysis. I guess we may say that decoherence teaches us something like this: In order for the agent to improve his predictions of the consequences of future actions on the system, he ought to take into account the openness of any realistic quantum system. He could take actions on the environment and on the composite system-environment complex to bring about facts that in turn help him update is predictions of what he may (or, more often in the case of decoherence, may NOT) expect to experience if he interacts with the system. Or, in absence of access to most environmental degrees of freedom, he might just adjust his prior according to some good guess about what the environment is like and what its interactions with the system are likely to be. In turn, I suppose he could also use his experiences of interactions with the system to update his state assignments to the environment.

These are just a couple of first, painfully vague attempts at wrapping my head around the decoherence + QBist complex. Maybe I've missed the target. At any rate, if you think it may be beneficial/worthwhile for you too, I would certainly enjoy any discussions surrounding QBist decoherence while you and Rüdiger work on the draft.

Max's Second Reply

I *finally* finished James' book today. I had read three quarters of it in one go (enthusiastically, in fact!), and then somehow got sidetracked by other things and didn't seriously pick it up again until today. The earlier preliminary assessment I had given to you in my email of July 28th (you got that one, didn't you?) still stands, though:

> "I found myself nodding in agreement many times as I was reading along. I also enjoyed James' prose and choice of words. I like the idea of a world that might be pluralistic at its core, a world whose future is not yet hammered out, a world that is not subsumed into a monistic, eternal, static One. I like the open-minded, non-dogmatic and practical (yet not mundane) nature of the pragmatist approach."

Most importantly, maybe, I have already applied some of the pragmatic ways of thinking to various issues that have come before me lately, and I've had some nicely head-clearing epiphanies in the process. So, thanks again for pointing me to this book. I shall certainly hear James' voice in the back of my head from now on.

Below are some of my favorite quotes – I haven't checked explicitly, but it's likely they'll have some overlap with the ones you sent me. Well, I guess that just proves the universal power and appeal of the Jamesian ideas …

The Present Dilemma in Philosophy

> Whatever universe a professor believes in must at any rate be a universe that lends itself to lengthy discourse. A universe definable in two sentences is something for which the professorial intellect has no use. No faith in anything of that cheap kind!
>
> **
>
> The history of philosophy is to a great extent that of a certain clash of human temperaments.
>
> **
>
> The more absolutistic philosophers dwell on so high a level of abstraction that they never even try to come down. The absolute mind which they offer us, the mind that makes our universe by thinking it, might, for aught they show us to the contrary, have made any one of a million other universes just as well as this. You can deduce no single actual particular from the notion of it. It is compatible with any state of things whatever being true here below.
>
> **
>
> The actual universe is a thing wide open, but rationalism makes systems, and systems must be closed. For men in practical life perfection is something far off and still in process of achievement. This for rationalism is but the

illusion of the finite and relative: the absolute ground of things is a perfection eternally complete.

**

The books of all the great philosophers are like so many men. Our sense of an essential personal flavor in each one of them, typical but indescribable, is the finest fruit of our own accomplished philosophic education. What the system pretends to be is a picture of the great universe of God. What it is—and oh so flagrantly!—is the revelation of how intensely odd the personal flavor of some fellow creature is.

**

But almost everyone has his own peculiar sense of a certain total character in the universe, and of the inadequacy fully to match it of the peculiar systems that he knows. They don't just cover HIS world. One will be too dapper, another too pedantic, a third too much of a job-lot of opinions, a fourth too morbid, and a fifth too artificial, or what not. At any rate he and we know offhand that such philosophies are out of plumb and out of key and out of 'whack,' and have no business to speak up in the universe's name.

What Pragmatism Means

So the universe has always appeared to the natural mind as a kind of enigma, of which the key must be sought in the shape of some illuminating or power-bringing word or name. That word names the universe's PRINCIPLE, and to possess it is, after a fashion, to possess the universe itself. 'God,' 'Matter,' 'Reason,' 'the Absolute,' 'Energy,' are so many solving names. You can rest when you have them. You are at the end of your metaphysical quest.

**

When the first mathematical, logical and natural uniformities, the first LAWS, were discovered, men were so carried away by the clearness, beauty and simplification that resulted, that they believed themselves to have deciphered authentically the eternal thoughts of the Almighty. (...)

But as the sciences have developed farther, the notion has gained ground that most, perhaps all, of our laws are only approximations. The laws themselves, moreover, have grown so numerous that there is no counting them; and so many rival formulations are proposed in all the branches of science that investigators have become accustomed to the notion that no theory is absolutely a transcript of reality, but that any one of them may from some point of view be useful.

**

Purely objective truth, truth in whose establishment the function of giving human satisfaction in marrying previous parts of experience with newer parts played no role whatever, is nowhere to be found. The reasons why we call things true is the reason why they ARE true, for 'to be true' MEANS only to perform this marriage-function.

Some Metaphysical Problems Pragmatically Considered

To treat abstract principles as finalities, before which our intellects may come to rest in a state of admiring contemplation, is the great rationalist failing.

**

When we look at what has actually come, the conditions must always appear perfectly designed to ensure it. We can always say, therefore, in any conceivable world, of any conceivable character, that the whole cosmic machinery MAY have been designed to produce it.

The One and the Many

I must therefore treat the notion of an All-Knower simply as an hypothesis, exactly on a par logically with the pluralist notion that there is no point of view, no focus of information extant, from which the entire content of the universe is visible at once. "God's consciousness," says Professor Royce, "forms in its wholeness one luminously transparent conscious moment"—this is the type of noetic unity on which rationalism insists. Empiricism on the other hand is satisfied with the type of noetic unity that is humanly familiar. Everything gets known by SOME knower along with something else; but the knowers may in the end be irreducibly many, and the greatest knower of them all may yet not know the whole of everything, or even know what he does know at one single stroke:—he may be liable to forget. Whichever type obtained, the world would still be a universe noetically. Its parts would be conjoined by knowledge, but in the one case the knowledge would be absolutely unified, in the other it would be strung along and overlapped.

Pragmatism and Common Sense

The scope of the practical control of nature newly put into our hand by scientific ways of thinking vastly exceeds the scope of the old control grounded on common sense. Its rate of increase accelerates so that no one can trace the limit; one may even fear that the BEING of man may be crushed by his own powers, that his fixed nature as an organism may not prove adequate to stand the strain of the ever increasingly tremendous functions, almost divine creative functions, which his intellect will more and more enable him to wield. He may drown in his wealth like a child in a bath-tub, who has turned on the water and who cannot turn it off.

**

But now if the new kinds of scientific 'thing,' the corpuscular and etheric world, were essentially more 'true,' why should they have excited so much criticism within the body of science itself? Scientific logicians are saying on every hand that these entities and their determinations, however definitely conceived, should not be held for literally real. It is AS IF they existed; but in reality they are like co-ordinates or logarithms, only artificial short-cuts for taking us from one part to another of experience's flux. We can cipher fruitfully with them; they serve us wonderfully; but we must not be their dupes.

**

Ought not the existence of the various types of thinking which we have reviewed, each so splendid for certain purposes, yet all conflicting still, and neither one of them able to support a claim of absolute veracity, to awaken a presumption favorable to the pragmatistic view that all our theories are INSTRUMENTAL, are mental modes of ADAPTATION to reality, rather than revelations or gnostic answers to some divinely instituted world-enigma?

Pragmatism's Conception of Truth

But the great assumption of the intellectualists is that truth means essentially an inert static relation. When you've got your true idea of anything, there's an end of the matter. You're in possession; you KNOW; you have fulfilled your thinking destiny. You are where you ought to be mentally; you have obeyed your categorical imperative; and nothing more need follow on that climax of your rational destiny. Epistemologically you are in stable equilibrium.

**

The truth of an idea is not a stagnant property inherent in it. Truth HAPPENS to an idea. It BECOMES true, is MADE true by events. Its verity is in fact an event, a process: the process namely of its verifying itself, its veri-FICATION. Its validity is the process of its valid-ATION.

**

The true thought is useful here because the house which is its object is useful. The practical value of true ideas is thus primarily derived from the practical importance of their objects to us. Their objects are, indeed, not important at all times.

**

Primarily, and on the common-sense level, the truth of a state of mind means this function of A LEADING THAT IS WORTH WHILE. When a moment in our experience, of any kind whatever, inspires us with a thought that is true, that means that sooner or later we dip by that thought's guidance into the particulars of experience again and make advantageous connexion with them.

**

Such is the large loose way in which the pragmatist interprets the word agreement. He treats it altogether practically. He lets it cover any process of conduction from a present idea to a future terminus, provided only it run prosperously. It is only thus that 'scientific' ideas, flying as they do beyond common sense, can be said to agree with their realities. It is, as I have already said, as if reality were made of ether, atoms or electrons, but we mustn't think so literally. The term 'energy' doesn't even pretend to stand for anything 'objective.' It is only a way of measuring the surface of phenomena so as to string their changes on a simple formula.

Yet in the choice of these man-made formulas we cannot be capricious with impunity any more than we can be capricious on the common-sense practical level. We must find a theory that will WORK; and that means something extremely difficult; for our theory must mediate between all previous truths and certain new experiences. It must derange common sense and previous belief as little as possible, and it must lead to some sensible terminus or other that can be verified exactly. To 'work' means both these things; and the squeeze is so tight that there is little loose play for any hypothesis. Our theories are wedged and controlled as nothing else is. Yet sometimes alternative theoretic formulas are equally compatible with all the truths we know, and then we choose between them for subjective reasons. We choose the kind of theory to which we are already partial; we follow 'elegance' or 'economy.' Clerk Maxwell somewhere says it would be "poor scientific taste" to choose the more complicated of two equally well-evidenced conceptions; and you will all agree with him. Truth in science is what gives us the maximum possible sum of satisfactions, taste included, but consistency both with previous truth and with novel fact is always the most imperious claimant.

**

Truths emerge from facts; but they dip forward into facts again and add to them; which facts again create or reveal new truth (the word is indifferent) and so on indefinitely. The 'facts' themselves meanwhile are not TRUE. They simply ARE. Truth is the function of the beliefs that start and terminate among them.

**

The rationalist's fallacy here is exactly like the sentimentalist's. Both extract a quality from the muddy particulars of experience, and find it so pure when extracted that they contrast it with each and all its muddy instances as an opposite and higher nature. All the while it is THEIR nature. It is the nature of truths to be validated, verified. It pays for our ideas to be validated. Our obligation to seek truth is part of our general obligation to do what pays. The payments true ideas bring are the sole why of our duty to follow them.

Pragmatism and Humanism

I read in an old letter—from a gifted friend who died too young—these words: "In everything, in science, art, morals and religion, there MUST be one system that is right and EVERY other wrong." How characteristic of the enthusiasm of a certain stage of youth!

**

'REALITY' IS IN GENERAL WHAT TRUTHS HAVE TO TAKE ACCOUNT OF; [fn: Mr. Taylor in his Elements of Metaphysics uses this excellent pragmatic definition.] and the FIRST part of reality from this point of view is the flux of our sensations. Sensations are forced upon us, coming we know not whence. Over their nature, order, and quantity we have as good as no control. THEY are neither true nor false; they simply ARE. It is only what we say about them, only the names we give them, our theories of their source and nature and remote relations, that may be true or not.

**

Lotze has in several places made a deep suggestion. We naively assume, he says, a relation between reality and our minds which may be just the opposite of the true one. Reality, we naturally think, stands ready-made and complete, and our intellects supervene with the one simple duty of describing it as it is already. But may not our descriptions, Lotze asks, be themselves important additions to reality? And may not previous reality itself be there, far less for the purpose of reappearing unaltered in our knowledge, than for the very purpose of stimulating our minds to such additions as shall enhance the universe's total value. "Die Erhöhung des vorgefundenen Daseins" is a phrase used by Professor Eucken somewhere, which reminds one of this suggestion by the great Lotze.

It is identically our pragmatistic conception. In our cognitive as well as in our active life we are creative. We ADD, both to the subject and to the predicate part of reality. The world stands really malleable, waiting to receive its final touches at our hands. Like the kingdom of heaven, it suffers human violence willingly. Man ENGENDERS truths upon it.

**

The essential contrast is that for rationalism reality is ready-made and complete from all eternity, while for pragmatism it is still in the making, and awaits part of its complexion from the future. On the one side the universe is absolutely secure, on the other it is still pursuing its adventures.

**

And this, exactly this, is what the tough-minded of that lecture find themselves moved to call a piece of perverse abstraction-worship. The tough-minded are the men whose alpha and omega are FACTS. Behind the bare phenomenal facts, as my tough-minded old friend Chauncey Wright, the great Harvard empiricist of my youth, used to say, there is NOTHING. When a rationalist insists that behind the facts there is the GROUND of the facts, the POSSIBILITY of the facts, the tougher empiricists accuse him of taking the mere name and nature of a fact and clapping it behind the fact as a duplicate entity to make it possible. That such sham grounds are often invoked is notorious. At a surgical operation I heard a bystander ask a doctor why the patient breathed so deeply. "Because ether is a respiratory stimulant," the doctor answered. "Ah!" said the questioner, as if relieved by the explanation. But this is like saying that cyanide of potassium kills because it is a 'poison,' or that it is so cold to-night because it is 'winter,' or that we have five fingers because we are 'pentadactyls.' These are but names for the facts, taken from the facts, and then treated as previous and explanatory. The tender-minded notion of an absolute reality is, according to the radically tough-minded, framed on just this pattern. It is but our summarizing name for the whole spread-out and strung-along mass of phenomena, treated as if it were a different entity, both one and previous.

Pragmatism and Religion

In short the only fully rational world would be the world of wishing-caps, the world of telepathy, where every desire is fulfilled instanter, without having to consider or placate surrounding or intermediate powers. This is the Absolute's own world. He calls upon the phenomenal world to be, and it IS, exactly as he calls for it, no other condition being required. In our world, the wishes of the individual are only one condition. Other individuals are there with other wishes and they must be propitiated first. So Being

> grows under all sorts of resistances in this world of the many, and, from compromise to compromise, only gets organized gradually into what may be called secondarily rational shape. We approach the wishing-cap type of organization only in a few departments of life. We want water and we turn a faucet. We want a kodak-picture and we press a button. We want information and we telephone. We want to travel and we buy a ticket. In these and similar cases, we hardly need to do more than the wishing-the world is rationally organized to do the rest.

30-06-09 *Disturbing the Solipsist, 2* (to H. M. Wiseman)

Wisemanism 41 : *Perhaps not this section, but the introduction states:*

> For, quantum mechanics-we plan to show in this paper-gives a resource that raw Bayesian probability theory does not: It gives a rule for forming probabilities for the outcomes of factualizable experiments (experiments that may actually be performed) from the probabilities one assigns for the outcomes of a designated counterfactual experiment (an experiment only imagined, and though possible to do, never actually performed).

Maybe I'm misunderstanding. I thought you were contrasting classical Bayesian reasoning with quantum Bayesian reasoning, and implying the latter had more structure. This would be wrong, IMO, for the reasons I gave earlier. But maybe you mean something else by "raw" Bayesianism.

You are indeed a friend in Australia: For who else would read the paper this thoroughly!

I don't want the passage to be misleading, but strictly speaking it remains correct and consistent with what I said yesterday. In a literal reading, the only thing this passage expresses is that the *judgment* $q(B) = (d + 1)p(B) - 1$ (for relating lower path to upper path in the diagram) is a judgment beyond raw Bayesian probability theory (i.e., beyond Dutch-book coherence). As you called me on in your earlier note, a judgment that $q(B) = p(B)$ would also be an addition to Bayesian probability theory, just a different one. And that is true. The passage you quote is simply silent on that.

There is a bit of discussion of this just after Eq. (169). And of course there is a bit of discussion just preceding Eq. (4). Finally some discussion on page 53 near the displayed equations.

I don't know that I should modify anything in the introduction, since as I say the passage is not inaccurate.

01-07-09 *Quick, Before Rüdiger Sees . . .* (to H. M. Wiseman)

Yesterday didn't work out the way I planned, and today Rüdiger says I can't write so much email (we need to work on our "Quantum-Bayesian Decoherence" paper in his last days in Waterloo). So, once again, you'll have to wait to learn whether you exist.

Wisemanism 42 : *Are you going to modify your introduction then, if you admit it misrepresents your position?*

It doesn't so much misrepresent it, as it just doesn't say it in any detail. (That's the way introductions are supposed to work.) My feeling was that I had covered myself with respect to *most* people by using the phrase "quick and dirty," by making the allusion to "EPR-criterion-of-reality considerations" along with Bell, and by explicitly putting "reads off" in quotes. We'll see. If I can find a pithy way to make it more accurate (i.e., without adding more than an extra sentence), I might try.

Wisemanism 43: *I'll have to read your response to Norsen, but in my correspondence with Norsen I disagreed with his claim that one can (and Bell did) derive his theorem from locality (in the strict sense Einstein and Bell used it) alone. I think it is clear that locality plus determinism, or local causality (which is slightly weaker) is needed. This was one thing I wanted to make clear in writing a review of RL & AT. So I suspect we agree on this.*

If I understand you correctly, then I think we agree to a large extent.

Wisemanism 44: *I'm not sure what your "WITHOUT RECOURSE TO" is supposed to mean.*

I'll come back to that when I tell you whether you exist.

Wisemanism 45: *Regarding who is a genuine realist, what I find puzzling is that you say you believe there is a world out there because you believe it can surprise you. But in cases where you believe the world can't surprise you, you don't believe it's real. That is, you seem to take predictability as the* counter-evidence *for reality, which is the opposite to the usual scientific argument for there being a real world.*

It probably helps explain my attraction to James, Dewey, and Schiller. But you mangle the point a bit: Predictability is not *counter*-evidence; it's just null. I hope I formulate the point relatively carefully in my "Anti-Växjö Interpretation of QM" pseudo-paper. Michel Bitbol makes the point pretty well in a letter responding to that paper. I'll paste it in below (point 4 in particular). [See preply to 10-12-03 note "First Meeting" with M. Bitbol.]

I'll be back when Rüdiger's not watching.

02-07-09 *Your Objections* (to G. M. D'Ariano)

Thanks for the extensive notes. They are good food for thought for me, and let us discuss at length when you come to Waterloo. At the moment, let me just comment on two of your items.

D'Ariano-ism 4: *1) You said (publicly) that you gave up the problem of deriving QM from "operational" principles.*

I'm very sorry to cause you distress on this. I can't exactly recall what I said, but I do remember this much: What I said was meant to be something of a joke (expressing that I have been failing so far), but it went way wrong. So much so, that you didn't know that I was joking! So please be less stressed: I still believe operational principles are the great starting point for our considerations.

D'Ariano-ism 5: *2) You mentioned possible "empirical" motivation for QM.*

Maybe I have not used the best word here, I don't know. I am discovering that it has connotations with many (like yourself) that I had not intended. I still very much want a great principle. But I believe that that great principle will express something about the character of our particular world. A different world would have had a different principle. I insert an excerpt from a note to Eric Cavalcanti below, where I reply to some points in his own correspondence with Howard

Wiseman. [See 29-06-09 note "Eric's Note" to E. G. Cavalcanti & H. M. Wiseman.] Perhaps these notes will help take some of the sting of my choice of words (at least they give the sense of what I meant by "empirical") … and perhaps I should modify my words to better ones in the future.

I look forward to seeing you soon … so I may better clear my name and restore your faith in me!

03-07-09 *Emailing: 0907.0416v1* (to G. L. Comer)

Comerism 23: *From your point of view, is it even necessary to talk about the "same quantum state"? Can't I just forget about the constituents, and say that there is a "widget" I'm gonna latch onto and that I'm gonna write down this wave function for? Then if I introduce "fundamental" constituents, it's only because I have some prior knowledge about their behavior that I want to take advantage of in trying to extract info from the widget?*

Yep. Things don't HAVE wave functions, we make them up. A line from my most recent paper:

> For, the essential point for a quantum-Bayesian is that there is no such thing as *the* quantum state. There are potentially as many states for a given quantum system as there are agents.

And that applies to anything whatsoever.

06-07-09 *The Verdict* (to H. M. Wiseman)

Wisemanism 46: *The discussion on p. 55 again opens you to accusations of solipsism. I don't care about your saying you're not a solipsist because the world can still surprise you. Tell me what your attitude to other people is! You talk about "categories of thought". That seems like a veil to hide behind. Do you believe other people are agents, equal to you, who exist even when you are not observing them, doing things when they are space-like separated from you?*

If yes, then you believe in hidden variables, despite your disparagement of them.

If no, then you are a solipsist in my book.

And I don't mean you as a hypothetical agent telling me the answer your quantum theory / philosophy tells you to say. I mean you, Chris Fuchs, the individual I believe in even when I'm not interacting with him. What do you believe about me?

I finally come to the reply you have been waiting for …

Of course you exist! If I didn't believe that, I wouldn't write you emails and expectantly await all the consequences your replies will bring about for me. You are no different in kind from any other quantum system I interact with. (I'm sorry if that is an insult. And by the way, you should note the similarity between the language in the second sentence of this paragraph and that used in Section 8.1—it is no accident.) Was this not already written so clearly in the paper?

But I continue to reject your statement, "If yes, then you believe in hidden variables, despite your disparagement of them." My understanding of "hidden variables" or, better, "ontic variables"—the sort of thing Bohmians and the like hope to reasonably show as undergirding quantum mechanics—is that these, when found, will give a *closed* description of the essential content of "quantum measurement" (which of course means a broad range of issues/things) without reference to the agent using the theory. For instance, the contextual hidden-variablists (Bohmians being one species) are happy to put a hidden variable in the device as well as the particle, and think that that takes all the trouble out of the quantum interpretation conundrum. But a device ain't no agent using the theory as a theory of gambling, and that is why I keep myself at a distance from the hidden-variable conception. I think we will have understood something deep when we understand why the agent is only so stubbornly removed from the conception of the theory. Frankly, I think it can't be done without incurring the even greater mysteries the advocates of those approaches simply ignore. (The endpoint of those researches, I am quite convinced, will be lifeless, block universes of one variety or another—ones that can never be resuscitated, no matter what amount of Dennettian-style sophistry.) Worse than that, I see the ontic variable program so conceived as a dead end for developing the next stage of physics.

Quantum mechanics (and all its babies, like quantum field theory or even, potentially, though not likely, string theory) cannot be the end of the story for our physical understanding. I tend to think it is only the beginning. But I don't see a development going forward that doesn't recognize the agent as the central point (the "center of narrative gravity") of any particular use of the theory.

I know these answers leave you deeply unsatisfied. Your worry was that I don't believe in your existence, but that's the easy part of the conundrum. The hard part is in assuring my own existence and efficacy, and that is what every physical theory up until quantum mechanics left out of its worldview. You shouldn't let the small corrective that quantum mechanics provides frighten you into thinking it gives the opposite of what it actually does!

Wisemanism 47: *See, I'm not really an anti-Bayesian ogre. :-)*

I never thought you were. You read our papers more *thoroughly* than anyone else on the planet, even in those moments when you are unsympathetic; surely that is revealing something.

06-07-09 *Emailing: 0907.0416v1, 2* (to G. L. Comer)

Comerism 24: *Now, for a little Devilishism:*

Is there not a uniqueness property for the Schrödinger equation? That is, for a given set of initial conditions, $\{\Psi(0,x),\dot{\Psi}(0,x)\}$, one gets a unique solution for Ψ. Sure, I can decompose in terms of a particular basis, but that doesn't change Ψ, right? For a specific example, take the classic Hydrogen atom problem. We specify boundary conditions, a coordinate system, energy eigenstates, and a solution is the result. Moreover, we get the Balmer, Lyman, etc series for the spectra, whose accuracy is without doubt.

Is there not a "best" wave function for this system, independently of the agent? I mean, if I'm a stupid agent—which is a pretty good assessment—I might place my bets based on the analogous solution for uranium. Obviously, the point is that the Schrödinger equation is a very good friend for those who want to make bets.

That is the perennial question, and it goes much deeper than quantum mechanics. It is a question about probability theory more generally. The Bayesian says, the apparatus of probability theory gives no means for saying whether one probability assignment is better than another (none that doesn't depend on a more primal probability assignment further back in the stream), just like the apparatus of mathematical logic gives no means for specifying which truth value a proposition ought to have (true or false). Truth-value assignments and probability assignments come from outside logic and probability *theory*.

It's a hard intuition to shake. Without opening a very long email exchange (which would surely be required), I'm afraid the best I can do is say to read Dennis Lindley's book *Understanding Uncertainty*: `http://books.google.com/books?id=z0ArJ_CDnssC&dq=Lindley+Understanding+Uncertainty&source=gbs_navlinks_s`.

The bottom line is, our common quantum-state assignments "work" in the way that a 50-50 assignment "works" for most coin tosses. There is nothing absolute in the statement. Only an expression of our doing our best to get along in a world that's not completely revealed to us.

06-07-09 *Test the Born Rule Another Way* (to R. Laflamme)

Now it is me who is a week behind on email!

Yes, of course, I'm still interested in an experiment. The final version of the paper I sent you can be found here: `http://arxiv.org/abs/0906.2187`. (It grew by a factor of two since the draft I had previously sent—the proposed experiment is now to be found in Figure 2 on page 20.) The paper just got an "invitation" from *Reviews of Modern Physics*—so that will be its final coordinates.

I'd be very flattered if you'd think about how it might be done with techniques readily available to your team. Aephraim Steinberg already has plans to do something similar—he tells me he's got two students on it, the equipment ordered, and plans drawn up. So I'm pleased that something serious will happen there. But I figure synergy, cooperation, and/or competition from you guys could only be a good thing. (De Martini, as well, seemed to take quite an interest in the idea when we met in Sweden, but that may mean nothing in the end.)

Anyway, if you'd like to talk, tell me when to come by.

06-07-09 *Refeeding Quantum Mechanics* (to B. C. van Fraassen)

Thanks for the notes, and indeed thanks for the interest! Thinking of your being in San Francisco, I should send you a picture of the painted lady my wife and I are making here in Waterloo. It is a shock to the system of the locals, though we think the color scheme is pretty standard/simple for such things.

I read your notes several times over to make sure I wasn't missing something: If you don't mind, you'll have to tell me! I think the main confusion might be localized in my usage of the label "Bayesian." Sorry to have caused you trouble over that.

First, responding to

van Fraassenism 14: *For the orthodox Bayesian, conditional probability on A, if* $p(A) = 0$ *has no sense.*

and

van Fraassenism 15: *I notice first of all that when you introduce conditional probability with equation (1):* $p(A, B) = p(A)p(B|A)$ *it is presented in a form that is satisfied also if* $p(A) = 0$*, provided only that* $p(B|A)$ *has some numerical value or other. But I guess you did not write it that way for that purpose*

I think this means I'm a heterodox Bayesian then. Because I had put (what I call) "Bayes Rule" in the given form for just that reason. And I do think $p(B|A)$ has sense when $p(A) = 0$. Funny, just the other day, Rüdiger Schack wrote me this:

Schackcosm 119: *I'll be waiting for you at arrivals, where you emerge from customs. If I am late, wait a little. We are only 8 minutes from Heathrow, so if I am not there (extremely unlikely, but we Bayesians can condition even on probability zero events), you can always call us at home.*

If the label is appropriate, maybe I should call myself something a "Richard-Jeffrey Bayesian". For he takes the same stance in his book *Subjective Probability, the Real Thing*. See the discussion in Section 1.4 (pages 18–20) of `http://www.princeton.edu/∼bayesway/Book*.pdf`.

Does that now fix everything up in your mind? Perhaps when we repost a new version of the paper, we should be more careful to define our particular flavor of Bayesianism (i.e., the Richard-Jeffrey style, etc.). What label would you give to the flavor? Is one already existent in the literature?

On one of your other points,

van Fraassenism 16 : *Really important: that coherence argument assumes that the events A are not just mutually exclusive but form an exhaustive list.*

you are absolutely right, and it was a mistake for me to leave that implicit.

I know I've invited you before, but any interest in giving us a visit in Waterloo sometime soon? (The wine list at our institute isn't half bad.)

07-07-09 *Deriving the Urungleichung from Fundamental Probability Theory* (to R. Adler)

Rüdiger and I have had a chance to study your note. Thanks again for the interest. I don't believe we've ever heard the compliment of anyone "obsessing over [our work] for months"! I assure you, it gives us a very pleasant feeling!

Anyway, to your point, it would be nice if it were so simple . . .

But you'll note that your x or Pr(state in the sky is $\Pi_i \,|\, \rho$) is not actually a probability distribution. If you sum over the index i, you do indeed get 1, but the individual x can go negative. For the extreme case of this, note that $Pr(\Pi_i$ observed on $\rho)$ can vanish if ρ is a density operator orthogonal to Π_i; thus x can go all the way down to $-1/d$. In fact, there is no good way to think of the Π_i as ontic variables (i.e., elements of reality).

It is true that for any *particular* measurement on the ground, one can scheme up a hidden variable explanation to go <u>from</u> $q(j)$ <u>to</u> $s(j)$ in our notation (though not the other way around). See Eqs. (52) and (53) in the paper. That's a little similar to your idea, though it takes the state $q(j)$ on the ground as more basic than the state in the sky $p(i)$. But that is only true for any *particular* measurement. When one stitches together all the urgleichung diagrams (like Fig 2) for *all possible* measurements, if full quantum mechanics does indeed arise from this process, then an all-encompassing hidden-variable interpretation (like the one just mentioned, but working for all measurements on the ground) must be excluded. We've been thinking hard about adding a subsection to the paper explaining this latter point (as we have already had to make it to Bacciagaluppi, Uffink, and Spekkens and think we'd now like to preempt its being asked again!). If we do write that and repost, I'll certainly let you know when the time comes.

You're a lucky person, living in New York. When I lived in New Jersey, I would always get such great inspiration by spending a day in the Village (and a morning in The Strand).

07-07-09 *Why Bell Is My Friend* (to B. Dreiss)

I apologize for keeping you waiting so long. Right after Sweden (where I wrote you from last), Schack came to Waterloo for two and a half weeks of collaboration, and all else got dropped. I'm only now catching up on emails.

The reason my paper confuses you is because I believe there is absolutely nothing wrong with Bell's derivation. And that remains true even if Bell himself wasn't clear-headedly Bayesian (he died too young). The derivation of Bell's original inequality and many other similar inequalities (like the Clauser-Horne-Shimony-Holt one or Hardy's, etc.) are just right, and Jaynes was wrong on this point. It is not that the derivation fails as soon as one takes into account a properly Bayesian understanding of probability.

And there are other, crisper ways to see this as well, without any inequalities at all. My favorite originally comes from Allen Stairs. I'll tell you about that, but first please reread the EPR section of Jaynes' "Clearing Up the Mysteries," particularly the first three paragraphs. The ultimate thing that powers Bell inequality violations in quantum mechanics is that EPR's reasoning reported there (and accepted by Jaynes) is just wrong. One can see that by not just considering two observables P and Q as EPR do, but by considering many overlapping ones, i.e., ones that have some (but not all) common eigenstates in an interesting interlocking fashion as one conceptually travels from one observable to the next. For *each* individual observable, under the assumption of locality, one can run through EPR's reasoning to assert that IT "must have had existence as [a] definite physical quantity before the measurement." But when you consider the whole lot, you find a contradiction—the observables are so interlocked that one and the same proposition ultimately has to be evaluated as both true and false, and that cannot be. So it is the EPR premise that is wrong—it is wrong to assert an observable "must have had existence as [a] definite physical quantity before the measurement." You can read this argument in more detail in Section V of my paper: `http://arxiv.org/abs/quant-ph/0608190` and also in the next mailing you can peruse one of my presentations of it. (The simplest proof of the statement can be had by contemplating two entangled "four level" systems rather than two qutrits; have a good study of Cabello's vectors in that presentation, and I think it will hit you over the head.)

Anyway, Bell's treatment is just (an earlier) probabilification of that kind of argument, and it is perfectly airtight: To be consistent with quantum mechanics, one either has to give up Einstein locality or preexistence of measurement values or some combination of the two. We QBists think that only preexistence need be given up—which is distinctly a positive for the William James side of my mentality.

Like I said, I'll send you one of my presentations. But also, let me attach two things to the present note. One is an old, very clear and nicely written article on the Bell point by David Mermin. I suggest reading it very carefully; it'll help get these things into your bones. The other article is also by Mermin. I attach it because it carefully attacks one of the more technical points Jaynes was trying to make in "Clearing up the Mysteries." Jaynes thought time-evolving hidden parameters would play a role in clearing everything up. But that path has since been developed extensively by Hess and Philipp and also by De Raedt, and it is still wrong (as Mermin shows in the HP case, others have shown for De Raedt).

In summary, here's where things stand between Jaynes and we QBists. Jaynes was absolutely right that quantum probabilities can only in the end be subjective, Bayesian probabilities, and that quantum states cannot themselves be elements of reality. He was also right when he said:

> Our present QM formalism is a peculiar mixture describing in part laws of Nature, in part incomplete human information about Nature—all scrambled up together by Bohr into an omelette that nobody has seen how to unscramble. Yet we think the unscrambling is a prerequisite for any further advance in basic physical theory

and

> Of course, the QM formalism also contains fundamentally important and correct ontological elements ... It seems that, to unscramble the epistemological probability state-

ments from the ontological elements we need to find a different formalism, isomorphic in some sense but based on different variables; it was only through some weird mathematical accident that it was possible to find a variable ψ which scrambles them up in the present way.

That is what our latest paper is indeed an attempt to do. Where we differ from Jaynes is in thinking that quantum measurement outcomes cannot represent features of some underlying unmeasured reality. That, we believe, is what Bell inequality violations (and the simpler Stairs style arguments) demonstrate. Jaynes held to his view because he thought that taking something like the QBist view would be tantamount to declaring "the Universe runs on psychokinesis." But we feel the Paulian Idea (Section 8 in our paper) is enough to block that extreme. The gambling agent is a crucial participant in the making or coming to be of a quantum outcome, but he cannot will the outcome he pleases. That is a crucial distinction, and with it one can have one's cake and eat it too.

I hope that helps.

So strange that you drove through Cuero. Not much to see there; it's great that you at least saw the one thing that's worth looking at. For some reason, I was almost about to say, "You're probably the closest to celebrity the town has ever seen — someone who has surfed both in Hawaii and Australia!" But then I remembered that John Wayne used to like to bird hunt at the Hamilton ranch. And when I worked at the corner gas station (where the McDonald's is now), one day I met a man who claimed to be Marlboro Man in their famous painting.

07-07-09 *PI Kids Quote?* (to N. Waxman)

Waxmania 1: *I thought that was a very neat observation from your daughter—may I put it in the newsletter some month (maybe this month?), in the little "PI Kids are Saying" section?*

I wrote it down as follows: ...

It was Katie, when she was 5. Sure, you can use it. But please change the quote to:

"Wow! It's bigger on the inside than it is on the outside!"[203]

Adding the "even" slightly takes away from the paradoxical nature of what she said, and in fact, I believe I have the quote exact.

08-07-09 *My Favorite Convex Set* (to R. Schack)

That boy wouldn't know the idea of simplicity if it bit him in the ass. It is clear as day why a SIC representation is to be preferred, and I have tried to express it to him countless times. He has never had a positive (or detailed) thing to say with regard to our program (though he professes to love Jaynes), and it starts to grate. Mostly it gets very old putting up with all these alpha-male wannabes—that is what his note was purely an expression of—and I thought it was time to express that clearly.

[203] At the time, we had no knowledge of "the doctor" and his TARDIS—now, the whole family and especially Katie are avid fans of the *Doctor Who* television series. We also now know that Katie's exclamation is where the resemblance between the TARDIS and Perimeter Institute ends: One represents an adventure in an infinitely surprising universe, whereas the other is a paean to a state of death, a.k.a. the "final theory" most of PI's residents yearn for. From today's standpoint, I wonder whether a better appropriation for Katie's wonderment might be to use it to describe quantum systems themselves: Even the minuscule qubit must have a huge interior. See 30-10-09 note "My Interiority Complex" to H. Barnum and other instances of the word "interiority" in the present document and "QBism, the Perimeter of Quantum Bayesianism," `arXiv:1003.5209v1`.

09-07-09 *Trying to Make a New Start* (to C. Ferrie)

Ferrie-ism 2: *On that note, I'd like at some point to discuss the various approaches to subjective probability with you and hear the case for the Dutch book as opposed to the others, e.g. Jaynes' robot.*

Attached is one interesting thing to read with regard to this (and Hacking has many more than that). [I. Hacking, Brit. J. Phil. Sci. **16**(64), 334–339 (1966).] Hacking gives a review of Kyburg and Smokler's collection on subjective probability, and in it he is careful to make a distinction between two kinds of Bayesianism, the "conservative," and the "radical." The first roughly corresponds to Jaynes' thought, and the second to roughly de Finetti and Ramsey (and made somewhat more radical still by Caves, Schack, and me).

I found this little article very useful to read myself, and I have you to thank for that. Particularly, Hacking's small remarks on J. S. Mill being an "ancestor" of the approach. That made a light-bulb flash in me. For, though I had realized I was led to de Finetti's version of Bayesianism partially because it gave me a tool with which to preserve *locality* in quantum mechanics, I had not quite appreciated that I was probably also drawn to it by my predilection for a Jamesian version of indeterminism (the republican-banquet pluralism I write of in the paper). The latter, as James knew, has its roots in Mill. (James dedicates his book *Pragmatism* to Mill.) And it is always good to know where one's prejudices are coming from.

09-07-09 *Potentially Useful* (to C. Ferrie)

This one seems to be a potentially useful point of entry as well: Peter C. Fishburn, "The Axioms of Subjective Probability," Stat. Sci. **1**(3), 335–345 (1986).

09-07-09 *My Favorite Convex Set* (to C. Ferrie)

Ferrie-ism 3: *You may be interested in our recent paper:* `http://www.iop.org/EJ/abstract/1367-2630/11/6/063040/`*. It mentions SICs.*

I have added a citation to this, and will elevate the point to an enlarged discussion in the section introducing SICs. Rüdiger commented this when we first got your note:

Schackcosm 120: *From his paper, I suspect that this guy knows a lot about quasiprobabilities. From his perspective, our paper shows just one out of many possible ways of representing q.m. using probabilities. What he is asking is why this particular way of doing it and not another. Itamar asked a similar question. I am not too sure how best to reply.*

Here is the way I would reply. The point of all the various representations of quantum mechanics (quasi-probability reps, as well as things like Heisenberg vs. Schrödinger picture issues and even path-integral formulations), is that they give a means for isolating or emphasizing one or another aspect of the theory—they help bring a particular aspect into plain view, even if all the representations are logically equivalent. In our case, we want to bring into plain view (and try to make compelling) the idea that quantum mechanics is an *addition* to Bayesian probability, not a generalization of it. With that goal in mind, the SIC representation has always struck me as particularly powerful tool. With it, one can see the Born Rule as "really" a *function* of a usage of the Law of Total Probability in another context (one different than the actual). That feature, as far as I can tell, does not leap out in the same way from the more general "deformed probability representations" you explore in your papers with Joseph. That in a nutshell is the reason for my love affair with SICs.

09-07-09 *Articulation* (to C. Ferrie)

Ferrie-ism 4: *Here is what I was trying to say. The sentence "The only way anyone has seen how to do it is ..." is very uncharacteristic of your otherwise beautifully written exposition. It stuck out and then stuck in my mind as I read on. It called out to me "well ... this isn't quite right but it was the best we could come up with ..." It has a very apologetic tone which forced the skepticism I felt while reading on.*

I really would appreciate it—and this is not just apologetics now—if you would articulate in greater detail the source of your skepticism. What in detail, indeed, made you feel "It seems an ad hoc addition to coherence contrived to bridge the Peresian slogan to your functional relation between q and p." As I tried to express last night, part of the reason behind my bad reaction was not that you were talking about an isolated page or two in the paper (I have no illusions that the paper is perfect, I certainly know that it could be made much better, or even rewritten from the start). It was that you were referring to the very point of the paper with your sentence. (It only dawned on me after your reply yesterday that perhaps you didn't know this, that maybe you thought you were referring to some small thing rather than the paper as a whole.) So, it's important for me to get it straight. ... And it'll be good practice for you in articulation. ☺

13-07-09 *Articulation, 2* (to C. Ferrie)

Contrived is a very different word than "unnecessary and distracting." "Contrived," at least in my usage, usually conveys bad intent.

Anyway, there are a few reasons I resist the Coxian understanding of probability. The most important is this: In the usual way the system is developed (and maybe it is necessarily so), $\Pr = 1 \;\Rightarrow\;$ TRUTH. But it is utterly important for Caves, Schack, and me that this isn't so; there is an ultimate disconnect between probability statements and truth values for us, and that in particular allows us to preserve locality in quantum mechanics in spite of Bell inequality violations. And Dutch-book definition of probability allows for just what we need.

Still, let me think further about the notation.

Chris's Preply

I'm no gambler and perhaps this is why the Dutch book argument has never sat well with me. I found Jaynes' robot argument much more intuitive. So let me conjure up his ghost (perhaps a younger, more naive and better looking version).

A bookie asks the agent to commit to $p(B)$ given a conditional A-lottery. The agent gives $p(A)$ and $P(B|A)$ and is forced through coherence to bet on $p(B)$ as calculated through the law of total probability. But the bookie reveals that there is no A-lottery. You would say that the agent is no longer committed to $p(B)$ as calculated before but now is committed to $q(B)$ (which is $p(B)$ without the A-lottery). Now Jaynes would say this is *inconsistent* as the 1st law of robots is a robot may not injure a human being ... wait ... no, it's consistency (the Jaynesian equivalent of Dutch book coherence I presume). There is a unique value of $p(B)$ no matter how you calculate it: $p(B)$ is $p(B)$ is $p(B)$ ....

If the agent is told something new then he is now committed to $p(B|\text{something new})$ and not $p(B)$. For the bet, the bookie really asked for $B|C$, where $C =$"The A-lottery has been performed", and then he later reveals that he will take bets on just B. Now "$q(B) \neq p(B)$" is just "$p(B) \neq p(B|C)$". This is something which should be obvious and much more clearly formalizes the statement "measuring A matters even if we don't reason about the outcome".

This is why I think the conditional lottery is unnecessary and distracting.

```
\begin{sarcasm}
```
You didn't get that from "contrived"?
```
\end{sarcasm}
```

13-07-09 *Quantum Randomness* (to K. Martin)

When Schack was visiting me last week, I got him to give me a copy of the paper he and Caves are writing on quantum random number generators (as seen from our quantum Bayesian perspective). Attached is—he tells me—a very ROUGH DRAFT. Still, I thought it might be useful to send it to you. Is that the sort of thing you were interested in?

Things are progressing somewhat on the SIC end. Schack and I spent most of the last two weeks hashing out our next paper—a companion piece to our "Quantum Bayesian Coherence." This one will be called "Quantum Bayesian Decoherence" and will be an attempt to put Zurek's decoherence in its place. Appleby is presently chasing down an idea in dimensions $1 \bmod 6$ and is as happy as fox in a henhouse. And get this, Aephraim Steinberg's group at University of Toronto are starting up a $d = 3$ SIC experiment.

15-07-09 *Some $d = 3$ Measurements* (to R. Laflamme)

Let $d = 3$ and $\omega = e^{\frac{2\pi i}{3}}$.

Set 1:

$$
\begin{bmatrix} 0 \\ -1 \\ 1 \end{bmatrix} \quad \begin{bmatrix} 0 \\ -\omega \\ \overline{\omega} \end{bmatrix} \quad \begin{bmatrix} 0 \\ -\overline{\omega} \\ \omega \end{bmatrix}
$$
$$
\begin{bmatrix} 1 \\ 0 \\ -1 \end{bmatrix} \quad \begin{bmatrix} 1 \\ 0 \\ \overline{\omega} \end{bmatrix} \quad \begin{bmatrix} 1 \\ 0 \\ -\overline{\omega} \end{bmatrix}
$$
$$
\begin{bmatrix} -1 \\ 1 \\ 0 \end{bmatrix} \quad \begin{bmatrix} -1 \\ \omega \\ 0 \end{bmatrix} \quad \begin{bmatrix} -1 \\ \overline{\omega} \\ 0 \end{bmatrix}
$$

Set 2:

$$
\begin{bmatrix} -2 \\ 1 \\ 1 \end{bmatrix} \quad \begin{bmatrix} -2 \\ \omega \\ \overline{\omega} \end{bmatrix} \quad \begin{bmatrix} -2 \\ \overline{\omega} \\ \omega \end{bmatrix}
$$

$$\begin{bmatrix} 1 \\ -2 \\ 1 \end{bmatrix} \quad \begin{bmatrix} 1 \\ -2\omega \\ \overline{\omega} \end{bmatrix} \quad \begin{bmatrix} 1 \\ -2\overline{\omega} \\ \omega \end{bmatrix}$$
$$\begin{bmatrix} 1 \\ 1 \\ -2 \end{bmatrix} \quad \begin{bmatrix} 1 \\ \omega \\ -2\overline{\omega} \end{bmatrix} \quad \begin{bmatrix} 1 \\ \overline{\omega} \\ -2\omega \end{bmatrix}$$

15-07-09 *Measurement in the Sky without Magic* (to C. Ferrie)

Dear CFe,

I know you want me to change my notation. Eventually I'll tell you why I resist that. The text surrounding the definitions as well as Footnotes 5 and 6, it seems to me, already capture everything I wanted to say.

Also I'm not quite sure what you want of the paper. (Your remarks, or at least your phraseology, do continue to put me off a little; perhaps I continue to misunderstand their goal.) My own goal isn't to be "surprising," only clarifying. My big dream is to say what the content of quantum mechanics is without ever making a priori mention of "positive semi-definite operators," or "homogenous self-dual cones," or the like, or any issues to do with nonlocal-boxology. Indeed I want quantum mechanics to shake out to be an absolutely trivial theory in the end, at least from the proper point of view. In that regard at least, I feel the urgleichung gives me some hope, and I feel we have made some progress by realizing it might be taken as one of the foundational principles. To the extent that I want there to be any surprise at all, it is that people eventually slap themselves on the head and say, you mean the essence of QM might be so very simple?!

> `\begin{relevant non-sarcastic mild modification of William James quote}`
> I fully expect to see the [quantum Bayesian view of quantum mechanics] run through the classic stages of a theory's career. First, you know, a new theory is attacked as absurd; then it is admitted to be true, but obvious and insignificant; finally it is seen to be so important that its adversaries claim that they themselves discovered it. Our doctrine ... is at present in the first of these three stages, with symptoms of the second stage having begun in certain quarters. I wish that this lecture might help it beyond the first stage in the eyes of many of you.
> `\end{relevant non-sarcastic mild modification of William James quote}`

If I understand your point, you appear to be using the language of Stage 2.

Confused regards,

rare-earth Chris (old and quite oxidized)

15-07-09 *Measurement in the Sky without Magic, 2* (to C. Ferrie)

Ferrie-ism 5: *I'm generally not a very excitable guy. But this stuff really gets me going. I guess I've adopted you as my sounding board. Perhaps that is not acceptable conduct for a student. I suppose I could understand if it wasn't. Your inbox is probably bombarded with half-baked ideas.*

To be honest, yes it is. Attached is another reaction to the paper. Here's an exercise for you: Tell me what's wrong with what the guy says.

But your own note wasn't half baked like that. I just didn't see that you were telling me something I didn't know ... so it was hard for me to put it in context as representing a breakthrough in your understanding. As far as I could tell, you wrote down Eq. (54) from the paper with changed notation:

- I.e., I wrote $q(j) = (d+1)s(j) - 1$
- You wrote $p(D_j|N) = (d+1)p(D_j|Y) - 1$

And I thought, yeah, that's what I wrote. (Where, though, it is key that Y and N don't refer to just any conditions, but an intermediate conditional lottery.)

Clearly—with hindsight—the changing of notation means something deep to you. I just haven't gotten what that something deep is.

I am *trying* to be a better person ...

15-07-09 *Bohmian Mechanics* (to J. Emerson)

Emersonia 2: *I am putting together a list of topics / lecturers for another edition of the interpretations/foundations course for this upcoming Winter. I'd like to put a bigger emphasis on de Broglie – Bohm theory and would appreciate your recommendations regarding potential lecturers.*

I would also like to hear your recommendations for many worlds and decoherent histories.

You might consider Wayne Myrvold for the many-worlds slot. He strikes me as the rare person who might be able to do this:

Emersonia 3: *I'm tempted to go with someone who will overview the approaches but who can also be critical of the conceptual and technical shortcomings of those approaches.*

What's rare is someone seriously knowing the details of one of these interpretations (to the last technical bone) without having been a full believer to begin with. I.e., belief most always comes first, details, if any, are far secondary.

16-07-09 *Some Things to Think About* (to C. Ferrie)

Let me give you something specific and mathematical to think about if you're interested. See pages 25 and 26 of the attached talk ["QBism at QTRF-5"]. I define something called a "maximal consistent" subset (MCS) of the probability simplex (over d^2 outcomes) there. It is not difficult to show that all maximal consistent subsets must be convex.

Also, all maximal consistent subsets have vaguely quantum-state-space-like properties. But how far does that go, I wonder? Thus let me pose a couple of specific questions to show the flavor of things that we might profit from exploring.

1) Let S be any MCS. Must its extreme points form a connected set? Or can one find a counterexample?

2) Let S be any MCS. Must its extreme points form a smooth manifold?

3) If so, what can be said about the dimensionality of that manifold? Can one place any bounds on the dimensionality?

These are the sorts of things Åsa and I are thinking about at the moment, and in the Fall when my students get here, I want to greatly expand the effort. Åsa has some intuition that the answer to 2) should be yes, but I've got no strong feeling, and certainly no idea how to prove anything in this regard. If you have any input, it'd be wonderful.

20-07-09 *Remembering Hans* (to H. C. von Baeyer)

The last couple of days I've been writing my intro for the CUP edition of my samizdat. Attached is where I've gotten so far. It formalizes a bit of the story I first told you and Marcus in the Black Hole Bistro one day (I had never told anyone else before):

> I should tell you the strange story of how I came to be a physicist in the first place. It had nothing to do with seeing or feeling some beautiful order in nature, like the kind of thing I would read about in the physics biographies. It was not like Einstein's childhood experience with a compass, where he came to the conviction that there had to be "something behind things, something deeply hidden."
>
> My career, instead, is to be blamed on the 1970s television stations of San Antonio, Texas, ninety miles down the road from my little hometown Cuero. In those days, there was a steady stream of science fiction and horror films coming from the antennas every Friday, Saturday, and Sunday. And every weekday there was an episode of *Star Trek* or *Lost in Space* waiting for me just as I got home from school. I gained a taste for two things: the image of the noisy, swirling atom that concluded each commercial break of Channel 5's late-late-night *Project Terror*,[204] and the idea that mankind knew no insurmountable bounds. I dreamed my friends and I could fly to the stars and back if we wanted. Television molded my idea of what the world ought to be: one of danger, constant adventure, and yet, with luck and hard work, one ultimately malleable to what we want to make of it.
>
> That thought led me into junior high school, where I decided life was too short: If I wanted to see myself flying to the stars with my loved ones (successfully) waiting behind to cheer my return, I had better get to the technical details of making it happen. So I read popular physics book after popular physics book looking for the ways and means. To my genuine surprise and deep sadness, no real-world method emerged; I was left with the science fiction I had started with. I only learned from the wisdom of physics that my dream would stay a dream.
>
> I suppose that is where my story might have ended, but it did not. Instead, it came to me slowly, and then more and more firmly, "Physics must be wrong!" I told myself that, and I was quite serious about it. I knew I had to become a physicist, not for the love of physics, but for the distrust of it.

There's much more to come in it, but I think I'll go ahead and send you the draft so far. As if you need more prodding, even in my autobiography you'll see this Pauli thing runs very deep with me. It was you who brought up the opportunity of writing something fresh; now I don't want to see it slip away!

[204] Look it up on YouTube.

22-07-09 *Charlie Stories* (to D. W. Leung)

Thanks for the comments. I cleaned up the Charlie story still a little more; I think it's reached its final form now. There's still so many stories to tell about everybody else, but I'll attach the latest draft for your amusement. It'll be a fun exercise when I finally get to John Smolin's story.

Leungism 1: *Saying teleportation marks the beginning of quantum information is a bit like saying that Shor's algorithm marks the beginning of quantum computation ☺ (guess what's the omitted punchline ...)*

That's right, I would say Shor's algorithm marked the beginning of quantum computation *as a field*. I.e., that's when outsiders widely started to pay attention to it. To help stave off confusion a bit, I have now italicized "as a field" in the footnote. Thanks for bringing this up to me.

23-07-09 *Fact Check?* (to B. W. Schumacher)

I've been working on an introduction for one of my books, and I just finished up a story on Brassard. In it I use an anecdote I heard from you, and I wonder if I can ask you to check its accuracy? I'm quite sure I screwed up some details—my memory is not that good. In any case, I'll certainly be tweaking the story (trying to get the best drama), but with this much down on paper, you can already see the kind of thing I'm aiming for. I just mostly need to get the facts straight. See attached file, starting page 6:

> Gilles Brassard, with Charles Bennett, is a father of quantum cryptography: The Bennett-Brassard 1984 quantum key distribution protocol started the field. But, from my perspective, he is dearest to me for all that he has enabled. Ben Schumacher once told me an anecdote worth repeating in this context. Ben says that when he first heard of the discovery of (Peter Shor's) quantum factoring algorithm, he thought it was a joke that Gilles had propagated—he didn't take it seriously. The reason he didn't is because a year earlier, at one of the "quantum information parties" Gilles regularly organized in Montréal,[205] Gilles joked around, "We're going to use quantum computers to factor numbers." This may have had no direct influence on Shor, but the tendrils of scientific discovery are sinuous, and one really never knows all the influences that come together in the making of an event. The greatest things happen not because of lone scientists in isolation, but because of communities.

Ben's Reply

> The anecdote agrees with my own memory. As I recall it, we were in Montréal and Dan Simon described the work he'd been doing there on quantum period finding. Gilles made this comment, grinning. I seem to recall that Shor had read Simon and was motivated thereby; I do not know if Shor had heard Gilles' joke (or if it had occurred to him independently).

[205]Like the one in 1993 that led to the discovery of the quantum teleportation protocol.

26-07-09 *Specifically Paulian* (to H. C. von Baeyer)

I'm sitting on my new front porch, waiting for a thunderstorm to roll in, and thinking Paulian thoughts. See attached photo; you can just see the chair I'm sitting in. (The porch isn't painted yet, but you'll get some indication of its ultimate colors from the second photo attached.)

... Storm just came, and I had to run inside. It's a fierce one! ... [Some time passes.]

The storm has mellowed a bit, and I'm now back on the porch. I'll finally reply to your note of yesterday. (Sorry that yesterday turned me into a liar.)

von Baeyerism 31: *I'm reading at this moment: H. Atmanspacher and H. Primas (eds.) Recasting Reality: Wolfgang Pauli's Philosophical Ideas and Contemporary Science, Springer 2009.*

Your writing this reminds me that I still do not have my copy. I purchased one at discount, while in Sweden, but Springer had to ship it to me. I will get on them.

von Baeyerism 32: *I find satisfaction in the overlap between some of its entries and my own essay, which is now on the web in the emag The Global Spiral, July/August 2009, search under Authors. (I'm not sure how to formulate a proper web citation.)*

You give a website? I have printed it out; it doesn't look so bad as you made it out to be. I haven't re-read it yet. Is it substantially different from the version I read in January (which I understood to be the finalized one)? In any case, I will read/re-read it at some point. I want to be better in your head, if nothing else to help anticipate the passages you might explore.

von Baeyerism 33: *The DO. The term "detached observer" does not merit an entry in the book's index. I think it is more important than ever to promulgate the idea, and have accordingly moved our joint project to the top of my writing agenda.*

Of course, I am very pleased to hear this! Interesting to hear that DO issues have very little representation in that book. I wonder why that's the case? If I recall correctly, I believe I did read one article there that *did* have some discussion on the subject. Could it be that it was just an oversight in the index?

It's probably worthwhile mentioning my self-analysis for why I don't completely remember the article, or even for sure whether it was in that book. The trouble is most everything these guys write is always the same and so becomes a blur. Nor, do they ever go an ounce beyond where Pauli went (or, at least, where the part of Pauli they've read has gone). Did you read the Enz entry in my Intro? The guy wrote 19 papers on Pauli, 19!—I read every one of them—and in the end didn't learn much more than I might have in three well chosen ones from the full list.

I had a similar experience with Folse on Bohr. 31 papers! They were all great on so many other details, but I never could get a sense of what Bohr really meant by "the quantum postulate." Folse used the term liberally. So I thought I would invite him to the "Shannon Meets Bohr" session I organized in Växjö in 2001 and get the issue settled. (This was the great meeting we had with Caves, Greenberger, Mermin, Peres, Schumacher, Smolin, etc., in attendance.) But to no avail. Folse said nothing new on that subject; he could say nothing beyond repeating the three word phrase. The thing that shocked me was that he seemed to have no sense that one should treat these things as *springboards* to deeper thoughts.

For once I'd like to see someone say (with reasonable analysis), "This is what Pauli would have made of the no-cloning theorem ... " Or, "Pauli would have understood that the no-cloning theorem didn't at all carry the essence of quantum mechanics." Or, "No, Pauli would have seen the deep statement of his unDO in the Kochen-Specker theorem, and here's why." Or, "Here's where quantum information theory might help us formalize a bit of what Pauli was after."

We can't go that far in our article, I know. But one thing I think would be nice is if we could push the reader to think of Pauli's ideas as the beginning of a bigger and better quest. Somehow give the reader the sense that there's something solid to do.

von Baeyerism 34 : *Pauli and religion. There is a lot of research on Pauli's legacy in such fields as philosophy, metaphysics, psychology, biology, cognitive science and the philosophy of mathematics, but I don't see much on religion per se. I will continue my interest in that.*

And I hope you will never stop keeping me apprised of what you're thinking even here. I try my best to gather data from all sources.

26-07-09 *A Memory* (to H. C. von Baeyer)

By the way, I remember you once writing me this about the CFS use of Kochen-Specker to establish the non-preexistence of measurement values:

von Baeyerism 35 : *I'm reading Caves, Fuchs, and Schack on quantum certainty, and thinking that I'm getting the drift, when I come up to an example – which is my way of understanding – and whammo, on page 10 you hit me with 33 states, which are (the cute little "of course" rubs salt in the wound) connected by 96 rotations and one shoulder separation. I can't envision that. Can't you use a simpler manifestation of KS like Mermin's very cogent* 3×3 *matrix, or maybe it was* 4×4*? As popularizer I'm always on the lookout for simpler versions.*

Did I ever make you aware of Cabello et al.'s version of KS? I well believe it can get no simpler. See attached file, page 11. Using it, the CFS-variation-of-Stairs argument is then powered via the use of two qudits, where $d = 4$.

29-07-09 *Pseudo-QBist State Spaces* (to Å. Ericsson)

I thought of a title for your paper. See above.

Also, thinking about your gingerly reactions yesterday, I thought I'd remind you of some of the words I put in the Mlodinow review:

> And the malaise of Professor Gardening (whose real identity is protected in the book), though I had not seen in it a professor, I had seen it in plenty of graduate students. The burdens of not just doing physics, any physics, but *important* physics, is sometimes too much—it is too elusive a phantom to even know how to get started.

The same goes with papers: Not every paper has to be important or conclusive, and in fact most aren't. Sometimes the only role of a paper is to get a problem started. Caltech tolerates elusive phantoms, I don't!

31-07-09 *Preskill Done* (to D. M. Appleby)

I finally got the Preskill story down. Boy that was hard! Here's an excerpt:

When we have discussed the interpretational issues of quantum theory, I have gotten the sense that what John finds most suspicious of the quantum Bayesian approach I promote is that he *thinks* it treats observers as unphysical systems. I say, "Not at all; John, you are a physical system to me." The real issue is one of inside versus outside. Contrary to the textbook exposition of quantum mechanics, a wave function that I write down about him is descriptive not of the outside, but of the inside, namely me: It captures what I believe will happen to me if I interact with him. If he knew what I believed, he'd probably do something to surprise me.

I think John's secondary worry is that unless one takes something like the Everettian approach to quantum mechanics, one cannot do quantum cosmology—the idea is that the observer must be excised from a fundamental role in the theory if one is going to address cosmological issues. (In a phrase, what is desired is a theory that is all outside and no inside.[206]) The Everettians think they do that, but a quantum Bayesian would say, "only in a way that leaves the observer's clothes behind." I tried to impress John once by writing down $|\,\Psi_{\mathrm{universe}}\,\rangle$ and saying, "Look, I can do that too." I don't think it worked.

Most recently, I've tried a new technique in my lectures. I draw a stick figure on the chalkboard along with a little blob near him, and say, "There's an observer with a small physical system in front of him: He can profitably use the formalism of quantum mechanics to estimate what might happen to him if he interacts with it." Then I say, "But there's nothing to keep us from talking about a larger physical system." I extend the blob, making it larger. I do this a couple of times, at first imperceptibly putting a bend in the blob, making it a little kidney-bean shaped with the observer at the center of its curvature. I make it more pronounced with each iteration and finally go for broke: The observer is completely surrounded by the physical system he is considering, and I declare in great triumph, "That's quantum cosmology!"

One of these days maybe I'll work up the nerve to show John.

Marcus's Reply

I realize that you have a lot to do so don't even think of trying to answer this now. But when you have the time I am curious: what is the criterion for being a physical system? What would Preskill have to do in order to convince you that he wasn't a physical system?

Also, how does this fit in with Pauli's synthesis of science and religion? Would Pauli agree that Preskill is a physical system? (just a physical system? [shades of vicious abstractionism]). And if he wouldn't, would he be wrong? Do you think?

I guess virtually every religion (absolutely every religion?) would say that a human being isn't just a physical system. I am not sure what they mean by this (I would ask of virtually every religion the question I just asked of you: how does one tell whether something is a physical system or not? What is the criterion?). But whatever they mean, I get the impression they do say it. I also get the impression it is an important feature of religion.

I am being a little disingenuous here, you see. I pretended not to know what is meant by saying a human being isn't just a physical system. And in one way that is true: I don't know how to explain what is meant (which is why I asked the question: perhaps

[206] On first pass, the Texan in me wanted to write "all hat and no cattle," but I repressed that.

you can explain?). But the statement kind of resonates. In another way (though not in a way I know how to explain) I do understand what is meant.

So, although very obscure, I do feel that this idea, that a human being isn't just a physical system, is an important feature of religion. Perhaps even an essential feature. So the question is: is this a feature of religion which has to be dropped in Pauli's synthesis? And, if it does have to be dropped, what is left? What kind of synthesis would it be which leaves out this feature of religion?

The old Soviet Union claimed to be a synthesis. Notionally Uzbekistan and the Russian Republic were equal partners. But that was, of course, a cheat. And I am thinking that a Paulian synthesis in which Preskill is just another physical system (vicious abstractionism again) would be something like that, with science playing the role of the Russian republic and religion playing the role of Uzbekistan.

Also, how does all this fit in with your wish to deconstruct physics? Given that aim, why do you say that Preskill is specifically a physical system? As opposed to just a system?

Perhaps we should say that Preskill is a deconstructed physical system. But in that case why not simply say that he is an unphysical system, and be done with it?

In short: what is the burden of the qualifier "physical" here?

Hans Christian von Baeyer's Comment

Marcus, the question seems to me to be related to reductionism — to "nothing buttery." A cathedral is a pile of bricks, but more. Even a shed is a pile of wood, but more. Steven Weinberg, the quintessential reductionist, admitted that he was not an uncompromising reductionist, but a compromising one. So you can learn a lot about a physical system, but you hit a snag of complexity when you want to understand what Preskill is.

The prettiest thought I learned in Phoenix the other day was this: Human nature is so exquisitely complex that you can't describe it, image it, limn it if you will, without recourse to a more complex language than that of mathematics. That language is poetry. So, to come to grips in any meaningful way at all with questions of morality, say, you need to read King Lear – neither legalese nor quantum mechanics have anywhere the resources required to do the job.

Preskill is a physical system all right — unfortunately he's so complex that this statement doesn't get us very far.

31-07-09 *Shelter Island and Bennett, Preskill, etc. Stories* (to D. Gottesman)

I learned the source of confusion over Shelter Island: The official name for the meeting was "Shelter Island Conference on the Foundations of Quantum Mechanics". On the other hand, a standard description of the conference goes:

> The general problem the conferees were asked to address was the impasse that elementary particle theory was perceived to have struck over the preceding decade and a half or so. Specific difficulties in quantum electrodynamics (QED) and in upper atmosphere meson phenomena were of particular interest, especially in light of Lamb's and Retherford's recent experimental findings on the fine structure of hydrogen, and

Rossi's experiments with cosmic rays. Both Lamb and Rossi were in attendance, and both were asked to report on their findings. Discussion of the problems raised by these experiments, and the papers that resulted from these discussions, produced significant advances in the development of QED.

And this is reflected in the list of participants:

Hans Bethe
David Bohm
Gregory Breit
Karl K. Darrow
Herman Feshbach
Richard Feynman
Hendrik Kramers
Willis Lamb
Duncan MacInnes
Robert Eugene Marshak
John von Neumann
Arnold Nordsieck
J. Robert Oppenheimer
Abraham Pais
Linus Pauling
Isidor Isaac Rabi
Bruno Rossi
Julian Schwinger
Robert Serber
Edward Teller
George Uhlenbeck
John Hasbrouck van Vleck
Victor Frederick Weisskopf
John Archibald Wheeler

I'd only consider Bohm, Feynman, von Neumann, and Wheeler as "quantum foundations" in the usual PI sense.

Speaking of history, you might enjoy some of the stories of people we know in the attached file. I just finished it; it's hot off the keyboard. (People stories start up on page 4.)

03-08-09 *Interpretation of Bayesian Probabilities* (to D. H. Wolpert)

Oh, I believe you: In practice people are most always "incoherent" in the Dutch book sense. I read Dutch book coherence (and hence the axioms of probability) normatively: It is what you should strive for.

The quote you refer to is not van Enk himself, but Frank Ramsey.

David's Preply

Skimming over your fun document, I came across your description of van Enk's view. I don't know what he precisely meant by saying that to measure "a person's belief . . .

propose a bet, and see what are the lowest odds which he will accept". But it is well-established experimentally that as far as bets are concerned, people have no consistent "degrees of belief" in events. In some situations, even if money is on the line, a person will at the same time take a bet that requires $P(a) > P(b)$ and also another bet that requires $P(b) > P(a)$.

Look up "Allais' paradox" on Google. Another good one is the Ellsberg paradox, if you want to be cured of the belief that people use Bayesian degrees of belief in the real world (as opposed to in philosophy land).

Here are some other great references:

- C. F. Camerer, *Behavioral Game Theory: Experiments in Strategic Interaction*, (Princeton University Press, 2003).
- C. Starmer, "Developments in Non-Expected Utility Theory: The Hunt for a Descriptive Theory of Choice under Risk," Journal of Economic Literature **38**, 332–382 (2000).

03-08-09 *Where I've Been* (to R. Schack)

Schackcosm 121: *Sorry, it isn't Logan, it's James Logue,* Projective Probability*.*

Oh, I see. Has it had any impact on reflection issues? What do you think of the main thesis of the book: "Based on a strongly subjective starting-point, with probabilities viewed simply as the guarded beliefs one can reasonably hold, the theory shows how such beliefs are legitimately 'projected' outwards as if they existed in the world independent of our judgements." ??

03-08-09 *Abner Story* (to A. Shimony)

I wrote a story about you: It's in the attached document, an introduction for the Cambridge U. Press re-issue of my original email samizdat. It'll be titled *Coming of Age with Quantum Information*. Your story starts on page 18, and I also say some things about you in the Zeilinger story on page 21. I hope you enjoy.

Let me also alert to a new paper of mine with Schack; it is my pride and joy from the last few months. The title is "Quantum-Bayesian Coherence," and you can find it here: `http://arxiv.org/abs/0906.2187`. In it, we show a new way of writing the Born rule, a way that makes it look very, very close in form to the Law of Total Probability. We use that then to argue that the Born rule should be viewed as an extra (contingent, empirical) addition to Dutch book coherence, to be used when one gambles on the outcomes of one's interactions with a quantum system. It is a way of having our Bayesian cake and eating it too. Section 8 addresses broader philosophical issues that may interest you: How (I see) to remain subjectivist Bayesian about quantum probabilities and still accept objective indeterminism as one of the deep conclusions of quantum theory.

I hope all is going well for you. I have not seen you in quite a while.

Abner's Reply

Your email novel (samizdat) is somewhat repetitious in plot, but as a compensation it is rich in characterization.

I was glad to be reminded of quoting Edward Lear's "They all went to sea in sieve, they did", which sums up my skeptical attitude towards a subjectivist interpretation of the probabilities of qm. Seeing the quotation reminded me that it was not original with Lear, since one of the witches in the fist act of *Macbeth* says, "But in a sieve I'll thither sail, And like a rat without a tail I'll do, I'll do, and I'll do" — wonderfully creepy!

04-08-09 *Counterfactualizable* (to R. Schack)

Schackcosm 122: *What do you think of this quote from Logue, attributed to L. J. Cohen's book* The Dialogue of Reason*:*

> ... people are naturally inclined to think in terms of counterfactualizable rather than non-counterfactualizable probabilities wherever possible, reflecting a general dominance of causal reasoning ... over reliance on bare statistics.

Nice. Does this mean the upper path in our diagram is the more basic?

04-08-09 *Personal Probability as ... Mode of Self-Attribution* (to R. Schack)

Schackcosm 123: *If you find it, maybe you could read those 1.5 pages. It's section 1, entitled "Personal Probability as Propositional Attitude and as Mode of Self-Attribution". I know nothing about the context or where in philosophy this kind of idea is discussed, but it sounds a lot like our conviction that one must not think of events or measurement outcomes as existing independently of the agent.*

Like usual, I have great difficulty *even* reading van Fraassen. I kind of doubt that that is what he is getting at, but I don't know. I did definitely note a kinship between us and Hacking, however. (At least if I read him correctly.) See section 6 of the attached on "personal possibility".

04-08-09 *Charlie and Sappho Sitting in a Tree, ...* (to C. H. Bennett)

Well, I'm not too proud to help you remember. Rüdiger sent me the note below, and I'm not ashamed to forward it on to you (to help you do so).

Rüdiger's Preply

> I had a long talk with Charlie Bennett at Dagstuhl, after his after-dinner speech on forgetting. I'd had quite a bit of that good Dagstuhl red wine, so although the discussion started with the reality of ψ, we then moved to logical depth, Homer, Borges, Kodaly, and Charlie's father's compositions in the octatonic scale which he played to me on the castle's grand piano.
>
> His talk was implying there is a sense in which Sappho's lost poems are not real. I said then that if I had to choose between the reality of Sappho's poems and the reality of ψ, I would choose the former. He clearly liked this formulation and said he would try to remember it (although when he tried to remember it the next day he misquoted it by stating the alternative as having a theory that does not give a complete picture of the world).

04-08-09 *Preskill and Sappho As Well* (to C. H. Bennett)

To rub a little salt in the wound, see the Preskill entry in the attached. Particularly, I hope you enjoy Footnote 18:

> In a phrase, what is desired is a theory that is all outside and no inside. [Footnote: On first pass, the Texan in me wanted to write 'all hat and no cattle,' but I repressed that.]

Charlie's Reply

> I like "all hat and no cattle" much better, and am glad you didn't repress it (putting it in a footnote does not constitute a successful instance of repression). I wish you wouldn't try so hard to persuade me of your interpretation of quantum mechanics. I think we can agree that the difference between preferring the reality of Sappho's lost poems vs. the reality of the wave function is a difference of interpretation, a matter of aesthetic or religious preference, not susceptible to being decided by rational argument or proof/refutation, since my interpretation logically contains yours and yours logically contains mine. Moreover, I don't think it would even be desirable for one or another interpretation to win out, because that would impede the intuitions, often leading to substantive progress, that are stimulated, at least in some people, by other interpretations. Perhaps one could say that the interpretations of quantum mechanics enjoy a complementarity reminiscent of quantum mechanics.
>
> I think Rüdiger's way of casting the question, as to which you would prefer if you couldn't have both, is an especially good way of explaining (to a lay audience likely to be bored by such arcane matters) what these different interpretations of quantum mechanics are all about, and why they are alternative interpretations, not alternative theories.

04-08-09 *Charlie and Sappho Sitting in a Tree, . . . , 2* (to C. H. Bennett)

Bennettism 36 : *. . . not susceptible to being decided by rational argument or proof/refutation, since my interpretation logically contains yours and yours logically contains mine.*

Aye, there's the rub: Because I do not believe that that is true.

I'm gonna go put on my hat now . . .

04-08-09 *The Mermin Challenge* (to C. G. Timpson)

I thought of you the other day when I was rereading through Mermin's paper, "Writing Physics." Particularly at this point where he writes:

> The puzzlement only arises when you try to combine what quantum mechanics tells you about the possible results of a group of mutually incompatible experiments. When you actually do any one such experiment you lose the ability to do any of the others. Why worry about what might have happened in the experiment you didn't do, if you no longer can do it? That's a problem for philosophers, not physicists.

> I'm inclined to agree. The problem is that most philosophers who do worry about quantum mechanics differ from the physicists who refuse to worry only because they worry and the physicists don't. The philosophers have, by and large chosen to embrace nonlocality as a natural phenomenon, rather than homing in on what bad habits of thought and expression make so implausible an inference so hard to resist. Uncharacteristically for philosophers, they ought to be more worried about the nature of language, how it can trap us into formulating questions that have no sensible answers, and whether it is possible to restructure ordinary language in a way that liberates us from those built-in errors that make it so hard to think clearly about quantum physics. They ought, in short, to be worried about writing physics.

I thought, "That's perfect for Timpson!" So, I'll call it Mermin's Challenge and pass it on to you. In that regard, let me also give you a little thing I just wrote (and the reason I was referring back to Mermin's article). See attached. The Benioff, Mermin, and Preskill entries have a little bit to do with Mermin's challenge, and so may be entertaining to you.

Looking forward to seeing you again finally!

10-08-09 *My Attraction to de Finetti's Side of the Force* (to P. G. L. Mana)

Attached are the two pieces of reading I was telling you about. Putting the two together, I think, starts to give some explanation for my attraction to the de Finettian side of Bayesianism. [See I. Hacking, "Subjective Probability," *The British Journal for the Philosophy of Science* **16**, 334–339 (1966) and the Introduction to C. A. Fuchs, *Coming of Age with Quantum Information*, (Cambridge University Press, 2011).]

11-08-09 *From Moore-ish Sentences to Bohrish Ones* (to C. G. Timpson)

In a better formulation, what is being claimed is this:

- "I am certain that if I interact with *it*, I will have experience x; but there is no intrinsic property possessed by *it* corresponding to x." Or,
- "I am certain that if I interact with *it*, I will have experience x; but my certainty is not correspondingly of an intrinsic property possessed by *it*."

Put this way, I feel the charge of our stating a Moore-ish sentence is diffused. Maybe you still disagree?

I hope we get a chance to discuss further today.

By the way, I'm not sure, but I think you may have taken my Mermin Challenge a bit too literally. My (unstated) focus was only on this part of his quote:

> for philosophers, they ought to be more worried about the nature of language, how it can trap us into formulating questions that have no sensible answers, and whether it is possible to restructure ordinary language in a way that liberates us from those built-in errors that make it so hard to think clearly about quantum physics.

Of which, I thought this of you: "If anyone is in a position to see that that is the central point, it is Timpson." Though, even I'm being a bit too loose here—for as I tried to express in the collection of stories I sent to you, it is not quite right that we need to "restructure ordinary language," but to find better choices of words for describing what is being talked about.

Have you by chance read Section 8 in my `http://arxiv.org/abs/0906.2187`?

12-08-09 *More on Moore* (to M. Schlosshauer)

Thanks for the remarks on the Moore-ish business. The way I further diffuse your (and Timpson's) higher level Mooresm in 1) is to have the agent admit in those cases, "Yeah, that's right, what I'm saying is, I can make it happen. I fully believe it." Yesterday at coffee break, the (probably over the top) imagery I used was that, in cases of certainty, the agent is viewing the quantum system a bit as a surrogate mother. He is confident that if he plants his seed there, the expected consequence will come about. (Of course, the world still has the right to surprise him infinitely.) There is a bit more on this on page 667 of the present build of "My Struggles" in my last reply to Timpson. (Maybe I was confused on other points there—I haven't reread it completely—but on this particular point I don't think I've changed my mind any.) [See 17-11-06 note to C. G. Timpson titled "Certain Comments."]

Anyway, remember the notion of indeterminism I am aiming for in Section 8 of the last paper (it is along the lines of that spelled out in the James quotes): It is only that each piece of the world truly has the power to make a contribution to the whole, a contribution that can't be seen from the outside ... but may well be surmised from the inside. And it is from the inside that the agent draws his probability assignments.

It'll be fun to read your choice James quotes (probably this weekend).

Max's Preply

Thanks for your further comments re: Moore-ism. It sounds like the key point of your argument is indeed, as I had suspected, to emphasize that bringing about the "outcome" requires the interaction of agent and system. In your note to Timpson you write:

> It just means that we should be a little more careful to say, "there is no fact in the object guaranteeing the outcome." Of course, there is no fact in the agent guaranteeing the outcome either; otherwise his certainty wouldn't be subjective certainty.

I understood the problem that's supposedly evidenced by Timpson's Moore-ish sentences as setting up a tension between "I am certain about what I will experience if I interact with the system" on the one hand, and "as a good Qbist, I must consciously proclaim that there's no fact guaranteeing what I will experience" on the other. Where could the fact reside? Per your quote above, it doesn't resides in either system or agent alone. Is there a fact in agent-plus-system? Plus the rest of the world? Is there ever a fact ANYWHERE that guarantees a particular experience to occur? I guess for the QBist the answer would be no; in your email you say: "Of course, the world still has the right to surprise him infinitely" – and wouldn't the agent, as a die-hard Qbist, have to take this insight to heart?

On the other hand, this just seems to be a completely generic issue. As long as the agent maintains that there are simply no facts, anywhere, before the agent/system interaction that guarantee a certain outcome, aren't we back to Timpson's original charge? (As I've said before, I don't believe this charge is a serious objection to begin with, but this whole discussion and attempt to rephrase the Moore-ish sentences is obviously built on the premise that it is indeed an objection, to an extent at least.) From Sec. 8 of your last paper:

> Whenever "I" encounter a quantum system, and take an action upon it, it catalyzes a consequence in my experience that my experience could not have foreseen.

Does my assessment of "could not have foreseen" take on any different flavor when I assign probability one (i.e., when I am certain about which consequence I will experience)?

(Well, I hope I'm not beating the proverbial dead horse here. Feel free to tell me if I do, and feel free to give this discussion a rest if you like.)

By the way, I like the ideas, however vague, spelled out in your note "Philosopher's Stone." Especially this one:

> Reciprocally, there should be a transmutation of the system external to the agent. But the great trouble in quantum interpretation–I now think–is that we have been too inclined to jump the gun all these years: We have been misidentifying where the transmutation indicated by quantum mechanics (i.e., the one which quantum theory actually talks about, the "measurement outcome") takes place. It should be the case that there are also transmutations in the external world (transmutations in the system) in each quantum "measurement", BUT that is not what quantum theory is about. It is only a hint of that more interesting transmutation.

I look forward to seeing these thoughts fleshed out; in the meantime, I'm just going to enjoy letting them play on my mind for a while.

12-08-09 *History Repeating Itself . . .* (to C. G. Timpson)

Timpsonism 13: *I'm stuck in bed with flu-like symptoms. I've emailed Philip to say I probably have to quarantine myself and stay in my room to avoid infecting everyone else, just in case it's swine flu; so I don't think I'm going to be able to give my talk tomorrow. Hopefully I'll be recovered to give it b4 the end of the conf, but I thought it might make a difference to your own talk preparation if I'm not going to be able to give mine before you tomorrow. I was just going to summarise my SHPMP paper on q Bayesianism (tho leaving out the Moore's sentence stuff as it takes too long to explain).*

I'm really crappy. I'm sorry to hear that. Do get better, and I really hope you can ultimately give your talk.

Indeed I was going to bank on it for a set-up on why I would seek an interpretation of the Born rule in terms of "an addition to coherence." But I'll survive!!

Do get better: I hope this is not a recurring thing *every* time we get together.

12-08-09 *History Repeating Itself . . . , 2* (to C. G. Timpson)

Rereading my note, I see I wrote in my first sentence: "I'm really crappy." That may be true! But I meant to say, "That's really crappy."

I think I'll stick with my present time, so as to get it over with. But I'll advertise your potential talk, and start off a bit like Bill Wootters did: "Suppose for whatever reason you ended up with an interpretation that looks like this. How could that interpretation *imply* any of the actual structure of quantum mechanics?" Then I'll just go down the SICkening path. With regard to why I cared to end up with an interpretation like that as my starting point, I'll refer to your (hoped for) talk on the strengths and weaknesses of the position.

If you feel well enough before going back to England, I'd like to have you and Marcus Appleby over for dinner (and wine and single malt) one evening. I'm very proud of my new library and liquor cabinet and like to show it off to the best people.

Get well!

15-08-09 *Roiling Mess* (to C. G. Timpson and R. W. Spekkens)

When you talked about the ontology of the roiling mess today, you brought my mind back to some lines in William James's essay "The Dilemma of Determinism." Maybe you've never seen them before:

> Let me, then, without circumlocution say just this. The world is enigmatical enough in all conscience, whatever theory we may take up toward it. The indeterminism I defend, the free-will theory of popular sense based on the judgment of regret, represents that world as vulnerable, and liable to be injured by certain of its parts if they act wrong. And it represents their acting wrong as a matter of possibility or accident, neither inevitable nor yet to be infallibly warded off. In all this, it is a theory devoid either of transparency or of stability. It gives us a pluralistic, restless universe, in which no single point of view can ever take in the whole scene; and to a mind possessed of the love of unity at any cost, it will, no doubt, remain forever unacceptable. A friend with such a mind once told me that the thought of my universe made him sick, like the sight of the horrible motion of a mass of maggots in their carrion bed.
>
> But while I freely admit that the pluralism and the restlessness are repugnant and irrational in a certain way, I find that every alternative to them is irrational in a deeper way. The indeterminism with its maggots, if you please to speak so about it, offends only the native absolutism of my intellect,—an absolutism which, after all, perhaps, deserves to be snubbed and kept in check. But the determinism with its necessary carrion, to continue the figure of speech, and with no possible maggots to eat the latter up, violates my sense of moral reality through and through. When, for example, I imagine such carrion as the Brockton murder, I cannot conceive it as an act by which the universe, as a whole, logically and necessarily expresses its nature without shrinking from complicity with such a whole. And I deliberately refuse to keep on terms of loyalty with the universe by saying blankly that the murder, since it does flow from the nature of the whole, is not carrion.

I thought you might enjoy the imagery of maggots. I'll cc this to Rob Spekkens for fun.

15-08-09 *Nice Word* (to R. W. Spekkens)

Well, I suspect our conversation didn't actually send you to wiki to learn about empiricism, but it did to me. Here's a nice word I just learned: `http://en.wikipedia.org/wiki/Hypokeimenon`.

I suppose I am a bit of a Lockean.

Rob's Reply

That is a good word, but too long to remember. Henceforth, I'll refer to it as your "Pokemon philosophy". :-)

17-08-09 *Footprints* (to M. Schlosshauer)

Schlosshauerism 4: *I just came across this sentence in Roberto Calasso's novel* The Marriage of Cadmus and Harmony*:*

"For every step, the footprint was already there."

A nice way of expressing the spirit of determinism, don't you think?

Yes, that's perfect!

And even "indeterminism" of the block-universe type that Timpson defended so strongly yesterday in our extended discussion. (There is a bit of that point of view in his talk at `http://pirsa.org/C09016`.)

17-08-09 *Timezones (a conversation)* (to M. Schlosshauer)

Yeah, it's a bit after 4:00 AM for me. I should get back to bed at some point; woke up at 2:30 and couldn't get back to sleep.

By the way, in that PIRSA talk, there are about 10 transparencies that you didn't see in Växjö. I drew them Wednesday in my PI office with your jazz streaming in the background. That's really very nice stuff. (I love jazz of all kinds, and have about 15,000 tracks of it in my iTunes folder.) Very impressive, that you perform and do serious physics as well. I'd like to see you and your group some day.

Schlosshauerism 5: *Thanks a lot for your kind words about my music! It's nice to hear that the tunes served as a soundtrack for your drawing session. I'll check out the video of your talk shortly and will try to figure out which transparency goes with what song.*

As you may have read on the website, all tracks are 100% live improvised. I.e., there's no planning, no sheet music, no pre-arranged chords or melody, nothing whatsoever, before we go on stage. So it's all created in the moment in an act of collective improvisation.

I've wondered in the past whether that might be a good metaphor for the kind of reality I'm trying to envision.

Schlosshauerism 6: *That's very nice!! Indeed it would seem like an apt metaphor.*

So once again it seems that the "temperament" (as James would say) informs quite consistently the way we each choose our favorites, be it in regards to our conception of reality, our style of music, or whatever else ...

Yeah, it's weak but see pages 495-496 in *My Struggles*. Also I'd like to think that's what I was thinking when I wrote the note to Garisto below ... but who knows. [See 13-08-01 note titled "Out of the Frying Pan ..." to Robert Garisto.]

In any case, you're much better positioned to develop the metaphor than me! Contemplate it.

Signing off for the evening ...

Schlosshauerism 7: *Thanks! I just had a look at pp. 495-496. I guess there were two notes of relevance? ("The Free City," on Christiania and "Inventory," on jazz and pragmatism.) Sweet little ideas and recollections in each of them, I thought.*

I'm sure you know that there's generally quite an affinity between physicists and music. Heisenberg and his piano playing come to mind, and of course our very own David Mermin. Somehow, though, there also appears to exist a bias toward classical music with most of these people! In some sense, classical music seems to me like the prototypical deterministic edifice, an "unrolling of the fabric of the past." (Don't get me wrong, I enjoy listening to this kind of music very much; it's just the spirit of actually playing it myself that never kindled for me.) To be sure, each musician brings his own "interpretation" to a piece, but the notes are all there and laid out already (could this be a metaphor for the usual interpretive programs of QM?!). Jazz, on the other hand, is spontaneous creation, as loosely constrained by rules and theory as one wishes.

I think I really like the jazz-and-QM metaphor ...!

Oops! I didn't realize the proximity of the Free City story. Oh well.

17-08-09 *Timpson* (to M. Schlosshauer)

Schlosshauerism 8: *I watched Timpson's talk this afternoon. Indeed a very nice and well-done presentation. I noticed that he made no mention of the Moore-isms. Did conversations with you convince him that there was maybe no serious problem after all?*

I think it shook his faith sufficiently that he preferred not to get into it in public. But of course I don't know for sure. I think that, at the end, he was still inclined to think he was right ... but couldn't vouch for it so confidently anymore.

I think the key point is, if one adopts a block-universe picture at the outset, the CFS claim will always look suspicious. For Timpson, there is just no sensible notion of "facts coming into being" and I think that might lie at the root of his continued worry. But that's a longer story than I feel like writing down at the moment. I wish I could have had a tape recorder for yesterday's 3-hour conversation between him, Appleby, Wootters, and me. I'll try to get it all down eventually, and then send you a draft at that point.

We just had a nice (but nearly trivial) result: Maximal consistent sets must be compact.

17-08-09 *Your Thoughts on Timpson* (to M. Tait)

You missed a really good meeting. Timpson's talk was excellent; I'd really recommend you watch it. All the talks can be found here: `http://pirsa.org/C09016`. I think my talk was fairly decent as well—unfortunately though, in this way of viewing things, you won't be able to see to where I'm pointing in the diagrams.

Timpson has another paper as well that should interest you. This one is directly about QBism. You can find it here: `http://arxiv.org/abs/0804.2047`. We had several discussions this week on the Moore-sentence point he brought up there. I'm pretty sure I've got that all safely wrapped up now. If you ever get to that point and need my notes; I don't mind sharing them. Sometime this year, Rüdiger and I will write a formal reply.

Sorry I haven't answered about your visit request. The second week of November is not so good for me; I have to go to North Carolina during that time. I'm free however Oct 27 – Nov 7, so I tentatively marked the time in my calendar. If that time is good for you, I'll send an official request in to the secretaries to check accommodation availability.

Attached are some stories I wrote about various characters in quantum information and quantum foundations. You might enjoy some of them—I don't know. A couple were also intended to carry philosophical messages as well (like the ones on Mermin and Preskill). [See Introduction to C. A. Fuchs, *Coming of Age with Quantum Information*, (Cambridge University Press, 2011).]

Morgan's Preply

> I wanted to say how sorry I am to have missed Chris Timpson's talk on Saturday (I had another commitment). I've read a couple of Timpson's papers on quantum Bayesianism:
>
> 1. 'Information, Immaterialism, Instrumentalism: Old and New in Quantum Information' forthcoming in A. Bokulich and G. Jaeger (eds.) *Philosophy of Quantum Information and Entanglement* (Cambridge University Press 2008)
> 2. 'Philosophical Aspects of Quantum Information Theory' forthcoming in D. Rickles (ed.) *The Ashgate Companion to the New Philosophy of Physics* (Ashgate 2008)
>
> and I would have dearly liked to see your reaction to his talk. I don't suppose anyone was filming the talk? If not, I hope we can have a conversation at some point about Timpson's take on your views (if in fact you think he is representing your view at all!).

17-08-09 *The Activating Observer* (to J. Rau)

It was good seeing you again. Sorry to be so very "thick"—I am a really slow thinker. I think the line of thought you (or you and Terry) are pursuing is a good one. After your prodding me yesterday, it does seem to me deeply connected to the point of view I'd like to see developed that unitaries be representable as sequences of measurement. You'll note for instance, in Section 8 of my recent `http://arxiv.org/abs/0906.2187`. I reserve the notion of an "action" on a quantum system to correspond to a POVM. I don't, for instance, think of unitaries as actions—which of course goes against the grain of almost everyone else in quantum information. (Where unitaries are usually viewed as the things you want to "do" to a system, and measurement is, well, something mysterious ... but more analogous to "looking.") What you guys are developing may help fill the gap for me.

I have always thought of the "engagement" of the observer in quantum phenomena as best expressed (or demonstrated) by the Kochen-Specker theorems (particularly Stairs's version of it, combining KS with considerations to do with entangled states). It would be interesting to see if a more direct connection between your considerations and KS could be fleshed out.

Anyway, I endorse. And at some point I'll come back and watch your talk again.

Let me now back up to the broad philosophical point. Attached are a couple of files that might entertain you. Maybe I gave you a paper copy of the "Resource Materials" file on your last visit? (If I haven't, maybe it will help give you further spiritual strength in wavering times.) But one file I know you haven't seen before—it has some funny stories in it, and some sad stories as well. [See Introduction in C. A. Fuchs, *Coming of Age with Quantum Information*, (Cambridge University Press, 2011).] The entry on Nielsen is directly relevant to our conversation above. (It makes a bit more sense if you read the Carl Caves entry first.)

18-08-09 *Question Regarding Your Preprint* (to B. R. La Cour)

La Courism 1: *I'm reading your paper, "Quantum-Bayesian Coherence," which you kindly gave preprints of during the Växjö conference this summer. In it you (and Rüdiger) speak of a "measurement in the sky" involving a SIC POVM. Now, in a d-dimensional Hilbert space, the measurement of any given observable can have at most d outcomes. How, then, do you construe that a SIC POVM may be used to perform, even hypothetically, a single measurement with d^2 outcomes?*

The measurement in the sky is a positive operator valued measure (POVM). POVMs are not restricted to d outcomes. A good place to start reading about this is:

`http://en.wikipedia.org/wiki/POVM`

and references therein.

19-08-09 *Question Regarding Your Preprint, 2* (to B. R. La Cour)

La Courism 2: *I understand that these are POVMs, so you assume that they may be measured simultaneously. But they are also (scaled) projection operators and, as such, may be thought of individually as standard, von Neumann measurements.*

The trouble is that, as a member of a SIC-POVM, they are assigned one probability and, as isolated measurements, they have another, larger probability. If you'll forgive the rhetorical question, how does one member of a SIC-POVM know that the others are being measured? Do you consider this a reflection of quantum contextuality?

You talk about a POVM as if it is a plural—your usage of "they" gives it away. Rather a SIC-POVM is a *single* measurement with d^2 possible outcomes. It is true that a POVM is written down mathematically as a set of hermitian operators, but those operators are only meant to *index* the outcomes of the measurement. (Much as the d eigenprojectors can be used to index the outcomes in a standard, von Neumann measurement.) In this context, the operators shouldn't be thought of as separate observables themselves.

If you want to think of a POVM in terms of the old von Neumann notion of measurement, you must make use of helper or ancillary systems. For instance, one way to instantiate a SIC-POVM on a three-level atom is to first let the three-level atom unitarily interact with a nine-level atom (i.e., 3^2), then take the nine-level off and perform a standard von Neumann measurement on it alone. That gives rise to a measurement with 9 outcomes and by way of the preceding interaction may be thought of as saying something indirectly about the three-level atom. (But the "indirect" here is a bit of a misnomer, since by this method, one probes the three-level atom more deeply than can be done by any standard measurement.)

So, in all, I would say you are contemplating two kinds of distinct measurement: One, a POVM with d^2 outcomes, $\frac{1}{d}\Pi_i$, $i = 1, ..., d^2$. The other, a POVM with two outcomes, Π_k and $I - \Pi_k$, say. How does the system know which is being measured on it? It takes two distinct kinds of interaction to enact them. In old terms, the first requires interaction with an ancilla, while second is made directly on the system (no ancilla needed).

Let me this time recommend something further than the wiki article. Have a look at John Preskill's notes referenced therein. As I recall, they were an excellent introduction to the nuts and bolts of POVMs.

Hope you are braving the Texas heat. I've been mowing the grass today and it's about killing me at 75 degrees!

19-08-09 *Utterly the Last Time* (to the QBies)

The more I think about it, the more I think I should make today the day of my concerted effort in the lawn. Kiki's trying to put a push to finish the porch today; so I'm going to put a push on getting the lawn ready for her parent's visit.

Marcus (sorry Åsa), if you need a break from pure writing, and want to talk pure philosophy for a while—i.e., how the world is not sentence shaped, but made of neutral stuff, etc., I can imagine that happening while I'm moving/stacking rocks and edging, as long as you're within ear distance and willing to sort of follow me around. If you get bored, feel free to drop by.

20-08-09 *More on the Cover Story* (to S. Capelin)

I took the words literally. It didn't say provide an *idea* for an image; it said provide an image. (One that would need to be approved, but a seemingly final image no less.) It didn't give me a sense that you have a design staff that does the real artwork.

Anyway, now that I understand that you are only seeking ideas, and that there is a real artist behind the scenes, I will try harder. The cover of Schumacher and Westmoreland's book is indeed very nice, beautiful even. And the meaning (I'd bet money) was not lost on me. The wave symbolizes a solution to the Schrödinger equation; the spots at the bottom left symbolize "its" (electrons, photons, whatever), the zeros and ones in the upper right symbolize "bits." The whole image is an encoding of John Wheeler's phrase "it from bit". Of course, many in the public won't know that, but it surely must be satisfying to Ben and Mike to have his deep idea encoded on the cover of his book in that way.

The two images I've sent you, amateurish though they were, were similarly infused with meaning for me. And in the hands of an artist with some imagination—I would well imagine—could be made to amount to something. You'd get your sales, and I'd go to bed in the evenings with a satisfied soul.

Capelinism 3: *If you really can't think of anything else, then we'll ask the designer to try to make something abstract using the psi image you sent. Is there any reason why what you supplied has the symbol three times? Or can we use just one?*

I don't know what to tell you at the moment, but I will try to think harder. I'd hope you'd listen harder as well, or put me in touch with your graphic artist directly so we could more efficiently bandy about ideas. What that image was trying to get at was a wave function $|\psi\rangle$ rising off of a physical object. That was the base idea I was trying to convey in some way. The wave function initially on the object, flies off of it, and moves still further away ... strengthening in color as it does. (I'm not wedded to that: I'd prefer some variation on my stick man if an artist with some imagination could make it more acceptable. But I already know it does nothing for you, so that idea is probably already dead in the water.) The symbol was there three times because I didn't know how else to give a sense of it flying off the object (the cube).

Could something be done with a $|\psi\rangle$ and an image of a Bohr atom? Maybe make a $|\psi\rangle$ fly out of a Bohr atom in some interesting way? It'd be easier if I could have a conversation with an artist directly. The image of $|\psi\rangle$ carries for me the very core of quantum mechanics. (It was a symbol invented in Cambridge, by the way, by Dirac.)

I'm not trying to cause trouble for you. If you want an image—as I now understand you to very much want—I'll try to work with you. (My anger stemmed only from having wasted a lot of time via the misunderstanding, trying to play a graphic artist when I am not.) If you just need hand sketches and ideas, I can shoot them out whenever they come. But it would be death to my spirit if the endpoint were to be something like the image on the book you mentioned—I really do dislike it, and its meaninglessness is very apparent to me.

20-08-09 *That Formulation* (to L. Hardy)

Boy did I botch that at lunch. Below is the true blue thing. [See 06-07-09 note "The Verdict" to H. M. Wiseman.] The key point is that previous to quantum mechanics agents had reason to doubt their own existence (at least in any deep sense). That is, it is not that quantum mechanics causes me to doubt your existence, but rather to have better reasons for believing in my own.

21-08-09 *Quantum Locality* (to R. B. Griffiths)

Griffithsism 1: *I have posted the item indicated below on* `arXiv:0908.2914`*; you will find the title and abstract at the end of this note.*

In addition to getting the science right I want to give proper recognition to other people's work, cite the most relevant material, present my own ideas in as clear a manner as possible, and remain courteous in disagreements. Any comments or suggestions in these or other respects are welcome.

> TITLE: Quantum Locality
>
> ABSTRACT: It is argued that while quantum mechanics contains nonlocal or entangled states, the instantaneous or nonlocal influences sometimes thought to be present due to violations of Bell inequalities in fact arise from mistaken attempts to apply classical concepts and introduce probabilities in a manner inconsistent with the Hilbert space structure of standard quantum mechanics. Instead, Einstein locality is a valid quantum principle: objective properties of individual quantum systems do not change when something is done to another noninteracting system. There is no reason to suspect any conflict between quantum theory and special relativity.

Thanks for the heads up. I'll read your paper with interest.

I'd like to think that I too have been a rather staunch one of the "some dissenting voices" you mention in the first paragraph of your introduction. Indeed it has been what has driven my epistemic (more particularly Bayesian) view of quantum states, expressed for instance in the opinion piece Peres and I wrote for *Physics Today* way back (that you and Todd commented on), more recently in `http://arxiv.org/abs/quant-ph/0608190` and most recently in `http://arxiv.org/abs/0906.2187`. Timpson also makes the point pretty clearly in his review of us: `http://arxiv.org/abs/0804.2047`.

So, with me you preach to the choir. But it is good indeed to see things from all angles, and it'll be fun reading your paper.

22-08-09 *A Stupid Question for Saturday* (to N. D. Mermin)

Merminition 180: *If it turned out that there is a dimension above which there are no SIC POVMs, would this wipe out their foundational significance?*

Yep, it certainly would. But as my wise student from Vietnam, Hoan Dang, tells me every time we find a new wonderful property for the SICs, "They have just become more expensive."

My opinion really is this: THEY HAVE TO EXIST. Too many things simply become too pretty (supposing only their existence) for them not to.

24-08-09 *The Penrose Tale* (to N. D. Mermin)

Merminition 181 : *Tell Hoan Dang to read Fermat's Last Theorem, by Harold M. Edwards, pp. 76–79, especially the last paragraph on the top of p. 78 for a cautionary historical parallel.*

Another cautionary tale, relevant to your own attitude. When I was a graduate student there was a story, no doubt apocryphal, about a guy who wrote a Ph.D. Thesis on analytic functions of a quaternion variable. He proved all kinds of spectacular properties — much more beautiful than analytic functions of a complex variable. When had written it all up, somebody discovered a proof that the only analytic functions of a quaternion variable are linear.

To be sure, you have many nontrivial examples, so the second cautionary tale is less frightening. But nevertheless, be wary! And challenge every mathematician you meet to find a proof that they exist in all d, or a counterexample.

Indeed I've been doing that for quite some time. Simon Kochen, John Conway, Elliott Lieb, Peter Shor, . . . The list is quite big. John Conway had a cute reaction — he had worked on the real-vector-space version in the late sixties and sometime in the seventies. There, the corresponding upper bound on the maximal number of equiangular lines is $d(d+1)/2$. But it is well known that the bound is saturated only in a few sparse dimensions. When I told John that it appears that the d^2 bound is always achieved in the complex case, he was quite delighted. He thought for just a couple of minutes and declared that he thinks the bound will indeed be achievable in all dimensions. But he quickly followed with, "But it will be very hard to prove it. There are too many of them." Unfortunately, I have no idea what he meant by that; we were interrupted immediately afterward, and I could never get back to him.

Anyway, I wanted to tell you a story about Roger Penrose. You probably know that the known $d = 4$ SICs are already quite nontrivial. See equations 26 to 29 in `quant-ph/0310075`. Here's a conversation I had with Penrose just before (and continuing immediately after) Harvey Brown's talk at last year's PIAF meeting.

> CHRIS: I have a mathematical problem that I think will interest you, and it's one I could use some guidance with. Here's the question. For a complex vector space of dimension d, what is the maximal number of equiangular lines you can have in it?
>
> PENROSE: You mean any two lines have the same angle between them?
>
> C: Yep, exactly that.
>
> P: Oh, that'd be a very hard question. [A bit of a grimace on his face.]
>
> C: Believe me! I and several others have been working on it for quite some time now. The interesting thing is the answer seems to be simply d^2.
>
> P: You mean order d^2.
>
> C: No, I mean precisely d^2.
>
> P: Oh! [His face lighting up like a child's.] That's very interesting. You mean the maximal number appears to be precisely d^2?
>
> C: Yep, out to dimension 47 at least. [Now we know it goes out to 67 at least.]

[The talk begins; we sit down. As the talk proceeds, I can see Penrose out of the corner of my eye; he's just sitting there politely, apparently listening to the talk. When the talk is over, he turns to me and says:]

P: Well, I can see that they exist in dimensions 2, 3, and 4. What's difficult to see is if one can construct a 3-dimensional set by suitably projecting a 4-dimensional one.

I was floored. When he started to tell me more details about the $d = 3$ case, I could tell he had used the same construction technique that Lane Hughston had used in his 2 months of work on the problem (Lane classified all solutions in $d = 3$ by studying cubic equations and Hessian forms or some such). In $d = 4$, Penrose said the same sort of thing generalized, but I remembered well that Lane had never been able to make it work. And Penrose did that much without pencil or paper!

26-08-09 *The Poetry of Chance* (to N. Gisin)

It was fun sparring with you yesterday as ever. And also as ever, I was struck that there are some points upon which we seem to agree on (or at least seem to feel as the right direction forward). One of them is the issue of will, if I understand you correctly. I want to send you two quotes of William James that I think are quite pretty and express the variant of chance and will that I was trying to convey to you at lunch. Maybe you will enjoy them, or maybe you will disagree. If it is the latter, I would like to understand your point.

> [Chance] is a purely negative and relative term, giving us no information about that of which it is predicated, except that it happens to be disconnected with something else—not controlled, secured, or necessitated by other things in advance of its own actual presence. ... What I say is that it tells us nothing about what a thing may be in itself to call it "chance." ... All you mean by calling it "chance" is that this is not guaranteed, that it may also fall out otherwise. For the system of other things has no positive hold on the chance-thing. Its origin is in a certain fashion negative: it escapes, and says, Hands off! coming, when it comes, as a free gift, or not at all.
>
> This negativeness, however, and this opacity of the chance-thing when thus considered *ab extra*, or from the point of view of previous things or distant things, do not preclude its having any amount of positiveness and luminosity from within, and at its own place and moment. All that its chance-character asserts about it is that there is something in it really of its own, something that is not the unconditional property of the whole. If the whole wants this property, the whole must wait till it can get it, if it be a matter of chance. That the universe may actually be a sort of joint-stock society of this sort, in which the sharers have both limited liabilities and limited powers, is of course a simple and conceivable notion.

> Why may not the world be a sort of republican banquet of this sort, where all the qualities of being respect one another's personal sacredness, yet sit at the common table of space and time?
>
> To me this view seems deeply probable. Things cohere, but the act of cohesion itself implies but few conditions, and leaves the rest of their qualifications indeterminate. As the first three notes of a tune comport many endings, all melodious, but the tune is not named till a particular ending has actually come,—so the parts actually known of the universe may comport many ideally possible complements. But as the facts are not the complements, so the knowledge of the one is not the knowledge of the other in anything

> but the few necessary elements of which all must partake in order to be together at all. Why, if one act of knowledge could from one point take in the total perspective, with all mere possibilities abolished, should there ever have been anything more than that act? Why duplicate it by the tedious unrolling, inch by inch, of the foredone reality? No answer seems possible. On the other hand, if we stipulate only a partial community of partially independent powers, we see perfectly why no one part controls the whole view, but each detail must come and be actually given, before, in any special sense, it can be said to be determined at all. This is the moral view, the view that gives to other powers the same freedom it would have itself,—not the ridiculous 'freedom to do right,' which in my mouth can only mean the freedom to do as *I* think right, but the freedom to do as *they* think right, or wrong either.

For myself, part of this vision of the universe as a "republican banquet" is to recognize that probabilities are not rigidly connected to nature, but are of the personalist Bayesian variety even in quantum mechanics. Nonetheless we do not have to agree on that to feel some overlap in our thoughts.

I have a fuller sketch of how I see the notion of chance above as fitting with my understanding of quantum mechanics, and also why I insistently call myself a "realist", in Section 8 of: `http://arxiv.org/abs/0906.2187`. You might find that section fun reading, even if you throw it in the bin afterward.

27-08-09 *'Empirical Coherence' and Invitation* (to I. Hacking)

You may not remember me, but we met at a meeting in the Carré des Sciences in Paris, June 2008. You seemed somewhat interested in the personalist Bayesian account of quantum probabilities that a few colleagues and I have been working out. And you also seemed somewhat intrigued by my remarks that we could still have (and quite desire) an "objective indeterminism" from quantum mechanics without ever once invoking objective chances (for instance Lewisian) or propensities. In that regard, let me call your attention to this paper that we've posted recently: `http://arxiv.org/abs/0906.2187`.

It is crucial to us that there is no such thing as a "right and true" quantum state. But on the other hand the Born rule for calculating quantum probabilities is indeed used all the time, and thus calls for an explanation in our terms. Our solution is not to think of it as defining a propensity, but something more along the lines of probabilistic coherence. In other words, the Born rule should be viewed as a normative principle for relating probabilities. The idea being that if one does not make sure his probability assignments (for the outcomes of various potential measurements) are related according to the dictum of the Born rule, Nature is liable to smack his hands. In contrast to Dutch-book coherence, however, the origin of the normative rule is not of a purely logical nature, but should be seen rather as dependent upon contingent features of our actual world.

Anyway, that's the sort of stuff in the paper, and I hope you will find parts of it entertaining and thought provoking. Particularly, any feedback you have for me on the Intro, the Dutch-book section, and the concluding Section 8 (on a William Jamesian "republican banquet" non-block universes), would be most appreciated. And I would be flattered to hear back from you. (Most recently I've been studying your "Slightly More Realistic Personal Probability" from 1967, and think parts of it are quite in line with the views we are working out, and crucial to us actually.)

That said, let me change subjects abruptly. I saw you at Nicolas Gisin's talk two days ago, but I was not able to catch you afterward to convey the following invitation. It would have saved me some writing!

Steve Weinstein (philosophy, U. Waterloo), David Wolpert (NASA), and I are organizing a meeting of physicists, philosophers, and mathematicians at the Perimeter Institute in Waterloo for next year titled, "Laws of Nature: Their Nature and Knowability." The target date presently is May 20-22, but we have some flexibility to modify that as needed to attract the best people. We envision about 20 external participants, plus 6 from PI. I have been assigned to contact you, Cheryl Misak, Huw Price, and Bas van Fraassen for a sort of pre-invitation before we send out other invitations more generally. I.e., we really want you to come, and think you'd be a great asset for attracting some of the others that we plan to invite. Of course, all your expenses would be paid by PI, and I personally am itching to have some refreshed face-to-face conversations with you.

Attached is a list of topics for the meeting written by my colleagues. I hope it will give you some sense of what the meeting will address.

I very much hope you will say yes, and I'll wait on needles until I hear back from you!

27-08-09 *Progress and Invitation* (to B. C. van Fraassen)

It is nice to have a reason to write you again, but unfortunately it is not yet to send you a draft of our paper "Quantum Bayesian Decoherence." Writing it has been painfully slow, but we do feel that we are really clarifying things with it. At the moment, we're working on an island within the paper that may become a paper on its own: We are making a strong endorsement of your reflection principle and want to give that a lot of care in presentation to ward off some of the evils we have seen you endure!!

Instead at the moment, I need to write you about something else. Steve Weinstein (philosophy, U. Waterloo), David Wolpert (NASA), and I are organizing a meeting of physicists, philosophers, and mathematicians at PI for next year titled, "Laws of Nature: Their Nature and Knowability." The target date presently is May 20–22, but we have some flexibility to modify that as needed to attract the best people. We envision about 20 external participants, plus 6 from PI. I have been assigned to contact you, Ian Hacking, Cheryl Misak, and Huw Price for a sort of pre-invitation before we send out other invitations more generally. I.e., we really want you to come, and think you'd be a great asset for attracting some of the others that we plan to invite. Of course, all your expenses would be paid by PI, and I personally am itching to have some refreshed face-to-face conversations with you.

Attached is a list of topics for the meeting written by my colleagues. I hope it will give you some sense of what the meeting will address.

I very much hope you will say yes, and I'll wait on needles until I hear back from you!

01-09-09 *Schumacher and Westmoreland Endorsement* (to S. Capelin)

Here you go:

> This is a fantastic book, with one of the authors no less than the very inventor of the word and idea of a qubit. When I opened the book for the first time, I found I couldn't stop reading through it and working out some of the problems. I should be ashamed to admit, but after 15 years as a professional quantum information theorist, I was still learning some elementary aspects of quantum mechanics. In presentation, the book strikingly reminded me of a conversation I had had with Schumacher several years ago. He told me that just after seeing the new *Star Wars* movie, he became quite depressed because he thought it was just a fantasy and he would never himself be a Jedi knight;

he would never know the ways of "the force." But one day it dawned on him, "Wait a minute, I am learning the ways of the quantum! I'm exploring its great mysteries, its real mysteries. I am a Jedi after all!" And so will be the reader who invests his mind in this book. There's no book out there I would recommend more for learning the mechanics of this quantum world.

If it is too long for you, you can trim some of it out, but please pass any changes you make by me before going to press.

01-09-09 *Interpretations, Closed Timelike Curves* (to C. H. Bennett)

Bennettism 37: *I would be interested to hear what you think of our (Debbie, John, Graeme, and me) new paper asserting the computational and discriminatory impotence of closed timelike curves. It involves questions about what is a reasonable way to formalize slippery notions like discrimination and (especially) computation. Such conundrums are very much up your alley, and I think you'll have interesting things to say about them, though I'm a little worried you'll go all theocratic again like you did in your emails about me and Sappho sitting in a tree. I'm not her type, anyway.*

I think your paper is indeed important for foundational issues. For instance, I think linearity of evolutions is absolutely required for an epistemic interpretation of quantum states. With nonlinearity, that interpretation goes right out the window.

Will study it with a fine-toothed comb. (And resist the temptation to infer that I'm devilishly referring to lice.) With regard to your remark on Sappho, oh I don't know: Maybe you don't watch the same movies I do.

02-09-09 *Sam Hurt's Eyebeam* (to N. Waxman)

Here are a couple of links that might jog your memory:

- `http://en.wikipedia.org/wiki/Eyebeam_(comic)`
- `http://eyebeam.com/`

02-09-09 *Inconsistencies* (to R. W. Spekkens)

Two little points of thought connected to yesterday's conversations.

1) With regard to your inter-theoretic pragmatism and intra-theoretic realism. I said I have a good bit of sympathy with that. But mulling over your particular choice of words, I'm not sure that one of the things you said makes sense. Intra-theory, you said, you could feel free to invoke a correspondence theory of truth. But I myself couldn't go that far. For I'd have to wonder, "correspondence with what *something* that's independent of the prior pragmatic choice?" There's nothing that the theory can give me a hook to by admission. So, really what I meant when I said I was in some agreement was something more along the lines of the following.

Once a theory like quantum mechanics is accepted (say for purely pragmatic reasons—i.e., for reasons that have directly to do with our practice and our survival in the world)—then one can step back and ask, "Well, what is implicit in this theory that is not directly to do with my practice?" That is, in positing the theory, I may be positing many things, not least of all the theorist's postulated limitations in interacting with the world, but I may also be positing things about the world itself (without the theorist). I wouldn't deny that, and that is our point of overlap. But those things are a distillate of the original pragmatic choice, and not girded up by a correspondence (that we could never know as actually holding or not).

Actually, my present position is decently close to F. C. S. Schiller's. See

`http://en.wikipedia.org/wiki/Ferdinand_Canning_Scott_Schiller`

or better, his paper "Axioms as Postulates" directly:

`http://en.wikisource.org/wiki/Personal_Idealism/Axioms_as_Postulates`

The outline at the beginning of this one, I think, is particularly useful. In the Wikipedia article, there is this nice explanation of one aspect of the thought. See below.

2) Yesterday, you said you preferred not to be political. What I am about to say is not an outright inconsistency, but I think it is an exhibition of expediency. It is about our conversation with Natasha on the cartoon. She wants some reference to many worlds because it will make quick connection to what little the readers may already know of the quantum foundations debate. But I think that, without finding a way to insult the view at the same time, that's a kind of cheap move, only further promoting an incorrect image of the theory in the public eye. I.e., on this issue I can see some real (albeit subtle and long-term) damage being done.

Anyway, thanks for provoking my thoughts. More on Schiller below. (Many typos fixed from the Wiki article.)

> In "Axioms as Postulates" Schiller vindicates the postulation by its success in practice, marking an important shift from *Riddles of the Sphinx*. In *Riddles*, Schiller is concerned with the vague aim of connecting the "higher" to the "lower" so he can avoid skepticism, but by 1903 he had clarified the connection he sees between these two elements. The "higher" abstract elements are connected to the lower because they are our inventions for dealing with the lower; their truth depends on their success as tools. Schiller dates the entry of this element into his thinking in his 1892 essay "Reality and 'Idealism'" (a mere year after his 1891 *Riddles*).
>
>> The plain man's 'things,' the physicist's 'atoms,' and Mr. Ritchie's 'Absolute,' are all of them more or less preserving and well-considered schemes to interpret the primary reality of phenomena, and in this sense Mr. Ritchie is entitled to call the 'sunrise' a theory. But the chaos of presentations, out of which we have (by criteria ultimately practical) isolated the phenomena we subsequently call sunrise, is not a theory, but the fact which has called all theories into being. In addition to generating hypothetical objects to explain phenomena, the interpretation of reality by our thought also bestows a derivative reality on the abstractions with which thought works. If they are the instruments wherewith thought accomplishes such effects upon reality, they must surely be themselves real.
>
> The shift in Schiller's thinking continues in his next published work, *The Metaphysics of the Time-Process* (1895): The abstractions of metaphysics, then, exist as explanations of the concrete facts of life, and not the latter as illustrations of the former [. . . .] Science [along with humanism] does not refuse to interpret the symbols with which it operates; on the contrary, it is only their applicability to the concrete facts originally abstracted from that is held to justify their use and to establish their 'truth.'

Schiller's accusations against the metaphysician in *Riddles* now appear in a more pragmatic light. His objection is similar to one we might make against a worker who constructs a flat-head screwdriver to help him build a home, and who then accuses a screw of unreality when he comes upon a Phillips-screw that his flat-head screwdriver won't fit. In his works after *Riddles*, Schiller's attack takes the form of reminding the abstract metaphysician that abstractions are meant as tools for dealing with the "lower" world of particulars and physicality, and that after constructing abstractions we cannot simply drop the un-abstracted world out of our account. The un-abstracted world is the entire reason for making abstractions in the first place. We did not abstract to reach the unchanging and eternal truths; we abstract to construct an imperfect and rough tool for dealing with life in our particular and concrete world. It is the working of the higher in "making predictions about the future behavior of things for the purpose of shaping the future behavior of things for the purpose of shaping our own conduct accordingly" that justifies the higher.

> To assert this methodological character of eternal truths is not, of course, to deny their validity [....] To say that we assume the truth of abstraction because we wish to attain certain ends, is to subordinate theoretic 'truth' to a teleological implication; to say that, the assumption once made, its truth is 'proved' by its practical working [....] For the question of the 'practical' working of a truth will always ultimately be found to resolve itself into the question whether we can live by it.

A few lines down from this passage Schiller adds the following footnote in a 1903 reprint of the essay: "All this seems a very fairly definite anticipation of modern pragmatism." Indeed, it resembles the pragmatist theory of truth. However, Schiller's pragmatism was still very different from both that of William James and that of Charles Sanders Peirce.

04-09-09 *Little Lemma, Big Theorem* (to N. S. Jones)

Thanks for the nice note. Have we ever met in person? Thanks too for telling me more of the story of "the remarkable theorem." That's what I actually call it in my presentations; in a few of them I've even promoted it to the stature of the no-cloning theorem—pointing out particularly that it's trivial to prove, but that it nonetheless says something very deep about the "shape" of quantum-state space. Also I always tell the story of how many big-time quantum information people simply weren't aware of it—it was a well-hidden little gem. I know because I have asked around very thoroughly. Here are the people I can recall who did not know the theorem until I pointed it out to them: Holevo, Lindblad, Lieb, Nielsen, Bengtsson, Calderbank, Ruskai, Gottesman, Kochen, Uhlmann, Mermin, Brukner, ... and there were surely others as well. It's a bit like the story I just wrote up on Wigner and the no-cloning theorem. See page 2 of the attached (barely started) draft of an upcoming paper.

I'm sorry to hear that you've left quantum information, but I hope you're happy in your new line of work.

Nick's Preply

> Dear Chris - I was just scoping around and found, in an interesting paper of yours, that you liked my little lemma. I always liked the lemma myself, but Noah and I

wrangled about whether it was worth hyping up more. From a mathematical perspective it's trivial to validate; yet (probably because I'm an incompetent) it took me two or three weeks to prove (because, when you only know the left hand side ...). I note Flammia apparently scooped me; I presented the idea in 2003 at the Informal Quantum Information Gathering, Max-Plank Institute for Quantum Optics 2003 and had proved it in the winter/spring of '03 I think (it was also in my thesis transfer report of that year). Noah then made me sit on it for a long time (to the frustration of a cocky graduate student) ... however, there doesn't seem a whole lot of point setting the record straight, as I suspect (like Noah) that, given the simplicity of the result, it must have been proved sometime in the 60's (and then yearly ever since) but we just don't know it. I think I remember being careful in the paper that we didn't explicitly claim that the result was new. Something I never quite seem to get around to is going to town with these equations from a Real Algebraic Geometry perspective.

[My recent favourite cute thing is that the digit sum of a random walk on the integers, shifted so that it never goes below zero, shows $1/f$ noise ... maybe all those papers on Self Organised Criticality and $1/f$ are just random walks represented wrong.]

You'll be pleased to hear that I left QI disheartened by my ability to make a scientific difference and am now something of a biologist (and also increasingly Bayesian)!

Btw—a smidgeon of flattery—it was some of your work that pulled me into the field of QI.

07-09-09 *Labor Day Recreations* (to R. W. Spekkens, D. M. Appleby, W. K. Wootters, and R. Blume-Kohout)

On this Labor Day morning (enjoying my new porch), I thought I'd spend a few minutes capping off our Friday lunchtime conversation. I never quite gave my own answer to Rob's question of "What is the purpose of science?" (Shy in a crowd, I am.) As usual, I'll answer the question with a couple of quotes written by someone far more eloquent than me. Here are two from William James that have struck me very deeply. The first answers the question straight out: [See James quote at the end of the 02-09-01 note titled "Intersubjective Agreement" to N. D. Mermin.]

I love the last two paragraphs especially. For in my own mind they capture the essence of the story. Our scientific theories are not descriptions of what the world *is*, nor are they positivist *prediction* devices predominantly—that idea fairly appals me—but they are tools for changing existing realities. They are like hammers in a very real sense: tools with which we can build and destroy, and on occasion finesse what we want to make happen.

The following quote probably paints my stripes still more brightly. I submit it with the understanding that you all tolerate me more or less.

> In many familiar objects every one will recognize the human element. We conceive a given reality in this way or in that, to suit our purpose, and the reality passively submits to the conception. You can take the number 27 as the cube of 3, or as the product of 3 and 9, or as 26 *plus* 1, or 100 *minus* 73, or in countless other ways, of which one will be just as true as another. You can take a chess-board as black squares on a white ground, or as white squares on a black ground, and neither conception is a false one.
>
> You can treat the adjoined figure as a star, as two big triangles crossing each other, as a hexagon with legs set up on its angles, as six equal triangles hanging together by

their tips, etc. All these treatments are true treatments—the sensible *that* upon the paper resists no one of them. You can say of a line that it runs east, or you can say that it runs west, and the line *per se* accepts both descriptions without rebelling at the inconsistency.

We carve out groups of stars in the heavens, and call them constellations, and the stars patiently suffer us to do so,—*though* if they knew what we were doing, some of them might feel much surprised at the partners we had given them. We name the same constellation diversely, as Charles's Wain, the Great Bear, or the Dipper. None of the names will be false, and one will be as true as another, for all are applicable.

In all these cases we humanly make an *addition* to some sensible reality, and that reality tolerates the addition. All the additions 'agree' with the reality; they fit it, while they build it out. No one of them is false. Which may be treated as the *more* true, depends altogether on the human use of it. If the 27 is a number of dollars which I find in a drawer where I had left 28, it is 28 minus 1. If it is the number of inches in a board which I wish to insert as a shelf into a cupboard 26 inches wide, it is 26 plus 1. If I wish to ennoble the heavens by the constellations I see there, 'Charles's Wain' would be more true than 'Dipper.' My friend Frederick Myers was humorously indignant that that prodigious star-group should remind us Americans of nothing but a culinary utensil.

What shall we call a *thing* anyhow? It seems quite arbitrary, for we carve out everything, just as we carve out constellations, to suit our human purposes. For me, this whole 'audience' is one thing, which grows now restless, now attentive. I have no use at present for its individual units, so I don't consider them. So of an 'army,' of a 'nation.' But in your own eyes, ladies and gentlemen, to call you 'audience' is an accidental way of taking you. The permanently real things for you are your individual persons. To an anatomist, again, those persons are but organisms, and the real things are the organs. Not the organs, so much as their constituent cells, say the histologists; not the cells, but their molecules, say in turn the chemists.

We break the flux of sensible reality into things, then, at our will. We create the subjects of our true as well as of our false propositions.

We create the predicates also. Many of the predicates of things express only the relations of the things to us and to our feelings. Such predicates of course are human additions. Caesar crossed the Rubicon, and was a menace to Rome's freedom. He is also an American schoolroom pest, made into one by the reaction of our schoolboys on his writings. The added predicate is as true of him as the earlier ones.

You see how naturally one comes to the humanistic principle: you can't weed out the human contribution. Our nouns and adjectives are all humanized heirlooms, and in the theories we build them into, the inner order and arrangement is wholly dictated by human considerations, intellectual consistency being one of them. Mathematics and logic themselves are fermenting with human rearrangements; physics, astronomy and biology follow massive cues of preference. We plunge forward into the field of fresh experience with the beliefs our ancestors and we have made already; these determine what we notice; what we notice determines what we do; what we do again determines what we experience; so from one thing to another, altho the stubborn fact remains that there is a sensible flux, what is *true of it* seems from first to last to be largely a matter of our own creation.

We build the flux out inevitably. The great question is: does it, with our additions, *rise or fall in value*? Are the additions *worthy* or *unworthy*? Suppose a universe composed of seven stars, and nothing else but three human witnesses and their critic. One witness names the stars 'Great Bear'; one calls them 'Charles's Wain'; one calls them the 'Dipper.' Which human addition has made the best universe of the given stellar material? If Frederick Myers were the critic, he would have no hesitation in 'turning down' the American witness.

Lotze has in several places made a deep suggestion. We naïvely assume, he says, a relation between reality and our minds which may be just the opposite of the true one. Reality, we naturally think, stands ready-made and complete, and our intellects supervene with the one simple duty of describing it as it is already. But may not our descriptions, Lotze asks, be themselves important additions to reality? And may not previous reality itself be there, far less for the purpose of reappearing unaltered in our knowledge, than for the very purpose of stimulating our minds to such additions as shall enhance the universe's total value. *'Die Erhöhung des vorgefundenen Daseins'* is a phrase used by Professor Eucken somewhere, which reminds one of this suggestion by the great Lotze.

It is identically our pragmatistic conception. In our cognitive as well as in our active life we are creative. We *add*, both to the subject and to the predicate part of reality. The world stands really malleable, waiting to receive its final touches at our hands. Like the kingdom of heaven, it suffers human violence willingly. Man *engenders* truths upon it.

No one can deny that such a role would add both to our dignity and to our responsibility as thinkers. To some of us it proves a most inspiring notion. Signore Papini, the leader of Italian pragmatism, grows fairly dithyrambic over the view that it opens of man's divinely-creative functions.

The import of the difference between pragmatism and rationalism is now in sight throughout its whole extent. The essential contrast is that *for rationalism reality is ready-made and complete from all eternity, while for pragmatism it is still in the making, and awaits part of its complexion from the future.* On the one side the universe is absolutely secure, on the other it is still pursuing its adventures.

We have got into rather deep water with this humanistic view, and it is no wonder that misunderstanding gathers round it. It is accused of being a doctrine of caprice. Mr. Bradley, for example, says that a humanist, if he understood his own doctrine, would have to 'hold any end, however perverted, to be rational, if I insist on it personally, and any idea, however mad, to be the truth if only someone is resolved that he will have it so.' The humanist view of 'reality,' as something resisting, yet malleable, which controls our thinking as an energy that must be taken 'account' of incessantly (tho not necessarily merely *copied*) is evidently a difficult one to introduce to novices. ...

The alternative between pragmatism and rationalism, in the shape in which we now have it before us, is no longer a question in the theory of knowledge, it concerns the structure of the universe itself.

On the pragmatist side we have only one edition of the universe, unfinished, growing in all sorts of places, especially in the places where thinking beings are at work.

On the rationalist side we have a universe in many editions, one real one, the infinite folio, or *édition de luxe*, eternally complete; and then the various finite editions, full of false readings, distorted and mutilated each in its own way.

Happy holiday.

07-09-09 *Awaits Part of Its Complexion from the Future ...* (to R. W. Spekkens)

You should be able to tell that I've been reading and thinking about your Friday diary entry this morning. You are an honest intellect, and I very much like that about you.

At the moment, I'm tumbling over the last paragraph in your entry (as I tumbled it over when you gave your brief introduction last Friday). There is something about the word "teleological" that I do *not* like; but there is something about the title of this note that I very much do like. Is that a contradiction? I'm not sure: So I keep tumbling these things about.

In the meantime I supply you of two more quotes that I think hint of why the word teleology (as often used) troubles me a bit.

The first is from William James:

> Our sense of 'freedom' supposes that some things at least are decided here and now, that the passing moment may contain some novelty, be an original starting-point of events, and not merely transmit a push from elsewhere. We imagine that in some respects at least the future may not be co-implicated with the past, but may be really addable to it, and indeed addable in one shape *or* another, so that the next turn in events can at any given moment genuinely be ambiguous, i.e., possibly this, but also possibly that.
>
> Monism rules out this whole conception of possibles, so native to our common-sense. The future and the past are linked, she is obliged to say; there can be no genuine novelty anywhere, for to suppose that the universe has a constitution simply additive, with nothing to link things together save what the words 'plus,' 'with,' or 'and' stand for, is repugnant to our reason.
>
> Pluralism, on the other hand, taking perceptual experience at its face-value, is free from all these difficulties. It protests against working our ideas in a vacuum made of conceptual abstractions. Some parts of our world, it admits, cannot exist out of their wholes; but others, it says, can. To some extent the world *seems* genuinely additive: it may really be so. We cannot explain conceptually *how* genuine novelties can come; but if one did come we could experience *that* it came. We do, in fact, experience perceptual novelties all the while. Our perceptual experience overlaps our conceptual reason: the *that* transcends the *why*. So the common-sense view of life, as something really dramatic, with work done, and things decided here and now, is acceptable to pluralism. 'Free will' means nothing but real novelty; so pluralism accepts the notion of free will.
>
> But pluralism, accepting a universe unfinished, with doors and windows open to possibilities uncontrollable in advance, gives us less religious certainty than monism, with its absolutely closed-in world. It is true that monism's religious certainty is not rationally based, but is only a faith that 'sees the All-Good in the All-Real.' In point of fact, however, monism is usually willing to exert this optimistic faith: its world is certain to be saved, yes, is saved already, unconditionally and from eternity, in spite of all the phenomenal appearances of risk.
>
> A world working out an uncertain destiny, as the phenomenal world appears to be doing, is an intolerable idea to the rationalistic mind.
>
> Pluralism, on the other hand, is neither optimistic nor pessimistic, but melioristic, rather. The world, it thinks, may be saved, on condition that its parts shall do their best. But shipwreck in detail, or even on the whole, is among the open possibilities.

> There is thus a practical lack of balance about pluralism, which contrasts with monism's peace of mind. The one is a more moral, the other a more religious view; and different men usually let this sort of consideration determine their belief.

The second comes from Richard Rorty:

> In this essay I shall focus on Whitman's phrase 'counts ... for her justification and success ... almost entirely upon the future'. As I see it, the link between Whitmanesque Americanism and pragmatist philosophy—both classical and 'neo-'—is a willingness to refer all questions of ultimate justification to the future, to the substance of things hoped for. If there is anything distinctive about pragmatism it is that it substitutes the notion of a better human future for the notions of 'reality', 'reason' and 'nature'. One may say of pragmatism what Novalis said of Romanticism, that it is 'the apotheosis of the future'.
>
> As I read Dewey, what he somewhat awkwardly called 'a new metaphysic of man's relation to nature', was a generalization of the moral of Darwinian biology. The only justification of a mutation, biological or cultural, is its contribution to the existence of a more complex and interesting species somewhere in the future. Justification is always justification from the point of view of the survivors, the victors; there is no point of view more exalted than theirs to assume. This is the truth in the ideas that might makes right and that justice is the interest of the stronger. But these ideas are misleading when they are construed metaphysically, as an assertion that the present status quo, or the victorious side in some current war, stand in some privileged relation to the way things really are. So 'metaphysic' was an unfortunate word to use in describing this generalized Darwinism which is democracy. For that word is associated with an attempt to replace appearance by reality.
>
> Pragmatists—both classical and 'neo-'—do not believe that there is a way things really are. So they want to replace the appearance-reality distinction by that between descriptions of the world and of ourselves which are less useful and those which are more useful. When the question 'useful for what?' is pressed, they have nothing to say except 'useful to create a better future'. When they are asked, 'Better by what criterion?', they have no detailed answer, any more than the first mammals could specify in what respects they were better than the dying dinosaurs. Pragmatists can only say something as vague as: Better in the sense of containing more of what we consider good and less of what we consider bad. When asked, 'And what exactly do you consider good?', pragmatists can only say, with Whitman, 'variety and freedom', or, with Dewey, 'growth'. 'Growth itself,' Dewey said, 'is the only moral end.'
>
> They are limited to such fuzzy and unhelpful answers because what they hope is not that the future will conform to a plan, will fulfil an immanent teleology, but rather that the future will astonish and exhilarate. Just as fans of the avant garde go to art galleries wanting to be astonished rather than hoping to have any particular expectation fulfilled, so the finite and anthropomorphic deity celebrated by James, and later by A. N. Whitehead and Charles Hartshorne, hopes to be surprised and delighted by the latest product of evolution, both biological and cultural. Asking for pragmatism's blueprint of the future is like asking Whitman to sketch what lies at the end of that illimitable democratic vista. The vista, not the endpoint, matters.
>
> So if Whitman and Dewey have anything interesting in common, it is their principled and deliberate fuzziness. For principled fuzziness is the American way of doing what Heidegger called 'getting beyond metaphysics'. As Heidegger uses it, 'metaphysics'

is the search for something clear and distinct, something fully present. That means something that does not trail off into an indefinite future ...

08-09-09 *Awaits Part of Its Complexion from the Future ..., 2* (to R. W. Spekkens)

Thanks, that's useful. Dennett's definition of "teleological explanation" makes it clear that what I'm talking about with the phrase "awaiting part of its complexion from the future"—whatever it is—is not that.

The world Dennett sets you to thinking about, the flavor of everything he says, is foreign to the landscape I see in James's writings. (It's certainly foreign to me.) "This exchange reveals one of the troubles with teleology: where does it all stop?" Part of the very point is that it doesn't. Nor is there one and only one all-inclusive chain (or 'hierarchy' in his terms) that one can imagine embedding the discussion in. An essential piece of what Dennett balks at is that no finite story can arise from what he views as the other side (i.e., teleological blah blah blah). To the extent that his other side coincides with my own landscape, *yes*, that is right: It shouldn't be any other way. But also, there is all this talk of "explanation" (in him and in you)—we just hit the rationalist/pragmatist (monist/empiricist) divide again. It is what sets us apart. He wants the world reduced; we say it cannot be. We say that to the extent that one can contemplate any toy reduction, one only does so by leaving essential things out. It is a divide that has plagued worldviews for a long time.

09-09-09 *Till Tomorrow* (to R. Schack)

I've done just a little to the abstract, intro, and acknowledgments. I'm going back to bed now. I'll try to get an hour more in before leaving for Niagara at 9:00 AM. Then I'll send you (what little) I have, and pick back up on it this evening.

One thing that confuses me (worries me!) is this line:

Schackcosm 124: *Quantum Bayesian state assignments are personalist in the sense that they are functions of the agent as well as the world outside the agent.*

Why the reversal from our now very infamous position?

10-09-09 *Phrases That Came to Mind* (to D. M. Appleby)

"Theory is a focal point for designing counterfactuals."

"Theory is a focal point that aids in designing counterfactuals."

10-09-09 *Euler and Classical Mechanics* (to P. G. L. Mana)

Marcus and I had a long discussion about your note yesterday as we were at Niagara (doing work-permit business and viewing the amazing falls). These are very important points you make.

Do you mind if I share your note with Rob Spekkens if the issue comes up in our on-going debate about the value (or unvalue in my opinion) of assuming a deterministic world?

Luca's Preply

I hope your research is going fine there! Unfortunately I am going to miss the new perspectives on the quantum state.

I wanted to send you the translation of Euler's passage and some comments on it a while ago, but I got the swine flu (no different from any other flu) and have been to Sweden and Rome afterwards.

Here are the passages from Euler that I found important. Recall that in that paper he is studying the condition for fluid equilibrium:

> Now, all comes to properly establishing the basic idea on which to base the reasonings to arrive at our goal: the idea of the nature of fluidity in general. For the equilibrium laws for fluids will not have to differ from those of solids but in the fact that the nature of fluids is different from that of solids. So the point is to know the genuine and essential difference that distinguishes the fluids from the solids — a question well bustled about amongst Philosophers and Physicists: but from all they have said about it we cannot deduce anything suitable to our plan. It is maybe true that the smaller elements of a fluid have no link with one another, and that they are in a perpetual movement; but this truth would be completely sterile for our researches . . . .
>
> Inasmuch as this essential property of fluids is to provide the principles of Hydrostatics, I find it only in this: that a fluid mass will not be in equilibrium unless it be acted upon all points of its surface by equal forces perpendicular to the surface. . . .
>
> Conceive an immaterial diaphragm in the interior of the fluid, cutting out a generic portion of it. Since this portion is in equilibrium, all the elements of the diaphragm will sustain forces of the same intensity . . . .

This paper is one of the most important in the history of classical mechanics, and it is full of gems. In the first paragraph, for example, Euler has very clear the difference between a general law ("the laws for fluids will not have to differ from those of solids") and a constitutive equation ("but in the fact that the nature of fluids is different from that of solids"). I know not a few physicists who do not have that difference clear today.

It is obvious that Euler is here looking for a model with which to describe and possibly deduce new properties of fluid equilibrium. He says clearly that he is not interested about "the real situation", because this may be too complicated and irrelevant for the phenomena under investigation. Rather, he wants a simple conceptual device from which to derive, mathematically and as simply as possible, the phenomena of interests; in this case, fluid equilibrium.

Note how his goal is limited to a particular range of phenomena, not *all* phenomena of this world; and how he adapts the means to the end.

And here 'conceptual' is in its original sense of something *conceived* or *conceivable*: something that can be taken in, imaginable. It does not matter if what is imagined contradicts "the real situation".

In fact, in this case Euler's device is to *imagine* any portion of a fluid (in fact, of any body) enclosed by an immaterial diaphragm, and to study the imaginary forces that would act on this diaphragm from the fluid outside it. A very simple thing to do with our imagination! But this obviously goes against the idea, of that time, of a fluid made of elements in perpetual motion and with no interaction. But who cares?

With this device all the equilibrium of fluids is summarised in a simple principle: the forces per unit area on any such diaphragm must be everywhere equal in intensity and perpendicular to it. With a very simple generalisation, from the same principle Euler obtains in the subsequent paper all phenomena of non-turbulent fluid motion. Isn't this genius?

This device was revolutionary and very fertile; indeed, every engineer learns it today: via Cauchy, it became our hodiern concept of stress, used even in general relativity. Thanks to it we can cross bridges, build very high buildings, make robust containers, fly from Canada to Australia, and do many other things (despite the fact that no such diaphragms nor stress forces appear in a molecular model, as every statistical mechanician knows).

It is also clear that the forces acting upon that imaginary diaphragm are hardly measurable. This was clear to Euler, and is clear to the engineer today. The way classical mechanics has always proceeded has been this: make some hypotheses about your model, work out the consequences, and if these match experience and experiment, feel more confident about your hypotheses.

Classical physics continually uses many fundamental hypotheses which *in principle* cannot be tested. Take the case of the Newton-Euler first law and inertial frames. The law states that, for an observer *in an inertial frame*,

$$\sum_i \mathbf{F}_i = m\mathbf{a} \ ,$$

the sum being extended to all forces acting on the body in question. How can we test whether we are in an inertial frame? Well, given all forces, the only way is to see whether the body's acceleration is proportional to their sum. But how can we be sure that we have not neglected some force? Well, given that we are in an inertial frame, we can check whether the sum of the forces considered is proportional to the body's acceleration. But how can we test whether we are in an inertial frame? We're going around in a circle. We cannot test both hypotheses, about the forces and about the frame: we have to *assume* the one and test the other. If and as long as everything works, we are confident about our untested assumptions.

So I think Euler's paper is one of the many which shows that:

- Classical physics is concerned about describing the world, but 'describing' does not necessarily mean 'saying how thing really are'. (In fact, after Wittgenstein we should know that 'how the world really is' has no meaning at all.)
- Classical physics is not based upon all-measurability and all-knowability: in it, hypotheses are everywhere made never to be proven, but to be held as long as their consequences agree with our experience, experiments, and taste.
- The models and hypotheses of classical physics are based on our imagination: the very concepts we use in it are extremely anthropomorphic, sublimations of our daily experience; sometimes they even contradict our thoughts about how things 'really' are.

What many people today say about 'classical physics', is not what it is and was, but what *they think* it *should* be and have been. Indeed, they very rarely present any single text of our past Masters (apart from the usual two lines by Laplace) to support their claims.

15-09-09 *The Primacy of Measurement* (to D. M. Appleby)

Fun reading on a depressing night. Rüdiger and I have a mistake in our paper and I've spent three days trying to fix it. (Luckily it doesn't infect my work with you and Åsa, but it remains a mistake in the public eye.) Anyway, we must talk much more of time when all this sickening paper-writing is done.

Marcus's Preply to Jochen Rau

I much enjoyed our discussions too. I also enjoyed your very stimulating paper.

I hope you won't take the following remarks as criticism. They are merely a few thoughts provoked by reading your paper. I believe that quantum mechanics is challenging us to develop a way of thinking about physical reality which is completely different from the one to which 300 years and more of classical physics have accustomed us (I say 300 years because that is the time elapsed since Newton's *Principia*—and I include the 20th century in that time span because it seems to me that, notwithstanding the mathematical innovations introduced by Schrödinger, Heisenberg et al, on a conceptual level we have hardly begun to get beyond the psychological cramp which seventeenth century science induced in us). I have the impression your attitude is similar to mine. If so you will agree that there is a long way still to go. And that is the motivation for these comments. I am thinking "what next?"

One of the obsessions of classical physics was the desire for what might be called *total* objectivity: a picture of the world from which every trace of the knowing subject has been removed. A picture of "things as they are in themselves", independent of them being conceived by us. I said something about this in my talk at Växjö. Like all simple-minded slogans it seems, on the face of it, an entirely reasonable demand. It seems (on the face of it) as though any qualification of the demand—any suggestion that things aren't quite as simple as it assumes—represents a surrender of the foundational principle of modern science, without which it wouldn't deserve to be called science. I think in many peoples' minds there is almost a moral dimension to this: that many people in physics regard (for instance) the Bayesian interpretation of the quantum state rather in the way that fundamentalist Christians regard liberal theologians. But the thing about fundamentalist Christianity is that it is doomed to failure for purely internal reasons. You cannot base yourself on a perfectly literal interpretation of the Bible because the Bible isn't consistent, either with itself or with the acknowledged facts (fundamentalist Christians often deny Darwin; not so easy for them, in these days of space travel, to deny Copernicus). And I think something similar is true of the fundamentalist demand for *total* objectivity. Its own internal inconsistencies mean that is simply not possible to carry the project through. This is obvious, really, just from the fact that it is a totally objective *picture* (or theory, or conceptualization) which is being demanded. For a picture (or theory, or conceptualization) is a human construction and it must inevitably bear the marks of that. Complaining that a theory has "subjective" elements (elements which reflect the fact that it is specifically *our* theory) is like complaining that a photograph is printed on paper, using ink—that it isn't literally identical with whatever it is a photograph of. As I said in my talk in Växjö I think quantum mechanics is finally forcing us to face up to this obvious point. Really it should have been obvious all along. However, there were features of classical physics which made it comparatively easy for those who wanted to conceal the truth from themselves. Nowadays it is much harder. Not that people don't still try. In fact, most of the effort in quantum foundations is devoted to the attempt to interpret quantum mechanics along objectivist lines. However, these attempts fail to carry conviction—which is why there continue to be all these arguments.

Anyway, that is by the way of preamble. Now for my first question. I am deeply interested in your idea, that maybe we should think of measurement as the primary thing. The contrary idea, that unitary evolution is the fundamental concept, and that the aim should be to explain measurement in terms of it, is closely connected with the classical ideal of *total* objectivity. Anyone who thinks in those objectivist terms must inevitably find the fact that measurement is treated in quantum mechanics (when interpreted along Copenhagen type lines) as an unexplained primitive, unacceptable. But if you reject that classical assumption the suggestion that we treat the concept of measurement as a conceptual primitive is no more objectionable than the suggestion that we treat the concept of logical inference as a conceptual primitive. Sure the idea of measurement makes essential reference to the agent who is doing the measuring. But so what? And since I take that view I am naturally very attracted to the idea that we should turn things round completely, and seek to explain unitary evolution in terms of measurement. However, it raises a question in my mind. It should, I hope, be clear that in rejecting the ideal of *total* objectivity I am not committing myself to a rejection of objectivity absolutely, in any shape or form. There is a (big) universe out there, and I believe it is the job of physics to say something about it. The fact that any statement we may make about a distant star (for instance) will contain subjective elements (will contain an essential reference to us, who are making the statement) doesn't mean that we simply can't make any valid statement. It only means that we need to be much more careful, and subtle, than classical physicists were wont to be. Objectivists would like to believe that unitary evolution is occurring in distant stars. I definitely don't believe that. And I suppose you don't believe it either. But the question is: what do we believe? Do we say that measurements are going on in distant stars? And if we do say that, what has become of the concept of measurement? Are they measurements without agents to do the measuring? Or what?

(Let me hasten to add that I am not expecting you to be able to answer the question. I certainly couldn't answer it myself. I am very uncertain what quantum mechanics says about distant stars. I am just wondering if you have any thoughts on the subject, however tentative and uncertain.)

My other question concerns your reference to "future attempts at constructing a truly timeless—and possibly measurement-based—theory of quantum gravity". I suspect that the classical demand for *total* objectivity has led to some deep-seated confusions about the nature of time. You talk about a "timeless" theory of quantum gravity. But it seems to me that there is an important sense in which the classical theory of relativity is already "timeless". That is, it leaves out some of the essential features of what we ordinarily call time. In the common sense conception of time the present plays a distinguished role. But in classical relativity there isn't really any concept of the present at all.

Now of course you might say that there is no reason to pay any attention to common sense on this. Copernicus simply ignored what was once the common sense assumption, that the Earth is *obviously* at rest. So why shouldn't Einstein ignore the common sense assumption, that the concept of "the present moment" is something more than a subjective illusion? In response to that question, I would agree that we are as free to ignore common sense on this as we are on anything else. But only if we can do it consistently. And I don't think modern physics does do it consistently. It seems to me that, on the contrary, although denying the concept of the present at the level of official theory (the 4 dimensional space time manifold), modern physics continually smuggles the concept in unofficially, at the level of actual thought and practice. Moreover, it does this surreptitiously, without comment, and mostly without anyone noticing.

To justify that statement I need to digress a little and say something about counter-factuality. I will come back to time in a moment. At least so far as its practical applications are concerned physics is a tool for answering counter-factual questions. For instance, an engineer wants to design a bridge. To do that s/he needs to ask themselves such questions as "if I put the girder *here* what will be the stress *there*?" Before arriving at the final design, which is actually built, the engineer runs through a multitude of other designs which never have more than a purely conceptual existence, inside the engineer's mind. In short, designing a bridge requires us to know the answers to questions about what *would* happen if one *were* to do something which, however, one never actually does do. In other words it requires us to answer counter-factual questions. And what goes for bridges also goes for just about any other technological application of physics. To a very large extent the practical utility of physics depends on its ability to provide answers to such counter-factual "what would happen if?" questions. I also think that to a considerable extent theoretical understanding depends on them too. For instance, understanding Newtonian gravity doesn't just mean knowing what the orbits of the planets *actually* are. It also means knowing what the orbits *would* be if they were (counter-factually) perturbed in some way. Similarly, you don't understand the geometry of a black hole if you don't know how (for example) to calculate how the geometry counter-factually would be affected if the black hole counter-factually did become more massive. So I would say that counter-factual reasoning is absolutely basic to physics. To a considerable extent it is what physics is about. But because such reasoning involves the consideration of situations which are in a certain sense imaginary it is felt that it is not really part of physics proper. (I use the prejudicial word "imaginary" because that is how physicists of a certain bent tend to regard it. However, I think one might question whether it is really the case that it is only true *in imagination* that this glass would have broken if I had dropped it [but didn't].)

Counter-factual reasoning is closely connected with the concept of possibility (it was *possible* for the engineer to span the river: meaning that s/he counterfactually *could* have built a satisfactory bridge if s/he had really tried), and that in turn is closely connected with the concept of free will (the engineer was *free* to build a bridge instead of a tunnel, if s/he had wanted to). But, notwithstanding the fact that one of the main practical uses of physics is to answer questions as to what is physically possible in various situations, these concepts are regarded with grave suspicion by what is still the dominant tendency in physics. Witness Bell's embarrassment (*Speakable and Unspeakable*, revised edition, p. 101 ff) when he was accused of postulating the existence of free will, and his strenuous attempts to explain away what is commonly called freedom as really something else. The reason that Bell didn't want to accept free-will (and the related concept of counter-factuality, which also plays a crucial role in Bell's argument) as a conceptual primitive is, I would suggest, the same as the reason he didn't want to accept measurement as a conceptual primitive. My own instincts are the exact reverse of his. Not only am I ready to embrace measurement as a primitive concept. I am also ready to embrace counterfactuality and free will as primitive concepts. And perhaps quite a few other things too. I think measurement is only the tip of the iceberg. I think the reason we still don't satisfactorily understand quantum mechanics is that we have hardly got started on the road it naturally suggests.

Which brings me back to time. I believe the ordinary, naive concept of time includes, as an essential element, the idea that we are free to alter the future, but not free to alter the past. In other words, the future is the domain in which we can use counter-factual reasoning to practical effect. Counter-factual questions can be interesting. For example, engineering students are taught how the designers of the Tacoma Bay bridge counter-factually *should* have designed it. Counter-factual questions are also highly relevant in a court of law. But the future is where counter-factual reasoning really comes into its own: because that is when we can do something about it.

Now, as I said, the fact that something forms an essential part of the common-sense conception is not in itself a reason for accepting it. However this way of thinking about time *also* plays an essential role in the application of modern physics (no one is currently trying to build a quantum computer in the past). Every modern physicist does *in fact* think in this way about time. It is just that they don't want to face up to the fact that they are thinking this way. Moreover, I strongly suspect that the reason they don't want to is nothing more than a philosophical prejudice, arising from the feeling that all talk of the observer and his or doings has no place in physics. I believe that does provide a reason for taking it seriously.

Though let me stress that I am not suggesting that we simply go back to common sense ideas about time. Quite the contrary. I would speculate that if we were to follow this line of thought seriously, and try to formulate relativity in a way that did proper justice to counter-factuality, and agency, we might arrive at new, and suprising physics.

In short I would suggest that perhaps what we need is a theory of quantum gravity in which, not only measurement, but also certain concepts such as counter-factuality and agency play a central role. I would also suggest that the theory which resulted wouldn't really be timeless. It wouldn't get rid of the concept of time. Rather what it would do is to conceive of time in a very different way from that to which we have become classically accustomed.

Which brings me to my question: does this make any sense to you?

16-09-09 *PIAF Quantum Foundations Conference – Late Reminder* (to M. Bitbol)

Bitbolism 2: *Thank you for your kind invitation. Unfortunately, I can't come. But I am delighted to see that this topic is now a top priority. The very word "state" is doubtful, and generates a lot of misunderstandings.*

Indeed I am in much agreement with your point. In connection with that, you may enjoy the little story I wrote about David Mermin (and quantum interpretation) in the attached file. It is partially on linguistical issues to do with quantum interpretation. See attached file, starting on page 21:

David Mermin: I cannot honestly call David Mermin a father of quantum information, but I can call him the godfather of it—he blessed the field through its formative years and continues to watch with pride as it approaches maturity. There are many reasons I say this, but one of them is told well in his own words in, "Copenhagen Computation: How I Learned to Stop Worrying and Love Bohr," `quant-ph/0305088`.

Then again, David always tells things well. N. David Mermin is the Horace White Professor of Physics Emeritus at Cornell University, and for years has been the writer extraordinaire of our field. I very much knew the latter when I first wrote to him, and believe me, it did take some effort to work up the nerve to critique his papers. But I did it for the reasons I have already explained. A further aspect that I had not completely appreciated at the beginning is something David argues so beautifully in his essay, "Writing Physics":

> Physicists traditionally replace talk about physics by a mathematical formalism that gets it right by producing a state of compact nonverbal comprehension. The most fascinating part of writing physics is searching for ways to go directly to the necessary modifications of ordinary language, without passing through the intermediate nonverbal mathematical structure. This is essential if you want to have any hope of explaining physics to nonspecialists. And my own view is that it's essential if you want to understand the subject yourself.[207]

I found that when I wrote to David, I wrote better—self assessment, of course—than I did to any of my other friends. It was a question of wanting to keep up with the Joneses, I suppose, but it had this lovely unintended consequence: I felt I understood things better and better just by touching my keyboard and having a new David-Mermin letter in mind to write. Better writing, not just any writing, made for better understanding.

I started to realize that the major part of the problem of our understanding quantum mechanics had come from bad choices of English and German words (maybe Danish too?) for various things and tasks in the theory. Once these bad choices got locked into place, they took on lives of their own. With little exaggeration, I might say that badly calibrated linguistics is the predominant reason for quantum foundations continuing to exist as a field of research. Measurement? I agree with John Bell—it is a horrible word and should be banished from quantum mechanics. But it is not because it is "unprofessionally vague and ambiguous" as Bell said of it. It is because it conveys the *wrong* image for what is being spoken of. *The* quantum state? That one is just about as bad. Who would have thought that so much mischief could be made by the use of a definite article? So many of these things came to mind as I would strive to be clear and entertaining in my writings to David.

I once had a piece of trinitite, that lovely green glass born in the heat of the Trinity test explosion, 16 July 1945. I was very proud of it and kept it displayed on a shelf in my library until the Cerro Grande Fire took it from me. It was a material reminder of Stanisław Ulam's words, "It is still an unending source of surprise for me to see how a few scribbles on a blackboard or on a sheet of paper could change the course of human affairs." But from my standpoint today, it is not those equations that changed the world. They were merely a center of attention for the layers and layers of verbal apparatus and practical action required to give them life. It is language that powers things, and in this thought David Mermin has been my leader.

[207] Mild paraphrasing from David's original.

16-09-09 *PIAF Quantum Foundations Conference – Late Reminder* (to J.-Å Larsson)

Larssony 3: *Sorry, I've booked a trip to idQuantique over just those dates.*

I've forgotten to remind you that I'd very much enjoy meeting you and Marcus at some point. (But the nearest that I can manage is probably November.)

Just let me know as your ideas firm up. Say hello to Nicolas Gisin for me. See the subtitle on page 3 of the attached file—it is a talk I gave at the meeting where Gisin won the John Bell Prize. [Title: Quantum Bayesian Coherence. Subtitle: The Anti-Nicolas-Gisin Interpretation of Quantum Mechanics.] I don't think he liked it! But in great part we see the world diametrically oppositely; so I thought why not be honest about it.

16-09-09 *The Primacy of Measurement, 2* (to D. M. Appleby)

Applebyism 36: *Do we say that measurements are going on in distant stars? And if we do say that, what has become of the concept of measurement? Are they measurements without agents to do the measuring? Or what?*

These are the crucial questions. My ideas for an answer have been forming since last New Year's Eve when I started to write you and Hans on the subject. I'll be curious to hear what Jochen answers you on this.

16-09-09 *QF Group Meeting, Thursday 4pm Bob Room* (to R. W. Spekkens)

Spekkensism 50: *This week's topic of discussion: Is the possibility of doing science contingent on the universe having a certain kind of locality? Einstein famously claimed something to this effect: "Without such an assumption of the mutually independent existence (the 'being-thus') of spatially distant things, an assumption which originates in everyday thought, physical thought in the sense familiar to us would not be possible. Nor does one see how physical laws could be formulated and tested without such a clean separation."*

Thanks for the quote. It reminded me of why I've been pushed to my rather radical Bayesian position about quantum probabilities. It's because over and over again, I always find myself agreeing with Einstein.

16-09-09 *Till Tomorrow* (to R. Schack)

Suppose we have already enforced the following: $nb = a-1$ and $am = n(b+1)$. (The latter condition being the one that arises from fixing the length of a posterior vector of an ISU measurement to be the length of the basis vectors.)

Now look at Eq. (163) in the RMP version of the paper. From the latter constraint it follows that we have m unit vectors with pairwise inner products $-b$. I'm going to make use of this in a moment. First though recall the precursor observation I made to you yesterday:

Take q normalized vectors $|f_j\rangle$ such that

1. $\sum |f_j\rangle = 0$, and
2. $\langle f_j|f_k\rangle = c$ for $j \neq k$.

Then c is fixed to $-1/(q-1)$. The converse is true as well: If $c = -1/(q-1)$ and 2), then 1) must hold necessarily.

But we have m unit vectors with pairwise inner products of value $-b$. Think of b as the free variable. Suppose $b = 1/(m-1)$. Then these vectors could not possibly all be proper probability distributions: For not all of them could live in the positive "quadrant" of the space and still give condition 1 above. On the other hand, if $b = 1/m$, it seems to me nothing obviously or immediately prevents us from augmenting our set of m supposed probability distributions with 1 more vector to get a simplex centered at the origin.

I.e., thinking of m as fixed, only $b = 1/m$ and smaller should be viable values.

I think this sketches the solution to our conundrum. Please think hard about it and see if you see any flaws. And see if you see a way to make it more rigorous—I'm going back to bed now. (Shockingly, if the reasoning above is correct, it vindicates most of the old argument, with a proper understanding of the direction of inequality now. But we should definitely scrap the old argument and use a rigorized version of the one above.)

May I call you at work after I reawaken (and get the kids off to school). Say about 10:00 AM my time?

16-09-09 *Ciao* (to G. Valente)

Many congratulations on your new position! That's wonderful to hear—though Alexei did clue me in some. I fully endorse your learning some true physics and very much sympathize with your sentiment about those "just pretending to know physics, as many philosophers do." To us on the inside, it is quite clear that many of them are indeed just pretending—they can't hide it.

I must admit that I now have Musil's book (two volumes) on my bookshelves, but I have not read it yet.

Let me point you to a new paper of mine: `http://arxiv.org/abs/0906.2187`. I hope some of the philosophy at the end (Section 8) will bring you back to some of our earliest discussions on the malleability of reality and alchemy. We've missed the real Giovanni on this side of the fence!

17-09-09 *Bumpy Yard* (to D. M. Appleby)

It's moles man! It's moles! Now, how do you get rid of moles? The bumpy yard has gotten much worse since you were here, and I've finally started to catch on to the pattern. It's most definitely moles.

Very depressing day of quantum foundations at PI. We had a big QF group meeting, and once again I realized I was orthogonal to most everyone in the audience. It's kind of a lonely and frustrating place.

18-09-09 *Happen?* (to the QBies)

Will either of you happen to go to the University today before coming to PI? If so, could one of you to pick up the following book while you are there?

Title: Conceptual problems of quantum gravity
Publisher: Boston : Birkhäuser, c1991.
Location: UW Davis. Book Stacks. Main Floor
Call Number: QC178.C63 1991

I think we should follow up thinking about yesterday's group meeting topic, and there is an important article by Stachel on the subject in that book.

19-09-09 *The Cabibbo Angle* (to R. Schack)

Cabibbo has an angle. Weinberg has an angle. Why can't we QBists too have an angle? Ours satisfies

$$\cos\theta = \frac{(n-m)}{(m-1)^2+(n-1)}$$

and we declare, for reasons "of a strong Bayesian flavor" that $\cos\theta = 1/2$.

But what are those reasons? We need something good. I can see at least three paths of attack, but beyond seeing that they're paths, I don't presently know how to proceed any distance down them. 1) is to try to supply a reason for your observation that adding an $(m+1)$'th $|\alpha_k\rangle$ gives a set that sums to the zero vector. 2) Is to try to supply a reason for the value $\cos\theta = 1/2$ outright. And here's a 3). Let $|r\rangle = \sum_k |p_k\rangle$. You can confirm that $\langle r|r\rangle = \frac{m^2}{n}$. Can we supply a reason that this quantity should be 1?

Note that $|r\rangle$ is not the mixture of the $|p_k\rangle$, but the sum. If we take the mixture, all useful information disappears because, no matter what m, the vector $\frac{1}{m}\sum_k |p_k\rangle$ is the uniform distribution over n outcomes.

2) very much looks like an extra symmetry assumption. Could we justify it from that angle? 1) really looks like a pretty direct statement about the spider-web character of Hilbert space. (See: `http://www.starmagic.com/MAGIC-LOOPS-Lotus-Flower.html` or do a search in Google Images of "flexi-sphere".) And 3) surely seems like a raw normalization condition of some variety.

Confused and confused. I wonder if Cabibbo was ever confused …

20-09-09 *One of the Essences of Things, Maybe?* (to R. Schack)

I spent a restless night alternating between dreams and meditating on $\cos\theta = 1/2$ and, sometimes, dreaming of meditating on the latter and meditating on dreaming of the latter. It was a wild mix of neuronal firings. The small residue left behind is perhaps more a vague feeling than anything else, but I'll share it nonetheless.

Previously we've been treating the *form* of the urgleichung as nearly the only empirical addition (i.e. nonBayesian) component in our reasoning. Certainly our emphasis was there. But important for this consideration, shouldn't we also include the scale of β? By considering measurements for which can have certainty over the outcomes, we are able to make a connection between m, n, and β, but the importance of the scale of β remains. I tend to think that that is the best way to think of it. What is interesting is that quantum mechanics takes β to be neither the smallest it can be 0, nor the largest $(n-2)/n$.

It's a bit like this maybe: Could one posit Schrödinger's equation as having empirical content, without at the same time as positing h to have such content as well?

Anyway, I wonder if we may have been off-base a bit, hoping to get a bit too much from "assumptions of a strong Bayesian flavor" as well as pure geometrical considerations. I.e., maybe indeed it is only empirics that gives $\cos\theta = 1/2$.

Or, am I giving up too easily?

Continuingly-Miserable Chris

20-09-09 *All Ways of Expression* (to R. Schack)

Maybe another way to put it is this. Would we really want an urgleichung so self-consistent that it had no adjustable parameters at all signifying *which* world we live in? Would we really want it completely fixed, save for the size of the system we were applying it to? I go up and I go down on this.

20-09-09 *A Way To Salvage Much of the Old* (to R. Schack)

I feel confident that what I am about to say is sound, but—warning!—I've had three glasses of wine, and I might not express myself as "clearly" as usual.

Suppose a device with m outcomes that achieves the ideal of certainty. Then that device defines m states in our proposed state-space. Let us make the restriction that a basis state can arise as the posterior consequent upon the outcome of such a measurement. I.e., we are in the usual setting of this last week, where $\beta = (n-m)/[n(m-1)]$. As we know, without further assumptions, there are no restrictions on m (other than that $2 \leq m \leq n$). BUT—and I'm only now starting to appreciate this—*we can still ask the question*: Are there any *further* potential states with the same symmetry as the first m of them? There's no claim here that such an extension *need* correspond to a measurement that achieves the ideal of certainty: By construction, there cannot be one. Instead, it is purely a question of symmetry. We are asking, is our space maximal in the sense of not allowing the addition of one more state with the appropriate relation with the previous ones? For given n and m, we know(?) we can do this if m is already sufficiently large in comparison to n. Thus what we ask is merely (humbly), what is the smallest m for which this symmetry property fails. To put it in still other words, what we are asking is that our ISU measurement that achieves the ideal of certainty generate a maximal set of states in the sense that adding even one more potential state must push it outside the valid state-space.

Now we use the mathematics from our previous argument (or an Åsa-ified version) to show that $m \geq$ blah blah blah. We choose m to be the extremal case as our postulate.

So the assumption is not one of impossibility of construction, but one of the symmetry properties of our space. Of course, why should one care about symmetry properties? I am staunchly belligerent to Jochen Rau whenever he invokes symmetry groups in his reconstructions of QM. But maybe we can really think of it more, again, as a maximality property. Our supposed measurements achieving the ideal of certainty have posteriors that "just fit into" the space.

OK, now four glasses of wine. Surely there will be problems above, but maybe it still indicates a productive path.

20-09-09 *PIAF Quantum Foundations Conference – Late Reminder* (to A. Plotnitsky)

Plotnitskyism 16: *On a different (or ever the same) subject, I have been reading some recent commentaries on the experimental verification of Hardy's paradox, which commentaries I found (unsurprisingly) confusing. My sense from Hardy's initial article and Mermin's article on it is that it is just a special and subtler case of quantum entanglement, which does not essentially change* *anything in terms of epistemology, although of course it is not about to stop the usual debates. I think more and more that nothing in any reasonably near future will stop them, and Hardy's paradox was used by Bohmians to support their view, just as the EPR experiment was.*

Yes, that's right: Just more of the same.

Plotnitskyism 17: *For instance, it seems to me one would still be easily able to maintain the Bayesian view you guys take, just as one can in the case of the EPR experiment. No? That is, does one need any special adjustments? Once again, sorry to miss your paper.*

No, not at all. The lesson of the Hardy paradox is as it is with the usual Bell inequality violation: If one assumes Einstein locality, then the outcomes of quantum measurements cannot pre-exist the act of measurement.

Sorry to hear you can't come. But I know we'll see each other again soon, somewhere, some sunny day.

21-09-09 *Wavering* (to R. Schack)

I'm starting to become disenchanted with the three-glass solution. I guess the transition is coming about because I started to appreciate tonight that it really seems to rely on the α_k representation for its statement. If you take the $|w_k\rangle$ representation, there doesn't seem to be an analogue. So, in what way is it an interesting symmetry assumption that there is no $(m+1)$'st state?

21-09-09 *Fantastic Talk* (to G. J. Chaitin)

Just wanted to let you know, I thought that was a fantastic talk today! Even though I knew most everything from having studied your papers in great detail in the mid '90s, I found it quite inspiring still.

Among other things, your remarks at the end on experimental mathematics struck a chord with my present situation. There's a certain kind of mathematical structure we (myself with Carl Caves and Rüdiger Schack) need to exist for our "quantum Bayesian" program in quantum foundations. But so far we only know it exists for spaces with dimension 2 to 67. Beyond that it has so far been too hard computationally. Nonetheless I plow ahead assuming these things exist in all dimensions, and I become amazed at how pretty the formal structure of quantum mechanics appears in terms of these structures. So as you say of the new axiom added to ZF set theory: Everyone believes these things exist, but we shouldn't let their lack of proof stand in our way. In case you're interested, here's a paper that gives an introduction to the formalism: `http://arxiv.org/abs/0906.2187`.

And yes, I fully believe "God plays dice" with the universe. Our QBism program takes that as the essence of quantum mechanics. See Section 8.1 in the paper cited above.

22-09-09 *The Great Hardy* (to R. Schack)

I just had a conversation with Lucien and he made a very keen observation. By construction, our $\cos\theta$ must be a rational number. Suppose we could give some desideratum so that it is a fixed number independent of n and m (exactly as we are doing with the Cabibbo angle postulate that it is 1/2). Then generally there will be no integer n and m solutions to the equation. He was guessing that $\cos\theta = 0$ and $\cos\theta = 1/2$ might be the only rational solutions.

But, Lord God, how would we prove that?

22-09-09 *Our Diophantine Equation* (to R. Schack)

Let $N = n - 1$ and $M = m - 1$. Then our demand is that there be integers N, M, q, r, with $q \le r$, such that

$$(q - r)N + rM + qM^2 = 0.$$

Wouldn't it be nice if that were a famous Diophantine equation that we could just look up?

Just solving the quadratic equation for M. We get that

$$r^2 + 4q(r - q)N$$

must at least be a perfect square. Which I think means that

$$4q(r - q)N$$

itself must be a perfect square.

Yow, this is too hard for me!! But I think it is almost surely our salvation!!

22-09-09 *Further Point* (to R. Schack)

I had previously said:

> Suppose we could give some desideratum so that it is a fixed number independent of n and m (exactly as we are doing with the Cabibbo angle postulate that it is 1/2).

But we wouldn't even need that further desideratum. The question is simply, when is there a solution. If the only strictly positive one is $\frac{1}{2}$, then we're done.

I've asked Peter Shor if he could help on the Diophantine equation front. No reply yet, but it's the sort of email that Peter actually replies to.

What a great turn of fortune. I'm so glad I had that off-hand conversation with Lucien today.

Cheers, as you wake up to a brighter morning.

22-09-09 *Router Bit* (to N. D. Mermin)

Merminition 182: *I'm happy to bring it along. Have it sent to me at 75 Hickory Road, Ithaca, NY 14850-9606.*

Ah, you mean the place made famous by the 75 Hickory Road Interpretation of Quantum Mechanics?

22-09-09 *Oxford-Austin Cuisine* (to T. Norsen)

I don't believe we've ever met, but I'm looking forward to some productive conversation with you at the PIAF meeting. I know Rob Spekkens says great things about you, and I have very much enjoyed the clarity in your Bell papers: They are great reading. Today I finally started (thinking about) preparing my talk for the meeting. I hope you at least enjoy the title ["Texas-Bavarian Home Cooking: A Quantum Bayesian Reply to Bell's (and Norsen's) la Nouvelle Cuisine," `http://pirsa.org/09090087/`], even if the content ends up appalling you.

I wonder if I might ask a favor of you, even before our first real hello? There are two talks on `pirsa.org` that I'd love you to have under your belt before we start talking in person: One by Chris Timpson, `http://pirsa.org/09080010/`, and one by me `http://pirsa.org/09080018/`. I think they much lay the groundwork for the particular way in which I will disagree with you in my PIAF talk, and I'm quite fearful that it is not something I can really convey properly in the 20 minutes allotted me. But if I could come to some productive conversation with you—learning and explaining and identifying subtle points—that's all I really care about. So, I hope you won't mind giving me this much of a head-start: I think it'd much help for building the necessary translation dictionary we'll need for comparing our worldviews.

23-09-09 *All QBbibbo Angles* (to R. Schack)

You were probably already aware of this, but let me record it since you didn't mention it.

You can find all valid QBibbo angles by rewriting the relation between n and m as such

$$n = m + \frac{2c}{1-c}\frac{m(m-1)}{2}.$$

In order for n to be an integer this means $\frac{2c}{1-c}$ must be an integer. (Take the $m = 2$ case if you have any suspicions.) This completely classifies all possible QBibbo angles. Letting k be that integer, we get

$$n = m + k\frac{m(m-1)}{2}.$$

The three lowest k-value cases give:

- $k = 0$, the classical law of total probability
- $k = 1$, something that looks like real-vector-space quantum mechanics
- $k = 2$, quantum mechanics

Discounting $k = 0$, it is darned frustrating that there is the $k = 1$ case in there below the beautiful quantum solution $k = 2$. Otherwise, we could have used an extremization-style axiom. I've been thinking all day in the back of my head how we might shut the RVS case out. Nothing so far, but 99% of my energy was thrown into Åsa's paper. Indeed we were wrong in our reasoning in the last version of the big paper, but we were oh so close to having the right answer. Is that meaningful? Or at least a hint about the next step.

On the upside, it is kind of cute that we get RVS-QM, when Hardy's axioms shut it out from the beginning, and have not so far found a way to be loosened so as to allow for it. (I know these things from lunch with Hardy and Wootters, the latter being quite interested in the real case.)

I think I remain with the conviction I outlined Sunday that this may be our most "physics filled" postulate. But given that it is nearly at the end of our scale above, maybe I'll reassess that in light of further, yet to be discovered, facts.

You might want to put some of the above in our paper; I don't know how much. In any case, we should thank Hardy at the end along with Myrvold. The conversation yesterday with him inspired much of this.

24-09-09 *Haute Cuisine* (to N. D. Mermin)

What exactly is it that you like so much about Bell's nouvelle cuisine article? In what way does it spook you? What is it in there that should really impress me or spook me? I read it, and I mostly felt nothing. Can you put it in words?

David's Response

> I don't have it with me now, but I'll try to send you some comments before I leave on Saturday. As I remember, it's the combination of the Jarrett argument, which always struck me as the most compelling way of isolating the assumptions behind the conditionally independent representation of joint distributions that underlies Bell inequalities, with Bell's talents as a writer, which I've always very much admired.
>
> More later, I hope. ...
>
> Took a quick look. It's really only two pages: Sections 6.9 and 6.10. Nothing about EPR arguments, determinism, probability 1 being certainty. Just a very general notion of what ought to count as an explanation of correlation. Lambda doesn't have to be EPR elements of reality. It can be attendant circumstances. As I remember my point was that this was the kind of argument that your critical remarks at the beginning of your paper ought to be addressing — not straw men.
>
> And of course he writes beautifully.

24-09-09 *That Bungling Mermin* (to N. D. Mermin)

Have you seen has how this guy `http://arxiv.org/abs/quant-ph/0607057` portrays all your expositions on Bell inequality stuff as bungled misunderstandings? How does his cuisine taste in your mouth?

As you can see, I've started preparing for my talk ...

24-09-09 *That Bungling Mermin, 2* (to N. D. Mermin)

The way he wants to argue (same as Bell but without the charm) is that "local causality" alone implies "local Mermin instruction sets" in an EPR scenario. Then Bell demolishes with his inequality local instruction sets. Consequently local causality all alone is demolished.

I want to say: no, no, no, local causality *alone* does not imply Mermin's instruction sets. There is a principle that you, Norsen (and I think Bell), take as so sacrosanct you don't even notice that it comes into play. It is that probability one assignments for a proposition should imply that the proposition has the truth value of TRUE. This is a significant component of what hides behind the EPR criterion of reality and a part that you accept without question. But we quantum Bayesians don't accept it at all. And therefore we don't have to accept that Bell inequality violations deny local causality. Instead they cap off our quantum Bayesian suspicions about the role of certainty (probability one).

24-09-09 *Timpson's Talk on Sept. 25* (to the QBies)

I hope you guys can come to Timpson's talk tomorrow. He's a really good speaker. Particularly, I thought he did a good job last month in this one `http://pirsa.org/09080010/` which might be a good lead in for tomorrow's talk.

> What would a consistent instrumentalism about quantum mechanics be? Or, why Wigner's friendly after all.
>
> Chris Timpson
> University of Oxford
>
> Instrumentalism about the quantum state is the view that this mathematical object does not serve to represent a component of (non-directly observable) reality, but is rather a device solely for making predictions about the results of experiments. One honest way to be such an instrumentalist is a) to take an ensemble view (= frequentism about quantum probabilities), whereby the state represents predictions for measurement results on ensembles of systems, but not individual systems and b) to assign some specific level for the quantum/classical cut. But what happens if one drops (b), or (a), or both, as some have been inclined to? Can one achieve a consistent view then? A major worry is illustrated by the Wigner's friend scenario: it looks as if it should make a measurable difference where one puts the cut, so how can it be consistent to slide it around (as, e.g., Bohr was wont to)? I'll discuss two main cases: that of Asher Peres' book, which adopts (a) but drops (b); and that of the quantum Bayesians Caves, Fuchs and Shack, which drops both. A view of Peres' sort can I, think, be made consistent, though may look a little strained; the quantum Bayesians' can too, though there are some subtleties (which I shall discuss) about how one should handle Wigner's friend.

25-09-09 *Some Geometry If You Want It* (to N. D. Mermin)

Merminition 183: *What is a Qbist?*

QBism – the foundational program of quantum Bayesianism. (See first sentence of Section 8 of the big paper.)

QBist – a practitioner of QBism.

The QBies – myself, along with my group of three grad students and Åsa our postdoc; maybe Appleby, our long-term visitor, as well.

The QBibbo Angle – 60 degrees; see Assumption 7 and equation 24 of my short paper with Rüdiger.

The QBicle – (a common meeting place for the QBies, yet to be determined)

David's First Reply

So I guess that would make me a QBissel?

David's Second Reply

Bissel is German, that's your problem. It means just a little. (As in: Sprechen Sie Deutsch? Nur ein Bissel.)

QBissel – One who is intrigued by QBism but not yet convinced.

25-09-09 *Why Such Radical Moves?* (to R. W. Spekkens)

It was interesting to watch your reaction again yesterday when I emphasized that in my picture of things, quantum measurement outcomes—the things the particular user of the theory, the agent, is gambling upon—are *personal* experiences, not happenings completely outside the agent. You showed a surprise as if you had never heard the idea before. Thinking about it tonight, I remember you having a similar reaction about a year ago, as if you had never heard of it before at that time either. Yet the personal aspect of the "dings" has been in my thought for at least four years, probably five. And I have presented it consistently so in my talks ever since. It is part of the content of the attached diagram which I know you've seen many times, and it was a significant part of my old tale of the two islands (one of nurturing wives, and one of bad girlfriends) in Konstanz and several talks later. Most recently I thought I gave a very careful statement at the reconstruction meeting, `http://pirsa.org/09080018/`, and I believe even Timpson did me right in `http://pirsa.org/09080010/` by emphasizing that the quantum Bayesians have an "extra layer" of agential involvement over the classical, radical Bayesian (say Richard Jeffrey, Brian Skyrms, etc.). You can confirm for yourself.

It's a learning experience for me: seeing this apparent potential barrier in you, and by extrapolation, to many, many of the ears I have been speaking to over the years. Come to think of it, there are only a few people who have challenged me on this aspect of the worldview. (One is Wayne Myrvold who tells me that I don't really believe it, and one is John Sipe who made the definition "consequence Bayesian" to try to capture the idea.) The lack of more and varied systematic challenges probably demonstrates that the idea isn't even getting to the level of awareness in people's minds where they can say, "ick!" if they want to. There's a conceptual potential barrier that's not even letting the idea get into people's heads. Somehow I'll use this information.

Anyway, yesterday, one of the things you prodded me about was: Why take such a radical stance on the character of measurement outcomes? I said to "preserve locality" among other things—but you talk too fast for me (and drop into attack mode too quickly sometimes), for me to give you more adequate responses. (I don't like that and wish it didn't have to be.) Locality—in my mind, in my usage—is a codeword for the idea that individual things have independent existences / independent essences of each other. It is as Einstein put it in part of the quote you sent out last week: "... it appears to be essential for this arrangement of things introduced in physics that, at a specific time, these things claim an existence independent of one another ..." I like that idea very much, that things "claim an existence independent of one another," so much so that I see Einstein's holy grail of a deterministic field physics—the thing he held to most dearly based on these considerations—as infringing on the very idea. He imagines a world where specifying a field on a boundary surrounding a spacetime point (a purported individual existence) completely determines the field at that point. I say, then the independent existence is only illusory: If you are *determined by*, you are not *independent of*. Period.

I see our quantum Bayesianism as the beginning of a correction in that regard; it embodies at its core the idea of individual existences closed off, in part, from the rest of the world. That is part of the lesson of quantum measurement outcomes as personal experiences. It gives me the means to identify something in physics that really is closed off from everything else. And all of this overconfident and little-justified talk of quantum mechanics *implying* "nonlocality outright" (Norsen's writing style does get under my skin) as very much a threat to the worldview of individual existences. But that is a bit of an aside.

When I set out to write this note, I simply wanted to say that there are more reasons for my adopting the radical move of measurement outcomes as personal experiences. And most particularly is the issue of a consistent account of Wigner's friend from the QBist point of view. I think that is part of the subject of Chris Timpson's talk tomorrow and hope you will go to it. Maybe that would be a good starting point for us to talk about it further some time.

There is a big, tightly knit package in my mind of thoughts on quantum things and a worldview arising from it that I am trying to think my way through. And it has a landscape so different from the quantum foundations chatter I hear around me all the time that it does make it very difficult to speak on the fly. I guess I am just asking for patience.

25-09-09 *The Scale of Engagement* (to H. C. von Baeyer)

Let me tell you the story of the last couple weeks: They have been quite miserable. Rüdiger and I were preparing a Ruedigerized version of Section 6 of our last paper, making it a stand-alone paper and hoping to linearize the thinking to make it clearer. Well, we linearized it indeed! So much so that we caught a flaw in our earlier derivation. Much, much gut wrenching followed, I can tell you, as we tried to salvage the result if not the derivation. And clarity only came very slowly. In the end, we had to face the inevitable—that our result would not be as powerful as it had appeared previously (giving something that looks identical to the quantum expression), but instead something that needs a further (possibly ad hoc) assumption to get to the quantum case.

Still with every cloud there is a silver lining! And now I think there is a greater opportunity than ever to frame the whole issue in terms of just how much the observer is engaged in quantum theory. Please look at the attached paper [`arXiv:0912.4252v1`]. I think you'll this one more of a pleasure to read than previously. (And I am now 99.9% confident that there are no mistakes in it other than grammatical ones!) Here is what leaps out that didn't before. The parameter β in the urgleichung

$$q(j) = \sum_{i=1}^{n} \Big(\alpha p(i) - \beta\Big) r(j|i)$$

signifies the degree to which the observer in quantum mechanics is undetached or engaged—for in the end, it signifies the amount of deviation there is from the law of total probability in this counterfactual games. When $\beta = 0$, we have a detached observer. The keen and interesting thing is quantum mechanics is not the very next step up, but rather the *second* step up in the hierarchy of possibilities. There is a potential theory with observer engagement more than classical but less than quantum. Then there are wild possibilities above quantum. See the discussion after assumptions 6 and 7.

I am now convinced that we ended up with a better playground than we had previously for our deeper foundational ideas. I hope reading this will inspire you, and I hope reinject you with some enthusiasm, so that maybe you'll re-pick back up on our AJP Pauli article. My guess it has slipped under the rug for a while.

I'd like to hear any thoughts you have (on any subject, much less the above).

25-09-09 *Beta is the Parameter to Rule them All* (to R. Schack)

But thank God there weren't nine parameters. See my story to Hans Christian below. [See note to H. C. von Baeyer titled "The Scale of Engagement," from 25-09-09.] In the order of ideas, I am fairly convinced now that it is β, a direct expression of the deviation from the Law of Total Probability, that is the key constant that we should be focusing on. Particularly I have always been reluctant to take m_0 (with the particular meaning as the number of distinguishable states) as the ultimate parameter. It evoked too much of a similarity to classical ideas.

Stream of thought. Associated with a system is a value of β. [Or maybe I could be convinced of α since α increases with dimension. But I sure like that minus sign in front of the β.] Wonder postulate: There are ISU measurements that achieve the ideal of certainty. That there can ever be certainty should remain a miracle from our point of view. β then determines the number of outcomes we can have in such a measurement. Self-consistency forces various rational and integer values. But β in the end rules them all. The constant q chooses which world we are in. Apparently one in which the observer is just a little engaged.

Student just came …

25-09-09 *More On Normativity and a Quantitative Measure on Degrees of Detached Observers* (to C. G. Timpson)

I woke up from my nap thinking I wasn't nearly as generous with you at lunch as I should have been. Your talk was just fantastic, and in point of fact, did in its way help me firm my thoughts on the Wigner friend issue. I very much liked the detailed exposition on "level discipline" (I think you called it) and that really is the key. Also you caused me to want to explore more thoroughly the tension between my "internalist"/"personalist" account of measurement and my respect for a kind of Copernican principle.

If you haven't seen it by now, I should tell you that I've always been in love with this paragraph of John Wheeler's, and with all these QBist explorations, every now and then I start to think I *might* know what it *might* mean:

> How did the universe come into being? Is that some strange, far-off process beyond hope of analysis? Or is the mechanism that comes into play one which all the time shows itself? Of all the signs that testify to "quantum phenomenon" as being the elementary act and building block of existence, none is more striking than its utter absence of internal structure and its untouchability. For a process of creation that can and does operate anywhere, that is more basic than particles or fields or spacetime geometry themselves, a process that reveals and yet hides itself, what could one have dreamed up out of pure imagination more magic and more fitting than this?

You'll see that John has that tension himself—on the one hand the "untouchability" and on the other the "anywhere." One of these days I so hope all of this will really fit together. Could I encourage you to write a proper paper on your talk? It would be so helpful for all of us and could give us a good focal point for thinking things further and pushing things along.

On another matter: Attached is one of my latest. It's an attempt to do much better on Section 6 from the last paper. There is a discussion on the idea of taking the Born rule normatively that might interest you. And also the way I now identify a parameter (q at the end of the paper) that is meant to characterize how "engaged" (meant to be the opposite of Pauli's "detached") an observer is in this theory. Classical has $q = 0$, quantum has $q = 2$. Why q is not 1 identically or strictly > 2, I do not know.

26-09-09 *Logo* (to H. C. von Baeyer)

von Baeyerism 36: *In my wanderings I came across a nice confirmation of our Möbius strip logo. It occurs in the book* Recasting Reality *(Atmanspacher and Primas, eds., Springer 2009) in the article entitled "Complementarity of Mind and Matter" by Primas. He defines: "Here, a Boolean description refers to a Boolean domain where all propositions are either true or false, characterized* *by the postulate of the excluded middle." And then, since a Boolean theory of matter is impossible, he goes on to say: "The most important example to get a globally non-Boolean description is to patch local Boolean descriptions together smoothly." How did we characterize the physics/psychic dichotomy? Locally contradictory, globally identical — Pauli's psychophysical reality combining mind and matter into one world (unus mundus).*

To my surprise I could only find one piece of email on the subject. [See note to D. M. Appleby, dated 26 April 2009, titled "Server Config."] It's below. I recall "locally different / globally the same." Possibly it was "distinct" instead of different. I'm not sure I like "contradictory." Are they contradictory? The thought I'd like to articulate or give some flesh to is that they're different categories (whatever that might mean).

30-09-09 *That Lovely Quote* (to Č. Brukner)

> The value of a [pluriverse], as compared with a universe, lies in this, that where there are cross-currents and warring forces our own strength and will may count and help decide the issue; it is a world where nothing is irrevocably settled, and all action matters. A monistic world is for us a dead world; in such a universe we carry out, willy-nilly, the parts assigned to us by an omnipotent deity or a primeval nebula; and not all our tears can wipe out one word of the eternal script. In a finished universe individuality is a delusion; "in reality," the monist assures us, we are all bits of one mosaic substance. But in an unfinished world we can write some lines of the parts we play, and our choices mould in some measure the future in which we have to live. In such a world we can be free; it is a world of chance, and not of fate; everything is "not quite"; and what we are or do may alter everything.
>
> — Will Durant, describing William James's philosophy

30-09-09 *37 Percent* (to R. W. Spekkens)

You piqued my paranoia: So I counted my transparencies from my talk yesterday. 18 of the 49 were completely new. Two others were major modifications to something old. Minor changes on about five others.

But no doubt, my core ideas are the same as they ever were. . . . same as they ever were . . . same as they ever were . . .

02-10-09 *Experience Primary, Events Secondary?* (to R. Blume-Kohout)

Events as intersections of experiences? Does that phrase or the one in the title bear any resemblance to what you were saying to me yesterday?

This is probably not your kind of reading, but let me put it on the table:

`http://psychclassics.yorku.ca/James/experience.htm`.

03-10-09 *From Dewey to Unger . . .* (to T. Homer-Dixon)

It was good meeting you—I'm back in my office at PI, immediately after the Unger talk . . . scratching my head, wondering what I heard. It could be that I'm just missing crucial vocabulary. In any case, my education in James, Dewey, Schiller, Putnam, Rorty, etc., didn't carry me to the brink of understanding Unger. Maybe better luck to me next time.

Still, one doesn't denigrate opportunities: I'm glad to have met another person in Waterloo interested in pragmatism. In case it might entertain you, let me offer one of my own spoutings on the subject. See section 8.1 of this paper: `http://arxiv.org/abs/0906.2187`. That section is much independent of the remainder and gives some orientation on how I think the physical world is put together along "fallibalist" lines.

06-10-09 *QF/Southwestern Ontario Philosophy of Physics Talk This Friday* (to D. Fraser & J. Berkovitz)

I'm so sorry I'm going to miss this. I don't get back to Waterloo from New Orleans until late afternoon. Good luck Jossi! The more de Finetti these guys are exposed to, the better!

Doreen's Preply

Jossi Berkovitz (U Toronto) will be giving a talk this Friday, October 9th at 11a.m. in the Alice Room:

> The World According to De Finetti
> Jossi Berkovitz (U Toronto)
>
> Abstract: Bruno de Finetti is one of the founding fathers of the subjectivist school of probability, where probabilities are interpreted as rational degrees of belief. His work on the relation between the theorems of the probability calculus and rationality is among the corner stones of modern subjective probability theory. De Finetti maintained that rationality requires that an agent's degrees of belief be coherent. I argue that de Finetti held that the coherence conditions of degrees of belief in events depend on their verifiability. On this view, the familiar constraints of coherence only apply to sets of degrees of belief that could in principle be jointly verified. Accordingly, the constraints that coherence imposes on degrees of belief are generally weaker than the familiar ones. I then consider the implications of this interpretation of de Finetti for probabilities in quantum mechanics, focusing on the EPR/Bohm experiment and Bell's theorem.

06-10-09 *New Orleans, RMP, and Capacities* (to N. D. Mermin)

Sorry I've kept you waiting so long for a reply. After that horrible meeting, I needed a couple of days away from anything professional. Then I jutted off to New Orleans for the next meeting. And I've been kept busy in all kinds of way since. Finally a moment to myself: I'm writing you from the poshest hotel bar I've ever written you from.

Just had dinner with Henry Folse (the Bohr scholar) and had a tour of his amazing house near the Garden District. It was the poshest house I ever visited before the poshest bar. An 1868 home with 14 ft ceilings and 10,000 square feet! The front hall was just amazing—about 12 feet wide and running all the way from the front of the house to the back. The dining room had two massive mirrors taken from an old New Orleans bordello. There was just so much character to the house and gardens. If I had a place like that, my thinking would be of such a higher order!

Anyway, keep the router bit, and thanks for the heads-up about the second referee. I hope to get you the revised Section 6 by Friday evening. I'll probably work on it mostly on Friday's flights (I got upgrades to business class).

On my flight over here, I read 90 pages of Nancy Cartwright's *The Dappled World*. Timpson was right: I do find much in her of value. I want to revise my language of what Hilbert-space dimension signifies—I rather like her terminology of "capacities." True enough it is "real" as I have emphasized before, but it should be thought of as a capacity like mass or charge. Its ontological role is of something of the same flavor. The way I want to emphasize things now is that what quantum mechanics has taught us is that associated with any piece of the physical universe is a previously overlooked capacity. Newton taught us that associated with any piece of the universe is a capacity to attract other bodies, quantified by the body's mass. I'm thinking something like that for Hilbert-space dimension. It's not like I haven't used language like this before, but now it seems to be more entrenched in my big picture of things. Don't know why, but the idea makes me tingle more than it had previously.

I wish you had been there for Friday's panel discussion. It was quite annoying but revealing. Psychologically, that is. This time Valentini called me a solipsist. What is it about these guys?!? Got a note from Norsen Saturday calling me a solipsist again too. I didn't bother to reply. If you want to stay on my good side, never call me a solipsist.

I'm glad you got something out of the meeting and (convinced yourself that) you enjoyed yourself. It meant a lot to me to see you again.

16-10-09 *The More and the Modest* (to L. Hardy)

I started writing the note below while in New Orleans, but only finished it today. It seemed a shame to rewrite the introduction, so I send it as is.

> It don't mean a thing if it ain't got that Zing!
>
> — Dean Rickles

Greetings from the land of the crawdad. This note is to say thanks again for your remarks at the panel discussion Friday. You did something that none of the other ones did—you caused me to think and clarify, rather than piss me off from a display of overt closed-mindedness. It amazes me the way Norsen and Valentini preach to me without understanding an ounce of the way I'm trying to see things. (I just got another note from Norsen yesterday accusing me yet again of solipsism.)

Your point on Hilbert-space dimension on the other hand was a productive one, and thinking about how I should reply to you has helped me realize that my language needs a significant overhaul. With better language, we inevitably get better understanding. Here goes.

I used to ask, "What is real of a quantum system?," and give "Zing" as a placeholder for the answer. What is Zing? The only thing I've been able to comfortably identify for it in the quantum formalism is Hilbert-space dimension. But that certainly can't be enough to get the world going—or at least, I think you would (and did) say something like this. John Sipe once wrote, "the quantum world of this interpretation is a fixed, static thing. It is a frozen, changeless place."

That is *at face value*, there's not enough engine, not enough gears and pinions, in this bare "reality" to account for motion and change and indeterminism and novelty and growth and evolution and . . . make the list just as big as you want . . . all the things we see around us. What is weird is that I agree. Such a minimalist world doesn't even track with what I myself believe. So it becomes a question of why I have doggedly resisted saying more.

I believe I have tracked down the troublemaker in my mode of expression, and it is this. My trouble is *not* that I believe that there is *nothing* in the world, or perhaps a minimalist number of things (too minimal), as the solipsism-chargers seem so obsessed with accusing me of. It is rather that my point of view admits *too many* things into the world—too many things of an independent and self-sustaining reality, things for which there are no equations; realities of which I am only willing to *point* to and say effectively, "Yeah the world includes that too."

This is because the ontology I imagine is the one of the humanist, rather than the trained or indoctrinated scientist. Take Democritus as an example: for him, the universe literally was "atoms and void." That simple phrase was meant to account for all that is. Similarly, the universe Einstein sought was literally meant to be a differentiable manifold supporting the solution to a very clever (though never found) differential equation—all else, even such as the flow of time, was simply illusion. (Recall Mermin's talk at PIAF.) The unifying theme in these two visions is that chairs and thumbs and bricks and all the like from our common experiences are secondary things—effective (operational) descriptions or illusions—having no real, primary existence of their own. For a most relevant example, consider David Wallace's universe. As far as I can tell, it is literally a single quantum state on a Hilbert space. That vector, timelessly unchanging in a rotating frame, is the universe's whole substance. The apparent indeterminism of the quantum world is subordinate to the greater monistic determinism and timelessness of the whole.

But here's the funny thing: It is exactly of Einstein's and Wallace's universes, not my own, that I would say, "the world of this interpretation is a fixed, static thing. It is a frozen, changeless place." To my mind, these are both completely barren visions for the world. I think our distaste for each other's proclivities comes from this: It is a very old philosophical divide, that between the rationalist attitude and the empiricist attitude. It has only become clear to me recently, but at my core I am an extreme empiricist.

Here is the way my friend William James put the distinction when he was in a relatively mild mood:

> By empiricism I mean the tendency which lays most stress on the part, the element, the individual, treats the whole as a collection, and calls the universal an abstraction. By rationalism I mean the tendency to emphasize the universal, and to make the whole prior to the part, in the order both of logic and of being. The temper of rationalism is dogmatic: it willingly claims necessity for its conclusions. Empiricism is more modest, and professes to deal in hypotheses only.

A more full-blooded statement of the issues involved, and just beautiful reading, can be found in a long quote I've plucked out for you from his essay "The Sentiment of Rationality." See subsection at the end of this note. If you find something worth reading in this note of my own composition, I hope you will take the time to read the longer quote of James. In the end, it has become very crucial to my thinking.

Let me give a briefer hint of the issue here. It has to do with the way James put the dangers of rationalism when he was in a fiercer mood:

> Let me give the name of 'vicious abstractionism' to a way of using concepts which may be thus described: We conceive a concrete situation by singling out some salient or

> important feature in it, and classing it under that; then, instead of adding to its previous characters all the positive consequences which the new way of conceiving it may bring, we proceed to use our concept privatively; reducing the originally rich phenomenon to the naked suggestions of that name abstractly taken, treating it as a case of 'nothing but' that, concept, and acting as if all the other characters from out of which the concept is abstracted were expunged. Abstraction, functioning in this way, becomes a means of arrest far more than a means of advance in thought. It mutilates things; it creates difficulties and finds impossibilities; and more than half the trouble that metaphysicians and logicians give themselves over the paradoxes and dialectic puzzles of the universe may, I am convinced, be traced to this relatively simple source. *The viciously privative employment of abstract characters and class names* is, I am persuaded, one of the great original sins of the rationalistic mind.

The way this is relevant to me is the following. Far from thinking the world is an empty place, a place only with me in it. I think it is full of things, overflowing with things. *All* distinct things, from head to toe. And literally so. It is not a world made of six flavors of quarks glued together in various combinations. It is not a world that maps to a single algorithm running on Rob Spekkens' favorite version of Daniel Dennett's mechanistic cellular automaton. It is a world of heads and toes and doorknobs and dreams and ambitions and every kind of particular. (And that is not a typo: It is a world in which even dreams and ambition have substance.) It is a world in which Vivienne Hardy is a distinct entity, not "constructed" of anything else, but a true-blue crucial piece of the universe as it is today—no less crucial than spacetime itself.

In modern parlance, I am not a reductionist. And when my world is judged as empty (of all but me), I claim it is because I am being interpreted from the standpoint of an (explicit or implicit) reductionist worldview. It is true that my envisioned world may be as cockamamie as James' heads of Borneo:

> Taken as it does appear, our universe is to a large extent chaotic. No one single type of connection runs through all the experiences that compose it. If we take space-relations, they fail to connect minds into any regular system. Causes and purposes obtain only among special series of facts. The self-relation seems extremely limited and does not link two different selves together. Prima facie, if you should liken the universe of absolute idealism to an aquarium, a crystal globe in which goldfish are swimming, you would have to compare the empiricist universe to something more like one of those dried human heads with which the Dyaks of Borneo deck their lodges. The skull forms a solid nucleus; but innumerable feathers, leaves, strings, beads, and loose appendices of every description float and dangle from it, and, save that they terminate in it, seem to have nothing to do with one another. Even so my experiences and yours float and dangle, terminating, it is true, in a nucleus of common perception, but for the most part out of sight and irrelevant and unimaginable to one another.

But it is not an *empty* world.

With this as a background, let me now return to Zing, Hilbert-space dimension, and the needed overhaul of my language. I ask, "What is real of a quantum system?" and answer, "its Hilbert-space dimension," but that is a very funny thing to say. There is *so much* that is real of a quantum system, why would I ever say that? I wouldn't say it of Vivienne Hardy, for instance,—I already declared this quite vocally—and she is a perfectly good example of a quantum system. So, what am I really up to?

It is a bit like this: Forget quantum mechanics, and think back to the days when the only physics known was basically Newtonian gravity. Would any Newtonian have ever answered the question, “What is real of a physical system?,” with the declaration, “Only its gravitational mass is real of it.”? Most definitely not. But that is because Newton merely/boldly taught us but a singular thing: That every body in the universe, that every thing that can be carved out from it, had a previously undisclosed capacity—a numerical capacity to (try to) attract every other body in the universe. On the one hand, I say “merely” because looked at in this way, it really is a very *modest* move—modest at least by the lights of the Steven-Weinberg-Stephen-Hawking-theory-of-everything generation: It was no theory of everything—never pretended to be. On the other hand, I say “boldly” because I certainly agree with my friend Hans Christian von Baeyer who wrote in one of his books:

> Great revolutionaries don’t stop at half measures if they can go all the way. For Newton this meant an almost unimaginable widening of the scope of his new-found law. Not only Earth, Sun, and planets attract objects in their vicinity, he conjectured, but all objects, no matter how large or small, attract all other objects, no matter how far distant. It was a proposition of almost reckless boldness, and it changed the way we perceive the world.

And therein lies the key, I think, to how I should modify my language. When I ask myself what have we learned with quantum mechanics, I want to say first and foremost that we have learned how we should more consistently gamble upon the consequences of our interactions with external physical systems. But why this new calculus for gambling? Because quantum mechanics is uncovering that every object in the universe has a previously undisclosed *capacity*.

I would have liked to have said “uncovered,” but at this stage of research I must still settle for “is uncovering”—it is an unfinished project to understand the significance of quantum mechanics in these terms. Hilbert-space dimension, like gravitational mass, is representative of some universal capacity. That’s the real idea. Dimension is a quality a body possesses in a way that, in a QBayesian understanding, it does not “possess” a quantum state. If we conceptually delete an agent gambling upon the consequences of his interactions with a quantum system—the QBist says—we also conceptually delete its quantum state. But there is no reason to believe the system and the system’s capacity are deleted as well.

Capacity for what? That’s where the hard part begins. Sometimes I say the capacity for birth and creation. Sometimes I say the capacity to entertain counterfactuals. Sometimes I say it is a capacity that can be harnessed to aid of computation, as in quantum computation. The truth is, I don’t yet know what I mean in any precise way. I only know that I have a strong inner tug to thinking that the SIC calculus will help reveal a precise idea.

Anyway, I write all this to put the key idea into perspective and to practice a way of speaking that I had not used to any great extent before. [Chris Timpson had pointed out that there are several similarities between the way I speak and the way the philosopher Nancy Cartwright speaks of “capacities.” And on this trip to New Orleans, I have confirmed it is very much so by starting to read her book, *The Dappled World*. So, at least I’m not alone in the world.] You were indeed right to suspect that Hilbert-space dimension doesn’t have enough gears and pinions to get things going, but neither did gravitational mass. Nonetheless, the disclosing of that old capacity—gravitational mass—“changed the way we perceive the world” (von Baeyer). And so I think of our new capacity.

Thus I end this instalment by saying thanks again for pointing out a great deficiency in my choice of words and for consequently causing me to think. I’ll leave you with a sentence that I wrote in this file, but could not quite find a way to use in the essay. It seems a shame to throw it away:

> Quantum mechanics calls out, “I will not be a representative of your monistic dreams!”

When Norsen, Valentini, and Wiseman call me solipsist (or worse), I think it is because they are working from the middle of a monistic dream.

Passage from William James' essay "The Sentiment of Rationality," (Compiled for Lucien)

Part of Immediate Interest

The facts of the world in their sensible diversity are always before us, but our theoretic need is that they should be conceived in a way that reduces their manifoldness to simplicity. Our pleasure at finding that a chaos of facts is the expression of a single underlying fact is like the relief of the musician at resolving a confused mass of sound into melodic or harmonic order. The simplified result is handled with far less mental effort than the original data; and a philosophic conception of nature is thus in no metaphorical sense a labor-saving contrivance. The passion for parsimony, for economy of means in thought, is the philosophic passion *par excellence*; and any character or aspect of the world's phenomena which gathers up their diversity into monotony will gratify that passion, and in the philosopher's mind stand for that essence of things compared with which all their other determinations may by him be overlooked.

More universality or extensiveness is, then, one mark which the philosopher's conceptions must possess. Unless they apply to an enormous number of cases they will not bring him relief. The knowledge of things by their causes, which is often given as a definition of rational knowledge, is useless to him unless the causes converge to a minimum number, while still producing the maximum number of effects. The more multiple then are the instances, the more flowingly does his mind rove from fact to fact. The phenomenal transitions are no real transitions; each item is the same old friend with a slightly altered dress.

Who does not feel the charm of thinking that the moon and the apple are, as far as their relation to the earth goes, identical; of knowing respiration and combustion to be one; of understanding that the balloon rises by the same law whereby the stone sinks; of feeling that the warmth in one's palm when one rubs one's sleeve is identical with the motion which the friction checks; of recognizing the difference between beast and fish to be only a higher degree of that between human father and son; of believing our strength when we climb the mountain or fell the tree to be no other than the strength of the sun's rays which made the corn grow out of which we got our morning meal?

But alongside of this passion for simplification there exists a sister passion, which in some minds—though they perhaps form the minority—is its rival. This is the passion for distinguishing; it is the impulse to be *acquainted* with the parts rather than to comprehend the whole. Loyalty to clearness and integrity of perception, dislike of blurred outlines, of vague identifications, are its characteristics. It loves to recognize particulars in their full completeness, and the more of these it can carry the happier it is. It prefers any amount of incoherence, abruptness, and fragmentariness (so long as the literal details of the separate facts are saved) to an abstract way of conceiving things that, while it simplifies them, dissolves away at the same time their concrete fulness. Clearness and simplicity thus set up rival claims, and make a real dilemma for the thinker.

A man's philosophic attitude is determined by the balance in him of these two cravings. No system of philosophy can hope to be universally accepted among men which grossly violates either need, or entirely subordinates the one to the other. The fate of Spinoza, with his barren union of all things in one substance, on the one hand; that of Hume, with his equally barren "looseness and separateness" of everything, on the other—neither philosopher owning any strict and systematic disciples today, each being to posterity a warning as well as a stimulus—show us that the only possible philosophy must be a compromise between an abstract monotony and a concrete heterogeneity. But the only way to mediate between diversity and unity is to class the diverse items as cases of a common essence which you discover in them. Classification of things into extensive "kinds" is thus the first step; and classification of their relations and conduct into extensive "laws" is the last step, in their philosophic unification. A completed theoretic philosophy can thus never be anything more than a completed classification of the world's ingredients; and its results must always be abstract, since the basis of every classification is the abstract essence embedded in the living fact—the rest of the living fact being for the time ignored by the classifier. This means that none of our explanations are complete. They subsume things under heads wider or more familiar; but the last heads, whether of things or of their connections, are mere abstract genera, data which we just find in things and write down.

When, for example, we think that we have rationally explained the connection of the facts A and B by classing both under their common attribute x, it is obvious that we have really explained only so much of these items as *is* x. To explain the connection of choke-damp and suffocation by the lack of oxygen is to leave untouched all the other peculiarities both of choke-damp and of suffocation—such as convulsions and agony on the one hand, density and explosibility on the other. In a word, so far as A and B contain l, m, n, and o, p, q, respectively, in addition to x, they are not explained by x. Each additional particularity makes its distinct appeal. A single explanation of a fact only explains it from a single point of view. The entire fact is not accounted for until each and all of its characters have been classed with their likes elsewhere. To apply this now to the case of the universe, we see that the explanation of the world by molecular movements explains it only so far as it actually *is* such movements. To invoke the "Unknowable" explains only so much as is unknowable, "Thought" only so much as is thought, "God" only so much as is God. *Which* thought? *Which* God?—are questions that have to be answered by bringing in again the residual data from which the general term was abstracted. All those data that cannot be analytically identified with the attribute invoked as universal principle, remain as independent kinds or natures, associated empirically with the said attribute but devoid of rational kinship with it.

Hence the unsatisfactoriness of all our speculations. On the one hand, so far as they retain any multiplicity in their terms, they fail to get us out of the empirical sand-heap world; on the other, so far as they eliminate multiplicity, the practical man despises their empty barrenness. The most they can say is that the elements of the world are such and such, and that each is identical with itself wherever found; but the question Where is it found? the practical man is left to answer by his own wit. Which, of all the essences, shall here and now be held the essence of this concrete thing, the fundamental philosophy never attempts to decide. We are thus led to the conclusion that the simple classification of things is, on the one hand, the best possible theoretic philosophy, but is, on the other, a most miserable and inadequate substitute for the fulness of the truth. It is a monstrous abridgment of life, which, like all abridgments, is got by the absolute loss and casting out of real matter. This is why so few human beings truly care for philosophy. The particular determinations which she ignores are the real matter exciting needs, quite as potent and authoritative as hers. What does the moral enthusiast care for philosophical ethics? Why does the *Æsthetik* of every German philosopher appear to the artist an abomination of desolation?

> Grau, teurer Freund, ist alle Theorie
> Und grün des Lebens goldner Baum.

The entire man, who feels all needs by turns, will take nothing as an equivalent for life but the fulness of living itself. Since the essences of things are as a matter of fact disseminated through the whole extent of time and space, it is in their spread-outness and alternation that he will enjoy them. When weary of the concrete clash and dust and pettiness, he will refresh himself by a bath in the eternal springs, or fortify himself by a look at the immutable natures. But he will only be a visitor, not a dweller, in the region; he will never carry the philosophic yoke upon his shoulders, and when tired of the gray monotony of her problems and insipid spaciousness of her results, will always escape gleefully into the teeming and dramatic richness of the concrete world.

Of Secondary Interest to the Present Discussion, but Worth Reading If You've Gotten This Far and Have Nothing Better To Do

So our study turns back here to its beginning. Every way of classifying a thing is but a way of handling it for some particular purpose. Conceptions, "kinds," are teleological instruments. No abstract concept can be a valid substitute for a concrete reality except with reference to a particular interest in the conceiver. The interest of theoretic rationality, the relief of identification, is but one of a thousand human purposes. When others rear their heads, it must pack up its little bundle and retire till its turn recurs. The exaggerated dignity and value that philosophers have claimed for their solutions is thus greatly reduced. The only virtue their theoretic conception need have is simplicity, and a simple conception is an equivalent for the world only so far as the world is simple—the world meanwhile, whatever simplicity it may harbor, being also a mightily complex affair. Enough simplicity remains, however, and enough urgency in our craving to reach it, to make the theoretic function one of the most invincible of human impulses. The quest of the fewest elements of things is an ideal that some will follow, as long as there are men to think at all.

But suppose the goal attained. Suppose that at last we have a system unified in the sense that has been explained. Our world can now be conceived simply, and our mind enjoys the relief. Our universal concept has made the concrete chaos rational. But now I ask, Can that which is the ground of rationality in all else be itself properly called rational? It would seem at first sight that it might. One is tempted at any rate to say that, since the craving for rationality is appeased by the identification of one thing with another, a datum which left nothing else outstanding might quench that craving definitively, or be rational *in se*. No otherness being left to annoy us, we should sit down at peace. In other words, as the theoretic tranquillity of the boor results from his spinning no further considerations about his chaotic universe, so any datum whatever (provided it were simple, clear, and ultimate) ought to banish puzzle from the universe of the philosopher and confer peace, inasmuch as there would then be for him absolutely no further considerations to spin.

This in fact is what some persons think. Professor Bain says —

> A difficulty is solved, a mystery unriddled, when it can be shown to resemble something else; to be an example of a fact already known. Mystery is isolation, exception, or it may be apparent contradiction: the resolution of the mystery is found in assimilation, identity, fraternity. When all things are assimilated, so far as assimilation can go, so far as likeness holds, there is an end to explanation; there is an end to what the mind can do, or can intelligently desire . . . . The path of science as exhibited in modern ages is toward generality, wider and wider, until we reach the highest, the widest laws of every department of things; there explanation is finished, mystery ends, perfect vision is gained.

But, unfortunately, this first answer will not hold. Our mind is so wedded to the process of seeing an *other* beside every item of its experience, that when the notion of an absolute datum is presented to it, it goes through, its usual procedure and remains pointing at the void beyond, as if in that lay further matter for contemplation. In short, it spins for itself the further positive consideration of a nonentity enveloping the being of its datum; and as that leads nowhere, back recoils the thought toward its datum again. But there is no natural bridge between nonentity and this particular datum, and the thought stands oscillating to and fro, wondering "Why was there anything but nonentity; why just this universal datum and not another?" and finds no end, in wandering mazes lost. Indeed, Bain's words are so untrue that in reflecting men it is just when the attempt to fuse the manifold into a single totality has been most successful, when the conception of the universe as a unique fact is nearest its perfection, that the craving for further explanation, the ontological wonder-sickness, arises in its extremest form. As Schopenhauer says, "The uneasiness which keeps the never-resting clock of metaphysics in motion, is the consciousness that the non-existence of this world is just as possible as its existence."

The notion of nonentity may thus be called the parent of the philosophic craving in its subtilest and profoundest sense. Absolute existence is absolute mystery, for its relations with the nothing remain unmediated to our understanding. One philosopher only has pretended to throw a logical bridge over this chasm. Hegel, by trying to show that nonentity and concrete being are linked together by a series of identities of a synthetic kind, binds everything conceivable into a unity, with no outlying notion to disturb the free rotary circulation of the mind within its bounds. Since such unchecked movement gives the feeling of rationality, he must be held, if he has succeeded, to have eternally and absolutely quenched all rational demands.

But for those who deem Hegel's heroic effort to have failed, nought remains but to confess that when all things have been unified to the supreme degree, the notion of a possible other than the actual may still haunt our imagination and prey upon our system. The bottom of being is left logically opaque to us, as something which we simply come upon and find, and about which (if we wish to act) we should pause and wonder as little as possible. The philosopher's logical tranquillity is thus in essence no other than the boor's. They differ only as to the point at which each refuses to let further considerations upset the absoluteness of the data he assumes. The boor does so immediately, and is liable at any moment to the ravages of many kinds of doubt. The philosopher does not do so till unity has been reached, and is warranted against the inroads of those considerations, but only practically, not essentially, secure from the blighting breath of the ultimate Why? If he cannot exorcize this question, he must

> ignore or blink it, and, assuming the data of his system as something given, and the gift as ultimate, simply proceed to a life of contemplation or of action based on it.

16-10-09 *Degree of Engagement* (to H. C. von Baeyer)

You might also contemplate this transparency from my last talk:

$$Q(D_j) = \left(\frac{1}{2}qd + 1\right) \sum_{i=1}^{n} P(H_i)P(D_j|H_i) - \frac{1}{2}q$$

with $q = 0, 1, 2, \ldots$ (character of the zing) and $d = 2, 3, 4, \ldots$ (value of a beable, how much zing).

For "character of the zing" read "degree of observer engagement" or "degree of observer activation". Or maybe the quantity q as "amount of alchemical potential." Mostly playing with words.

16-10-09 *The Sister Passion and the Shape of F-Theory to Come* (to R. W. Spekkens)

I wrote the note below with Lucien in mind, but I might send it to you as well. [See 16-10-09 note "The More and the Modest" to L. Hardy.] When composing it, I was struck by how much the first three paragraphs of the associated attachment sounded like what I deem of your philosophy of what makes good science. (Tell me if I'm right.) Also, in the actual note (i.e., below, not attached), I further flesh out some thoughts that really, rightly started in a discussion in your office. So, really you deserve some credit as well.

17-10-09 *The More and the Modest, 2* (to N. D. Mermin)

Some reading you might enjoy on a Saturday morning—see below. [See note to L. Hardy, titled "The More and the Modest" and dated 16-10-09.] I'll get back to fixing section 6 in the Revs Mod Phys paper Tuesday, after my visiting brother leaves. It's been hard to focus with the New Orleans meeting and then my brother's visit.

You never did say what you thought of that Weyl quote.

The word is out, by the way, that Grassl and Scott have now proven SICs to exist in dimensions 35 and 48. Two more dimensions in the list now! Infinity can't be all that far away.

17-10-09 *The More and the Modest, 3* (to N. D. Mermin)

I'm the youngest of five: two brothers and two sisters. The order was sister, brother, brother, sister, me. Weyl quote below:

> Finally and above all, it is the essence of the continuum that it cannot be grasped as a rigid existing thing, but only as something which is in the act of an inwardly directed unending process of becoming … . In a given continuum, of course, this process of becoming can have reached only a certain point, i.e. the quantitative relations in an intuitively given piece $\mathcal{S}$ of the world [regarded as a four-dimensional continuum of events] are merely approximate, determinable only with a certain latitude, not merely in consequence of the limited precision of my sense organs and measuring instruments,

> but because they are in themselves afflicted with a sort of vagueness ... . And only "at the end of all time," so to speak, ... would the unending process of becoming $\mathcal{S}$ be completed, and $\mathcal{S}$ sustain in itself that degree of definiteness which mathematical physics postulates as its ideal ... . Thus the rigid pressure of natural causality relaxes, and there remains, without prejudice to the validity of natural laws, room for autonomous decisions, causally absolutely independent of one another, whose locus I consider to be the elementary quanta of matter. These "decisions" are what is actually real in the world.

19-10-09 *Decisions* (to N. D. Mermin)

Merminition 184: *Calling the constituents of the real present "decisions" is a bit strange, though.*

Expand on that a bit if you can. I'm quite attracted to what I think I read of his idea.

19-10-09 *Cartwright* (to M. Tait)

Taitism 1: *I should also say that unlike Chris Timpson, I don't think that imposing a Cartwrightian metaphysics on QBism, or any other ready-made ontology, is necessarily helpful.*

Well, I'm with you on the "ready-made" part. I shouldn't think anybody's system will fit me perfectly. On the other hand, I have now read some of Nancy Cartwright's *Dappled World*, and I think Chris Timpson was right to perceive some similarities between Cartwright and me. You'll see what I mean if you read the note below and the attached. [See 16-10-09 note titled "The More and the Modest" to Lucien Hardy.]

Thanks for your proposal; it was good reading.

19-10-09 *Purple Haze* (to M. Tait)

Taitism 2: *I'm still a little hazy on the notion that the Born rule should be seen as an 'empirical addition' to Bayesian reasoning. It is clear that it is a normative rule that goes beyond Dutch book coherence; it less clear to me how we ought to interpret this additional constraint, though I'm still working through the meatier parts of your paper with Schack 'Quantum Bayesian Coherence'.*

Well, I'll make no bones about it: I'm hazy as well. There is however a slightly better discussion in the new (attached) paper. [See `arXiv:0912.4252v1`.] It'd be great if you could contribute to getting these ideas straight.

Also, there was quite a mistake (a technical one) in Section 6 of the bigger paper. That is fixed in the attached one. I still need to modify the big one and re-post. Anyway, fixing the mistake has led to some really good stuff: A new parameter crops up that I like to think of as quantifying the degree to which the observer is engaged in quantum mechanics. (By "engaged observer" I am aiming for a contrasting term for Pauli's "detached observer".) See other attachment for a quick illustration:

$$p(D_j) = \left(1 + \frac{1}{2}qd\right) \sum_i p(H_i)p(D_j|H_i) - \frac{1}{2}q \,,$$

where $q = 0, 1, 2, \ldots$ signifies the "character of the zing," and $d = 2, 3, 4, \ldots$ signifies the "value of a (local) beable, how much zing." [See also 25-09-09 note titled "The Scale of Engagement" to H. C. von Baeyer.]

20-10-09 *Howard vs Jammer* (to W. C. Myrvold)

Remember our discussion on Don Howard's versus Max Jammer's version of the Einstein-Ehrenfest conversation. See Don's discussion at:

`http://www.nd.edu/~dhoward1/Early%20History%20of%20Entanglement/sld026.html`.

I think you were right: Don definitely wins.

20-10-09 *My First Dean Rickles Quote* (to D. Rickles)

You'll now find yourself immortally samizdatized. You can find it here:

`http://www.perimeterinstitute.ca/personal/cfuchs/nSamizdat-2.pdf`

starting at page 785 of text (page 813 wrt the raw pdf page numbering), in a note titled, "The More and the Modest." [See 16-10-09 note "The More and the Modest" to L. Hardy.]

Does this capture a little bit of (or have any overlap with) the way you were trying to defend me against Valentini?

Dean's Reply

> I'm deeply honoured.
>
> The 'more' versus 'modest' distinction hits the nail on the head actually. I was thinking about (what I think is) an analogous situation in modal logic, where you have your basic propositional calculus together with operators, including a modal operator. You define rules for these things (specifying when you have a well formed formula). Quantum mechanics can be set up initially like this: a formal schema. The job of interpretation is to latch this on to something. In modal logic the formal system can latch on to a range of things that are related only by their functional relations. For example, you might think in terms of possible worlds, of states in a computer program, of temporal instants, etc. These provide the semantics: the interpretation. They can all satisfy the basic formal schema, but they are obviously very different beasts. And indeed, some semantics (e.g. states in a computer program) seem more modest than others (e.g. possible worlds).
>
> This reminded me of what was going on in the debate you and Rüdiger were having with Anthony. You were saying: the formal system isn't latching on to the stuff "out there, hidden from view" (or it is only in some very general sense: Hilbert space dimension) and Anthony was saying, No, it Is precisely latching onto stuff out there and hidden from view. One is indeed more Modest and one is More: but both satisfy everything that needs to be satisfied, formally and empirically. One says QM is limited in what it can say about "the world"; one doesn't.

21-10-09 *Since It's My Birthday . . .* (to H. C. von Baeyer)

Since it's my birthday, and I'm feeling myself get older by the minute—very, very finite today—I'll feel free to try to stoke your coals again.

Adding to the note I had sent you last month [see note to H. C. von Baeyer dated 25-09-09, titled "The Scale of Engagement"], I'll remind you of that cool Pauli quote where he mentions a "degree of detachment of the observer." It is quite nice.

W. Pauli, letter to Niels Bohr, dated 11 March 1955, photocopy obtained from the Niels Bohr Institute via Henry Folse.

Dear Bohr,

I find your letter of March 2nd very youthfull, which is just the reason that it is not easy for me to answer. Although we have the same view "as regards the fundamental physical problems which fall within the scope of the present quantum mechanical formalism" and although I agree with some parts of your letter, the situation is now complicated by your use in a publication of a phrase like "detached observer" (without comment!) which I used already in some publications in a very different way. I believe that this should be better avoided to prevent a confusion of the readers[208] and I don't cling at all to particular words myself. I also felt, already before your letter arrived, that my brief characterisation of the observer in quantum theory as "non-detached" is in one important respect misleading. As is well known to both of us, it is essential in quantum mechanics that the apparatus can be described by classical concepts. Therefore the observer is always entirely detached to the *results* of his observations (marks on photographic plates etc.), just as he is in classical physics. I called him, however in quantum physics "non-detached", when he chooses his experimental arrangements.[209]

I shall try to make my point logically clear, by defining my concepts, replacing hereby the disputed phrase by other words. As I was mostly interested in the question, *how much informative reference to the observer an objective description contains*, I am emphasizing that a communication contains in general *informations on the observing subject*.

Without particularly discussing the separation between a subject and the informations about subjects (given by themself or by other persons), which can occur as elements of an "objective description", I introduced a concept "degree of detachment of the observer" in a scientific theory to be judged on the kind and measure of informative reference to the observer, which this description contains. For the objective character of this description it is of course sufficient, that every individual observer can be replaced by every other one which fullfills the same conditions and obeys the same rules. In this sense I call a referency to experimental conditions an "information on the observer" (though an impersonal one), and the establishment of an experimental arrangement fulfilling specified conditions an "action of the observer"—of course not of an individual observer but of "the observer" in general.

In physics I speak of a detached observer in a general conceptual description or explanation only then, *if it does not contain any explicit reference to the actions or the knowledge of the observer.* The ideal, that this should be so, I call now "the ideal (E)" in honor of Einstein. Historically it has its origin in celestial mechanics.

There is an important *agreement* between us that we find Einstein not consequent in this formulation of the "ideal E". Indeed, there is no a priori reason whatsoever to introduce here a difference between the *motion* of the observer on the one hand, and the realization of specified experimental conditions by the observer on the other hand. If Einstein were consequent he had to "forbid" also the word coordinate system in physics (as not being objective). That the situation in quantum mechanics has a

[208] An explaining remark about it in your *new* article would be most welcome!

[209] I still believe today that this more restricted use of my terminology is very good and that it has been unhappily obscured in your article in a non-logical way!

deep similarity with the situation in relativity is already shown by the application of mathematical groups of transformation in the physical laws in both cases.

In this way I reached the conclusion to distinguish sharply between the "ideal of an objective description" (meaning science) on the one hand (which I warmly supported just as you do) and the "ideal of the detached observer" on the other hand (which I rejected as much too narrow).

What really matters for me is not the word "detached", but the more active role of the observer in quantum physics, which is already implied in your [constatation?] of the "indivisibility of the phenomena and the essential irreversibility involved in the very concept of observation". According to quantum physics the observer has indeed a new relation to the physical events around him in comparison with the classical observer, who is merely a spectator: The experimental arrangement freely chosen by the observer lets appear *single* events *not* determined by laws, the ensembles of which are governed by *statistical* laws.[210] It is not relevant to me, if you say the same thing using *different* terminologies (but please use [essentially?] different words than I). They will only confirm my statements again as all these statements on the observer are part of an "objective description".

I confess, that very different from you, I do find sometimes scientific inspiration in mysticism[211] (if you believe that I am in danger, please let me know), but this is counterbalanced by an *immediate* sense for mathematics. The result of both seems to be my kind of physics, whilst I consider epistemology merely as a logical comment to the application of mathematics in physics.[212] Thus when I read a sentence as "how to eliminate subjective elements in the account of experience" my immediate association is "group theory" which then determines my whole reaction to your letter. Although the first step to "objectivity" is sometimes a kind of "separation", this task excites in myself the vivid picture of a superior common order to which all subjects are subjected, mathematically represented by the "laws of transformations" as the key of the "map", of which all subjects are "elements".

I hope that it will be possible to find a terminology which will turn out to be satisfactory for both of us, but it is no hurry with it. I propose to resume this discussion only when your new article will be ready, which I am eagerly awaiting. It will show me your terminologies in more general cases of objective descriptions, of which I am most interested in the application to biology, in connection with your new expression "natural evolution".

From March 16th till about 27th I am away in Germany and Holland and when I come back I hope either to see you or to hear from you (I wrote to Basel to get informations on your lecture there).[213]

Hoping that you will in the future (just as I do myself) enjoy the enrichment coming from the different kind of access to science by different scientists, expressed in different, but not contradicting terminologies, I am sending, also in the name of Franca, all good

[210] In this way we obtain just the logical foundations of an "*objective* description" of the incidents (Ein begriffe) which the quantum mechanical observer makes within his surroundings with his experimental arrangements. Attention: there is *no* logical contradiction between a word like "trouble" and a possibility of its objective observation and description.

[211] By the way: the "Unity" of everything has always been one of the most prominent ideas of all mystics.

[212] We are here *both* in our letter in a realm of information on the writing subject, which do *not* belong to the "objective content of the communications".

[213] Meanwhile I heard from P. Huber in Basel, [Fierz is in the United States], that your lecture there is on March 30. On this date I am very glad, because I shall be back from my trip by then. Paa Gensje!

wishes to yourself, to Margrethe and to the whole family,

as yours complementary old
W. Pauli

21-10-09 *All the Things that Got in My Way* (to R. Schack)

Here is the question that has been haunting me since yesterday's drive to Guelph. Suppose I judge two systems to be of Hilbert-space dimensions d_1 and d_2, and that they are each localized in space, a distance r from each other. Other than that, I make no commitments in what I think of them. I.e., whether they are spin systems, elaborate multi-level quantum dots, a combination of the two things, caffeine molecules, ion traps, etc., etc. Just "raw" Hilbert spaces. What further things should I judge of them, even with this minuscule, isolated information?

21-10-09 *PI/FQXI Workshop on Laws of Nature (May 2010)* (to S. Weinstein & D. H. Wolpert)

Sorry for the long absence.

I'm not as impressed with Unger as Lee is: I tried reading his *Pragmatism Unbound* and he just impressed me as an amateur who like to use big words and confusing constructions more than anything. In the end I got less than halfway through it. [You guys do know, or should know, I try to read everything there is on pragmatism.] I had a similar reaction at his recent talk at CIGI—I didn't understand a single word of it; I didn't even know what it was about ... though maybe that's just ignorance on my part. Maybe he does better in this video blog `http://www.cigionline.org/blogs/2009/10/roberto-unger-cigi09-video-blog`. Tell me what you think. STILL—with regard to my own leanings with regard to these "law without law" issues —I can certify that at least his heart is in the right place. Thus I don't see any harm in inviting him, particularly if his presence will help Lee be a more effective cheerleader.

Concerning Hacking, I'm writing him again right now.

Concerning Nancy Cartwright, I finally took the time to read her book *The Dappled World*—I have never read any of her, despite Timpson's urging. And I find her truly interesting, and I would guess that she's got quite a unique point of view with respect to the other participants. My sense of adventure says, "She should certainly be invited, and if we have the budget why not?"

22-10-09 *Coming of Age with Quantum Information* (to S. Capelin)

Capelinism 4 : *I was wondering where we stand with your book. the main thing we're still in need of before we can hand the book over to production is an idea for the front cover.*

I tried googling Quantum Computer Images and came up with some interesting pictures. You could try it. Given the problems we're having finding something striking and suitable, how would you feel about using something like that?

I came to a standstill precisely because of the issue of the cover. (And to be honest, because of several other things that have taken my time as well.) But having wine with my brother visiting the other night may have led to a potentially viable idea. What would you think about doing something with the image on my webpage. (Using it as a core with perhaps some other things around it or in the background or vice versa or something.) That's a photo my brother took of me when I was about 11 or 12. He still has the actual photo; so we could get a higher version. ... I know you'll be "brutally honest" so I'm bracing myself ...

22-10-09 *QBism House Draft* (to N. Waxman)

Attached is the result of my day's labor. My LaTeX program shows 920 words; that's probably not exactly right, but is probably pretty close. Be honest in telling me what you think: It won't hurt my feelings, but you may find me being a stubborn old fart if I have a vested interest in this or that phrase you'd like to see dashed. If you think I should cut it some I can work at it (cutting part of the details of Kiki's reconstruction, or our research group's projects, or some of the big quote). But, of course, I like the balance of the essay as it is now—wouldn't have written that way otherwise—and if I can get away with keeping it mostly intact, I'd like to do that. But I certainly understand your space limitations.

Thanks for encouraging me on this. It was satisfying to write, and your enthusiasm flatters me. (I like to be flattered.)

QBism House Opens for Business

Ideas, like children, need homes where they can be loved, nurtured, and raised to independence. PI researcher Chris Fuchs brought an idea to Waterloo that he feels finally has a proper home. The home is called QBism House, and the idea, if it can be put in a few words, is that a consistent foundation for quantum mechanics reveals our universe as no universe at all, but a *pluriverse* instead. It is the sort of world the philosopher William James described as a "republican banquet ... where all the qualities of being respect one another's personal sacredness, yet sit at the common table of space and time." It is a world of "partially independent powers [where] each detail must come and be actually given, before, in any special sense, it can be said to be determined at all." Will Durant wrote in his masterful history of philosophy:

> The value of a [pluriverse] as compared with a universe, lies in this, that where there are cross-currents and warring forces our own strength and will may count and help decide the issue; it is a world where nothing is irrevocably settled, and all action matters. A monistic world is for us a dead world; in such a universe we carry out, willy-nilly, the parts assigned to us by an omnipotent deity or a primeval nebula; and not all our tears can wipe out one word of the eternal script. In a finished universe individuality is a delusion; "in reality," the monist assures us, we are all bits of one mosaic substance. But in an unfinished world we can write some lines of the parts we play, and our choices mould in some measure the future in which we have to live. In such a world we can be free; it is a world of chance, and not of fate; everything is "not quite"; and what we are or do may alter everything.

Take an 1886 home with 10 and 12 foot ceilings, the willpower of Kiki Fuchs to restore it to its historical grandeur, a good carpenter to build a library of solid-oak bookshelves to house nearly 1,000 books on this subject, a covered porch and a chalkboard to discuss these matters at length in the warm summer air, and one has the base for some fantastic, new physics. The house is called QBism House in honor of its "quantum Bayesian" heritage—a certain point of view about quantum mechanics developed by Fuchs, along with Carlton Caves, Rüdiger Schack, Marcus Appleby, and Howard Barnum. From that view, a quantum state is not a real thing, like a rock or a tree or a quark, but "a biological function, a means of orientation in life, of enabling and facilitating action, of taking account of reality and dominating it." Without doubt, this is a soft-edged idea, but it is one with a sharply defined mathematical core, and it is the latter that the research program of quantum Bayesianism is about. Still, sharp cores and soft edges complement each other, much like the sharp glassed lines of Perimeter Institute and the curlicued Victorian corbels of QBism House.

Making the home young again, while preserving its memories and wisdom, has been a labor of love for Kiki Fuchs. The walls had to be opened to replace the rusting pipes and the early-century electrical wiring; the chimneys had to be reconstructed from scratch; the basement had to be closed to the elements it had been subjected for years; crushed sewer pipes dug up and replaced; walls stripped of wallpaper and repainted; floors refinished; kitchen modernized; the dull, crumbling paint on the external walls given full-life Victorian colors; fencing, landscaping, and gardening—the to-do list went on and on for two years. The home that emerged is now a Waterloo landmark.

Bolstered by a grant of $512,000 from the United States Office of Naval Research and PI's contribution of much-valued office space and computer support, Fuchs is building a group to plow ahead on the technical aspects of the QBist project: particularly, developing a good probabilistic representation of quantum states and dynamics by considering the so-called symmetric informationally complete (SIC) quantum measurements. At the moment, the group is busy exploring whether these structures exist in all finite-dimensional Hilbert spaces, what the geometry of quantum-state space looks like when written in these terms, how quantum mechanics itself might be derived from the supposition of their existence, and characterizing the convex theories (generalizations of quantum mechanics) this representation most naturally fits into. All told, the QBies—yes, the QBies—consist of PI visiting researcher Marcus Appleby, associate postdoctoral fellow Åsa Ericsson, University of Waterloo PhD students Hoan Dang and Gelo Tabia, and MSc student Matthew Graydon. The students' desks can be found in room 415 at PI: the QBicle, of course.

This Fall and Winter, the group will meet once a week at PI (at a day and time yet to be settled). But once the weather is warm, the weekly meeting will be on the porch of QBism House, where the ghosts of pragmatist philosophers past (William James, John Dewey, and F. C. S. Schiller) can listen in with satisfaction about how their ideas of an unfinished, malleable world take a more exact form with the help of modern quantum mechanics. Anyone at PI is welcome to join the meetings, research, and discussion. The QBies and QBism House are open for business!

23-10-09 *SICs and Reality* (to C. M. Caves)

Strange question, coming from you at least. I got the impression that you had really gotten the point of the big paper with Rüdiger. (I'm now depressed a little bit.) Let me attach another attempt at explanation: This one is predominantly from Rüdiger's beautifully crisp pen.

The role of a SIC in these diagrams is purely as a counterfactual (an "action" that could be taken on the system but isn't). The idea is that the Born rule *supplements* the usual rules of probability with a coherence-like (or Dutch-book-style) rule for: How probabilities should be related between a factual situation and a counterfactual one.

There is no implication here that the SIC elements should be thought of as representing potential "elements of reality" in the EPR sense. (I.e., that there is one TRUE one of the d^2 potential ones, maybe not known, but TRUE nonetheless.) Indeed, if they were to be thought of in that way, then one should relate the factual and the counterfactual via the usual law of total probability: One might say that usual Dutch-book coherence requires it.

The agent is involved in bringing about measurement outcomes in this picture, just as much as he has always been for me. The measurement "on the ground" is a factual *action* that the agent takes upon the system; the measurement "in the sky" is a counterfactual *action*. No self-supporting hidden variables here: Outcomes that come about, come about because of the agent's actions.

With regard to another of your points: One should not think of the SICs as supreme in any way over other informationally complete measurements—instead, only as convenient. They should be thought of as a convenient "coordinate system for the problem at hand." Here's the way I put it in an abstract once:

> As physicists, we have become accustomed to the idea that a theory's content is always most transparent when written in coordinate-free language. But sometimes the choice of a good coordinate system is very useful for settling deep conceptual issues. Think of how Eddington-Finkelstein coordinates settled the longstanding question of whether the event horizon of a Schwarzschild black hole corresponds to a real spacetime singularity or not. Similarly we believe for an information-oriented or Bayesian approach to quantum foundations: That one good coordinate system may (eventually!) be worth more than a hundred blue-in-the-face arguments.

And here's the way I explained a related point to a student here:

> The point of all the various representations of quantum mechanics (quasi-probability reps, as well as things like Heisenberg vs. Schrödinger picture issues and even path-integral formulations), is that they give a means for isolating or emphasizing one or another aspect of the theory—they help bring a particular aspect into plain view, even if all the representations are logically equivalent. In our case, we want to bring into plain view (and try to make compelling) the idea that quantum mechanics is an *addition* to Bayesian probability, not a generalization of it. With that goal in mind, the SIC representation has always struck me as particularly powerful tool. With it, one can see the Born Rule as "really" a *function* of a usage of the Law of Total Probability in another context (one different than the actual). That feature, as far as I can tell, does not leap out in the same way from the more general "deformed probability representations" you explore in your papers with Joseph. That in a nutshell is the reason for my love affair with SICs.

The SICs just emphasize and make clear the point that I want made. At the end of the day—after all our foundational worries are overcome—they can be thrown away as mere scaffolding.

Does that clarify anything for you? Did I miss something that you think is a more important point than I've addressed?

I think I lay out the whole program particularly clearly in these two talks: `http://pirsa.org/09080018/` and `http://pirsa.org/09090087/`. Probably much better than anything I could write to you. I'd be very flattered if you'd watch them, and even give me feedback (good and bad, though keep in mind the weight watcher's thing ... don't make fun of me). [Sometimes Firefox doesn't work so well with these files; if you have any trouble—like not having the pictures of my transparencies, etc—change to Internet Explorer.] Do they help clarify the worldview (that I partially ascribe to you, as you'll see)?

23-10-09 *QBism House Draft, 2* (to N. Waxman)

Waxmania 2: *Attached is an version of QBism House, with my proposed edits. These aim to focus the piece more on the ideas of QBism House, while still paying homage to the work of physical recreation involved. I also moved the Durant quote to become a stand-alone "sidebar" item. One other question I have is "authorship"—I'd think it quite logical to adjust the 3rd person references to first, and have you attributed as the author of the piece, unless you're uncomfortable with this in any way. Just let me know your preference.*

My first reaction is that it doesn't sound like me anymore. (First sentences and first paragraphs are always very powerful things for me; when I see changes there I get spooked right away.) When do you really need the final draft? I'd rather give you a reasoned reply, rather than an emotional reaction, and it'll probably take me a few hours to get my head in the right place. But I'll work by your deadlines.

24-10-09 *Dimension as Capacity* (to D. M. Appleby)

How are you feeling today? I hope better, and I hope you've taken my advice to relax some.

I was feeling sentimental this morning, so I had a look back at the introduction and concluding section of this paper: `http://arxiv.org/abs/quant-ph/0404122` where I first start thinking out loud of dimension as a kind of capacity. I also cryptically hint at a connection between dimensionality and gravitational concerns. As long as you're relaxing, you might join me in on these wild musings if you wish.

Get well!

Marcus's Reply

I am certainly feeling better than I did yesterday, perhaps because I did take your advice to relax. Though it had got to the point where I didn't have much choice: I couldn't have worked even if I had wanted to. But this afternoon I decided I felt sufficiently reinvigorated to come into PI to see if I could do some work. Which is when I looked at my email and found your two notes.

Let me say first of all that what you said about Hilbert space dimension and the holographic principle really struck a chord in me. I have the strong sense that there is something there. But what exactly? How to take it forward? —Here I struggle. What follows is just a few incoherent thoughts. I am going to ramble, in other words. Because rambling is all I can do.

I like your story about the guy who asked "what is energy?" It is a very good question. It is curious, however, that most people would instinctively agree with your assessment that this is an easier question than "what is Hilbert space dimension?" People think they know what energy is. At least I assume they do. It is, at any rate, an observable sociological fact that whole conferences will spend days agonizing over Hilbert space. But I have never heard of anyone agonizing about the meaning of energy.

I wonder why that is? It is a priori evident that Hilbert space is a much more obscure concept than energy?

Here I am reminded of my experience as a teacher. How do you explain what energy is to someone who has never met the concept before? —I used to find it very hard. What I usually used to do was to start off with light bulbs. Light bulbs are labeled with their wattage, so most kids have already met the idea of that a 100W bulb produces more light than a 60W one. I used to get them to calculate the relative costs of the different light bulbs: how many pence per hour. Then I would go on to computers, televisions, cookers etc, and the relative costs of those (amazing how few people realize that an electric cooker is vastly more expensive to run than a light bulb). Then I would introduce electric motors, and from that it would be a natural progression to something non-electrical such as car engines. And from that I would introduce them to kinetic energy. Then I would move on to cranes, and introduce potential energy. Then perhaps I would talk about bows and arrows, and medieval siege engines so as to introduce elastic potential energy (the medieval allusion being desirable because I don't want the concept to be tied in their minds to modern high-tech shiny boxes). Then maybe I would talk about Rumford's experiments with boring gun barrels. And so on. In short, I would adopt what in Jamesian language might be called a shrunken head approach. That is, I would introduce them to a richly variegated mass of diverse phenomena, all articulated by this mysterious number, the energy.

I say "mysterious". But is it mysterious? What makes it seem mysterious?

I suppose because one can't give a simple one sentence definition: energy is *this*. End of story. But then one can't give a simple one sentence definition of length. Is length mysterious? Well, actually, yes. It is to me. But clearly it doesn't seem mysterious (the sociological evidence suggests that it doesn't seem mysterious) to the average quantum foundationalist. There isn't a discipline called "length foundations". Or a discipline called "energy foundations". (Perhaps there should be?)

Like I told you, this is an unashamed ramble. I am just putting down thoughts as they occur to me, in a directionless way, without any idea of trying to build a coherent argument.

I suppose energy seems mysterious (not to the average quantum foundationalist, but to the crazed guy in the elevator at the University of Texas, or to me faced with the problem of giving an articulate, intellectually respectable account of it to a class of 16 year olds) because actually the only way I know of introducing it to someone who hasn't met the concept before is by using the kind of shrunken head approach I outlined above.

You said that I was an empirical mathematician: that I had a shrunken head attitude to mathematics. And there is some truth to that. But I am a recent convert. I used to be an out-and-out rationalist in such matters. I used to hate number theory, just because it is all shrunken heads, and no unifying rational theme. My conversion happened as a direct consequence of my work on the SIC problem, which forced me to think about number theory. On the other hand I have been teaching physics for 30 years, and for almost all of that time I was forced to say things which went clean against my rationalist conscience. In particular I was forced to teach energy in a shrunken head spirit, not because I liked it, but because there is no other way of doing it. At least no other way of doing it that I could discover.

I used to particularly dislike the way I found myself forced to start with electrical energy. I felt that logically one ought to begin with the simplest case: projectile motion and the like. Talking about light bulbs raises the question, where the energy is coming from. So logically one shouldn't talk to a physics class about light bulbs until one has introduced them to generators, and currents and voltages and ohm's law and so on and so on. I used to feel it was positively immoral to treat a light bulb as an unexplained primitive. But I had to do it because it works: the kids understand if you start off with light bulbs because that connects more directly with the things they already know.

I suppose what I am trying to say is that my rationalist instincts were pulling me in a reductionist direction: building the complex up out of the simple. But we are organic beings, and we do not learn reductively. Instead we learn by a process of assimilation. Learning is like eating: a process similar to the way a tree sucks nutrients up from its roots, and works them into its already existing structure.

Anyway, as I say, I used to have a really bad conscience about the way I taught energy. So after I had given them my shrunken heads spiel I would ask the class: "So what have I told you about energy?" Can you now say what energy is? —And, of course, they never could. For the very good reason that I couldn't myself. It is exactly because it is impossible to say what energy is that I was forced to teach it in the way I did.

It didn't usually bother them I hadn't told them what energy is. It was *me*—my rationalist conscience—that was bothered. Not them.

Kids are funny, in the questions they ask and the questions they don't. They would often complain that I hadn't explained why two bodies attract with a force proportional to the product of the two masses and inversely proportional to the square of their distance apart. And if I responded with the rhetorical question, whether the biology teacher had explained any of the innumerable number of individual facts of which biology consists, they would think I was cheating. I suppose they take it for granted that it is the job of a physics teacher to explain things, but not the job of a biology teacher.

Perhaps it is the influence of all those popular science programs on TV? All this nonsense about theories of everything has penetrated the consciousness of the average 16 year old, to such an extent that they come to the subject expecting the teacher to explain literally *everything*, with no bald assertions of empirical fact at *all*?

If so it is interesting that they don't seem to have picked up the reductivist disease. Because, it is of course the reductivist bacillus in me that makes me (I use the present tense here because I don't I think I am completely free of the disease even now) unhappy with a shrunken head approach to the concept of energy. But then now I come to think of it reductionism isn't the kind of thing that usually is stressed in popular science programs. I wonder why that is? —Perhaps it is just that claims to know the mind of God are sexy, in a way that reductionism isn't.

Anyway, the kids as they come into the educational system, with only the prejudices they have absorbed from the popular culture, do not, in my experience, usually have a bias towards reductionism. In fact I am not sure they even have the concept of reductionism. And for that reason a shrunken head approach to energy doesn't bother them.

Of course it doesn't bother them. Because when you come right down to it I don't believe an explanation can ever be anything but a shrunken head type of explanation. If Einstein had succeeded in his program he would have been able to say something along the lines of "there just is this object, the stress-energy tensor, and "energy" just is the name we give to the 0-0 component of it". And it is something like that the person with reductionist intellectual tendencies (such as I used to have, and to an extent still do have) always has in mind as the model of how a fundamental physical concept *ought* to be defined. But they are deluding themselves of course, and this I think should be obvious to anyone who has had the job of teaching fundamental physical concepts from the ground up (the word "should" needs to be stressed here: because I was doing that job for many many years before this obvious point actually did occur to me). If you went into a class of 16 year olds and gave them something along the lines of Einstein's ideal definition you would be met with blank stares. They wouldn't have a clue what you were talking about. The statement would be meaningless. And I really do mean *literally* meaningless. It would make no impact at all. It wouldn't even arouse a sense of puzzlement. It would be like presenting a musical score to someone who didn't know how to read music—who didn't even have the concept that it is possible to read music.

Einstein's ideal definition makes sense to someone like the mature Einstein. But it wouldn't make any kind of sense to the immature Einstein. Come to that it probably wouldn't make sense even to the mature Einstein, before Grossman had taught him tensor calculus.

There is only one way for the abstract statements of theoretical physics to acquire meaning, and that is by a long-drawn out process of assimilation, by which the abstract concept acquires numerous connections with the pre-existing body of knowledge and understanding. In short: shrunken heads are unavoidable. People who think otherwise (the majority of our colleagues, I guess) are deluding themselves.

(I say "pre-existing" body of knowledge and understanding because I think the tabula rasa idea of the 18th century empiricists is nonsense. A child grows from a fertilized egg cell. Not from nothing. And similarly with a child's understanding. And, what is more, learning really is a process of *growth*. Not imprinting. The process by which a human being learns is of an observably different nature from the process by which one programs a computer).

Anyway, what has all this to do with the holographic principle and Hilbert space dimension? Possibly nothing. Like I say I feel confused and all I aimed to do was to spout forth, and see what my fingers typed. But now that they have finished typing maybe I can see a connection.

For one thing I suddenly felt much more interested in your emphasis on Hilbert space dimension when you made a connection with entropy (I know you have been doing that for years, but this was the first time I really took it in). It is like the kids and the light bulbs: here is a connection with something I already know.

For another thing. There was a suggestion to my mind that you are introducing length alongside Hilbert space dimension as a kind of conceptual primitive (perhaps I have got you wrong?). Which is fine. I don't mind conceptual primitives at all. The only thing is that, as soon as I think of length, I find myself thinking of time, and as soon as I think of length and time together, I think of differentiable 4 manifolds and there I am, in two blinks of an eye, with the whole block universe nightmare. So length is OK. But I want something to hang on to, to keep myself from sliding down all the way down to the bottom of that horrible slope. So I guess I have had at the back of my mind the last few days the thought that, although it is OK to talk about length (of course it is OK), we have somehow got to find a different twist on it. A new angle, which doesn't descend into differentiable 4 manifolds. And that has kind of got me to asking: how do we *define* length? What is length? —which, of course, is similar to the question "what is energy?" So you can regard the foregoing as a meditation on the question: what sort of definition should we be looking for here? How do we set about defining a fundamental physical concept?

And, finally, for a third thing. I think one of my worries about (to quote from your note to Greg Comer) "just the single, lonely number—the dimension" has always been precisely the fact that it is lonely. I think what I would like is something like the shrunken head definition of energy. A richly textured, multi-faceted phenomenological account.

Maybe. Or maybe not.

I don't actually agree with James that it is *either* rationalism *or* shrunken heads. Can't one contrive to have both?

24-10-09 *Dimension as Capacity, 2* (to D. M. Appleby)

Applebyism 37: *I don't actually agree with James that it is either rationalism or shrunken heads. Can't one contrive to have both?*

I think he does contrive to have both. A simple piece of evidence is in the longer quote I had attached for Lucien. I think you said you hadn't read it. Here are a couple of small excerpts:

> A man's philosophic attitude is determined by the balance in him of these two cravings [rationalism and empiricism]. No system of philosophy can hope to be universally accepted among men which grossly violates either need, or entirely subordinates the one to the other.
>
> Each additional particularity makes its distinct appeal. A single explanation of a fact only explains it from a single point of view. The entire fact is not accounted for until each and all of its characters have been classed with their likes elsewhere. To apply this now to the case of the universe, we see that the explanation of the world by molecular movements explains it only so far as it actually is such movements. To invoke the "Unknowable" explains only so much as is unknowable, "Thought" only so much as is thought, "God" only so much as is God.

In summary: There is nothing wrong with invoking some rationalism. But it explains only so much as is rational.

I'm glad you're starting to feel better. I was actually starting to get a bit worried since I hadn't heard from you in so long.

24-10-09 *Detached Observer . . .* (to H. C. von Baeyer)

I'm not sure what you're asking. Can you make your question more specific?

The first part of the Pauli quote refers to what the philosopher Thomas Nagel famously called "the view from nowhere". Google his book of the same title.

With regard to the second part, it's funny but I found a bit of similarity between it and a quote I read in a James biography I just started reading. (It seems every two years or so, I feel the need to read a new biography of him.) The quote was this: "Individuality is founded in feeling and the recesses of feeling, the darker, blinder strata of character, are the only places in the world in which we catch real fact in the making, and directly perceive how events happen, and how work is actually done."

Does he explain why he finds the NO-view-from-nowhere view "more satisfactory"? That would be interesting to see.

I'm happy to hear you've been dragged back to the subject!!

Hans's Preply

Dear Chris, your persistent encouragement has had the effect of dragging me back to the subject. The price you have to pay is that occasionally I will ask for advice. Here is a snippet from a letter to Bohm — almost the last words before Pauli broke off the correspondence because he thought Bohm was a "fool" (his term in a letter to Fierz):

> Since Descartes it was the ideal of natural philosophy to conceive a system of laws in which an entirely loose and untied observer is looking from outside at a part of the world completely determined by these laws. For me, however, it is much more satisfactory if the laws of nature themselves exclude in principle the possibility even to conceive the disturbances in the observers (sic) own body and own brain connected with his own observations.

This was written in English, so if it's difficult to understand the fault lies with Pauli's command of the language, not with the translator.

Without going into the whole background of this statement, what do you make of it?

Hans's Reply

> Bohm says in the P.S. to his letter of 20 Nov. 1951:
>
> > Finally I shall say that even though we cannot at present correct for the disturbance due to the measuring apparatus, we can conceive of how the human being disturbs the apparatus in precise terms. It is true that such a conception presupposes that the person who conceives of this is left outside the system. ... This means that as in classical physics one can conceive of the part of the world under consideration as existing in a state that is substantially independent of what is going on in the mind of the man who is conceiving of it.
>
> To which Pauli replies on 3 December as I wrote you previously.
>
> I understand Bohm's claim, and Pauli's first sentence. But in his second sentence, why does he focus on a disturbance *in the observer*? Why doesn't he say that the laws of nature should exclude conceiving of the state of the system without including the effect of the observation on *the system* as well as *on the observer*?

25-10-09 *Metaphysical Club* (to D. M. Appleby)

Applebyism 38: *Is it true to say that only one of those guys (Peirce) had any appreciation of physics? It seems clear to me that neither James nor Holmes did. And I think that is significant. If you don't know physics then you are missing something important.*

I think that's probably true. James's real thing was biology/physiology, before psychology. James's father though had much wanted William to go into the sciences. And he at least seemed to have some amount of respect for physics: He once went to England to meet with Faraday, and he was taught by Joseph Henry in Princeton. (You probably don't recall, but John Wheeler was the "Joseph Henry Professor of Physics" at Princeton.)

25-10-09 *Another Factoid* (to D. M. Appleby)

James met with Mach in Prague for four hours of conversation in 1882. He also went one of Mach's lectures on gravity. He wrote to his wife, "I don't think anyone ever gave me so strong an impression of pure intellectual genius. ... He apparently has read everything and thought about everything, and has an absolute simplicity of manner and winningness of smile when his face lights up that are charming."

Sometime later that year or the next, James went to a lecture of Helmholtz on gravity and wrote that he heard Helmholtz, "give the most idiotic lecture I ever listened to."

25-10-09 *More Factoids* (to D. M. Appleby)

Of course, James was in no way a physicist like Peirce truly was. But more factoids from Richardson's biography of James:

p. 51,

> On the opening page of a notebook he started this fall of 1862, William copied down comments that show his new interest in the nature of force. William Grove's *Correlation of Forces* maintains ... William had also been reading Michael Faraday's *Experimental Researches in Chemistry and Physics*. ... [In his notebook] he quoted Faraday: "For my own part, many considerations urge my mind towards the idea of a cause of gravity which is not resident in the particles of matter merely, but conjointly in them and in all space." James, from now on, had a marked interest in physics, especially in questions of energy and force, an interest he encapsulated some time later as "matter is motion, motion is force, force is will."

p. 165,

> But it was science, especially new science and its procedures and assumptions, that now commanded his deepest, steadiest attention. He maintained his interest in Darwin and Darwinism; in 1875 he was reading in modern physics as well. ... In May 1875 James read and reviewed a book called *The Unseen Universe* by physicist and mathematician Peter Guthrie Tait ... and physicist and meteoriologist Balfour Stewart [a book on Maxwell, ether, etc].

[**NOTE:** The spelling of "Qubism" in the title of this note differs markedly from my standard QBism. I am ashamed of this (what surely was a) mistake, but I leave it for historical accuracy.]

Sorry for my tantrum the other day. Scientists with ambitions of writing are like little kids.

Attached is a modified version of my story. I used some of your suggestions, but in a way that made me feel like the whole thing was still coming from my voice. Overall, I was shooting for a kind of artistic effect, rather than journalistic effect. I hope that helps explain some of my extraneous phrases, like "all told," etc. Still, I was able to trim to my satisfaction, and I think to yours. Your version from late last week had 860 words (after all the instructions, etc., were stripped from it). The present version has 858, under the same conditions.

I think I would like to keep the article in third person, but signatureless. For some reason it feels more right to me that way.

Picture coming soon.

Thanks for putting up with me!

QBism House Opens for Business

Ideas, like children, need homes where they can be loved, nurtured, and raised to independence. PI researcher Chris Fuchs brought an idea to Waterloo that he feels finally has a proper home. The home is called QBism House, and the idea, if it can be put in a few words, is that a consistent foundation for quantum mechanics reveals our universe as no universe at all, but a *pluriverse* instead. It is the sort of world the philosopher William James described as a "republican banquet ... where all the qualities of being respect one another's personal sacredness, yet sit at the common table of space and time," a world of "partially independent powers [where] each detail must come and be actually given, before, in any special sense, it can be said to be determined at all."

Take an 1886 home with 10 and 12 foot ceilings, the willpower of Kiki Fuchs to restore it to its historical grandeur, a good carpenter to build a library of solid-oak bookshelves to house nearly 1,000 books on this subject, a covered porch and a chalkboard to discuss these matters at length in the warm summer air, and one has the base for some fantastic, new physics. The house is called QBism House in honor of its "quantum-Bayesian" heritage—a point of view about quantum mechanics developed by Fuchs, along with Carlton Caves, Rüdiger Schack, Marcus Appleby, and Howard Barnum.

In the QBist view, a quantum state is not a real thing, like a rock or a tree or a quark, but "a means of orientation in life, of enabling and facilitating action, of taking account of reality and dominating it" (Tilgher). Without doubt, this is a soft-edged idea, but it is one with a sharply defined mathematical core, and the latter is QBism's research program.

Yet sharp cores and soft edges complement each other, much like the sharp lines of Perimeter Institute and the curlicued Victorian corbels of QBism House. Making the home young again, while preserving its memories and wisdom, has been a labor of love for Kiki Fuchs. The walls had to be opened to replace rusting pipes and early-century electrical wiring; chimneys had to be reconstructed from scratch; floors refinished and the kitchen modernized; the dull, crumbling paint on the exterior refreshed to full-of-life Victorian colors—the work went on for more than two years. The home that emerged is now a Waterloo landmark.

Bolstered by a grant of $512,000 from the United States Office of Naval Research, Fuchs is building a group to plow ahead on the technical aspects of the QBist project, particularly, developing a probabilistic representation of quantum states through so-called symmetric informationally complete (SIC) quantum measurements. At the moment, the group is busy exploring whether these structures exist in all finite-dimensional Hilbert spaces, what the geometry of quantum-state space looks like in such terms, how quantum mechanics itself might be derived from the supposition of SICs, and characterizing the convex theories (generalizations of quantum mechanics) this representation most naturally fits into.

All told, the QBies (yes, the QBies) consist of PI visiting researcher Marcus Appleby, associate postdoctoral fellow Åsa Ericsson, University of Waterloo PhD students Hoan Dang and Gelo Tabia, and MSc student Matthew Graydon. The students' desks can be found in room 415 at PI: the QBicle, of course. This Fall and Winter, the group will meet once a week at PI, Fridays 1:00–3:00. But once the weather is warm, the meeting will be on the porch of QBism House, where the ghosts of pragmatist philosophers past (William James, John Dewey, and F. C. S. Schiller) can listen in with satisfaction about how their ideas of an unfinished, malleable world take a more exact form with the help of modern quantum mechanics.

Anyone at PI is welcome to join the meetings, research, and discussion; contact Chris Fuchs at cfuchs@perimeterinstitute.ca. The QBies and QBism House are open for business!

Boxed Sidebar: The Optimism of Pluralism and Indeterminacy

Will Durant, from his masterful *The Story of Philosophy* (1926):

> The value of a [pluriverse] as compared with a universe, lies in this, that where there are cross-currents and warring forces our own strength and will may count and help decide the issue; it is a world where nothing is irrevocably settled, and all action matters. A monistic world is for us a dead world; in such a universe we carry out, willy-nilly, the parts assigned to us by an omnipotent deity or a primeval nebula; and not all our tears can wipe out one word of the eternal script. In a finished universe individuality is a delusion; "in reality," the monist assures us, we are all bits of one mosaic substance. But in an unfinished world we can write some lines of the parts we play, and our choices mould in some measure the future in which we have to live. In such a world we can be free; it is a world of chance, and not of fate; everything is "not quite"; and what we are or do may alter everything.

Potential Boxed Sidebar: A Pretty Equation

$$q(D_j) = (d+1)\sum_i p(H_i)p(D_j|H_i) - 1$$

This equation is something of a logo for the QBists: It represents the Born Rule when written in SIC terms, rather than in standard quantum-state/measurement-operator terms. $q(D_j)$ is the usual quantum probability for the outcomes of a von Neumann measurement; $p(H_i)$ is the probability for the outcomes of a standardized SIC measurement; $p(D_j|H_i)$ are the conditional probabilities of one measurement outcome given the other; d represents the Hilbert-space dimension of the system in question. To Bayesian eyes, this form is particularly beautiful as it shows the Born Rule to be a subtle variation (with major consequences!) of the old Law of Total Probability.

27-10-09 *Partially Sipe Inspired* (to J. E. Sipe)

Sipesm 12: *Thanks for this! Very interesting ....* [See 16-10-09 note "The More and the Modest" to L. Hardy.]

To perhaps start a discussion on the points you raise here: I have not read anything by Cartwright yet, but how do I distinguish between the kind of "capacity" you are arguing for and the kind of Aristotelian idea of "potentia" that Heisenberg advocated in his later years, and saw embodied in the wave function. Are you, by chance, sleep-walking towards Copenhagen? ☺

Maybe I shouldn't have made the aside in that note to Lucien about Cartwright. Her name apparently carries lots of baggage (she seems to be the first thing everyone with a little philosophical background, like Healey, Timpson, etc., picks up on). Just think of it along the lines of gravitational mass as you normally understand it, as I tried to give an image of in the note.

28-10-09 *Gauge Freedom as Room for Art* (to R. Healey)

Sorry, my mind wasn't completely engaged in our group meeting yesterday: I couldn't seem to tear my mind away from an inequality I wanted to derive. But I did want to make a remark right at the end of the session: As usual I was too late. So here it is just to get it off my chest.

It struck me that the discussion of whether the "equivalence class" was the real thing or not was off the mark with respect to actual physical practice (i.e., actual physicists' practice). When *trying* very hard to solve one problem or another—i.e., not just pontificating on the nature of reality or the character of the world, but actually using the theory to do something—we are often very happy for gauge and coordinate freedoms. These freedoms give the practicing physicist some room for art—they help him solve problems that he might not have been able to solve otherwise. In other words, a theory, among perhaps other things, gives us a catalog of tools for our disposal—tools for actually doing something with the theory. Thinking of it that way, then, for instance, the spacetime manifold shouldn't be thought of as a topological space upon which, *if we wish* we can draw some coordinate charts, but rather is the other way around: It is more literally the collection of charts we might avail ourselves of when trying to work out some problem.

This thought has its origin in the opening lines of an abstract I wrote for a talk some time ago. I'll record part of it here for completeness.

> As physicists, we have become accustomed to the idea that a theory's content is always most transparent when written in coordinate-free language. But sometimes the choice of a good coordinate system is very useful for settling deep conceptual issues. Think of how Eddington-Finkelstein coordinates settled the longstanding question of whether the event horizon of a Schwarzschild black hole corresponds to a real spacetime singularity or not. Similarly we believe for an information-oriented or Bayesian approach to quantum foundations: That one good coordinate system may (eventually!) be worth more than a hundred blue-in-the-face arguments.

John Stachel makes a similar point (about the manifold issue) in one of his historical articles on Einstein, but I don't have it with me at home to quote from it. If anyone wants to see it, I have it in my office.

30-10-09 *Abelard Etc.* (to J. R. Brown)

Abelard doesn't exist anymore, just like Atticus. We went to BMV near the university, and one other one nearby, and then to Steven Temple Books on Queen. The latter guy said he was the last used-book store left on Queen. This is really a shame.

Nonetheless I managed to find 13 books that resonate somewhat with where I want to take things in physics. Attached is a strange little piece on my house, my research group, and my ambitions for the world, written for the PI newsletter. In it you'll find that Durant quote I put up at the very end of the meeting:

> The value of a [pluriverse], as compared with a universe, lies in this, that where there are cross-currents and warring forces our own strength and will may count and

> help decide the issue; it is a world where nothing is irrevocably settled, and all action matters. A monistic world is for us a dead world; in such a universe we carry out, willy-nilly, the parts assigned to us by an omnipotent deity or a primeval nebula; and not all our tears can wipe out one word of the eternal script. In a finished universe individuality is a delusion; "in reality," the monist assures us, we are all bits of one mosaic substance. But in an unfinished world we can write some lines of the parts we play, and our choices mould in some measure the future in which we have to live. In such a world we can be free; it is a world of chance, and not of fate; everything is "not quite"; and what we are or do may alter everything.

Thanks for the radio programs; I'll listen. And thanks for the opportunity for good interaction yesterday.

30-10-09 *My Interiority Complex* (to H. Barnum)

Here's that quote of William James on matter that really moved me:

> To anyone who has ever looked on the face of a dead child or parent the mere fact that matter *could* have taken for a time that precious form, ought to make matter sacred ever after. It makes no difference what the principle of life may be, material or immaterial, matter at any rate co-operates, lends itself to all life's purposes. That beloved incarnation was among matter's possibilities.

Attached are three further quotes by the man that connect to our conversation last night: The theme is that indeterminism is a manifestation of (some kind of notion of) interiority. I say further things on this in connection to QM in Section 8 of `http://arxiv.org/abs/0906.2187`.

Thanks; I had fun last night.

Howard's Reply

> Thanks. That is indeed a powerful quote. It captures something of what I think about the mind-ishness, or perhaps spirit, of matter. I'm not sure, that it is in itself opposed to some kind of compatibilism, or ephiphenomenalism, about mind. In my more happy-with-compatibilism-and-epiphenomenalism/reductionism moods, I used to say to myself that "I *am* that assemblage of matter, so even if it is the evolution of that matter according to deterministic laws that is my doing this, or experiencing that, it is still *me* doing it". I guess I still half-believe that. But still, on that picture, I find it hard to understand why there should be something it is like to be that assemblage of matter. And I think that there is probably something deeply wrong about confusing the picture drawn by the equations, with the thing. The deeper question, though, is whether consciousness and will — interiority — are essentially connected with that gap between the picture drawn by the equations and the thing. I'd like to think it is so, indeed I think it probably is, and that that has something to do with it.
>
> I used to also think that quantum indeterminism, or other probabilistic indeterminism involving probabilities prescribed by a scientific theory, could not help with e.g. the problem of free will, because a free choice is not supposed to be random. It's not an idealized computer-science coin toss. Although the idea that it's more like an idealized classical-physics coin toss—determined, but from the point of view of the theory that involves the probabilities, we just don't know what determines it—is interesting!

I now understand your quantum Bayesian point of view in its present incarnation as perhaps taking something like the point of view that last sentence suggests—that *from the outside point of view* it looks like probabilities, but *from the inside point of view* it looks like choice. That seems quite explicit in what you said last night about "every little thing having some ability to make choices" (apologies if the quote is garbled).

A long time ago, I used to worry that you rejected potentially realist interpretations of the quantum state just on the basis that you wanted room for free will. The idea that quantum probabilities were making room for free will seemed to me a bit dubious because of the view that choices shouldn't be random (see above), but I now think I may have been misguided about that. I also thought that the viability, even if unpleasant, of the relative-state interpretation made it clear that QM wasn't *forcing* us to make room for free will. Now, as you know, I'm more inclined to think relative states is not viable, and some of the above discussion makes me more willing to think that QM might be telling us that the limits to our attempts to take the Nagelian "outside" view are not just manifest in our sense that this is somehow incompatible with the fact that there is—*really is* an inside view—but are manifest in the scientific theory that actually results from our attempts to take this outside view: that theory itself has to make room for interiority. I would really like that to be right. A more fully developed version of this might end up involving a "sewing together of all the perspectives" of the sort I hoped for in my long SHPMP paper. But there I probably wasn't thinking of such a deep connection to metaphysical questions as your view of perspectivity in QM. I just wanted some sense of an overall picture that includes all the perspectives in a consistent way, but in which the "outside" perspective is just one of all these perspectives somehow coexisting, not a possibly nonsensical perspective similar to the ones of beings within the world but "from outside the world". I am not sure you are as concerned with the kind of overall consistency I would still sort of like, though.

31-10-09 *Dennerlein, Sacred Matter, Capacities* (to M. Schlosshauer)

I ran across someone playing the Hammond B3 in my (still largely unexplored) jazz mp3 collection – Barbara Dennerlein – and I thought of you. What I'm hearing sounds like a very different style than you, but it was enough to set the mental wheels in motion on this thoughtful, Fall-leaved morning. I've been up since 7:00 AM, reading on (yet) another biography of James—I seem to do a new one about every two years, following near upon a birthday. This one is Richardson's. Not remarkable so far, but it is helping to remind me of some old things and, here and there, introducing me to a turn of phrase that I might incorporate into my collection. For instance, here's a quote of James that I missed upon my (now ancient) reading of *Pragmatism*, but that very much strikes me now:

> To anyone who has ever looked on the face of a dead child or parent the mere fact that matter *could* have taken for a time that precious form, ought to make matter sacred ever after. It makes no difference what the principle of life may be, material or immaterial, matter at any rate co-operates, lends itself to all life's purposes. That beloved incarnation was among matter's possibilities.

I hope you are doing well and absorbing all the insights into life that only Copenhagen can give.

Below (with an accompanying attachment) is a recent further amble down the QBist path. [See 16-10-09 note to Lucien Hardy titled, "The More and the Modest."]

Just saying hello.

31-10-09 *Thinking of Our Friend . . .* (to R. W. Spekkens)

. . . as I read these words in Richardson's book this morning:

> Every university has around it somewhere one person who is more loved and listened to than most, who tutors and prepares his friends for their exams but who never takes his own, who is generally acknowledged as the most brilliant and gifted of all, who has every gift except the ability to use his gifts. He is the one who never quite finishes, never quite succeeds, never quite writes the great book — a person like Sherlock Holmes's older brother Mycroft (who solves Sherlock's thorniest problems by sheer force of mind without stirring from his chair), or like a member of Melville's choice circle of the Divine Inert who stands wholly, tragically superior to the working world and the arts the working world requires for success and fame. In the American Cambridge of the 1860s and 1870s this figure, the village Socrates who lived in the minds of his great students was Chauncey Wright.

02-11-09 *Furthermore* (to C. Ferrie)

Ferrie-ism 6: *Sciencewise, I've been thinking about a lot of things trying to find a thesis topic. Over the past few days I've been thinking about this quote from Jeffreys (from "Epistemology in Modern Physics", 1941):*

> But in accounts of quantum theory we are presented on the first page with at least $\sqrt{-1}$, and usually with matrices or numbers not satisfying the commutative rules of multiplication. These cannot be necessary. They may be convenient, but if so it should be shown that rules satisfied by the probabilities are such as to make them convenient.

I certainly agree with this. And as you know, I contend that the SICs will help us best in seeing why $\mathrm{GL}(d,\mathbb{C})$ gives the simplest form for the calculus.

Do you have that paper in electronic form? Can I get a copy from you? (I couldn't find it on Google Scholar.)

I have not thought about the Markov stuff before. So, sorry I can't give any guidance here.

By the way, see the flyer I wrote for this month's PI Newsletter. You're welcome to come any of these meetings you wish.

02-11-09 *One Good Rant Deserves Another* (to M. Schlosshauer)

Thanks for the further Hammond pointers. It'll be fun looking them up a little later in the week.

Schlosshauerism 9: *At a recent workshop in Utrecht I heard a talk by Carl Hoefer, who you may know? He quite vigorously defended a form of objective Bayesianism, which seemed motivated by his view that subjective probabilities are insufficient. Here is how he put it in a recent essay:*

> Now, I have nothing to say against the idealization of human agents as Bayesian subjective probability-bearing entities; I am sure it is useful for many purposes, and reasonably faithful to reality in a few. But the ontic weaknesses of subjective probabilities, I would say, make them an unsuitable bedrock on which to try to mount a program that aims to capture *all* probabilities. . . . The exquisite precise and reliable probabilities found

> in casinos and in physics laboratories deserve to be accounted for in *some* way or the other.

After reading de Finetti and some other texts, I became quite convinced that the subjective viewpoint is the only reasonable one to opt for. I wonder what your general take would be on a program like Hoefer's?

You asked some good questions. "How you would try to respond to those rationalist, hard-nosed scientists?" In the coming months, I plan to work on this, honing out a satisfactory response. One thing I intend to do for practice is read some things by (and about) Nancy Cartwright, just to get straight where we are the same, and where we differ, and study the shape of the tomatoes that have been thrown at her. The Carl Hoefer response is easier; I'd just need some time to compose it properly. The key to the story is this thing Rüdiger wrote me after reading Logue's book *Projective Probability*:

> Logue makes this interesting point. Often coherence is regarded as a minimalist constraint on probabilities. But coherence has incredibly far-reaching consequences. Coherence alone guarantees that two agents with exchangeable priors that are nonzero everywhere will converge to a joint belief. Coherence alone leads an agent to certainty that he is calibrated in the long run. I like this. I like the idea that Dawid's calibration result is a strength of subjectivism, not a problem for it.

The key point is that if one is coherent with as many of one's beliefs as one can, that leads to all kinds of constraints on one's isolated assignments. So many constraints as to start misleading one into thinking the end results must be objective. But as I say it'd take me some time to do this job right.

Finally, for that awaited rant. In the week before the PIAF meeting, I tried to do a really honest job of reading many of Travis Norsen's papers. Spekkens, you see, thinks Norsen is the clearest thinker since Socrates, and I thought it was my duty to try to understand this clarity ... so that I might find the small chink in the armor, if there be one. I didn't realize what I was in for: The end result wasn't enlightenment, just depression. A really very serious depression.

Check out `http://pirsa.org/09090098/`, the panel discussion that Norsen and I both participated in. One of the questions was, what would it take for you two to switch sides. I laid out a set of criteria for what would turn me Bohmian, and I was honest. When it came to Norsen's turn, he said, "Nothing!" Not surprising at all now that I know him.

03-11-09 *Noncolorable, Maximally Consistent Sets* (to A. Cabello)

I almost forgot to send you electronic versions of the papers we discussed yesterday. The two main ones on the `arXiv` are: `http://arxiv.org/abs/0910.2750` (this one I gave you) and `http://arxiv.org/abs/0906.2187` (this is the one with the most meat and motivation in it, for this whole way of looking at quantum mechanics).

Also, I gave you a paper that I have not yet posted. I will attach it to the present note.

Thanks for spending a little time with me yesterday. There are insights my QBist program needs that I think you are nearly the only person on earth to be consulted on! I look forward to any insights you might have. Part of the question is what is the best question to make progress on!

(Attached also, by the way, is a little blurb written for the PI newsletter. It reveals in a little more poetic way, where I think "QBism" is heading at the "metaphysical" level. See particularly the side bar near the end.)

04-11-09 *QK, QB, QR – First Read* (to H. Barnum)

I gave your "quantum knowledge" draft a *first* read through yesterday. (I'll be reading it again before saying anything too substantial.) At the moment, let me just quickly comment (in my usual time-saving way) on two points in the draft.

With regard to the first point, I'm not quite sure which piece of your text I'd like to pluck out for display with regard to what I'm responding to, but maybe this one will do well enough:

> I worry that they are underselling the extent to which we can have both all the objectivity anyone could reasonably want for at least some quantum state ascriptions—a degree of objectivity which, moreover, it seems to me would be unreasonable not to grant in some cases—while also not reifying the quantum state as an object out in the world, and especially, not as an object localized at the system whose state it is.

Please go to `http://www.perimeterinstitute.ca/personal/cfuchs/nSamizdat-2.pdf` and find the 08-11-06 note to David Mermin titled "November 8th" on page 655 (page numbering at the bottom of each page). With regard to overall pdf page counting, that is page 683 in the file. The point put there is a mundane one: *Classical* thermodynamical heat tables might be described in your terms as "having all the objectivity anyone could reasonably want" (publishing houses, for instance, found it profitable to publish them because of their seemingly universal use), but in what way did physics *not* benefit by Jaynes's constant reminder that all these numbers have their origin in *subjective* probability assignments? These same tables would be of no use and no universality for a Maxwellian demon for instance. And I say it is good to recognize that.

The danger, it seems to me, is not in overemphasizing the subjectivity of probability assignments (and then backing off in those cases when agents, for whatever reason, have similar-enough priors as to potentially come into agreement later or even to be in agreement presently), but rather in *forgetting* their subjective origin. The usual physicist's knee-jerk reaction is to do just that, to reify something that shouldn't be … to the distraction of all the conundrums that mistake leads them to. I view the great lesson of Ed Jaynes' work to be this: Remind always of the principle (that probabilities are subjective), rather than of the convenience (that in many cases agents agree and then sloppily get in the habit of thinking a probability to be of the same logical category as a fact).

Read the piece to Mermin: It is better.

Now on to this one:

> I agree that *if one does* give a quantum description of the measuring device, the operation it performs will be dependent upon one's assignment of a quantum state to it—one's beliefs about it. But who says a quantum analysis of the apparatus is needed? From a point of view from which what we take to be quantum depends upon our purposes and the experiments we plan to do or other projects we plan to undertake, to suddenly require that we do a quantum analysis of the apparatus seems to put us in danger of becoming unwitting victims of the cult of the larger Hilbert space.

Please see page 694 in the file (page 722 by raw pdf accounting), picking up at the line starting with, "The logic goes like this." Please read that paragraph along with the referee's comments above it that I am addressing. It is true that Carl often seems to skirt quite close to being an "unwitting victim of the cult of the larger Hilbert space," but I do not.

That circuit argument is Carl's favorite one, but it is not mine. Mine is simply this: With respect to a fiducial informationally complete measurement, *any* other measurement can be represented as a collection of conditional probability distributions. Think, for instance, of my beloved urgleichung. If all probability assignments are subjective (in the sense of being functions solely of the agent rather than the object), then so are these conditional ones, and then so is the POVM associated with a measuring device.

I'll certainly read your draft again in a day or two (and I'll certainly have more to say).

04-11-09 *QK, QB, QR – First Read, 2* (to H. Barnum, D. M. Appleby, and M. Tait)

Rereading this note, and also some others of my old writings, let me also recommend the note "Prepare Yourself" on page 711 (page 739 by raw pdf accounting). It further expands on the subjectivity-because-of-input-state-in-quantum-circuit account of the subjectivity of POVM ascription, and it also says some things on Mermin's "disembodied-fact account of quantum states" which seems to have some similarity to what Howard is striving for.

06-11-09 *The Interiority of John Preskill* (to H. Barnum)

I had forgotten that I had tried to make a statement on the interiority business in my John Preskill story. "If he knew what I believed, he'd probably do something to surprise me." And, "In a phrase, what is desired is a theory that is all outside and no inside. [Footnote: On first pass, the Texan in me wanted to write 'all hat and no cattle,' but I repressed that.]" Have a look at the Preskill section, pages 26–28, of the attached:

> When we have discussed the interpretational issues of quantum theory, I have gotten the sense that what John finds most suspicious of the quantum Bayesian approach I promote is that he *thinks* it treats observers as unphysical systems. I say, "Not at all; John, you are a physical system to me." The real issue is one of inside versus outside. Contrary to the textbook exposition of quantum mechanics, a wave function that I write down about him is descriptive not of the outside, but of the inside, namely me: It captures what I believe will happen to me if I interact with him. If he knew what I believed, he'd probably do something to surprise me.

06-11-09 *Renouvier on Kant* (to M. Tait)

See entry 291 (pages 102–106) of "The Activating Observer" document I sent you. See also

`http://en.wikipedia.org/wiki/Charles_Bernard_Renouvier`.

And finally the attached files if you're interested. [See Shadworth H. Hodgson's "M. Renouvier's Philosophy–Logic," *Mind* **6**(21), 31–61 (1881) and "M. Renouvier's Philosophy–Psychology," *Mind* **6**(22), 173–211 (1881).] The one on Logic is particularly on Kantian things.

06-11-09 *Quotable Schopenhauer* (to M. Tait)

It was this passage of James from an 1870 diary entry that struck me as sounding a bit Schopenhauer-esque when you brought it to my attention:

> Hitherto, when I have felt like taking a free initiative, like daring to act originally, without carefully waiting for contemplation of the external world to determine all for me, suicide seemed the most manly form to put my daring into; now, I will go a step

further with my will, not only act with it, but believe as well; believe in my individual reality and creative power.

Morgan's Preply, "Quotable Schopenhauer"

Anticipating James, though (perhaps) with a less cynical moral:

> The discovery of truth is prevented more effectively, not by the false appearance things present and which mislead into error, not directly by weakness of the reasoning powers, but by preconceived opinion, by prejudice.

Take heart QBists:

> All truth passes through three stages. First, it is ridiculed. Second, it is violently opposed. Third, it is accepted as being self-evident.

On Hegel:

> ... a commonplace, inane, loathsome, repulsive and ignorant charlatan, who with unparalleled effrontery compiled a system of crazy nonsense that was trumpeted abroad as immortal wisdom by his mercenary followers ...

On Kant's early reception:

> Great minds are related to the brief span of time during which they live as great buildings are to a little square in which they stand: you cannot see them in all their magnitude because you are standing too close to them.

On Suicide:

> They tell us that suicide is the greatest piece of cowardice ... that suicide is wrong; when it is quite obvious that there is nothing in the world to which every man has a more unassailable title than to his own life and person.

09-11-09 *Vienna Indeterminism* (to A. Zeilinger)

Thank you for the very nice letter—nice in so many aspects. A week for a visit to Vienna is definitely doable; a month sounds very intriguing. What is the most beautiful period of Vienna's springtime? But maybe more practically, when would be the best time for the meeting you want to organize? Or more practical still, if you decide you have an interest in doing a SIC experiment, perhaps I should fly over earlier rather than later to talk about these things more deeply. (I could always come back for a longer visit later ... ?)

I'll write you more about the SICs in a moment, in a separate note.

Your mention of Laurikainen reminds me that I once read a note you and someone else wrote on his passing away. Do I have that right? I'm pretty sure it was you. If so, would it be possible for you send me a copy? I did a search for the article on the web, but could not find anything. Hans Christian von Baeyer and I are writing an article for *American Journal of Physics* on Pauli's notion of the detached observer (more particularly its opposite), and it'd be nice to have all possible resource materials available. (I think you know Hans Christian, but you may not have known that Markus Fierz's brother was Hans's godfather, and that Fierz himself was Hans's father's best friend in their college days.)

With regard to Exner, that's not a quote by him. It is from Cormac McCarthy, a novelist that Carl Caves likes. I only recently learned that Exner was my academic great-great-great-great grandfather, but I had known about his argument for indeterminism for a very long time. I learned of it from Paul Hanle's article "Indeterminacy before Heisenberg: The Case of Franz Exner and Erwin Schrödinger" (Historical Studies in the Physical Sciences, vol **10**, 225–269, 1979). I tried to get a copy of that from the web to send to you, but I couldn't. Still, I did find some newer tidbits on him that I had not read before, by an author named Stöltzner. I'll attach them for you—they look quite interesting.

09-11-09 *Seeking SICs* (to A. Zeilinger)

Let me now address this part of your letter:

Zeilingerism 1: *These SIC-POVMs: where can I learn more about them? Why do you think they are among the deepest structures of quantum mechanics? You probably mean deepest in a conceptual/foundational way.*

I make my most comprehensive statement in this paper "Quantum-Bayesian Coherence": `http://arxiv.org/abs/0906.2187`. Here's the way to read it. First, jump to page 50 to see the color figure, and read the figure caption. That sets the agenda. Then, jump to page 20 and look at that figure and caption. That is a schematic of the experiment I would like to see done: It could be billed as an experimental test of the Born Rule. The idea would be: First, to perform a set of runs with only one or another regular quantum measurement performed on the systems. But second, perform a set of runs with a SIC measurement first, before the regular quantum measurement at the end. Then, one just shows that the equation at the bottom of page 20 is satisfied to within experimental tolerance.

Where I think the experiment would be most interesting and dramatic would be for $d = 3$ and $d = 4$ (single qutrits and two qubits). Particularly, for $d = 3$, one can make easy comparisons to Gleason's theorem, and also my students would have the best chance of providing some visual aids to thinking (graphs and slices will more effectively depict lower-dimensional spaces). Equation 24 on page 15 shows an exact expression for a $d = 3$ SIC—performing that measurement would be the difficult part of the experiment.

Two things to beware of in the paper:

1. The introduction is going to be completely rewritten. The referee thinks it gives Feynman too much credit, that Feynman wasn't anywhere near the key idea of this paper, and that I undersell myself and the result by diverting so much attention upon him.

2. Section 6 has a very interesting, but isolated, mistake in it. I doubt you'll read that section, but just in case, I thought I should warn you. I say "interesting" because in fixing the mistake, one finds something really deep: an extra handle within quantum mechanics that I believe quantifies how much the observer is "attached" or "undetached" in this theory. I will soon fix the mistake and repost the paper, but in the meantime let me offer another paper where the mistake is fixed; it is attached. I also attach an image to show how the equation becomes modified with this new handle—the classical world is the case $q = 0$, the quantum world is the case $q = 2$. The case $q = 1$ is something else still, something between classical and quantum. A value $q = 3$ or above, means an even more "engaged" observer—quantum mechanics is nowhere near the top of the hierarchy! If you're interested, see a more philosophical explanation below that I had originally sent to Hans Christian.

So there, that's the way to learn more about SICs; the papers I pointed you to are the best I can do for saying why I think they're deep without talking to you directly.

10-11-09 *QF Group Meeting Tuesday at 4pm in the Alice Room* (to R. W. Spekkens)

Spekkensism 51: *Our next group meeting will be tomorrow in Alice at 4pm. The topic of discussion will be: what conceptual ingredients of quantum theory are responsible for its superiority for computation (to the extent that we believe that it is superior). There will be no official discussion leaders. Rather, those who have an opinion should come prepared to say a few words about it.*

Metaphors, it's always metaphors with me. My weakness, and hopefully (in longer term) my strength. I'm not sure I will be in the office this afternoon to be able to come to the meeting: Emma is at home with an ear infection and ongoing fever. But below is my take on the matter. See old note to Gottesman, pasted in below. [See note to D. Gottesman titled "Bristol, 3 AM," dated 25 January 2008.] It is a metaphor only, of course, but one that I feel captures the essence. QM—for the QBist—seems to be a calculus for calculating probabilities for *factual* situations from *counterfactual* situations. And what is most interesting is that the quantum rule generically gives tighter distributions than the corresponding classical rule would. "It gives a reward of more certainty for this or that when an intermediate step (in the intermediate reasoning) is not taken physically."

Take factoring. The purpose of building a computer is so that, after an appropriate number of steps, one is fairly certain that if one looks at it, one will find the unknown factors. One cannot gamble (better than a flat distribution) what the factors will be initially, but one *can* gamble with near certainty that one will obtain them by having a look at the computer's output at the appropriate time. That's the point of writing an algorithm. But in this way of putting things, factoring becomes more obviously a probabilistic question. Analyze the primitive steps, and then make a probability calculation: Have an actual look when the probability for finding what you want rises to nearly one. Now transfer to the metaphor of my beloved urgleichung. First analyze conceptually in classical probabilistic terms—using conditioning, the law of total probability, etc.—but at the end of the day, use the magical quantum modification to that classical reasoning. Generically, it will give more *certainty* for some aspect of something. And more certainty—so the hope goes—should signify the need for fewer "computational steps" in between.

Not without connection to this metaphor is Andrew Steane's (less metaphorical) paper, "A Quantum Computer Only Needs One Universe," `quant-ph/0003084`. I definitely recommend discussion of it, if someone has sufficient knowledge of it.

10-11-09 *Broken Ends* (to H. Barnum)

Coming back to a Toronto conversation: Heidegger was Husserl's student, as I had faintly remembered. I just read it in wiki as I was trying to get a feel for what "phenomenology" is. Still don't know the latter, but I was pleased to run across the former.

10-11-09 *Hippy Shack* (to D. B. L. Baker)

Bakerism 5: *Somehow, only you could turn what would be a nerdfest into something that could possibly be cool. Since the name "Quantum Cowboy" is already taken, I guess you qualify as a Hilbert Space Hippy. Perhaps it is you, not I, that needs a beret.*

Did I ever recommend Louis Menand's book, *The Metaphysical Club: A Story of Ideas in America*, to you? Look it up at `amazon.com`. A Pulitzer prizewinner. It's got lots of good stuff about Emerson, the Civil War, the 54th Massachusetts Regiment (Shaw's), Oliver Wendell Holmes, all intertwined with stuff on Darwin, my hero William James, and the philosophical vision I'm shooting for. It was the very best book I read in 2003.

Hilbert Space Hippy is a way cool moniker; I'll wear it proudly!

11-11-09 *The Peirce Quote* (to R. Healey)

> If you look into a textbook of chemistry for a definition of *lithium*, you may be told that it is that element whose atomic weight is 7 very nearly. But if the author has a more logical mind he will tell you that if you search among minerals that are vitreous, translucent, grey or white, very hard, brittle, and insoluble, for one which imparts a crimson tinge to an unluminous flame, this mineral being triturated with lime or witherite rats-bane, and then fused, can be partly dissolved in muriatic acid; and if this solution be evaporated, and the residue be extracted with sulphuric acid, and duly purified, it can be converted by ordinary methods into a chloride, which being obtained in the solid state, fused, and electrolyzed with half a dozen powerful cells, will yield a globule of a pinkish silvery metal that will float on gasolene; and the material of *that* is a specimen of lithium. The peculiarity of this definition—or rather this precept that is more serviceable than a definition—is that it tells you what the word lithium denotes by prescribing what you are to *do* in order to gain a perceptual acquaintance with the object of the word (2.330).

12-11-09 *Probability is Single Case, or Nothing* (to R. Healey)

Healeyism 1: *From the abstracts, I expect to be quite sympathetic to Appleby's line. I certainly don't defend a frequentist view of probability, and agree that probability applies to the single case. But I don't think that makes all probabilities subjective, just as I don't think there are objective chances. I'm still holding out for probabilities that are authoritative for a rational agent in a specific physical situation, in the sense that his degrees of belief should match these probabilities if he has good empirical reasons to accept a theory that prescribes them.*

"Oh, where are the lines of quantum theory?" (I think I want to use that line in a play someday.)

16-11-09 *A Happy QBism House* (to N. Waxman & E. Goheen)

Thanks a million for the work on putting that together. I never imagined we'd make the front page too—I'm very flattered and grateful. And what a great coincidence that Bill Wootters's favorite equation is the same equation as mine, just written in different form! (Or did you set that up Natasha?)

Is there any chance I could get an electronic copy of the newsletter (either Word or PDF formats)? I'd like to send the issue to my "watchers" at the Navy. Also, could I get one more hard copy? I'd like to send my mother. (It's kind of like being on the cover of *The Rolling Stone*.)

18-11-09 *In the Maelstrom of Modernism* (to J. E. Sipe)

Finally finished the book. I liked it OK, but I was struck at how abruptly it ended: It really skimped on the last 8 years of James's life, the period when he was actually the hardest working and most productive in his life. And that period when James turned to full-blown philosophical efforts is, of course, the most intellectually interesting one for me personally—so I felt like I invested a lot in reading the early parts of the book only to be let down at the end. I honestly got the sense that the author had just gotten tired of writing on this project.

Still, there was plenty for me in there. For one thing I gained an appreciation for how much I need to read James's three psychology books. Particularly, I gained an appreciation for how much his ontology (of "pure experience") is based on his model of the mind. ["Pure experience," by the way, I think is an unfortunate name—he only means by that something that is neither material nor mental, but both and neither.] Also, because of Richardson, I finally feel the need to read James's *Varieties of Religious Experience*. Finally, I gained an appreciation for the influence of James's wife Alice on some of his thoughts—I hadn't realized she played such a large part in his intellectual life, and I want to learn more about that.

So, thanks for recommending the book to me. Below are the points of interest I recorded while reading it. A note to you seems like a good depository for me to record them in.

Oh, one last thing: I picked up a quote from this book that I had certainly read before (in James's *Pragmatism*), but strangely it didn't strike me then (I have no memory of reading it before). Reading it now though makes my skin tingle and come alive. It is surely the right idea:

> To anyone who has ever looked on the face of a dead child or parent the mere fact that matter *could* have taken for a time that precious form, ought to make matter sacred ever after. It makes no difference what the principle of life may be, material or immaterial, matter at any rate co-operates, lends itself to all life's purposes. That beloved incarnation was among matter's possibilities.

19-11-09 *Psychology and Physics* (to H. C. von Baeyer)

Psychology has been much on my mind the last two weeks. The note below [see note to J. E. Sipe, dated 18-11-09, titled "In the Maelstrom of Modernism"] gives some story of the cause: It was in reading Robert Richardson's biography of William James, where a lot of attention is paid to his construction of *The Principles of Psychology*. I also started to realize from the book that there may be a more continuous thread from James to Jung than I would have expected. For instance, there are already relatively explicit statements of the collective conscious in late James (pre Jung). There are so many veins I must still explore! Our key to physics (as Pauli was already guiding) really must be in all this stuff.

20-11-09 *Chris's Picks* (to R. Healey)

Needless to say, I enjoyed yesterday's discussion from beginning to end.

And I liked one of the things you said near the end, which I think you described as a "new attitude" about reading some philosophy, to mine it for ideas, and worry about the logic later. I think that's a healthy thing. (But maybe I only say that because I'm a physicist, and physicists are opportunists.)

For fun, I was thinking this morning that I might suggest a collection of readings. (The list started because I wasn't sure you'd remember the name of the James book I suggested, but then it gathered steam on its own.)

Anyway, here goes:

- Rorty, *Philosophy and the Mirror of Nature*.

- Rorty, *Philosophical Papers Volume 1: Objectivity, Relativism, and Truth*. This is the one that starts off with this spiel that I have recorded in my computer:

> The six papers that form Part I of this volume offer an antirepresentationalist account of the relation between natural science and the rest of culture. By an antirepresentationalist account I mean one which does not view knowledge as a matter of getting reality right, but rather as a matter of acquiring habits of action for coping with reality.
>
> Philosophers in the English-speaking world seem fated to end the century discussing the same topic—realism—which they were discussing in 1900. In that year, the opposite of realism was still idealism. But by now language has replaced mind as that which, supposedly, stands over and against "reality." So discussion has shifted from whether material reality is "mind-dependent" to questions about which sorts of true statements, if any, stand in representational relations to nonlinguistic items. Discussion of realism now revolves around whether only the statements of physics can correspond to "facts of the matter" or whether those of mathematics and ethics might also. Nowadays the opposite of realism is called, simply, "antirealism."
>
> This term, however, is ambiguous. It is standardly used to mean the claim about some particular true statements, that there is no "matter of fact" which they represent. But, more recently, it has been used to mean the claim that *no* linguistic items represent *any* nonlinguistic items. In the former sense it refers to an issue within the community of representationalists—those philosophers who find it fruitful to think of mind or language as containing representations of reality. In the latter sense, it refers to antirepresentationalism—to the attempt to eschew discussion of realism by denying that the notion of "representation," or that of "fact of the matter," has any useful role in philosophy. Representationalists typically think that controversies between idealists and realists were, and controversies between skeptics and antiskeptics are, fruitful and interesting. Antirepresentationalists typically think both sets of controversies pointless. They diagnose both as the results of being held captive by a picture, a picture from which we should by now have wriggled free.

- James, *Some Problems of Philosophy*. For me a wonderful little book because it pretty well expresses what I think quantum mechanics is indicating at least for the small philosophical scale ... how far one can carry it I don't know. It is that everything has an inside—a true inside—that cannot be mathematized from the outside. This is a bit of Pauli's thought as well.

- James, *Pragmatism*. There's nothing you'd call a rigorous argument in here, but it paints a picture quite beautiful to me, one that certainly changed my life. There are all kinds of beautiful gems in here, including this quote:

> To anyone who has ever looked on the face of a dead child or parent the mere fact that matter *could* have taken for a time that precious form, ought to make matter sacred ever after. It makes no difference what the principle of life may be, material or immaterial, matter at any rate co-operates, lends itself to all life's purposes. That beloved incarnation was among matter's possibilities.

- Ralph Barton Perrry, *The Thought and Character of William James, Volume II: Philosophy and Psychology*. This book is still the best of its type around; it is the book that caused me to "want to be" William James. If you want to know what you should watch out for, so as not to be sucked into the James cult, approach this one cautiously.

- Dewey. I know I should suggest something by Dewey, but it is hard, as I just cannot stay awake while reading this guy. Still I have the impression that he is "mostly James" (in contrast to Peirce, say), but rigorized. Flipping through Rorty will tell you what of Dewey to read if you want any suggestions—Dewey is Rorty's hero. Still, let me offer this much:

- F. Thomas Burke, et al, *Dewey's Logical Theory: New Studies and Interpretations*. The introduction gives some nice orientation.

- H. S. Thayer, *Meaning and Action: A Critical History of Pragmatism*. This is a really very good reference; it covers literally everything of the pre-Rorty as far as I can see.

- And finally, if you (late in the game, after you've read some of the stuff above) really want to have a look into the wild side—I reveal my biggest dreams here—have a look at some of F. C. S. Schiller (remember, mining, mining): F. C. S. Schiller, "Axioms as Postulates". (I can make a copy and send it to you.)

20-11-09 *Wheeler on Quine* (to R. Healey)

This was the Quine quote that Wheeler liked to use when arguing that ultimately physics should shed the continuum:

> Just as the introduction of the irrational numbers … is a convenient myth [which] simplifies the laws of arithmetic … so physical objects are postulated entities which round out and simplify our account of the flux of existence. … The conceptual scheme of physical objects is [likewise] a convenient myth, simpler than the literal truth and yet containing that literal truth as a scattered part.

It comes from his paper, "On What There Is".

And by the way, I told you that the Pragmatism Cybrary classifies Quine as a "recent pragmatist"; you can find their classification here: `http://pragmatism.org/`.

21-11-09 *SICs, Reason, and Faith* (to the QBies)

Continuing on with our discussion from Wine & Cheese yesterday: Particularly, on how *belief* itself can *sometimes* be the very cause of a reality. That, without a belief first, without a *faith* that something *ought* to be,—in some cases!—it simply would not be. I'm thinking of that part of our conversation. Anyway, on these things, I was led back to William James's speech "Reason and Faith." I attach the full thing, and excerpt below the part of it that is important to our little group.

I can do nothing but admit that in coming to the conclusion that the foundation of quantum mechanics should be built on SICs, I climbed a "faith-ladder" in the sense that James defines it below:

> SICs are *fit* to be true. It would be well if they *were* true. They *might* be true; they *may* be true; they *ought* to be true. They *must* be true! They *shall* be true! For me at least!!

And so with it, faith brought a little bit of reality into being. It is the ONR funding and our little group, and all the results positive and negative we shall find over the course of the next few years.

> Faith uses a logic altogether different from Reason's logic. Reason claims certainty and finality for her conclusions. Faith is satisfied if hers seem probable and practically wise.
>
> Faith's form of argument is something like this: Considering a view of the world: "It is *fit* to be true," she feels; "it would be well if it *were* true; it *might* be true; it *may* be true; it *ought* to be true," she says; "it *must* be true," she continues; "it *shall* be true," she concludes, "*for me*; that is, I will treat it as if it *were* true so far as my advocacy and actions are concerned."
>
> Obviously this is no intellectual chain of inferences, like the *Sorites* of the logic-books. You may call it the "faith-ladder," if you like; but, whatever you call it, it is the sort of slope on which we all habitually live. In no complex matter can our conclusions be more than *probable*. We use our feelings, our good-will, in judging where the greater probability lies; and when our judgment is made, we practically turn our back on the lesser probabilities as if they were not there. Probability, as you know, is mathematically expressed by a fraction. But seldom can we *act* fractionally—half-action is no action (what is the use of only half-killing your enemy?—better not touch him at all); so for purposes of action we equate the most probable view to 1 (or certainty) and other views we treat as naught.

22-11-09 *More Reason and Faith* (to H. C. von Baeyer)

von Baeyerism 37 : *I will gladly read "Reason and Faith" in the spirit you propose, with one reservation. James, in his context, speaks about religious faith, but I would like to distinguish between the concepts of faith and religion. In my Pauli speech I referred to a book by James P. Carse entitled* The religious case against belief *(2008). My brother, a psychologist in Saskatoon, was so taken with it when I told him about it that he gave a sermon to his Unitarian church (appropriate since James was speaking to Unitarians too.) The abstract of the sermon put it succinctly:*

> Belief systems are wilfully closed and certain, and are the enemy of religions, which are so open to debate, uncertainty, and reinterpretation that it takes thousands of years for these discussions to run their course. In his 2008 book, theologian James P. Carse explains how the essence of religion is poetry or mystery or a higher form of ignorance rather than a didactic set of claims or beliefs. This book turned my understanding of religion on its head.

The relevance of all this to your thinking is further complicated by the difference between the words "faith" and "belief", which I am not prepared to discuss here. All I want to do is to make sure that religion is properly decoupled from the conversation about SICs.

Thanks for your brother's abstract; I think I'd like to take a look at this book during the Christmas holidays. I don't think you have anything to worry about with regard to James pushing 'belief systems' in the sense you mention.

Particularly, the more I thought about it today, I think he might have been served well to use the word "decision" rather than "belief." This can be seen in the last essay I sent, but it can be seen even more clearly in the attached essay. (It is from his book *Some Problems of Philosophy*, but I picked it up from a badly scanned copy on the internet; then I spent some time cleaning it up in TEX. It struck me as the sort of thing I'd like to have a good copy of in my computer.) This particular essay is less about religion, but more about the idea that the world can be changed by our actions. The faith-ladder once again makes an appearance in it.

Faith and the Right to Believe

(Appendix from William James's book *Some Problems of Philosophy*)

'Intellectualism' is the belief that our mind comes upon a world complete in itself, and has the duty of ascertaining its contents; but has no power of re-determining its character, for that is already given.

Among intellectualists two parties may be distinguished. Rationalizing intellectualists lay stress on deductive and 'dialectic' arguments, making large use of abstract concepts and pure logic (Hegel, Bradley, Taylor, Royce). Empiricist intellectualists are more 'scientific,' and think that the character of the world must be sought in our sensible experiences, and found in hypotheses based exclusively thereon (Clifford, Pearson).

Both sides insist that in our conclusions personal preferences should play no part, and that no argument from what *ought to be* to what *is*, is valid. 'Faith,' being the greeting of our whole nature to a kind of world conceived as well adapted to that nature, is forbidden, until purely intellectual *evidence* that such *is* the actual world has come in. Even if evidence should eventually prove a faith true, the truth, says Clifford, would have been 'stolen,' if assumed and acted on too soon.

Refusal to believe anything concerning which 'evidence' has not yet come in, would thus be the rule of intellectualism. Obviously it postulates certain conditions, which for aught we can see need not necessarily apply to all the dealings of our minds with the Universe to which they belong.

1. It postulates that *to escape error* is our paramount duty. Faith *may* grasp truth; but also it may not. By resisting it always, we are sure of escaping error; and if by the same act we renounce our chance at truth, that loss is the lesser evil, and should be incurred.

2. It postulates that in every respect the universe is finished in advance of our dealings with it;

That the knowledge of what it thus is, is best gained by a passively receptive mind, with no native sense of probability, or good-will towards any special result;

That 'evidence' not only needs no good-will for its reception; but is able, if patiently waited for, to neutralize ill-will;

Finally, that our beliefs and our acts based thereupon, although they are parts of the world, and although the world without them is unfinished, are yet such mere externalities as not to alter in any way the significance of the rest of the world when they are added to it.

In our dealings with many details of fact these postulates work well. Such details exist in advance of our opinion; truth concerning them is often of no pressing importance; and by believing nothing, we escape error while we wait. But even here we often cannot wait but must act, somehow; so we act on the most *probable* hypothesis, trusting that the event may prove us wise. Moreover, not to act on one belief, is often equivalent to acting as if the opposite belief were true, so inaction would not always be as 'passive' as the intellectualists assume. It is one attitude of will.

Again, Philosophy and Religion have to interpret the total character of the world, and it is by no means clear that here the intellectualist postulates obtain. It may be true all the while (even though the evidence be still imperfect) that, as Paulsen says, 'the natural order is at bottom a moral order.' It may be true that work is still doing in the world- process, and that in that work we are called to bear our share. The character of the world's results may in part depend upon our acts. Our acts may depend on our religion,—on our not-resisting our faith-tendencies, or on our sustaining them in spite of 'evidence' being incomplete. These faith-tendencies in turn are but expressions of our good-will towards certain forms of result.

Such faith-tendencies are extremely active psychological forces, constantly outstripping evidence. The following steps may be called the 'faith-ladder':

1. There is nothing absurd in a certain view of the world being true, nothing self-contradictory;
2. It *might* have been true under certain conditions;
3. It *may* be true, even now;
4. It is *fit* to be true;
5. It *ought* to be true;
6. It *must* be true;
7. It *shall* be true, at any rate true for *me*.

Obviously this is no intellectual chain of inferences, like the *sorites* of the logic-books. Yet it is a slope of good-will on which in the larger questions of life men habitually live.

Intellectualism's proclamation that our good-will, our 'will to believe,' is a pure disturber of truth, is itself an act of faith of the most arbitrary kind. It implies the will to insist on a universe of intellectualist constitution, and the willingness to stand in the way of a pluralistic universe's success, such success requiring the good-will and active faith, theoretical as well as practical, of all concerned, to make it 'come true.'

Intellectualism thus contradicts itself. It is a sufficient objection to it, that if a 'pluralistically' organized, or 'co-operative' universe or the 'melioristic' universe above, were really here, the veto of intellectualism on letting our good-will ever have any vote would debar us from ever admitting that universe to be true.

Faith thus remains as one of the inalienable birth-rights of our mind. Of course it must remain a practical, and not a dogmatic attitude. It must go with toleration of other faiths, with the search for the most probable, and with the full consciousness of responsibilities and risks.

It may be regarded as a formative factor in the universe, if we be integral parts thereof, and co-determinants, by our behavior, of what its total character may be.

How We Act on Probabilities

In most emergencies we have to act on probability, and incur the risk of error.

'Probability' and 'possibility' are terms applied to things of the conditions of whose coming we are (to some degree at least) ignorant.

If we are entirely ignorant of the conditions that make a thing come, we call it a 'bare' possibility. If we know that some of the conditions already exist, it is for us in so far forth a 'grounded' possibility. It is in that case *probable* just in proportion as the said conditions are numerous, and few hindering conditions are in sight.

When the conditions are so numerous and confused that we can hardly follow them, we treat a thing as probable in proportion to the *frequency* with which things of that *kind* occur. Such frequency being a fraction, the probability is expressed by a fraction. Thus, if one death in 10,000 is by suicide, the antecedent probability of my death being a suicide is 1-10,000th. If one house in 5000 burns down annually, the probability that my house will burn is l-5000th, etc.

Statistics show that in most kinds of thing the frequency is pretty regular. Insurance companies bank on this regularity, undertaking to pay (say) 5000 dollars to each man whose house burns, provided he and the other house-owners each pay enough to give the company that sum, plus something more for profits and expenses.

The company, hedging on the large number of cases it deals with, and working by the long run, need run no risk of loss by the single fires.

The individual householder deals with his own single case exclusively. The probability of his house burning is only 1-5000, but if that lot befall he will lose everything. He has no 'long run' to go by, if his house takes fire, and he can't hedge as the company does, by taxing his more fortunate neighbors. But in this particular kind of risk, the company helps him out. It translates his one chance in 5000 of a big loss, into a certain loss 5000 times smaller, and the bargain is a fair one on both sides. It is clearly better for the man to lose *certainly*, but *fractionally*, than to trust to his 4999 chances of no loss, and then have the improbable chance befall.

But for most of our emergencies there is no insurance company at hand, and fractional solutions are impossible. Seldom can we *act* fractionally. If the probability that a friend is waiting for you in Boston is 1-2, how should you act on that probability? By going as far as the bridge? Better stay at home! Or if the probability is 1-2 that your partner is a villain, how should you act on that probability? By treating him as a villain one day, and confiding your money and your secrets to him the next? That would be the worst of all solutions. In all such cases we must act wholly for one or the other horn of the dilemma. We must go in for the more probable alternative as if the other one did not exist, and suffer the full penalty if the event belie our faith.

Now the metaphysical and religious alternatives are largely of this kind. We have but this one life in which to take up our attitude towards them, no insurance company is there to cover us, and if we are wrong, our error, even though it be not as great as the old hell-fire theology pretended, may yet be momentous. In such questions as that of the *character* of the world, of life being moral in its essential meaning, of our playing a vital part therein, etc., it would seem as if a certain *wholeness* in our faith were necessary. To calculate the probabilities and act fractionally, and treat life one day as a farce, and another day as a very serious business, would be to make the worst possible mess of it. Inaction also often counts as action. In many issues the inertia of one member will impede the success of the whole as much as his opposition will. To refuse, *e. g.*, to testify against villainy, is practically to help it to prevail.[214]

The Pluralistic or Melioristic Universe

Finally, if the 'melioristic' universe were *really* here, it would require the active good-will of all of us, in the way of belief as well as of our other activities, to bring it to a prosperous issue.

The melioristic universe is conceived after a social analogy, as a pluralism of independent powers. It will succeed just in proportion as more of these work for its success.

[214] Cf. Wm. James: *The Will to Believe*, etc., pp. 1–31, and 90–110.

If none work, it will fail. If each does his best, it will not fail. Its destiny thus hangs on an *if*, or on a lot of *ifs*—which amounts to saying (in the technical language of logic) that, the world being as yet unfinished, its total character can be expressed only by *hypothetical* and not by *categorical* propositions.

(Empiricism, believing in possibilities, is willing to formulate its universe in hypothetical propositions. Rationalism, believing only in impossibilities and necessities, insists on the contrary on their being categorical.)

As individual members of a pluralistic universe, we must recognize that, even though we do *our* best, the other factors also will have a voice in the result. If they refuse to conspire, our good-will and labor may be thrown away. No insurance company can here cover us or save us from the risks we run in being part of such a world.

We *must* take one of four attitudes in regard to the other powers: either

1. Follow intellectualist advice: wait for evidence; and while waiting, do nothing; or
2. *Mistrust* the other powers and, sure that the universe will fail, *let* it fail; or
3. *Trust* them; and at any rate do *our* best, in spite of the *if*; or, finally,
4. *Flounder*, spending one day in one attitude, another day in another.

This 4th way is no systematic solution. The 2d way spells faith in failure. The 1st way may in practice be indistinguishable from the 2d way. The 3d way seems the only wise way.

'*If* we do *our* best, and the other powers do *their* best, the world will be perfected'—this proposition expresses no actual fact, but only the complexion of a fact thought of as eventually possible. As it stands, no conclusion can be positively deduced from it. *A conclusion would require another premise of fact, which only we can supply. The original proposition per se has no pragmatic value whatsoever, apart from its power to challenge our will to produce the premise of fact required.* Then indeed the perfected world emerges as a logical conclusion.

We can *create* the conclusion, then. We can and we may, as it were, jump with both feet off the ground into or towards a world of which we trust the other parts to meet our jump—and *only so* can the *making* of a perfected world of the pluralistic pattern ever take place. Only through our precursive trust in it can it come into being.

There is no inconsistency anywhere in this, and no 'vicious circle' unless a circle of poles holding themselves upright by leaning on one another, or a circle of dancers revolving by holding each other's hands, be 'vicious.'

The faith circle is so congruous with human nature that the only explanation of the veto that intellectualists pass upon it must be sought in the offensive character to *them* of the faiths of certain concrete persons.

Such possibilities of offense have, however, to be put up with on empiricist principles. The long run of experience may weed out the more foolish faiths. Those who held them will then have failed: but without the wiser faiths of the others the world could never be perfected.

(Compare G. Lowes Dickinson: "Religion, a Criticism and a Forecast," N. Y. 1905, Introduction; and chaps. iii, iv.)

23-11-09 *CoE Proposal* **(to H. Price)**

Sorry to keep you waiting. That's a genuinely nice document ... even if I did cringe at the thought of being associated with something that says this: "A striking example is the attempt to understand quantum 'nonlocality' (the 'spooky action at distance' in quantum theory, as Einstein famously called it). Nonlocality was characterised mathematically by John Bell in the 1960s, and later confirmed experimentally by Aspect and others." (The implication is pretty clearly that 'spooky action at a distance' is 'confirmed'. And you know of course, that that's about the last thing I think Bell inequality violations confirm.) … Still, I was seduced back by the small homage to these, I would say, closer-to-correct words, "the real breakthrough will come when we start to realise the connections between reality, knowledge and our actions." … And finally overpowered by that beautiful closing argument, "The quest to understand reality is one of humanity's fundamental projects. Each generation inherits new challenges on the shoulders of the last. In our generation, some of the deepest puzzles require the joint skills of physics and philosophy. Our goal is to lead the world in directing the best available intellectual resources to these challenges."

I'd be proud to be associated with this project. And you can list me for a 20% time commitment as you wish.

One final thing, I was amused by this line in the proposal, "What is the status of probability in Quantum Bayesianism?" I would have thought that is the one thing that is a settled issue by now! Attached is a draft I'm writing at the very moment, where effectively I say so. Rue the day your funding agents ever see my own writings about this question! They might just take that portion of the money back.

23-11-09 *CoE Proposal, 2* (to H. Price)

By the way, I like that way of writing "Quantum Bayesianism" as you do in the proposal, with both "Quantum" and "Bayesianism" capitalized. I just adopted the convention myself!

23-11-09 *My Visit, James, Lotze, and the Malleable World* (to A. Zeilinger)

Then let's settle it. I will come for the week of Jan 17–23, with possibly some extra time around the front or back edge of that range.

Funny, just this morning (because of a further grant proposal our Australian partners in the PI-AF quantum foundations collaboration are working up), I read the *New Scientist* thing on you from last month. They write,

> Zeilinger specialises in quantum experiments that demonstrate the apparent influence of observers in the shaping of reality. "Maybe the real breakthrough will come when we start to realise the connections between reality, knowledge and our actions," he says.

Nice. With that in mind, I give you a little gift: One of my favorite discussions from William James's little book *Pragmatism*. I hope you enjoy the attached short file, and I am very much looking forward to January.

23-11-09 *GRW and Bayes* (to G. J. Milburn)

Milburnism 3: *I gave a 'reading' of your paper "Subjective probability and quantum certainty" to our PIAF group on Wednesday. Some way through the discussion the question of what to make of spontaneous localisations in GRW came up. Have you, Carl or Rüdiger thought about this from a quantum bayesian point of view?*

I would guess that neither Carl nor Rüdiger nor I have thought much about GRW in these terms. In my case, not only would I guess, but I know that I haven't! It's a symptom of the thing I described in the draft I sent you and Huw, etc., a couple of hours ago. GRW is usually thought of in terms of reified states doing the collapsing, i.e. the states *are* the dynamical variable. The main point of the quantum Bayesian movement is to explicitly remove the quantum state from the observer-INdependent world, leaving no trace behind. If GRW can be posed in such a way that the thing jumping is not a quantum state, then maybe there's a chance of analyzing it in our terms. But I don't know of such a way.

I hope that helps answer things, and that our old paper didn't give you or the other guys too much of a headache.

23-11-09 *While Translating* (to J. Berkovitz)

Thanks much for this remark in your paper:

> "Probability, too, if regarded as something endowed with some kind of objective existence, is no less a misleading misconception, an illusory attempt to exteriorize or materialize our true [i.e. actual] probabilistic beliefs." (de Finetti 1974a, p. x) ... Here the translation from Italian seems incorrect. The word 'vero' could be translated as 'actual' or 'true', and it is clear that here it should be translated as 'actual'.

It cleared up a good mystery for me. I had never liked the seeming use of true there. But it prompts another question for me. In the fuller quote below, should it really be an "or Fairies and Witches" or rather an 'and'. The 'or' has always struck me as out of place.

> The abandonment of superstitious beliefs about the existence of Phlogiston, the Cosmic Ether, Absolute Space and Time, ..., or Fairies and Witches, was an essential step along the road to scientific thinking. Probability, too, if regarded as something endowed with some kind of objective existence, is no less a misleading conception, an illusory attempt to exteriorize or materialize our true probabilistic beliefs.

I haven't forgotten that I want to comment extensively on your draft. I sure hope to do it in the coming couple of weeks.

Jossi's Reply

> As for the translation, the word 'o' in Italian is usually translated as 'or' but could sometime be translated as 'and'.

24-11-09 *New Apologies: Me, Me, Me* (to N. Waxman)

Another week has passed and I still haven't put the *Physics in Canada* paper in your hand. I feel completely ashamed. On the other hand, I can honestly admit to having put an embarrassing amount of time into writing. (You'd probably not believe me if I told you.) Trouble is I've been proceeding with my two paper concept being very careful with my word choices:

> *To wit, from my previous note to you and Rob Myers*: How strict is the 2500 word-count limit going to be for the *Physics in Canada* thing? I ask because I just reached that number and still have a ways to go with my draft. I think what I am going to do,

now that I'm on a roll and really liking what I've written so far, is just plunge ahead, writing what feels right internally, and then let Natasha go at it with an ample scalpel. (I justify this in my mind by thinking, at the end I'll have two articles for the price of one. I'll find some place to send the longer one off to, even if only `arXiv.org`.)

The manuscript is, at the moment, just at 4000 words. Hopefully, if I get it done right, a significant portion of that will be simply detachable, and then we can smooth it out thereafter. But there's no denying, I've been writing the big version for me, me, me—trying to say things in a way that will have lasting value and persuasiveness.

Anyway, I felt I should write you this morning because, actually, I must take two days off this week and I feel very guilty about that: today and Thursday. Today, because I have to go to U. Toronto to work with the experimental team that's doing an experiment on one section of my *Physics in Canada* article (something called a SIC). Then Thursday because of American Thanksgiving, which is a big family tradition for us. But Wednesday and Friday, I'll give the paper my all—I promise.

To make a long grovel short: Can you—*please*— wait until Monday for the finished product???

25-11-09 *Modest Theories (with a capital M)* (to L. K. Shalm)

OK, Krister, your turn. (I'll cc Aephraim in case he's interested in these wispier things too.)

Thanks for your continued interest in this "QM as a single-user theory business"—I really do appreciate your efforts to get it straight, whether you accept OR reject in the end. The endpoint doesn't matter as much as the effort; the effort alone is flattering. (Plenty of so-called professional philosophers of science, for instance, reject the view at the outset without ever making an ounce of effort to understand what is new in it.)

First, on your particular question from yesterday. For it, please refer to a long note I constructed for Lucien Hardy after the last PIAF meeting. It can be found `http://www.perimeterinstitute.ca/personal/cfuchs/nSamizdat-2.pdf` starting at page 813 by raw pdf accounting (with regard to LaTeX page numbering, instead, that is page 785). The note is titled, "The More and the Modest". [See 16-10-09 note "The More and the Modest" to L. Hardy.] The idea argued for there is the sense in which Quantum Theory is a very modest theory. Not modest in the sense of saying it is merely about "black boxes"—as you were describing yesterday—but *Modest* in the way of Newton's theory of universal gravitation. I say this to contrast it with Weinberg, Witten, or Hawking's dream of a "theory of everything". Newton's theory is not that, but on the other hand it is still a sweeping statement about nature. So too I think for quantum theory—that though it is a single-user theory, it is nonetheless a sweeping and universal statement about the character of the things in the world. Here's the best way I know how to put the point: What I am aiming for is that quantum theory is a theory of ONE ASPECT of everything.

Read the note to Hardy (including the supplementary material in it); it'll do a better job than what I can write here in a single paragraph.

Further, let me attach a paper that I'm writing at the very moment. [See "QBism, the Perimeter of Quantum Bayesianism," `arXiv:1003.5209v1`.] Sorry, it's only halfway finished, but the beginning material may do a better job of motivating the single-user aspect of the program than previously. I have been trying to write it in an entertaining way; so hopefully it will draw you in.

If this stuff shakes anything loose in your thinking, please let me know. Or, if there is an aspect of it all that still strikes you of solipsism (or sophism!), please try to articulate it, and I'll give it my best shot of a thought-out reply. From every challenge I take on, I learn a little more.

30-11-09 *QELS* (to Z. E. D. Medendorp & A. M. Steinberg)

- This is Bayes' Rule or Bayes' Theorem:
  `http://en.wikipedia.org/wiki/Bayes\%27_theorem`
  See the first equation in.

- On the other hand, this is the Law of Total Probability:
  `http://en.wikipedia.org/wiki/Law_of_total_probability`
  See the third equation in.

My rewrite of the Born Rule (using SICs) is an analogue of the latter rather than the former.

30-11-09 *NOT Recommended* AMS Notices *Article* (to M. B. Ruskai)

I'm sorry to take so long to get back to you. I read the Chernoff article, and the end of it is indeed horrible: "In addition, experiments have been done which suggest that influence from one system to the other propagates enormously faster than light. These experiments point toward instantaneous transfer of information." There was just no call for any of that kind of discussion in an article about Gleason. On the other hand, is it worth a battle? This kind of crap happens all the time, everywhere you look—Nicolas Gisin is guilty of it, Alain Aspect is guilty of it: The list of otherwise good physicists just goes on and on. I try to fight the fight when I have to—for instance, see the present article under construction (and required of me from PI for a special issue)—but then sometimes I just get tired of building the background, trying to get the uninitiated to see the trouble after they've already had an untrustworthy introduction. [See "Quantum Bayesianism at the Perimeter," `arXiv:1003.5182`.]

I don't know, I partially fear taking on another project that'll probably leave me unsatisfied and more frustrated with the community in the end, at this time when I'm already far behind on all the other things I need to do.

01-12-09 *Hawaii in April?* (to H. Price)

It dawned on me that if we're going to have that meeting in April, I probably ought to get on planning it before December is out. [. . .]

As I said when I volunteered for this, I'd like to make the theme of the workshop: Contextuality, Perspectivalism, Pragmatism, or some combination/variation of that. In that regard, what do you think about inviting any non-PIAFers? I ask mostly because Richard Healey visited us for a couple months, and you should see the change in this guy (to the far-more interesting): He is now calling his research project for the next few years something like "developing a consistent pragmatism". See this fantastic talk he gave `http://pirsa.org/09110136/` at the end of his visit. Anyway, I think I'd like to invite at least him into the mix if we've got the budget for it.

Once we set some dates, I'll probably get Holly onto taking care of the hotel booking and logistics, etc. But first I want to hear back from you, then I'll start testing the waters more broadly within PIAF.

By the way, did you know you can be found on YouTube? I found you as I was looking up pragmatism talks!

07-12-09 *Eric's Note, 2* (to E. G. Cavalcanti)

Cavalcanti-ism 5: *I found this message gathering some dust in my mailbox.*

Taking your cue, I think I'm going to have to let your own note gather some dust in my mailbox. I just don't have time for a proper reply at the moment. I'll try to come back to you more properly after the New Year!

Cavalcanti-ism 6: *I am still very confused about this, even after reading your paper and listening to your talk. If this "dressing" of raw probability theory has an empirical component, doesn't it have a fundamentally distinct origin as the rest of probability theory? The extra structure that is added by quantum mechanics seems to have, in this view, a contingent nature, dependent on the specific ontology or the laws of nature of our world, and it is not a pure "law of thought" as plain-vanilla Dutch-book coherence.*

I mean, I could, in a very similar way, propose a theory of "gravitational decision theory", which claims that, on top of Dutch-book coherence, we should add a normative principle about gambling on the outcomes of experiments involving the relative movement of massive objects. But really, the best way of thinking about this, of course, is that Dutch-book coherence is all there is to probability theory, and anything added on top is just an instance of a good-old law of physics. In this case it would be a category mistake to confound the two. What is essentially different in your view that makes it not the same type of category mistake?

Ok, I will partially answer my own rhetorical question: underlying the probabilities in the example above is a deterministic, noncontextual hidden-variable theory. And now comes a non-rhetorical question: is there something about probabilities which do not allow noncontextual hidden-variables that makes your kind of position immune against the category-mistake criticism above?

On another note, another important feature of quantum probabilities is that they refer to **fundamentally** *counterfactual (or complementary, in Bohr's words) measurements, as opposed to the classical ones which could always in principle be performed simultaneously (and complementarity is a necessary—perhaps sufficient?—condition for the failure of noncontextual hidden variables. That is, in a world where all measurements can be performed at once there is always a noncontextual hidden variable model). Do you think perhaps you could say something along the lines that the extra normative assumption you propose can be justifiably called a normative rule of decision theory (as opposed to a law of nature) in a world where complementarity exists?*

In the meantime, I know there is a lot of repetition with what you have already seen, but let me recommend these two presentations:

- `http://pirsa.org/09090087/`
- `http://pirsa.org/09080018/`

I explicitly address some of your questions about the interaction between normative rules and physical law there.

Hope things are going well for you.

I certainly liked reading this line of yours:

Cavalcanti-ism 7: *And perhaps even Leibniz's monadology can accommodate something like the "republican banquet" you (and I!) have in mind.*

And finally let me give you a hint of an answer to this:

Cavalcanti-ism 8:

> [CAF wrote:] The other night Ruediger and I were semi-jokingly saying that the dimension d of a quantum object quantifies how much "will" it has. But, maybe some variant of that will not turn out to be so much of a joke after all.

That sounds interesting. Can you expand on that?

See attached excerpt from "My Struggles ..." [See 16-10-09 note "The More and the Modest" to L. Hardy.]

10-12-09 *Lawless World / Malleable World / Pluriverse* (to N. Cartwright)

I was glad to see today that Steve Weinstein could send you an invitation to our meeting on laws. (I am only a minor player in organizing this meeting.) I thought I might tell you independently how much I really hope you can come. Sad to say, I've only recently discovered your work, but that said, now that I know it, I am greatly enthusiastic about it.

I offer evidence that our thoughts on laws, etc. are in some sympathy with a few pieces of my own writing (see attached):

1) The introduction to my Cambridge U Press book *Coming of Age with Quantum Information*—you might find some of my early life (especially my distrust of "laws of physics" at the age of 12 or so) reported in the first few pages amusing. You might also enjoy some of my stories in there about some people you surely know—for instance, Abner Shimony and Jeff Bub.

2) An excerpt from my samizdat *My Struggles with the Block Universe* where I describe my extreme empiricism and how I am starting to see the Hilbert-space dimension of quantum systems as a "capacity" in a sense (I think) quite similar to your own. [See 16-10-09 note "The More and the Modest" to L. Hardy.]

3) The beginning of a paper I'm writing for *Physics in Canada* describing my "Quantum Bayesian" program for interpreting quantum mechanics. Though, I don't have the section on "Hilbert dimension as capacity" written yet, it will give you some introduction to the way I am starting to think of quantum mechanics in "normative terms," and maybe you can use your imagination on how to fill in the last sections.

Anyway, I hope these things whet your appetite a bit—i.e., to see that there is a (practicing) physicist who very much believes that there is no law that cannot be broken, that the world is malleable, and that the concept of a capacity is just what the doctor ordered for understanding quantum mechanics.

Of all our participants, I feel I could learn the most from a few well-placed conversations with you. I very much hope you can come.

14-12-09 *Invitation to Lecture* (to J. Emerson)

If I understand correctly, my lectures are March 9 and 11. Assuming that's correct, I've marked my calendar.

Title: Quantum Bayesianism at the Perimeter

Abstract: Theses lectures give a summary of the Quantum Bayesian point of view of quantum mechanics, originally developed by D. M. Appleby, H. Barnum, C. M. Caves, A. Peres, R. Schack, myself, and others. It is a view that arose from and depends crucially upon the tools of quantum information theory. Work at Perimeter Institute continues the development and is focussed on the hard technical problem of a finding a good representation of quantum mechanics purely in terms of probabilities, without amplitudes or Hilbert-space operators. The best candidate representation involves a mysterious entity called a symmetric informationally complete quantum measurement. Contemplation of it gives a way of thinking of the Born Rule as an addition to probability theory, operative when one contemplates gambling on the consequences of one's interactions with a new universal capacity: Hilbert-space dimension. (Newton gave us gravitational mass as a universal capacity; with hindsight one can say that the founders of quantum mechanics gave us another universal capacity.) The lectures end by showing that the egocentric elements in this point of view represent no impediment to pursuing quantum cosmology and outlining some directions for future work.

(I stripped both title and abstract for a *Physics in Canada* article I'm just finishing this week.)

18-12-09 *Sorters and Jokes* (to D. Bacon)

Hey, you're a man who likes a good stiff joke. Tell me whether a couple of my anti-Everett snide remarks hit the right tone in this paper I'm writing at the moment. See attached. Number 1 can be found in the last paragraph just before the section "Quantum States Do Not Exist" begins:

> The Everettian world, on the other hand, purports to have no observers, but then it has no probabilities either. What are we then to do with the Born Rule for calculating quantum probabilities? Throw it away and say it never mattered? It is true that much effort has been made by the Everettians to rederive the rule, but to many in the outside world, it looks like the success of these derivations depends upon where they are assessed: for instance, be it Oxford [8] or Cambridge [9] instead.

Number 2 is in the mid paragraph of the right column of page 3; scan for the word "lizard":

> The point is, far from being an appendage cheaply tacked on to the theory, the idea of quantum states as information has a simple unifying power that goes a significant way toward explaining why the theory has exactly the mathematical structure it does. By contrast, who could take the many-worlds idea and derive the structure of quantum theory back out of it? This would be a bit like trying to regrow a lizard from the tip of its chopped-off tail: The Everettian conception never purported to be more than a reaction to the formalism in the first place.

29-12-09 *. . . And Happy New Year* (to H. C. von Baeyer)

. . . or, better, Happy New Decade

Thank you for your nice Christmas Day note. I'm sorry to say it has taken me this long to reply to you. The Saturday before Christmas I started coming down with (I guess) a sinus infection, general congestion, deep cough, chest congestion, muscle aches, etc. At first I thought it was the flu (perhaps brought on by the flu shot I got the day before), but since I never developed fever, my guess now is that it was just probably a badly placed bacterium. Anyway, I have been very slow to get over it, and the thoughtful/philosophical/reading-filled break I was hoping to have from PI is now starting to disappear. (Don't get me wrong, the holiday with the family was still quite good and satisfying family-wise; I just haven't had the thought-filled time I had planned for.)

I had dreams of writing you and Marcus all kinds of stuff on the "neutral stuff" that I'd like to start thinking of "quantum events" (called "measurement outcomes" when one starts to think of one term as an agent) as exemplary of. It was a theme of thinking I started last year at this time and has been in the background of my thoughts since … trying, I can tell, to solidify into some kind of articulable entity. Though it is not there yet, at least a little progress has been made. If I could just put what little bit I've got onto paper, I know that would accelerate the process.

As a poor substitute, let me attach another draft in progress. It at least helps lead up to the point I want to get to in personal conversation … in ways perhaps that I have not articulated before. Even though incomplete, I hope you enjoy. [A few warnings: 1) Figure 2 is not quite right; that should be $Q(D_j)$ in the box—it's an old picture and will be redrawn. 2) Most of the exposition is stabilized up until the last two paragraphs of the "capacity" section. Thereafter, all bets are off, including the references I cite. 3) If you print this, the hand-drawn illustrations, until better cleaned up, will come out much better on a color printer.]

Maybe too, I'll leave you with an intellectual challenge if you're looking for a little diversion. I'll give it the code name, "What Did He Read and When Did He Start Saying It?" Pauli, as you know, used the terms "psychophysically neutral," "neutral language" and "neutral" itself quite often. But where did he pick the term up from? Is it a self-invention? Or did he pick it up from Jung? Or in reading William James or Bertrand Russell or still someone else? Did Pauli read Russell's book *The Analysis of Mind* (1921) where the word is splattered everywhere?

James himself has these two passages in "Essays on Radical Empiricism":

> First of all, this will be asked: "If experience has not 'conscious' existence, if it be not partly made of 'consciousness,' of what then is it made? Matter we know, and thought we know, and conscious content we know, but neutral and simple 'pure experience' is something we know not at all. Say *what* it consists of — for it must consist of something — or be willing to give it up!

and

> In 'Does Consciousness Exist?' I have tried to show that when we call an experience 'conscious,' that does not mean that it is suffused throughout with a peculiar modality of being ('psychic' being) as stained glass may be suffused with light, but rather that it stands in certain determinate relations to other portions of experience extraneous to itself. These form one peculiar 'context' for it; while, taken in another context of experiences, we class it as a fact in the physical world. This 'pen,' for example, is, in the first instance, a bald *that*, a datum, fact, phenomenon, content, or whatever other neutral or ambiguous name you may prefer to apply. I called it in that article a 'pure experience.' To get classed either as a physical pen or as some one's percept of a pen, it must assume a *function*, and that can only happen in a more complicated world.

Did Pauli, by chance, read this book? It's not a very well written article, but one easy source for you to find some other literature that Pauli might have read is the Stanford Encyclopedia article on neutral monism: `http://plato.stanford.edu/entries/neutral-monism/`.

Anyway, there are the few thoughtful thoughts I can muster this morning. For the rest of the day my alter ego must come out and work on Marcus's latest masterwork. I'm giving it my final run-through, and with some luck we'll get it posted before the week is out—it should have been posted two weeks ago, except for my dragging things on like this. I'm just trying to catch typos at this stage, but I've got nearly 30 pages to go, and I'm finding it particularly taxing in this condition. In case you need a diversion for your brain's other hemisphere, I'll attach it as well.

January 15 to 25 I'll be in Vienna giving the Zeilinger group some lectures on SICs. It would sure be wonderful if you could be in town at the same time! Now that's a place to walk and talk and get some insight on quantum mechanics!

All the best to you and Barbara, and really a happy New Year.

Hans's Reply

> I'm looking forward to reading your *Physics in Canada* piece at leisure.
>
> In the meantime, I have done a quick check of my Pauli library to find what seems to be the first reference to "neutral language." Provisionally I believe it occurs in an unpublished 1948 essay reproduced on p. 179 of *Atom and Archetype: The Pauli/Jung Letters*. Do you have it to hand? "Neutral" appears on p. 182.
>
> Interestingly Pauli goes on to answer your question (What did he read?) on the bottom of p. 188. As is often the case, he throws us a curve! Pauli does not always look to higher authority, as most of us do, and as you suggest in your list of possible inspirations. Often he looks to *lower* authority, by which I mean that he reads something with which he strongly disagrees, but which he then corrects and extends. In this case it is by an author whom he batters into the ground before picking his brain. At the end he has the priceless comment: "Regardless of any justified criticism, however, we can again ascertain from the spontaneous manifestations of this author's unconscious that…" I love the pat on his own back implied by the word "justified", and the idea that the poor guy wasn't even *conscious* of what he taught Pauli.

29-12-09 *New Year, New Decade, New Physics!* (to M. Schlosshauer)

These coincidences keep happening to us, and it is a strange thing. The very day you wrote your note below, I was literally thinking about you as I was walking home from PI. I was thinking it would be nice to send you some of the latest foundational thoughts on quantum mechanics, jazz, nonreductionism, and metaphysical pluralism, all stirred into a soup—the time seemed ripe again. But as I walked home, I started to feel worse and worse and found myself in the beginning of a holiday-long sinus/cold/cough/congestion/flu sort of thing, and I'm only starting to recover decently now. BUT that evening when I opened my email at home, I saw your greeting and, indeed, noted the new round of synchronicity!

I hope you have a great coming year, and indeed a great new decade, filled with all the same things you wished for me.

It is a sorry substitute for saying something more personal, and particularly using this time to think more deeply about the context of jazz, but let me attach something that I hope to return to writing in the next few days after I really get recovered. Most of the document is pretty well stabilized, at least up to the last two paragraphs of the "capacity" section. Thereafter, I guess all bets are off. [And warning: Figure 2 is not quite right. That should be $Q(D_j)$ in the box—it's an old picture and will be redrawn eventually.] Comments for improvement certainly welcome, though if my health keeps improving I hope to have it posted next week.

Sorry to say, Rüdiger still hasn't come through on the promised decoherence draft. I'm dropping in on him for a day Jan 25, on my way between Vienna and Texas, and I'm hoping to tighten the screw to a very uncomfortable level then.

And by the way, we need to come back to the idea of a PI visit this Spring or Summer if you'd still like to do it. If you could flag potential dates, that'd be great. At the moment, it looks like I should be able to pay all your expenses.

Anyway, once again: Happy New Year and happy New Physics!

30-12-09 *Gentle Rib* (to H. C. von Baeyer)

von Baeyerism 38: *Like all Americans you are color-blind to the distinction between ie and ei. The lady's name is GIESER as in Fierz (which you always get right).*

That's funny: I tried to be so careful about that! (I am aware of my shortcomings.) I remember even looking at the cover of the book before writing my sentence "to make sure" I got it right. So much for surety.

Anyway, look at Gieser's book, page 45. There she says: "According to Mach direct experience is *psychophysically neutral*." Now a question on my mind is whether Mach himself ever used that kind of terminology.

BTW, I often check my spelling of Fierz too.

30-12-09 *Happy New Year Again* (to H. C. von Baeyer)

von Baeyerism 39: *Provisionally I believe it occurs in an unpublished 1948 essay reproduced on p. 179 of* Atom and Archetype: The Pauli/Jung Letters. *Do you have it to hand? "Neutral" appears on p. 182.*

Interestingly Pauli goes on to answer your question (What did he read?) on the bottom of p. 188.

Thanks, I had a look at that. From Gieser's book I find that he wrote Fierz on the subject at almost the same time, 21 August 1948. See PLC III [971] on page 561. It might be good to look at that.

But even earlier than that I note that Pauli writes Jung in a 28 October 1946 letter, "It appears that Fludd's voice, which was ignored at the time, is imbued with new meaning, since for the moderns the objectifying of space had only limited validity. The *neutral language of the 'Blond'* in the dream (he did not employ such terms as 'physical' or 'psychic' but just talks of people who 'know what rotation is' and those who do not know) seems to be reanimating that intermediary layer where the infans solaris used to be. The modern unconscious speaks here of a 'radioactive nucleus'."

Somehow I suspect though that it really must go earlier than that, but I've got no evidence. If you read the Preface and first 8 pages of the Introduction to E. C. Banks' book *Ernst Mach's World Elements: A Study in Natural Philosophy* (on Google Books) you'll see his take on Mach was that he was actually espousing a neutral monism with his world elements. And Pauli would certainly, I would think, have read Mach very carefully. But see Pauli's letter to Jung dated 31 March 1953—there he definitely describes Mach's elements as psychical rather than neutral. [By the way, doesn't Banks' book look fascinating?]

I might write Gieser eventually. She seems to have noted what books precisely were in Pauli's library. It would be interesting to know exactly which James books (if any), which Russell books (if any), etc., Pauli gives evidence of having read.

On another subject, it looks like we're going to get that Appleby masterwork (now finalized) on the `arXiv` this evening! With that, my 2009 work is done and I myself can look toward the new decade!

31-12-09 *Last Posting of the Decade* (to C. H. Bennett)

I've got to say I was jealous this morning when I saw that you had the last posting of the decade. That's because a few weeks ago I was dreaming of myself trying to nab that coveted spot. But I ended up pushing myself so close to the edge of the deadline that I didn't even finish the paper! (With another paper, I did at least get position #4 of the new year.)

Anyway, with the end of the day here, and the thing still not finished, I thought I might send you the present draft of the less fortunate one. It might give you a smile (and some significant horror) to see what might have, with more diligence, been in the place of the beautiful reverse Shannon theorem. (You might also particularly enjoy Figure 3.)

I hope you and Theo and all the kids and grandkids are doing well and perched for a happy and productive new decade. Greetings to you all from Kiki, the kids, and me. [The kids know of you from the (around our house, famous) Charlie and the Christmas-Tree Cookies story.]

31-12-09 *QB at the Perimeter of Understanding* (to H. C. von Baeyer)

von Baeyerism 40: *I have spent a very pleasant last afternoon of 2009 reading your draft. It is, of course, perfect for me in my role as Sagredo to your Salviati and your critics' Simplicio. Since the decade will be over in a few hours, I do have a wish. I think your argument has, indeed, stabilized, but it should not be allowed to fossilize. I read your accounts of Bayesianism and SICs with growing understanding. Nevertheless. I still don't have a truly internalized grasp of Figure 2. Seeing it yet again does not help me. So I have the hope and wish that in the new decade you will invent a new version that looks at the same issue from a slightly different point of view. (Feynman praised the ability to recast the same problem into different formulations.) Maybe your visit to Vienna will result in a simplified version of what Anton will actually DO to verify equation 6 – and what he would expect to find in a classical world. Or maybe there is a useful analogy to the double slit experiment.*

So that's the challenge: Your words are new and fresh, your formulas are immutable, can you come up with new pictures?

I will do my best, and you will probably find me consulting with you on the issue. (Maybe I need to be like a salesman in a dress shop.)

In the meantime, let me attach the figure of the Steinberg group qutrit SIC experiment (in an abstract submitted to the QELS meeting). It doesn't depict the meaning of the old diagram, but maybe it will give you some sense of one way of to do the experiment.

I send this to you, and then I go drink my first round of bubbles for the evening!

Hans's Reply

> I trust the bubblies were uplifting!
>
> Thank you for the Steinberg paper. Maybe it shook something loose in my brain. The attempt is to make *actual* SIC measurements, and this brings them down to Earth

for me. My trouble was precisely with the point you labeled "unheard of in physical science", namely the reference to counterfactuals. These have always been vaguely mysterious to me. First you called them measurements in the Bureau of Standards. Then they moved to the sky. For me this language was perhaps a little too mystical. Now the SIC measurements have moved down to Steinberg's or Zeilinger's lab, so you might call them "Toronto measurements" or, narcissistically, "Perimeter measurements."

I guess I had clothed them in magnificent raiments, when they should have been as naked as the emperor. They simply provide a unique universal characterization of a quantum system, usurping the role of the wave function. Is the word counterfactual a little too suggestive here? I mean, when I step on my bathroom scale, I am tacitly saying that "if I were to weigh myself, counterfactually, against the kilogram in Paris, this is what I would find." This statement is then transferable to any scale in the world. (Of course that's what you had in mind in the first place.) But I never use the word counterfactual in my bathroom.

I will try to find language, such as "standard description" or "naked description" or something, that I'm more comfortable with.

I'm sorry to be so obtuse and thank you for providing me with an AHA moment to start the decade with.

03-01-10 *New Decade, Three Days In* (to M. Schlosshauer)

I've had a wonderful afternoon with the Hammond B3. My three girls went out skiing, and I built a fire and put Larry, Larry, Barbara, Max, and all the Water Babies on in the background, just letting the music loop and loop. A very relaxing and thoughtful afternoon—exactly the sort of thing I had been hoping for all vacation . . . but just as PI is about to open up again! Too bad . . . but at least I got one day of it.

Schlosshauerism 10: *Thank you for the attached paper. . . . I was happy to see that you're including a little section on the Deutschian quantum-cosmology argument in your paper. I completely agree with you that the argument is "nonsense." Deutsch's quote breathes the same spirit as those shopworn claims that it's only the Everett picture that "takes QM seriously." Here's another statement by Deutsch – you probably know it already – that seems to fall into a similar trap:*

> But in fact, there is only one known interpretation of quantum theory. . . . Perhaps one reason why the dichotomy between 'formalism' and 'interpretation' has been accepted so uncritically is that the debate has been conducted almost exclusively among theorists. Thus it has revolved around the question, 'what exactly does quantum theory imply about reality?' Putting it that way can make it seem natural to try to separate the 'scientific' (mathematical, predictive) core of the theory from its explanatory structure, and to keep the former fixed while adjusting the latter to one's philosophical prejudices. But no good can come of such an exercise. The formalism of quantum theory did not come out of nowhere. It is the solution of a scientific problem and, as always in science, the problem was not primarily what mathematical formula best predicts the outcomes of experiments. It was what mathematical structures correspond best to reality. If we alter the 'interpretation' of the theory without regard to the second question, we can conjure up virtually any world we like. But it will not be the real world. The real world is the multiverse, and it does contain many universes.

And thanks for the long note, Deutsch thought, typo, and all the rest. Most especially for the news that you and your wife will be having a baby! (You look so young to me that I had never expected you to be married ... much less nearing fatherhood.) As David Mermin (I think!) told me just before our first was born nearly eleven years ago: Nothing in your life will be harder or nothing more rewarding. Your children will shape you just as much as you shape them. And if you're like me, they will inspire sentences and paragraphs in your papers, and all kinds of natural philosophy in your mind.

I think I doomed myself by writing you last week, "I hope to have it [my draft] posted next week." That means that, of course, the draft changed nearly none at all from the first version I sent you! And there's no way it will now be posted this week, as—first thing—I've got to stop working on the extended version and get to work on the smaller extract (long overdue and must be gotten in to the editor this week). But I did read through the whole thing again, tweaking things a little when I could. One substantial point though: There was something quite misleading in the quantum de Finetti discussion. Since you indicated you might be reading those early parts, let me send you the present draft even though I still haven't completed the damned thing (and, as I say, probably will have to leave developing for much of the week): I just want to divert as much potential damage as possible in your thoughts on de Finetti.

There are a few more lines at the end of the capacity and cosmology sections, but not too much. Particularly, though, I found myself playing with Shakespeare as I was driving home from the library today, and I just had to record it. And now apparently I just have to send it to you as well! (I get tickled with myself when I feel I have made a good phrase.) Somehow I will make those lines fit properly into the paper when it's all done:

> These our actors, as I foretold you, were all spirits
> And are melted into air, into thin air ...
> We are such stuff as
> Quantum measurements are made on.

At the moment, all of July seems to be open for me. (Jan Vienna, Feb Nagoya, Mar Portland, Apr Chapel Hill NC, May nothing, Jun Växjö, Jul nothing, Aug Leipzig possibly, ...) So, let's tentatively pencil in July. If you have any weeks to suggest, let me know, and at least that will provide some points of resistance if anything tries to intrude. (We don't have to set them in stone yet, but points of resistance are good for helping promote well-meant plans to reality.)

I did very much enjoy (finally!) learning about the two Larry's today—I'm sorry I put it off for so long. That is really good stuff. Larry Young's version of Monk's Theme, for instance, really took me. Please do give me more recommendations as you think of them. Tell me about some of the Jimmys I should be looking out for.

Congratulations again on the baby. That's really nice news. What's your wife's name? Where's she from, etc.

03-01-10 *Slightly Better Rhyme* (to M. Schlosshauer)

Well, the girls came home from their day of skiing, full of stories of grand adventure. That went on for some hours as their mother and I poured more and more wine, eating cheese, laughing, wincing, and smiling at their stories, enjoying our everlasting pride in them. (When I said "three girls" earlier, by the way, I meant their mother and the two younger ones—total of three.) But then they left me all alone tending this fire that simply won't die! (I have tried to speed it along, but it is as procrastinating as I am in writing papers.) Anyway, I had nothing to do in this stuporous state but write a little more on the *Physics in Canada* draft—and you are the guinea pig. Attached is the result of a drunken fit: I rearranged a rhyme! See the Shakespearian modification!

Danger becoming one of my correspondents, it is!

04-01-10 *Birth Notes* (to M. Schlosshauer)

More later on various subjects in your note, when I need a second break! For the moment, I'll just say I do know Bill Evans very well (love him), and let me comment on this:

Schlosshauerism 11: *Thanks for your congratulatory wishes on the baby! ... The assessment of "nothing in your life will be harder or nothing more rewarding" is wonderful. What I like about the whole prenatal period is this exhilarating mixture of certainty and uncertainty. One knows that there will be a child added to your life in a mere few weeks. Yet there's so little one can figure out in terms of what the whole experience will actually be and feel like, until it all happens. (Excuse the crude and somewhat geeky analogy, but it's almost like with quantum measurement: You know there will be an outcome, but you don't know what it will be.*

It's not geeky at all. You remember my story about Christiania? Below are some more respectable variations on the moniker that story was about. [See notes: 28-07-00, "The Role of Registered Phenomena," to David Baker; 03-09-01, "Subject/Object," to Michael Nielsen; 20-09-01, "Praise, Folly, Enthusiasm," to Bill Wootters; 19-07-03, "Definitions from Britannica," to David Mermin; 18-05-04, "Agents, Interventions, and Surgical Removal," to Jim Woodward; 17-06-04, "Preamble," to Hideo Mabuchi; 27-02-09, "Vivienne and the Universe," to Lucien Hardy.] My opinions have certainly changed on some things since the earliest notes, but the common thread, that quantum measurement and birth are identical in a very deep sense, seems to have weathered the storms.

Thanks for giving me the impetus for this little stroll down memory lane. I once read a book by Ludwik Fleck, *Genesis and Development of a Scientific Fact*. It was mostly a study of how the diagnosis and treatment of syphilis developed over the years. What was so interesting to me in it was how the science that developed did so because, long before there was any science at all to the matter, and long before anyone had a right to think so, syphilis came to be viewed as a "blood condition." And this of course suggested the idea of blood tests for syphilis, and treatments that had nothing to do with the outward symptoms, etc. You're wondering why I'm telling you this. Well, in this stroll down the memory lane of birth, creation, and measurement, I started thinking how I had thought I was writing something fresh in this new paper of mine! Calling Hilbert space dimension a capacity, etc., etc. *But no*, I was calling it a capacity already in 2004, long before I had a right to think so, and particularly long, long before Eq. (9) in the present paper was even dreamed of!

No lesson here yet, but it is a curiosity to me.

05-01-10 *Three Attachments ... No, Four* (to M. Schlosshauer)

Thanks for your musings on the psychology of quantum foundations. It is a vexing issue, and one that I come to in my own head from time to time. Appleby and I also discuss it quite often, usually in frustration over something Rob Spekkens, or Harvey Brown, or Jeremy Butterfield, or Matthew Donaldson, has said—it seems those four are very often the foci of our conversations on these matters. They are our friendly foils. Appleby gets particularly riveted—you should see him in action—going on about how they desire a dead universe or how they can't possibly *really* believe what they say. He claims that if one *really* believed in a deterministic world (despite one's going about life in a normal way), it would be tantamount to insanity; so he thinks deep down they're all speaking lies.

Sometimes, I tend to think the rationalists derive a kind of religious comfort from determinism. It takes all the responsibility off their shoulders at some very deep level.

I think you hit the nail on the head when you talk about the influence of the PhD advisors—certainly in the vast majority of the cases. Of course, I feel immune on this issue myself, as I tried to make clear in my "How to Stuff a Wild Samizdat," but I do really think it true for the vast majority of the cases. There was one Bohmian postdoc we had here at PI (actually you saw him speak at a PIAF meeting in Sydney when I first met you) who very clearly could have fallen into any line of physics if his PhD advisor had just been a different one. And when he was having trouble finding his next position, I told Kiki several times (she was concerned because she knew the wife) that, "If he had just had a better luck of the draw field-wise ..." Anyway, I definitely worry about this with my own students: I almost wish they would disagree with me more and try to articulate reasons for holding their ground. It worries me that they sometimes seem to accept QBism a little too easily.

Schlosshauerism 12: *This desire might be so ingrained in us, not only intuitively but also in terms of the general scientific mindset, that anything that departs from pursuing a deterministic program is akin to giving up on of the very ideals of science itself. (I bet you've heard people say that about your program!)*

Indeed I have! Many times over. Attached is a report to Asher Peres of the first time I can recall of it—it's from `Notes on a Paulian Idea`. It was the first time David Albert beat me up (though it wasn't the worst licking he ever gave me). If you look at the "disclaimers" page in NPI, you'll find these words:

> Various deletions of text have been made to the original letters. The purpose of the vast majority of these is to spare the reader of the "merely personal" in my life. A smaller fraction are for the sake of protecting the innocent, protecting the correspondents, and protecting the illusion that I am good-natured.

Well, I intentionally left one personal insult in that document (and one by accident). The intentional one was about Albert. (I'll tell you about his worst thrashing of me the next time we see each other—it's a story I don't feel like writing at the moment.) [...] And, yes, I rearranged the Shakespearian thing again—this time I finally got it right, and will make it a piece of the ending of the paper.

Schlosshauerism 13: *Basically, the upshot is this. Genomics tries to make us believe that life is basically nothing but DNA.*

And funny you bring that up; I used DNA among my examples today in the "nothing but" section of the paper. In the PiC draft, do a search on the word "Carbon"—you might enjoy some of things in my list that DNA has characteristics in common with.

Schlosshauerism 14: *How about yourself? I know — from your Samizdats — that your wife's (nick-?) name is Kiki and that you have two daughters. But that's about it.*

Yep, Kiki is a nickname. When she was a baby, her older brother couldn't pronounce Kristen, and it stuck. The happy story of how I met her is attached (written in a larger context of a rather sad story). [See 16-02-02 note titled "Some Things Should Not Pass."] Her present career is refurbishing this rotten old house, but she was an elementary-school teacher in the past (until Emma, aka 11 years ago). Final attachment(!) is a story on the interplay/intersection of our two careers.

OK, I should stop boring you! (And certainly don't read any of that crap if you don't feel like it. It's just my long habit of regurgitating stories—sometimes I can't stop. I'll not be bothered at all if you've got better things to do.)

Max's Preply, "Randomness, Temperament, Genomics"

Thanks so much for these very thoughtful and thought-provoking musings about birth. They're very inspirational, in the best sense of the word. (I.e., they're the proverbial opposite of the "inspirational" associated with the tacky tele-evangelist. Not that I'd ever confuse you with a member of that creed.)

Many thoughts came to my mind when I was reading these notes of yours. Two of them really stuck out. They're both, in a way, personal contemplations about why other people hold certain opinions, or, in particular, arrive at particular conceptions of the universe (or quantum mechanics, for that matter). I hope you don't mind if I just throw them at you. They probably amount to hardly anything new.

The first one is – and it's something that's occupied me for a while – the issue of determinism. During the era of classical physics, determinism may have seemed like an inevitable consequence of what science was telling us. And people – philosophers, scientists, and lay persons – tried to come to terms with this development. They did so either by trying to find an escape route from the confines of the block universe, or by accepting determinism while still trying to seek out a niche where our intuition about an open future that's in continual creation could continue to exist in some way.

But then quantum mechanics came along. And suddenly we had the strongest indicator (not proof, of course) of some form of intrinsic ("irreducible") randomness – indeterminism – that one could possibly dream up. (Really, could you imagine a *better* way? So simple, so abstract, so mind-boggling, and so far-reaching?)

And what seem many, if not most, people working in foundations these days engaged in? To me, it seems to be programs geared toward restoring determinism, may it be in form of Bohmian trajectories, a global Everettian "quantum universe," or whatever. I'm not inclined to judge these approaches, I simply and plainly find them puzzling. And so I wonder (a lot) why so many people pursue such programs.

I have no good answer. Right now, I can mainly think of one reason, namely, that the ideal of science itself all along has all been one of determinism. Not just one of causality, but one of linking the occurrence of event A to the definite consequence of event B. This desire might be so ingrained in us, not only intuitively but also in terms of the general scientific mindset, that anything that departs from pursuing a deterministic program is akin to giving up on of the very ideals of science itself. (I bet you've heard people say that about your program!) I know I'm probably not saying or observing anything new here; I'm just trying to make some sense of the sociology of foundational scholarship.

The other thought is actually something I was contemplating again earlier today, and your note struck the same chord. (Another one of those coincidences, it seems.)

More precisely, it was your quote of James (a quote that I highlighted, *and* later marked in the margins, when I was reading James' book):

> The history of philosophy is to a great extent that of a certain clash of human temperaments. Undignified as such a treatment may seem to some of my colleagues, I shall have to take account of this clash and explain a good many of the divergencies of philosophies by it. Of whatever temperament a professional philosopher is, he tries, when philosophizing, to sink the fact of his temperament. Temperament is no conventionally recognized reason, so he urges impersonal reasons only for his conclusions. Yet his temperament really gives him a stronger bias than any of his more strictly objective premises. It loads the evidence for him one way or the other, making a more sentimental or more hard-hearted view of the universe, just as this fact or that principle would. He *trusts* his temperament. Wanting a universe that suits it, he believes in any representation of the universe that does suit it. He feels men of opposite temper to be out of key with the world's character, and in his heart considers them incompetent and 'not in it,' in the philosophic business, even though they may far excel him in dialectical ability.
>
> Yet in the forum he can make no claim, on the bare ground of his temperament, to superior discernment or authority. There arises thus a certain insincerity in our philosophic discussions: the potentest of all our premises is never mentioned. I am sure it would contribute to clearness if in these lectures we should break this rule and mention it, and I accordingly feel free to do so.

If you look back at the set of questions I sent you for the interview book that I'm putting together, there was one question that asked precisely about this issue of predisposition, of temperament, of philosophical prejudice, with respect to one's choice of foundational program. This influence may start very plainly, very simply, at the level of one's PhD supervisor. As you may have observed yourself, there are many people in foundations who work on a particular interpretation that "happens" to also be the favorite interpretation of their adviser. But of course it goes much deeper than that. A Bohmian may not be a Bohmian simply because he likes so much the form of the guiding equation and the double-slit imagery of trajectories, but also because it fits a more deeply rooted fundamental affinity toward a classical particle-based world view. Again, I'm not stating anything new here, but I think that some of the emotional debates in foundations would have some chance of leveling off to some extent if everyone just clearly stated their philosophical convictions and these convictions' influence on their (i.e., the people's) attitudes.

This is a very long-winded way of saying that I'm very fond of the birth imagery in quantum mechanics. If I see a lifeboat that has promise of staying afloat, and may actually take me to a new island, why hold on to the old sinking ship of determinism?

OK, I think I'm entering the "rambling" territory, so I better stop before this ship is drifting even more off course.

PS. Against all better intuition, here's another off-topic addition to the theme of our conversation. Last night I finished reading a little book on Darwin, genomics, and the "book of life." (The book is in German, but it's not really relevant anyway.) Basically, the upshot is this. Genomics tries to make us believe that life is basically nothing but DNA. What we are, what makes us human, is encoded in this sprawling sequence of

ACGTs. Figure out the sequence, and what proteins it codes, and you've got it all. The author of the book argues, quite persuasively I thought (mostly by appealing to recent scientific evidence, but also via more philosophical insights), that this is a gross oversimplification, and that we ought to be ever-cautious of such simplifications. In a very vague sense, this reminded me of the debate in quantum mechanics: how we try to read the formalism as reality, as describing everything there is, thus taking reductionism to its extreme. (Witness the Deutsch quote I sent you.) In this terribly vague and surely oversimplified way, quantum states strike me as akin to the ACGT of molecular biology. Both are *our* ways of dealing with the world, of deciphering it and coming to terms with it and trying to manipulate it. But they are not the world (or the human, or life) itself.

05-01-10 *That Thoughts Matter* (to M. Schlosshauer)

I worked hard to find something in Marcus's email corpus that would instantiate/corroborate what I told you of his reactions to determinism-seeking psychologies. I don't feel I've been all that successful (I'm sure there's something better out there), but I give up for the time being. Anyway, attached are two things: 1) A draft of an article Hans Christian von Baeyer was writing at the time, and 2) Marcus's reaction to it. It's the latter that I wanted to exhibit to you, but I included the former for completeness.

Marcus's writing is in PauliNotes.doc. For entertainment, you might pick about at page 6 where he starts talking about believing positivism as having the potential to lead to suicide. And then again at the bottom of page 8, where he asks "why people find it so hard to accept that thoughts actually matter." Oh, here's a choice one: Look on page 10 where he writes, "Materialists affect to believe—believe themselves to believe—that we are nothing more than complicated machines." Thereafter, there's some interesting stuff up to page 13 at least. Actually, there's further good stuff throughout. Just food for thought.

Now, maybe, I go to bed!!

05-01-10 *Importance of Humanism and Dogs* (to M. Schlosshauer)

Wow! Maybe even more than for the music, let me thank you for this! Particularly for the parts between the 1st and 2nd diamonds:

Schlosshauerism 15 : *I was very pleased to see that you gave an explicit run-down of the Wigner's-friend scenario (page 6). I think most readers will agree that the worry over an assignment of different quantum states by Wigner and his friend is dissolved in the personalist framework.*

Still, your argument may not—at least not at this point of your paper—dissolve all the concerns people get tangled up in when thinking about this thought experiment. What they might continue to worry about may not have so much to do with quantum-state assignments but with "what is really out there." On the one hand, Wigner's friend is believed to have seen one outcome. On the other hand, Wigner could, in principle, perform an experiment demonstrating interference effects between different outcomes. So the casual reader will ask: "How can it be that the friend has observed one outcome, but Wigner can do an experiment that would seem to require that no single outcome has occurred?" And furthermore, "Is this mystery, after all, reducible to the subject of quantum-state assignments? Or do I need to go further and embrace a different worldview, like the one you outline in the 'Capacity' section? Or do these two questions come down to the same thing?" You do point to this new mindset already on page 6:

> *The point of view here is that a quantum measurement is nothing other than a well-placed kick upon a physical system—a kick that leads to unpredictable consequences for the very agent who made it.*

So things should be clear, worries dissolved, even for the casual reader, even at this point of the paper—but maybe they're not, and I wonder if the argument on page 6 could therefore be made even more forcefully? À la, "This outcome is mine only. If you want an outcome too, you have to come over and elicit one for yourself."

Just a thought.

I had already had a nagging fear that I wasn't doing that part quite right, and you've pushed me over the edge. It's true I need to do that better. This sentence: "This outcome is mine only. If you want an outcome too, you have to come over and elicit one for yourself." Is that one of mine from somewhere? Or is it your own? Either way, I love it and definitely want to use it! You are also quite right in the parts between diamonds 2 and 3:

Schlosshauerism 16: *In the context of discussing Wigner's friend, you also mention unitary evolution and describe it as something that adjusts "the beliefs with the flow of time." I think it would be useful to elaborate a little bit on this issue.*

After all, there will be people who, just as they've opened their minds and hearts and have readied themselves to embrace a personalistic notion of quantum states, are suddenly stopped dead in their tracks by asking themselves why, in the world, their personal beliefs should change (or be updated) according to the Schrödinger equation. They will point to the usual text-book understanding of unitary evolution as being given by the Hamiltonian, which in turn is usually thought of as something objective defined by the physical situation under consideration. And thus they will perceive a clash between subjective quantum states and the supposedly "objective" evolution of these states.

So maybe it would be helpful for the reader to hear exactly what the status of unitary evolution in the QBist framework is, and how and why consistency of the subjective viewpoint requires one to understand evolution operators (and, generally, quantum operations) as subjective entities, too.

I should put more about unitary evolution there (and/or also in the SIC section). At this point in the "extended" version (whatever it means for it to be "extended" over something when it is the original draft, and wherever it is going to go), there is not much point in being overly economical with words. [That, by the way, was my original reason for not broaching time evolution in any detailed way.] I'll fix it! Your first comment, I will probably pass on and take my chances:

Schlosshauerism 17: *Page 2:*

> The trouble with all these interpretations as quick fixes for Bell's hard-edged remark is that they look to be just that, really quick fixes. They look to be interpretive strategies hardly compelled by the particular details of the quantum formalism, giving only more or less arbitrary appendages to it.

I certainly agree with this assessment. However, I wonder what an Everettian would say in response to your charge that his interpretation depends on "more or less arbitrary appendages" to the formalism. I imagine him exclaiming, "My interpretation is the most economic of them all. In fact, I don't need anything else besides the bare formalism. So what are these appendages you're talking about?" You mention the need of making sense of probabilities, but I suppose the Everettian might dispute to what extent this need constitutes an "appendage," rather than just an exploration of the consequences and features of the formalism itself. Similarly for the "many worlds"—to an Everettian, they're not an ontological appendage, but a consequence of the formalism.

Trying to beat off a committed Everettian is like opening a can of worms or Pandora's box—it's not something that can be won. (Too many conversations, too many experiences … this is exactly the sort of thing we end up talking about when Marcus and I get riveted over Harvey Brown. The gulf is deeper than quantum interpretation, it's whole worldview definitely.) I'll just remain with my well-placed insult about Cambridge vs Oxford.

The sentence may not be quite right as it is presently, but it was meant to be "bald" (naked, bare, etc.)

Anyway, I really, really, really appreciate these comments. They were very constructive for me. I'll try not to let you down.

You know, your understanding of this business is certainly getting to the point where you could express aspects of it in your own voice and probably do a much better job than me. I was serious before, but I'm more serious now: You might try your hand at telling your own version of the story, or how it relates/contrasts to Everettism, etc., being critical and pointing out all the holes in QBist thinking wherever need be. Understanding criticism is far, far better than un-understanding criticism, and there is no doubt we QBists need continued stretching: Life is, and should be, a struggle.

BTW: Do you ever have any interaction with Ulfbeck there? I have always had some sympathy with this sentence from one of his papers with Aage Bohr:

> The click with its onset is seen to be an event entirely beyond law. … [I]t is a unique event that never repeats … The uniqueness of the click, as an integral part of genuine fortuitousness, refers to the click in its entirety, with all the complexity required for a break-through onto the spacetime scene. … [T]he very occurrence of laws governing the clicks is contingent on a lowered resolution.

From my one meeting with him, I suspect he is a recalcitrant sort, but there are definitely some interesting elements in his thought.

05-01-10 *If You Take Quantum Mechanics Seriously …* (to M. Schlosshauer)

Schlosshauerism 18: *I imagine him exclaiming, "My interpretation is the most economic of them all. In fact, I don't need anything else besides the bare formalism. So what are these appendages you're talking about?"*

By the way, one of the buzz phrases that bugs me the most from the Deutsch-Saunders-Wallace-Greaves set is, "if you take quantum mechanics seriously" (always, to my ears, delivered with immense smugness). Those words, even when nothing further is said, so get under my skin. Deutsch *et al.* act as if it is a completely unambiguous, value-free statement, containing no prejudice whatsoever, and I think, "Hey, I take quantum mechanics seriously too! **I** just take it seriously in the way **it** is pleading to be taken."

Attached are three slides from my (awful) talk "13 Quotes from Everettian Papers and Why They Unsettle Me" on `pirsa.org`. It really is an awful talk—quotes far too long, printed too small; it was duller than anything else I've ever done, and a lot of people fell asleep—but it did have a couple of zingers in it that I remain proud of … and I guess one of them is the title! One thing of interest with regard to yesterday's discussion is that I just found out by reviewing the first five minutes of it that I presented it as "a case study in psychology"—I had forgotten that.

Read the slides in the order: "Seriously," "Saunders," "Mirror-World." The last slide could have been done much better and made more effective with some work, but it says something of the point.

Seriously

Taking Quantum Mechanics Seriously, 1

> At the conference, the strongest "Everettian" was physicist David Deutsch of the Center for Quantum Computation at University of Oxford. Deutsch asserted that people have been wasting time for decades debating whether or not the Copenhagen Interpretation is meaningful because, "Only Everett's theory consists of taking quantum mechanics seriously."
>
> — Peter Byrne, "Many Worlds in Oxford," at `blog.sciam.com`

> It's sad enough when cranks churn out this tawdry old excuse for refusing to contemplate the implications of science [*i.e., the Everett interpretation*], but when highly competent physicists — quantum physicists — dust it off and proudly repeat it, it's a crying shame.
>
> — David Deutsch, posted on `Fabric-of-Reality@egroups.com`, 16 July 2000, commenting on a paper by Fuchs and Peres

> Let quantum be quantum. — Wojciech Zurek, his talk at this meeting

Saunders

Taking Quantum Mechanics Seriously
(Simon Saunders version, this meeting)

- The theory is to apply universally.
- Without any special mention of 'the observer' or 'measurement'.
- And without any special interpretative assumptions or additional [???] ...

Mirror-World

Taking Quantum Mechanics Seriously
(Quantum Bayesian Version)

- The decision theory should be a normative ideal for all physical agents, universally.
- Without any special mention of a speculative ontology behind the agent's experiences (at least before the first necessary moment).
- And without any additional ad hoc structures introduced for the fuzzy feeling of an *ontologized* dynamics (i.e., that which is usually called "unitarity").

05-01-10 *Out with the Old, In with the New!* (to C. H. Bennett)

... oh I can't resist. At first I was disappointed that I didn't get the last `quant-ph` number of the last decade, but learning this morning that I got the first one of the new decade, I got quite tickled. Maybe it means there's some hope for my quantum foundations program yet! ... dig, dig, dig.

05-01-10 *New Decade, Five Days In* (to D. M. Appleby)

I saw this morning that the toil of your paper-writing troubles turned out to be the first paper of the decade on the `quant-ph` archive (not number 4 as I thought it would be). And with that, I finally got happy about my screw-up, my long dragging of feet: Maybe it is actually a beautiful sign that we nabbed that spot. (The last paper of the last decade stars Charlie Bennett, a devoted Everettian, as its first author.) Maybe this means that our way of looking at things, or at least the one we are trying to develop, will find a prosperous home in this coming decade. As I'm learning from you and Hans and Pauli and Jung: Symbols are important.

Myself, I have been slaving to write something lasting: It started as a super-long extension of that PiC paper you saw me working on last month, but now I feel it is much more than that—that it will capture the hopes and dreams of where this program of ours can be taken and will serve as a focal point for people to develop this worldview-to-be. I hope to unveil the paper to you and Rüdiger, etc., by next week: We shall see.

But why I really write this note is not to tell you all that. I wanted to thank you: You have profoundly influenced me the last three years, and I thought you should know that. What struck me particularly as I worked through your Lie-algebra draft last week is your utter fearlessness. It is remarkable, really. The calculations were so elementary in this case, but it was *you* and you alone who had the bravery to push them through. You were the one fearless enough to step into the river of experience and see where it took you. And it dawned on me, you're always like that—that is what I have come to know of you: It permeates your whole being. There really is some hope that we're going to do big things this coming decade, but the hope is here because you are here.

Happy New Year, Happy New Decade.

06-01-10 *You Dog!* (to C. H. Bennett)

Bennettism 38: *Quantum Theory Needs No 'Interpretation' Besides Ours.*

I just found this on the web while I was trying to find something nasty that David Deutsch had said about me way back (so I could make a gibe at him to Max Schlosshauer). I find Charles Bennett instead! With friends like you, who needs ... How does that saying go?

06-01-10 *Deutsch's Proof* (to M. Schlosshauer)

Schlosshauerism 19: *By the way, what also irks me about Deutsch is that he claims flat-out that interference experiments PROVE the existence of parallel worlds – conveniently leaving out all the assumptions required for such a claim, not to mention the philosophical predispositions etc. Somehow I just don't find that, well, academically honest.*

Yes, indeedy, I was absolutely appalled when I got the impression of that in his book. Attached is the passage I'm thinking of (from my 13 quotes talk), and I'm pretty sure somewhere in the book he calls it a proof:

> **Deutsch "explaining" one-particle-at-a-time interference:**
>
> So, if the photons do not split into fragments, and are not being deflected by other photons, what does deflect them? When a single photon at a time is passing through the apparatus, what can be coming through the other slits to interfere with it? ...
>
> I shall now start calling the interfering entities 'photons'. That is what they are, though for the moment it does appear that photons come in two sorts, which I shall temporarily call *tangible* photons and *shadow* photons. Tangible photons are the ones we can see, or detect with instruments, whereas shadow photons are intangible (invisible) – detectable only indirectly through their interference effects on tangible photons. ...
>
> Thus we have inferred the existence of a seething, prodigiously complicated, hidden world of shadow photons. They travel at the speed of light, bounce off mirrors, are refracted by lenses, and are stopped by opaque barriers or filters of the wrong colour. Yet they do not trigger even the most sensitive detectors. The only thing in the universe that a shadow photon can be observed to affect is the tangible photon it accompanies. That is the phenomenon of interference. ...
>
> ... Thus we have reached the conclusion of the chain of reasoning that begins with strangely shaped shadows and ends with parallel universes. Each step takes the form of noting that the behaviour of objects that we observe can be explained only if there are unobserved objects present, and if those unobserved objects have certain properties.

Is that what you're referring to?

Does it shock you that I made an attempt to read his book? Well, the truth is my arm was twisted by circumstance. Deutsch was scheduled to speak at the QCMC conference in Cambridge, MA a few years ago, and I had never forgotten something that Michael Nielsen alerted me to in 2000. It was a chat at this place (just found it after that aside on Charlie Bennett): `http://groups.yahoo.com/group/Fabric-of-Reality/message/17`. Deutsch said, "They really need to read FoR, don't they?" So I read much of the damned thing (as much as I could stomach) with the intention of shaking his hand at QCMC, and introducing myself with, "Hi. I'm Chris Fuchs, and I read the Fabric of Reality." But he foiled me! He accepted his award at the meeting and gave his talk by video conference.

06-01-10 *13 Quotes* (to M. Schlosshauer)

By the way, that title was a play on Arthur Lovejoy's old essay, "The Thirteen Pragmatisms."

06-01-10 *13 Quotes, 2* (to M. Schlosshauer)

Schlosshauerism 20: *Aha! I hadn't spotted that. Thanks for enlightening me!*

Well, I would have been very surprised if you would have spotted it. I suspect I'm nearly the only physicist who's ever heard of it, and there might well be less than a handful of the (so-called) "philosophers of physics" who've ever heard of it themselves. (I remember Bill Demopoulos saying that he had never heard of it, or the book of the same title, even though he had great respect for Lovejoy and had read many of his books.) Particularly, I was tickled, amused, and appalled when

Chris Timpson apparently felt a need to include a footnote like this, defining pragmatism!, in his paper `arXiv:0804.2047v1 [quant-ph]`:

> Pragmatism is the position traditionally associated with the nineteenth and early twentieth century American philosophers Pierce[215], James and Dewey; its defining characteristic being the rejection of correspondence notions of truth in which truths are supposed to mirror an independently existing reality after which we happen to seek . . .

Mind you this paper appears in *Stud. Hist. Phil. Mod. Phys.*—a philosophy of science journal!

06-01-10 *New Decade, Five Days In, 2* (to D. M. Appleby)

May I forward this inspiring note (excluding my personal bit) to Max Schlosshauer, who I've been in a lot of contact with recently. Max is one who has made the transition away from Everettism (after even writing a book on decoherence and all that) and is now leaning very much in our direction. And he too is very much concerned with "what will come next," now that he finally feels something WILL come next.

I see you're very late, but I guess I should expect no less of you.

Marcus's Preply

> I felt it was significant that we were the first paper of the decade. Though actually I don't think we need rely on Jung and Pauli and symbolism here. I think it's automatic. At least, I think it is automatic that Everett (Hawking, Turok, etc etc) will go out of fashion some time soon ("soon" as measured on a generational timescale: in this context 20 years would count as "soon"). The only question is what will replace them? That, of course, is a question of will. It depends on us, and it is far from automatic. It is in the sphere of human freedom. In this case your freedom, and mine.
>
> When I am faced with the dominant orthodoxy as it presents itself during (for example) lunch-time conversations in the Black Hole Bistro I always think of the court of the Bourbons in the 1760's or 1770's. A visitor to the French court in the second half of the eighteenth century would doubtless have been very impressed by the surface magnificence. Superficially it might have looked as though the monarchy would last for ever. But in fact it collapsed more or less overnight, almost without bloodshed. There was lots of bloodshed afterwards, of course, but that was the revolutionaries fighting each other. In 1789 the power of the monarchy simply evaporated, with no significant fighting at all.
>
> I think something similar applies to the situation which faces us. In conversations at conferences, the Black Hole Bistro etc etc it always seems as though you and I are in a tiny minority. Which, I guess, we are. But if one looks a little more closely I think one can see that the dominant orthodoxy in early 21st century physics, like the 18th century Bourbons, is supported by virtually nothing. When the time comes it will be blown away like smoke.
>
> When I was talking to Åsa's office mate (I have forgotten his name: the post doc who came up to you, me and Howard at wine and cheese, just before you left) he strongly emphasized (a) his atheism and (b) his strong belief in Everett. Afterwards I got to wondering what exactly was the difference between his belief in Everett and the religious

[215] And note the mispelling of Peirce.

belief he rejects. He cannot claim that his belief in many worlds is better supported by the empirical evidence than a belief in God. Everettianism, being expressed in terms of equations, may superficially look more scientific than the Bible, or the Koran. But when it comes to the crucial test, of empirical support, it fails completely. There is no more empirical reason for believing in many worlds than there is for believing that God created the world in seven days. Moreover, when you ask an Everettian what their belief does rest on they will typically appeal to simplicity and beauty. I think someone might give similar grounds for believing in religion. Fundamentalist religion is certainly simple. And, although religion does not appeal to the aesthetic sensibilities of the average PI resident, it surely does appeal, very strongly, to the sensibilities of the devout (and even the non-devout: many aetheists like to listen to Gregorian chants, or Verdi's requiem mass). In these respects Everettianism is very like a religion. However, there is one important difference. Religious belief speaks to something deeply rooted in the human soul, and it is very tenacious. Everettianism is an altogether more superficial psychic phenomenon. I can't see people giving up a belief in the approximate validity of Newtonian mechanics within its domain of application, because of the weight of empirical evidence, and because of its practical utility. Nor can I see them giving up a belief in religion any time soon, because of its deep-seated psychic attractiveness. But Everettianism lacks both the practical usefulness of science, and the psychic appeal of religion. It is nothing more than a transient intellectual fashion. Sooner or later the fashion will change, as fashions always do.

So I don't think we need worry about defeating the current orthodoxy. That will take care of itself. As in 1789 the important question is, not the revolution itself, but what comes afterwards.

I am looking forward to reading your new paper.

07-01-10 *Writing Is So Very Hard!* (to H. C. von Baeyer)

I can't get papers finished; I can't even get emails finished! How on earth could you make writing such a large part of your career without having committed suicide by now?

Below is a note I started writing you some time back. (It was originally titled, "New Decade, Three Days In," if that gives you a hint.) I'd like to finish writing that tonight or tomorrow, or at least pick up where I left off. At the moment, though, I don't really want to break my train of thought of trying to reduce the big paper to the little one. (Read the note below to see what I'm talking about.) And I thought: If Hans is out there with nothing better to do (yeah, right), maybe I could ask your advice (with all your experience of editing). Of course, feel free to say "Go away pest!" and in the harshest terms!

Anyway, attached is the big paper and the latest partial reduction of it.

At the moment, I've managed to cut it down from 16 pages (12,217 words) to 7 pages (4,886 words). And my understanding is, I really should reduce still $\frac{3}{4}$ of page more text-wise. The trouble is, at this stage, I can't see where to trim it anymore!! Already the smaller document feels lifeless, soulless to me. But maybe as an outside (relatively uninitiated) reader you can more easily see some large chunk that can be lopped off without affecting the drama, conceit, and essential content of the message. Maybe at this stage, at some point in the draft, I'm still fighting battles from philosophers past—battles that don't need to be aired to the general public in this venue.

Just a thought: If you see something you can suggest to lop off wholesale, please let me know what you think.

More on counterfactuals later.

Dear Hans,

Thanks for the notes. I'm certainly glad to give you an AHA moment when I can. This morning, I've got to get back to work on the articles—with the "extract" version taking top priority. It absolutely must be finished, or I will be in deep trouble with PI. That article will only cover the stuff *before* the capacity section, leaving the parts less friendly to the usual physics prejudices (i.e., the thoughts of those who say, "We're going after a theory of everything! That's what physics is all about!") for another venue. Contrast that with the parts in the longer version, where I write some lines like this:

> Everything experienced, everything experienceable, has no less an ontological status than anything else. You tell me of your experience, and I will say it is real, even a distinguished part of reality. A child awakens in the middle of the night frightened that there is a monster under her bed, soon to reach around and grab her arm—that experience has no less a hold on onticity than a Higgs-boson detection event would if it were to occur at a fully operational LHC. This is because the world of the empiricist is not a sparse world like the world of Democritus (*nothing but* atom and void) or Einstein (*nothing but* unchanging spacetime manifold equipped with this or that field), but a world overflowingly full—full beyond anything grammatical (rule-bound) expression can articulate.

Yep, that's not going into an issue of *Physics in Canada*, true as it is, and true as every practicing physicist should recognize it to be.

Anyway, I attach the latest version of the big one for the heck of it. The last three sections are still in transition, far from finished, but I guess mostly I send it to you because of the earlier part that you did read: There was something quite misleading in the discussion of the quantum de Finetti theorem, and I have that fixed up now. You shouldn't be misled any longer than you have to be!

Speaking of which ...

von Baeyerism 41: *They simply provide a unique universal characterization of a quantum system, usurping the role of the wave function. Is the word counterfactual a little too suggestive here? I mean, when I step on my bathroom scale, I am tacitly saying that "if I were to weigh myself, counterfactually, against the kilogram in Paris, this is what I would find." This statement is then transferable to any scale in the world. (Of course that's what you had in mind in the first place.) But I never use the word counterfactual in my bathroom.*

I think this may indicate a little confusion, and I want to see if I can clear it up. You're absolutely right that one would not normally speak in the manner of, "If I were to weigh myself, counterfactually, against the kilogram in Paris, this is what I would find"—the point of oddity being the word "counterfactual." But that is not how I am using it when I am using it.

07-01-10 *The Question Is: What comes next?* (to M. Schlosshauer)

Since you and I have been in so much contact recently, I asked Marcus if I could forward you the note he sent me last night. [See 06-01-10 note to D. M. Appleby titled "New Decade, Five Days

In, 2."] I thought it hit the mark, and in an eloquent way: What comes next? That's the only really important question.

I'm feeling doubly good today. I feel I had a very deep insight this morning just as I was getting into the shower. It is the inevitable conclusion to draw from this QBist trek I've been taking, but I only feel that I really saw it with clarity this morning. In a single sentence, it goes like this: Just as quantum theory is not in conflict with probability theory, only an *addition* to it, quantum mechanics is not in conflict with the normal, empirically perceived world of common experience (sometimes called the classical world); it is only an *addition* to it. It is not that the classical world undergirds quantum mechanics, as I read Bohr as saying; it is not that the classical world should be *derivable* from quantum mechanics (a thought that you are very familiar and probably still quite sympathetic with). It is that one is an *addition* to the other, just as quantum theory is an addition to Bayesian probability. It is an overpowering feeling I have in my chest, a feeling like I've only had a few times in my career—my whole body is most definitely reacting to this thought.

Anyway, I pray (metaphorically) that I can articulate this properly in some short number of paragraphs. We shall see—I will try my best and whatever the result, it will be incorporated into the manuscript you have been reading over. I feel I have to say it now and not wait to write another paper.

In lesser progress, I have the distillated version down to 6 pages now. Somehow I've got to get rid of still one more, even though it already feels like a dead, lifeless document in comparison to its parent. The consolation is that it will be in a journal that no one reads. But the antithesis to this is that many of people who will read this particular issue are my PI colleagues (those who wouldn't normally read me, cosmologists, string theorists, etc.)—and I would much rather them read the long version!

08-01-10 *Oh Editorship* (to H. C. von Baeyer)

Thanks again for helping me out. I followed through on nearly all of your suggestions I believe, save maybe 2 or 3. Some of your suggestions too, weren't just about size, but flow—I'm particularly grateful for those things, especially when they were with regard to sentences that I could just never get right. For instance, that very first sentence of the paper—I must have rewritten it a 100 times, with all kinds of little variations.

Attached is the version of the paper I finally turned in. It didn't cover nearly as many subjects as I had originally intended for it. (For instance, since I knew PI people would be reading it, I wanted to make sure I said something about quantum cosmology ... but alas.) Still, for what it does cover, I don't think it does a bad job.

Really, thank you very much for the help. The experiences I've had with your editing have been quite new to me—they're the first to ever give me respect for the trade: My writing is visibly better after your input. I would be hard pressed to think of a time I've ever thought that about anyone else's input (even in isolated instances).

Funny too, that this has happened at a time when I had read this article in the *New York Times*: `http://www.nytimes.com/2010/01/03/opinion/03galassi.html?scp=1&sq=electronic%20 books&st=cse` on the value of a good editor.

Tomorrow, I'll try to write you an extended version of the clarifying stuff on counterfactuals if you still need it. For the moment, I'll just write the definition from `dictionary.com` and put it into context: *Counterfactual: a conditional statement the first clause of which expresses something contrary to fact, as "If I had known."*

"If I had thrown the system up to the sky and let it cascade through that device back down to the one on the ground, I would have gambled this way (usual Law of Total Probability)." But that is contrary to fact: I do not actually throw it up to the sky, I throw it directly to the one on the ground. Quantum theory says, "Don't waste your old calculation. Just stretch it a little, and subtract a bit off afterward (Eq. 5 in the present draft)." The claim is, that's the meaning of the Born Rule—it tells us how we ought to rewrite our counterfactual probabilities.

That said, could I ask you to try to articulate what you do not like about Figure 2, or what confuses you about it? [Recall, it's still a bit inaccurate—I haven't redrawn it yet to fix the new notation. The quantity in the lower left box should be $Q(D_j)$ rather than $P(D_j)$.]

Have a look at the new conclusion as well. It gives the hint that I'm going to get downright alchemical before the bigger version is all over with. Eventually, you'll see what I mean.

Lucky Barbara, to be in Paris for as long as she can. I've been trying to convince Emma she should go to college there so I could come visit her often!

09-01-10 *The Duke of Chartres* (to H. C. von Baeyer)

One last point to address then,

von Baeyerism 42: *So, forgive me, but I don't like your "sky" nomenclature any more than the NBS. But unlike Mermin with his qbits I'm not going to fight you, as long as I and others understand you.*

Indeed I wouldn't want a fight. But I wouldn't mind suggestions either. Following your advice, I should not fossilize. There is nothing about my previous attempts at expression (sky, NBS, etc.) written in stone — they were just the best that came to mind at the point.

My student Matthew Graydon once gave a presentation to our group, where the SIC was placed near the bottom of a wishing well. You throw the quantum system down the well and, after interacting with the SIC, it is blown back up to ground level by a fan. We all had a good giggle.

You want a more drastic change than that. I'm open: I just need a better understanding of how the present imagery is ineffective and some suggestions for what should be put in its place. What part of what is going on is not being captured adequately?

At times, I've toyed with making a modification of my usual activating observer image (Fig 1 in the paper): One frame showing him giving a 1-2 punch with his measurement-device hands, and one frame showing him giving a real whammy with just one hand, a knockout punch. But that's probably nothing like you're thinking.

In your Swing book, I read this:

> If I were as rich as the Duke of Chartres, I would sponsor an international competition for the design of a modern atomic logo. The jury would include writers, painters, sculptors, physicists, chemists, and teachers. Somewhere, I feel, there must be a mind creative enough to come close to translating the well-understood mathematical language of quantum mechanics into visual terms ...

and ever since then, whenever I see a Bohr atom (as I have multiple times recently on some cable channel), I think back to it and wonder how I could do better.

You've got the bully pulpit secured; use it!

09-01-10 *Challenge* (to H. C. von Baeyer)

von Baeyerism 43: *That's quite a challenge but I'll give it a shot. Before I do, though, I need to go through a check list of properties of SIC measurements, strictly in words. Is it correct that:*

von Baeyerism 44: *The quantum system does not include the agent or his instruments.*

True.

von Baeyerism 45: *The quantum system comes with a description of the apparatus that has prepared it*

False. At this moment, I'm thinking of a particularly big, particularly interesting quantum system: Hans Christian von Baeyer. I mentally delimit him as a system (a decently defined piece of the world), yet have not at all made any attempt to write down all the things I believe might come about if I were to interact with him. (I.e., give him a well-placed kick of one sort or another.) Thus I hold the thought of him in my mind separately from any quantum state I might ultimately write down for him.

In my last few papers, you probably won't find the word "prepared" anywhere in them. This will be connected with one of the further answers below.

von Baeyerism 46: *It may be simple or complicated*

True.

von Baeyerism 47: *A spin 1/2, after passing through a bunch of magnets, is a simple system with dimension 2*

Without having seen you for several months, I posit that you are about 160 pounds. As a hypothesis, let's say you're exactly 160 pounds. I didn't need to put you on a scale to make that hypothesis—if I wanted to check it, I might put you on a scale, etc., but that is secondary in the logical order of things. Your weight is something you possess independently of any of my manipulations of you. Similarly with an ejectum of a hot piece of tungsten—I posit that, with regard to the part of it I might tweak with a Stern-Gerlach "hand" (Fig 1), it's about 2-d worth. If I wanted to check that, I could put a SG device near the tungsten and see whether I get two stripes, or three, or more, but that is secondary in the logical order of things.

Think this way: "system" is akin to a "rock", "HS dimension" is akin to the "rock's mass", "quantum state" is akin to "the chance I think this rock will break that window, if I throw it as hard as I can."

von Baeyerism 48: *An electron, with all its properties, is an example of a complicated quantum system*

More complicated at least. Better imagery is simply, "has more stuff." Has more dimension.

von Baeyerism 49: *A SIC measurement is often difficult, but can ACTUALLY be done anywhere*

True. Anywhere, anytime.

von Baeyerism 50: *A system can be prepared in the same way over and over again*

Nothing wrong with that so far as it goes. But this word "preparation" often carries with it a way of thought that is not-so-Bayesian. *Sometimes* quantum states do come about because of "preparations"—precise laboratory procedures—and for those cases, I might be willing to write down the same state over and over after each new instance of the procedure.

More on this below.

von Baeyerism 51: *If a complete set of SIC measurements is done on this system, and statistics have been collected, an agent has as much information as can possibly be gathered.*

Sounds very unBayesian. Think first of simple probability assignments: Bayesians leave unanalyzed where the priors come from—the answer to the question of why one possesses this or that prior is outside the apparatus of probability theory.

The same we say for a quantum state: It is only (and you have to take "only" very seriously here) a state of belief. Writing a quantum state down is tantamount to expressing what one believes of the d^2 possible outcomes to a single SIC measurement. My beliefs with regard to what will happen just once. As I can have a belief about whether the world will end or not tomorrow, I can hold a belief about a singular SIC measurement. And if I do hold such a belief, THAT is a quantum state assignment.

I don't use the word "information" much anymore to say what quantum states are, except to make the transition to speaking of quantum states as beliefs. So, also, for instance, I would not speak of a pure-state assignment to your spin-1/2 as "having as much information about the system as I can have". A pure state is a belief state of a certain variety, but I might hold that belief state for religious reasons rather than "having gathered statistics". Bayesians leave the origins of priors unanalyzed; the calculus kicks in once one has been set. Similarly of quantum mechanics.

von Baeyerism 52: *"Thinking of a quantum state as literally an agent's probability assignment for the outcomes of a potential SIC measurement" implies making many measurements for each i on the system as prepared. Why do you use the singular of the word measurement?*

See discussion above, for von Baeyerism 51. To make the point extreme, consider the pulsar PSR B1919+21. Astronomers have had their eyes on it since 1967. Wiki says it has a period of 1.3373 seconds and a pulse width of 0.04 second. And I'm sure lots of other things are known about its spectra. My friend Greg Comer, who works on the fluid and superfluid mechanics of neutron stars, could take that data, make various assumptions, and impose a "maximum entropy" calculation à la Jaynes, to come up with a quantum state for the star's core. There's no preparation here, no really significant statistics in the usual probabilistic sense, and no *unique* way to turn the observational data into a quantum state assignment. But with the tools of MaxEnt, one can give *some* quantum state assignment, and that's what people usually do. The QBist says, "Ah, what's going on here is that the theorist is expressing his full catalogue of beliefs about that system." And that is tantamount to posing the question of what the theorist believes will come about if a super-duper-big SIC were brought up to the neutron star and allowed to kick it. There would be one outcome, and only one, and the quantum state the extent to which one believes it will be this or that or that.

Maybe this is why I habitually put the SIC in the sky—it makes it inaccessible. I don't want anyone to think of it as a measurement that need be performed in order to have a quantum state assignment in the first place. An initial quantum state assignment is a *prior* from the point of view of quantum theory. A prior about what? About my SIC up in the sky.

von Baeyerism 53: *For a spin 1/2 a SIC requires finding the probabilities for pointing up or down in the four directions defined by a tetrahedron*

Yes.

von Baeyerism 54: *Equation 5 relates the probability of finding a spin 1/2 pointing up in the direction defined by the geographical coordinates of Waterloo, say, to the measurements along path 2.*

Yes, if I understand correctly.

von Baeyerism 55: *For a spin 1/2 system only one kind of Von Neumann measurement (a Stern-Gerlach) is possible, but for a more complicated system all sorts of conventional measurements are possible – but only one set of SIC measurements (except for a little bit of choice).*

If by "one kind" you mean the class of all Stern-Gerlach orientations. SICs start there: I.e., if you give me one SIC, I can mathematically produce a continuous infinity of other SICs by acting on the original with an arbitrary unitary operation. $\Pi_i \longrightarrow U\Pi_i U^\dagger$. But it's even more interesting than that. There are even more SICs than that. By that I mean, not all SICs are unitarily equivalent. But for the Bureau of Standards, you only need one. Pick any one you want and don't change it. I.e., pick your coordinate system and stick with it.

Thanks for the book review; I'll read it tomorrow morning in my comfy library chair and my coffee. Now I'm off to build a fire and a chance to beat Kiki at Scrabble. (It happens once every blue moon.)

10-01-10 *SIC* (to G. Zauner)

Thank you for your kind note. It is quite nice meeting you, and seeing that you still have some interest in this baby of yours. Perhaps you would like to visit our group at Perimeter Institute sometime and become even more involved? We could easily bring you in for 1 week, 2 weeks, or even a month and pay your expenses if you have the time.

I am most curious about your last remark on the quantum Bayesian program. Would you expand a little? What sort of thing are you thinking? The reason I am most interested in SICs is because 1) they are 2-designs, and thus give me a way of thinking of the Born Rule as a kind of "quantum law of total probability", but 2) give rise to a probability space with the same dimensionality as the space of density operators. Any 2-design with a larger number of outcomes would have the valid quantum probability distributions confined to a proper subspace within the probability simplex. It's for this reason that I have thought of SICs as "closer to the truth" and emphasized using them for the purpose of the QBism program. But I wonder what sort of criterion you have in mind?

Attached is a kind of semi-popular account of the QBism program just finished for the magazine *Physics in Canada*. [See "Quantum Bayesianism at the Perimeter," `arXiv:1003.5182`.]

11-01-10 *Analogy?* (to H. C. von Baeyer)

von Baeyerism 56: *Is the following analogy too misleading?*

SIC measurements are like Fourier analysis. An experimentalist launches a square wave pulse of light at a window. He can either predict directly what he will see, or theoretically *decompose his square wave into sine waves and then launch the sine waves at the window. The sine waves are universal, in that they work for any input signal whatsoever. In order for this to work he needs an equation that relates the two paths to each other. That this relationship is far from trivial is demonstrated by the Gibbs phenomenon (discovered by Wilbraham).*

I realize that this analog pays no attention to Bayesianism, but it seems to me to reproduce certain features of your scheme. Not the least of which is that it justifies an experimental check of Equation 5, just as the Gibbs phenomenon only gained traction when it was investigated experimentally.

It's not misleading, it's exact. Eq. (5)

$$Q(D_j) = (d+1)\sum_{i=1}^{d^2} P(H_i)P(D_j|H_i) - 1$$

comes about because of Eq. (3)

$$\rho = \sum_{i=1}^{d^2}\left((d+1)\,P(H_i) - \frac{1}{d}\right)\Pi_i\,,$$

and Eq. (3) simply expresses that any quantum state (pulse) can be decomposed into a linear combination of SIC elements (sine waves). The sine waves are a basis for the vector space of all continuous functions; the SIC elements are a basis for the vector space of $d \times d$ matrices.

And like launching your pulse at the window: If an agent knows how he would gamble on the ground outcomes *given* a "preparation" Π_i, and he also knows how he will gamble on the Π_i's themselves (up in the sky), then he will also know how to gamble on the ground outcomes directly. The analog of reintegrating the Fourier analysis is Eq. (5).

So that much of what say is exact. Maybe the Gibbs phenomenon part of what you say is a bit trickier. The Gibbs phenomenon comes about because one is trying to decompose a function outside of the vector space (a discontinuous function) with a basis for the continuous functions. I'm not sure that I know an analog of that for our SICs.

von Baeyerism 57: *Not the least of which is that it justifies an experimental check of Equation 5, just as the Gibbs phenomenon only gained traction when it was investigated experimentally.*

Most recently in my correspondence (describing Steinberg's or Zeilinger's interest), I've gotten in the habit of calling it a "demonstration" rather than "experiment." I think the word "experiment" should really only be used, say, as with the LHC, when one genuinely does not know what the outcome will be (whether the Higgs will be seen or not). In the case of "checking" Eq. (5), there is no doubt it will be confirmed.

Still, my nitpicking aside, you are completely right about the traction thing. My feeling has been that if Anton were to do a demo, it would bring a lot of attention to the SICs. That's really my most significant motivation for him to play with them.

By the way, Marcus, Steve, and I got a very nice letter from Gerhard Zauner yesterday saying he had read our most recent paper, some of the quantum Bayesian papers, and watched the talks from our "Seeking SICs" conference from a couple years back. Zauner, you probably don't know, was the *real* inventor of SICs! His 1999 thesis

`http://gerhardzauner.at/documents/gz-quantumdesigns.pdf`

was on them, though I didn't know of it until many years later. And in fact, until yesterday, I always thought he had fallen off the planet (he works for a financial firm or something). I always credit Caves too with the invention of the idea (summer of 1999), but we were really taking baby steps in comparison to what Zauner had already done. Zauner had already had the connection to the Weyl-Heisenberg group conjectured and proven their existence up to dimension 5 when we only knew about dimension 2 and 3 and didn't about the Weyl-Heisenberg connection at all (til Robin Blume-Kohout discovered it in 2002 or 2003). Zauner had also already had Marcus's (2004) order-3 symmetry conjecture way back then. (Not that any of us have ever read the thesis; we just know these things from Markus Grassl.)

Just as I write all this, it finally registers in me that that PhD was done in Vienna!! This is perfect for my talk next week! I'll definitely use it.

I've always wondered what Zauner might have been up to when he was studying these things—why was he interested in the question. And just now, I see from some of his references (Gudder, Accardi) that he had some knowledge or interest in quantum foundations. I'm glad I looked up the thesis to give you a link! If you've got some time, would you mind snooping through it to see what he gives as a motivation for what he's doing. Clearly almost all of the thing is about mathematics, but because of the references there must be something about foundations. (For some reason, I can't seem to do a word search in the document, otherwise I'd try to give you some page numbers.)

In our case, the original motivation came from trying to prove the quantum de Finetti theorem. Before we had a proof of it, at some point Carl thought we would need these structures in our proof—that's what motivated him to think of the idea, and he knew they existed in $d = 2$ because Feynman had mentioned them in a paper, but he didn't know whether they existed in any other dimension. Luckily though we did not actually need them—I figured out how to make the de Finetti proof work with *any* minimal informationally complete POVM with rank-1 elements. So, the symmetry was an extra condition that was not needed. But then the SIC question took on a life of its own—for no good reason really. They were just so damned pretty. And their elusiveness made them that much more desirable. I got the feeling (for no good reason again) that they had to be very deep structures, revealing something very important about quantum mechanics. And that thought ever so slowly carried me all the way to the urgleichung.

But maybe Zauner was already there, long, long ago.

Further note attached below (written to Max Schlosshauer) on the mysterious byways that lead to scientific discovery. [See 04-01-10 note, "Birth Notes," to Max Schlosshauer.]

11-01-10 *Born, Heisenberg, and the QBies* (to H. C. von Baeyer)

Have a look at this nice article:

`http://philsci-archive.pitt.edu/archive/00004759/01/SHPMP_paper_07_10_09.pdf`

by Guido Bacciagaluppi and a student. I was knocked over with a Wow! when I read it a little while ago. Particularly, see the discussion right before and right after Eqs. (2) and (3) in it. It was Born and Heisenberg's terminology that took me: "[I]t should be noted that this 'interference' does not represent a contradiction with the rules of the probability calculus."

Compare that to my discussion around Eq. (7) starting with "But beware:" in the present draft of my longer paper (attached).

Maybe it's the ghosts of Heisenberg and Born that have been haunting me all along, and not Pauli after all!

11-01-10 *Psi-ontologists* (to R. W. Spekkens)

In the PiC paper I sent you earlier, there is a line that goes:

> What considerations like this tell the objectifiers of quantum states is that, far from being an appendage cheaply tacked on to the theory, the idea of quantum states as information has a unifying power that goes a significant way toward explaining why the theory has the mathematical structure it does.

And the extended version of the paper, the corresponding line goes:

> What considerations like this tell the objectifiers of quantum states—i.e., those who to attempt to too-quickly remove the observer from quantum mechanics by giving quantum states an unfounded ontic status (status as a state of reality)—was well put by Spekkens: [A quote of you follows, then I pick up with the "far from being ...."]

These strike me as the perfect place to make a joke. I'm toying with the idea of coopting your term, if you'll let me, in place of "objectifiers". If I were to use the term, and put a footnote right at it giving you credit for inventing the term, would you mind? I'd probably write it as ψ-ontologists, and the footnote would read something like \footnote{Not to be confused with the Scientologists. This term was coined by R. W. Spekkens blah, blah, blah.}.

If you want to reserve the term for one of your own papers, I won't be hurt. But it is such a cool term, and so fits my pre-existing sentences, the desire to use it is just getting the better of me.

11-01-10 *... and the Smell of Postmodernity* (to M. Schlosshauer)

[Replying to Max's note "The Spell of Modernity" ...]

Sorry to take so long to get back to you! I've listened to Brad Mehldau, Jimmy Smith, Dr. Lonnie Smith, and Jazz Side of the Moon now. All really great stuff!

Attached is the final version of the essay for *Physics in Canada*. Nothing new in there for you to read, but I send it to you for completeness since I thank you in the back.

I'm going to hold off on personally answering your questions on classicality for the moment, and just try to do it really well in the draft. If I don't address everything, you can take another shot at me at that point.

12-01-10 *... and the Smell of Postmodernity, 2* (to M. Schlosshauer)

Schlosshauerism 21: *I retrospectively thought my from-the-gut reply to your ideas on "addition" and "classicality" wasn't very pointed, and I apologize if it came across as either not too bright or as just plain insufficient in responding to your enthusiasm.*

There is absolutely nothing to apologize for! I was very flattered to see your immediate response that day. I've just been swamped taking care of PI things, getting ready for Vienna, spending time with my students, trying to figure out how to get an internet link at my mom's house while I'm visiting her (after Vienna), etc. I was just saving myself time writing, and I knew I'd be addressing all your points in a later draft of the paper. They were exactly the questions that needed asking—it's not that they were not too bright, but TOO bright! And I knew it would take me some work. So I took the easy way out until I could recover my forces.

I'll probably be more in touch once I get to Vienna and get away from family duties etc. Already got one experiment on the old SICs going (see attached). If I can get Zeilinger interested in showing a demo in his own way that would be really cool—probably a fat chance, but it's worth a shot.

Send that balanced Everettian paper when you've got it done. It's about my turn to read something of yours!

12-01-10 *May 2010 Laws of Nature* (to R. Couban)

Thanks for your intriguing note. I had never thought of efforts to understand quantum mechanics as being clouded or thwarted by capitalism before! It does make me smile, but on the other hand I am intrigued as well. What could he mean? I snooped on the web a bit and saw that your professor has some interesting credentials—for instance, a senior thesis with H. S. Thayer, who wrote the masterful *Meaning and Action*. It's a history of pragmatism that sits on my bookshelf.

I also think there is a lot to learn from DeLeuze's metaphysics of "difference." I'm very much intrigued by his idea that difference goes all the way down. (I might also recommend that you read the beginning parts of Nancy Cartwright's *The Dappled World* and John Dupré's *The Disorder of Things*.)

About the meeting, I'm sorry, it's an invitation only thing, and we have it in an already tight room. The idea was to put everyone in each other's face, and I think we succeeded at that. However you can watch all the talks on `pirsa.org`—they'll be taped with good quality, showing up on the website the very next day after they're given live. I hope that will be a good substitute for you.

Rachel's Preply

> I was just curious about the upcoming conference, where I would be interested in keeping my ears open and my mouth shut. I don't belong to any websites, blogs or societies.
>
> I work at a research institute, and last year a new post-doc was seated in the cubicle next to mine and conversed with me about some theoretical problems of statistics. These conversations reminded me of George Caffentzis' arguments on the knowability of natural laws ("physics is not only 'about' Nature and applied 'just' to technology, it's essential function is to provide models of capitalist work"), which Prof. Caffentzis explained to me are influenced by his 1978 thesis that "we will not be able to have a coherent conception of quantum physics until humanity transcends capitalism." (!)
>
> Meanwhile at my home in Oakville I have been cleaning the basement and sent home movie film and other ephemera from the 1920's to the Tuxedo Park Historical Society in New York. (One of my predecessors had a place in Tuxedo Park.) I read about the Loomis Laboratory at Tuxedo Park, and it reminded me of the Perimeter Institute. I think Caffentzis arguments may be answered by Gilles Deleuze's series of discussions of paradox in his book *The Logic of Sense*, but I lack the cognitive ability to formalize this opinion. I am going to order the 1978 thesis (*Does Quantum Mechanics Necessitate a Theoretical Revolution in Logic?*) through InterLibrary Loan. Maybe reading this will provide some traction for my idea of the Deleuzian (non-mystical) paradox.

16-01-10 *The Tetragrammaton* (to H. C. von Baeyer and D. M. Appleby)

Greetings, dear alchemical friends, from Vienna!

Earlier today I sent Anton that quote from Heisenberg's essay "Wolfgang Pauli's Philosophical Outlook" that I like so much:

> In the alchemistic view "there dwells in matter a spirit awaiting release. The alchemist in his laboratory is constantly involved in nature's course, in such wise that the real or supposed chemical reactions in the retort are mystically identified with the psychic processes in himself, and are called by the same names. The release of the substance by the man who transmutes it, which culminates in the production of the philosopher's stone, is seen by the alchemist, in light of the mystical correspondence of macrocosmos and microcosmos, as identical with the saving transformation of the man by the work,

> which succeeds only ‘Deo concedente’.” The governing symbol for this magical view of nature is the quaternary number, the so-called “tetractys” of the Pythagoreans, which is put together out of two polarities.

and since then I’ve been walking around the area of Franz Joseph’s imperial palace thinking all kinds of crazy thoughts. Just stopping into a coffee shop to write you.

Lovely imagery: The SIC of a qubit (“two polarities”) has four outcomes (“tetractys”). How much closer to the unspeakable name of God could we come with this!

With a smile, and a hunger for schnitzel …

16-01-10 *Paulian Alchemy, Sunday Reading* (to A. Zeilinger)

You asked me last night what I have been working on. I said, “SICs,” but something like these lines from Werner Heisenberg’s essay “Wolfgang Pauli’s Philosophical Outlook” might have been closer to the mark!

> In the alchemistic philosophy, he had been captivated by the attempt to speak of material and psychical processes in the same language. Pauli came to think that in the abstract territory traversed by modern atomic physics and modern psychology such a language could once more be attempted …
>
> In the alchemistic view “there dwells in matter a spirit awaiting release. The alchemist in his laboratory is constantly involved in nature’s course, in such wise that the real or supposed chemical reactions in the retort are mystically identified with the psychic processes in himself, and are called by the same names. The release of the substance by the man who transmutes it, which culminates in the production of the philosopher’s stone, is seen by the alchemist, in light of the mystical correspondence of macrocosmos and microcosmos, as identical with the saving transformation of the man by the work, which succeeds only ‘Deo concedente’.” The governing symbol for this magical view of nature is the quaternary number, the so-called “tetractys” of the Pythagoreans, which is put together out of two polarities.

The connection between what I said last night and what I say today is that (a little tongue in cheek, but only a little): Performing a SIC would “release the spirit that dwells in matter.” (It is interesting too that a SIC for a qubit has four outcomes—a SIC is its tetractys!)

Anyway, if you want some light reading for Sunday (and it actually is), see the attached draft. It is an essay I am hoping to finish in Vienna—to give it the right spirit so to speak. All that’s left really is finding a respectable way of saying this crazy alchemical stuff in “Hilbert-Space Dimension as a Universal Capacity” section!

A very pleasant day today walking around the city and thinking.

17-01-10 *Oh Translator* (to H. C. von Baeyer)

This passage of Pauli is now taking on such an important role in my newest version of that damned paper that I’m wondering if it is translated correctly:

> The objectivity of physics is however fully ensured in quantum mechanics in the following sense. Although in principle, according to the theory, it is in general only the statistics of series of experiments that is determined by laws, the observer is unable,

> even in the unpredictable single case, to influence the result of his observation—as for example the response of a counter at a particular instant of time. Further, personal qualities of the observer do not come into the theory in any way—the observation can be made by objective registering apparatus, the results of which are objectively available for anyone's inspection. Just as in the theory of relativity a group of mathematical transformations connects all possible coordinate systems, so in quantum mechanics a group of mathematical transformations connects the possible experimental arrangements.

There's something awkward about the English in a couple of places of it. For instance, "the observer is unable, even in the unpredictable single case."

The translation comes from pp. 117–123 in *Writings on Physics and Philosophy.* You think there's any way we can dig up the original text and check? Any idea how we can get our hands on that old journal? So far I haven't had any luck with Google Scholar, but maybe I'm not being too smart.

The longer passage of interest to me (but not all of it is used in the present paper) is below.

> Einstein's opposition to it [the so-called "Copenhagen interpretation"] is reflected in the papers which he published, at first in collaboration with Rosen and Podolsky, and later alone, as a critique of the concept of reality in quantum mechanics. We often discussed these questions together, and I invariably profited very greatly even when I could not agree with Einstein's views. "Physics is after all the description of reality," he said to me, continuing, with a sarcastic glance in my direction, "or should I perhaps say physics is the description of what one merely imagines?" This question clearly shows Einstein's concern that the objective character of physics might be lost through a theory of the type of quantum mechanics, in that as a consequence of its wider conception of objectivity of an explanation of nature the difference between physical reality and dream or hallucination become blurred.
>
> The objectivity of physics is however fully ensured in quantum mechanics in the following sense. Although in principle, according to the theory, it is in general only the statistics of series of experiments that is determined by laws, the observer is unable, even in the unpredictable single case, to influence the result of his observation—as for example the response of a counter at a particular instant of time. Further, personal qualities of the observer do not come into the theory in any way—the observation can be made by objective registering apparatus, the results of which are objectively available for anyone's inspection. Just as in the theory of relativity a group of mathematical transformations connects all possible coordinate systems, so in quantum mechanics a group of mathematical transformations connects the possible experimental arrangements.
>
> Einstein however advocated a narrower form of the reality concept, which assumes a complete separation of an objectively existing physical state from any mode of its observation. Agreement was unfortunately never reached.

Hans's First Reply, 17-01-10

> OK, here's the story. On 7 January 1958, in the middle of his fight with Heisenberg about their doomed theory, Pauli gave an address at the ETH on the occasion of the unveiling of an Einstein bust. The talk was entitled "Albert Einstein in der Entwicklung der Physik." Five days later it was published in the Neue Zürcher Zeitung, a national daily newspaper. It was collected in *Aufsätze und Vorträge über Physik und Erkenntnistheorie* (Viehweg 1961 and 1984) *which I do not own.* This book was translated by

Robert Schlapp into the volume you cited. Schlapp, whose name means "slack", was a decent translator, but not a great one. I think checking is a good idea.

Pauli's German book is quite prominent, so there are many ways to get a copy. I will ask my distant cousin Klaus Hepp, emeritus at the ETH (and Planck medal winner!) to send me a scan of the article. In Vienna there are copies galore. I will also try interlibrary loan. U. of Toronto might well own a copy!

If you find the passage in the institute library or somewhere – maybe even Anton's private library – please send me a copy. I will proceed at this end.

Hans's Second Reply, 19-01-10

With the German and the English texts in front of me I can try to answer questions. In general the translation is good, but you are talking about nuances of meaning that I can't disentangle by changing a few words here and there. Instead, you have to tell me what's bothering you.

According to the paragraph preceding, Einstein thought that QM sacrifices objectivity. To which Pauli answers: Objectivity is vouchsafed in the following sense:

1. Theory can determine only the statistics of a series of experiments.
2. However, the observer cannot influence the unpredictable outcome of a specific, single measurement. (This sounds like "a kick that leads to unpredictable consequences ...")
3. Furthermore, the theory contains no references to the observer's personal characteristics or properties. The measurement can even be made by an apparatus.

How are the Viennese reacting to your views?

17-01-10 *Holocaust Memorial* (to H. C. von Baeyer)

BTW, I went to see the memorial today. Stirring, as all such memorials are. It was an empty square on a grey day, and the name kept ringing in my ear: Judenplatz.

I liked your imagery. I'm full tilt on quantum mechanics while here and getting close to writing the section in the paper where I say that each piece of the world has something within it that the rest of the world cannot get. (Your words start to work a little for me: It is not hidden variable, but something like soul.) Each piece of the world is a little like your box inside out—it contains a universe within.

17-01-10 *Oh Translator, 2* (to H. C. von Baeyer)

You can see why I want to get the passage right: I disagree with it! See words at top left corner of page 7:

> *Whose information?* "Mine!" *Information about what?* "The consequences (for *me*) of *my* actions upon the physical system!" It's all "I-I-me-me mine," as the Beatles sang.
>
> The answer to the first question surely comes as no surprise by now, but why on earth the answer for the second? "It's like watching a Quantum Bayesian shoot himself in the foot." Why something so egocentric, anthropocentric, psychology-laden, myopic, and positivistic as *the consequences (for me) of my actions upon the system*? Why not

simply say something nice and neutral like "the outcomes of measurements," or fall in line with Wolfgang Pauli and say,

> The objectivity of physics is … fully ensured in quantum mechanics in the following sense. Although in principle, according to the theory, it is in general only the statistics of series of experiments that is determined by laws, the observer is unable, even in the unpredictable single case, to influence the result of his observation—as for example the response of a counter at a particular instant of time. Further, personal qualities of the observer do not come into the theory in any way—the observation can be made by objective registering apparatus, the results of which are objectively available for anyone's inspection.

To the uninitiated, our answer to *Information about what?* surely appears to be a rash abandonment of realism. But it is the opposite. The answer we give is the very injunction that keeps the potentially conflicting statements of Wigner and his friend in check (Pauli's wouldn't have done that), and, more importantly, gives each agent a hook to the external world in spite of QBism's egocentric approach.

You see, for the QBist, the real world, the one each agent is embedded in—with its objects and events—is taken for granted. What is not taken for granted is each agent's access to the parts of it he has not touched.

Gotta give my talk tomorrow, but, of course, haven't prepared anything specific on it yet (having such a bank of old talks). First thing tomorrow I've got to get some new shoes—with the coming of REAL winter in Waterloo, I had forgotten that I had a hole in my more casual shoes. Then I'll get ready for my talk!

But sleep? Maybe a little later.

19-01-10 *Translation* (to H. C. von Baeyer)

von Baeyerism 58: *How are the Viennese reacting to your views?*

Probably a better reaction than Caves would give me!

More details tomorrow when I'm sober again. Just back from my time with Gerhard Zauner. Apparently—and I believe it!—he had proven the existence of MUBs in prime-power dimensions before (and not knowing of) Wootters. And SICs? He first got the idea of the concept around 1991 (mentioned in his master's thesis)! Though he (mistakenly, stubbornly) believed them to *only* exist in prime-power dimensions—he simply thought they could not exist otherwise. In 1996 he got the idea to check in composite dimensions, and (nearly trivially with a quick check) they existed there too, so he decided to follow through with a PhD on it (despite his initial advisor's discouragement). He kept going on about how two-designs (SICs and MUBs and a set of similar objects) were his objects of study because they had the potential to express quantum mechanics in a non-algebraic way. I didn't understand what he meant, but I definitely felt he was on the tip of something.

There is no doubt, he knows things that Marcus does not know, but he only sporadically thinks about all these things. For instance, in 2004 when in a hospital for 6 weeks with a head injury; he had amnesia for a bit, but the first thing that came back to him was a two-design question that he had first come to him in the early 1990s. I am much, much intrigued. Tomorrow, when I write, I'll tell you about Rankin-Bass and the "Island of Misfit Toys": I swear, Marcus, Zauner, and I all come from that place. Zauner never published (not even one paper!) because when he solicited the level of interest of anyone he could think of that should have been interested, they yawned. It is a tragedy for the development for quantum mechanics: People could have been thinking about SICs since 1991 if someone (probably nearly anyone) had just given some encouragement to the guy!

More tomorrow, as I say. Too much beer! I've had a great time here this visit. It is good to literally get in the lab (fascinating actually): I felt so alive this morning when I saw their Kochen-Specker experiment. I joked that I always talk of reality creation, but these guys, with that equipped lab table, are actually doing it. Anton said, "Well, you yourself are doing it all the time, you just don't know it." I agreed, and offered my daughters as examples.

I'll try to make my questions on the Pauli article pointed when I come back.

19-01-10 *The Reason I Like Your Axiom 1* (to Č. Brukner)

... particularly the second part, "All systems of the same information carrying capacity are equivalent" ... has to do with the ideas I'm trying to formulate on "dimension" as a capacity analogous to (or in the spirit of) gravitational mass. Somewhere in your axiom 1 is an analogy to the Eötvös experiment.

See the two elevator stories in: `http://arxiv.org/abs/quant-ph/0404122` (i.e., see the introduction and conclusion of this paper, skipping everything else). Platinum and magnalium were the two elements in the Eötvös experiment.

The yet-to-be-written capacities section will have some of that in it and some of the attached rant, originally written to Lucien. [See 16-10-09 note titled "The More and the Modest" to L. Hardy.] I'll definitely be citing your new paper too.

20-01-10 *Bohr was Bayesian?* (to C. Ferrie)

Good to hear from you. I'm in Vienna trying to get some SIC demonstrations going with the Zeilinger group, and trying to write this damned paper. Since you seem to need some good Bayesian-support-group amens, I'll go ahead and attach the paper as it stands. The last three sections still have a have a good ways to go, but much of the rest of it is stabilized.

I suspect there'll be aspects you like, and aspects you hate ... but I can't do much about that. The key, for your respect though, I think, is that I am a realist—there is no doubt about it—I am just not a hidden-variable realist. (And the same statement is true of Bohr.)

Anyway, such as it is, see attached. And hold tight through those quantum foundations classes! I'll see you in a couple weeks.

Chris's Preply

> The usual attacks were made on Bohr at the latest lecture of the interpretations course. Those with enough intellectual responsibility to read the Bohr quotes without joining in on the laughter saw that what Bohr actually said and the "Copenhagen Interpretation" philosophy which is attributed to him are in fact polar opposites. I sat there thinking Bohr was really a Bayesian but didn't know it. Then I thought that you must have come to this realization as well, provided you had read any Bohr, which I assumed you did. So I started searching your PDFs for "Bohr" and found that exact phrase!
>
> It is now obvious to me that you are far more well read in Bohr than I am. Ironically, the only things of Bohr I have read are cherry-picked quotes intended to support the

claims that Bohr was either schizophrenic or an evangelist for the "Copenhagen Interpretation", which I now doubt ever even existed. Fortunately, I committed to neither claim then and re-reading them now (after my Bayesian enlightenment) his words are more clear than unclear.

I felt sorry for Bohr that you were not there to defend his legacy. But at the time I could only sit in silence as I tried to think of a coherent defense of Bohr coupled with a rebuttal to the inevitable charges of solipsism or antirealism.

20-01-10 *Bohr was Bayesian?, 2* (to C. Ferrie)

And yes, the letters may not completely indicate it (all that crap is too sporadic), but I have tried to read everything Bohr wrote on quantum interpretation pretty darned carefully. (Also I've read plenty of things by the "Bohr scholars" Folse, Faye, Plotnitsky, etc.) He is not my hero in the game (Pauli is), but there is plenty in Bohr's gropings to think hard about and try to make clear "in the new modern way" (from a country song, Tom T. Hall). Attached is a picture of one of my visits to the old man himself. Below is a story about his desk. [See 03-02-04 note titled "The Land of Bohr" to G. L. Comer.]

I've got to say, I had the greatest experience the other day. At some point in a big discussion in Anton Zeilinger's office, I got up to write something on the chalkboard. The chalkboard was pretty rough, not nearly as nice as the one Kiki installed on our porch (it was more like the plywood she had once painted with chalkboard paint). . . . AND . . . I was just about to say something, making some smart remark that would come off as clever and sound like a joke—that's the thing I try to do all the time. Bad habit. But just in time I saw a brass plaque at the bottom of the board . . . and caught myself! It said it was Ludwig Boltzmann's chalkboard! I almost fell over. I was so excited; my heart skipped a beat, and I acted like a little boy. Thereafter I tried to find every excuse I could to write some more on it. Anton caught on, and that turned out to be my big joke.

Look, hold on tight. You've survived my bastardly wrath—you're a strong guy. Your Bayesianism is on the right track. And the very fact that you've had an epiphany (one of any sort, any sort whatsoever), already sets you apart from the rest of the foundations pack. Few foundations folk are ever really stirred by anything that takes them by surprise. Just learn to articulate yourself, defend yourself, and the battles themselves will lead to clarity. Crown yourself emperor, and you may get a nation.

20-01-10 *Translation, 2* (to H. C. von Baeyer)

I guess it's only the phrase "even in the unpredictable single case." It's the "even" that confuses me. Is it really part of his construction? Is it a term of contrast? For instance, who might have thought he could "influence" the "unpredictable single case"? "Nope, even in that case, I can't do it." That's the sort of thing that's confusing me and making me wonder whether it is an artifact of the translation or whether he really meant it that way?

Hans's Reply

OK – here we go. I have added some emphases.

> Pauli: **Obwohl** nach der Theorie im Prinzip im allgemeinen nur die Statistik von Versuchsreihen gesetzmässig bestimmt ist, kann der Beobachter **auch** im nicht voraussagbaren Einzelfall das Resultat der Beobachtung – wie zum

> Beispiel das Ansprechen eines Zählers in einem bestimmten Zeitmoment – nicht beeinflussen.
>
> Schlapp: **Although** in principle, according to the theory, it is in general only the statistics of series of experiments that is determined by laws, the observer is unable, **even** in the unpredictable single case, to influence the result of his observation—as for example the response of a counter at a particular instant of time.

The word **auch** could be translated as even, or as also. But the initial **although** demands the stronger contrast provided by **even**.

It seems to me that the fault is Pauli's, not in the word "auch" but in the phrase "kann… nicht" which is translated as "is unable." Maybe he should have said "does not" rather than "is unable." What I have in mind is the difference between classical and quantum. In a series of coin tosses the beautiful law emerges without the help of the observer. But the observer certainly *does* influence a single throw. If we knew enough about it, we could predict the throw. In QM, on the other hand, the observer does not influence the throw even in principle.

This uncertainty in principle was not Pauli's emphasis here. He wanted to establish the objectivity of physics – almost by introducing a detached observer who is at the mercy of the objective world out there. He can't even influence a single observation. And of course the bell curve is not his creation either.

Once your head is clear I would be grateful for your keen analysis.

20-01-10 *Translation* (to H. C. von Baeyer)

OK, I guess I've got nothing to say: So much for my "keen analysis." I will let it stew in the back of my head however—maybe your point about the classical coin toss is a good one.

Tonight is my last dinner with Anton, and tomorrow the taxi arrives at the hotel at 5:45 AM—I'm off for a day and an evening with Rüdiger Schack in London. Then it's to the hicksville of Texas, where I hope the cellular modem I had shipped there will work with my computer … otherwise I'm going to be in a world of cybermisery.

21-01-10 *Coffee and Spirits* (to Č. Brukner)

I think I'm going to go work in that café of the building where Exner, Hassenohrl, and Schrödinger worked. I'll show up at the institute early afternoon. Writing is a very painful thing for me to do. I'm Exner's spirit might give me a bit of guidance.

21-01-10 *God Likes Qutrits* (to C. Schaeff & the Vienna Qutrit Guys)

I just set a tab in my address book titled "The Vienna Qutrit Guys". If there's anyone out there who doesn't want to be in this list, let me know. Also if I've missed anyone who should be here, let me know that too.

I've been trying to articulate why the qutrit is a really important state space, and the best I have at the moment is this: Gleason's theorem shows that if you can characterize the set of probability functions allowed by the structure of quantum measurement in $d = 3$, then you can characterize it in all dimensions. So all the weight of the probabilistic interpretation of quantum mechanics bears down on the qutrit. From the experimental perspective, if an experimentalist wants to say "our experiments have mapped out the essence of quantum theory" then he has to be ready for the rejoinder, "Well then, do you have the capability of performing every kind of measurement in dimension 3, including POVMs?" "Unless you can do that, you have not fully explored the features of that state space." I want to say something like that, and find a way to make it pithy and convincing.

21-01-10 *On Realism* (to C. Ferrie)

Here are some notes I took on Henry Folse's papers on Bohr. I'd be curious to hear what you think of his reading of Bohr.

You're absolutely right on the six billion varieties of realism. When I said about myself that "I am a realist" I meant something somewhat close to the attached Martin Gardner quote—that the world is made of something that doesn't a priori require the existence of human minds. That's all I meant. But as you point out, you surely wouldn't be able to figure that out by looking at wiki.

Ferrie-ism 7: *It seems that what is overlooked in all these debates about "interpretations" is the assumptions that quantum theory is either "The Truth" or the next logical step to it. But what if that assumption is wrong?*

Well, even with all my love for trying to get the meaning of quantum theory straight, you would not hear me say that quantum theory is the Truth or the next logical step to it. Do you know the old Dr. Hook song, "On the Cover of the Rolling Stone"? If not, look at: `http://www.youtube.com/watch?v=-Ux3-a9RE1Q`. I just had a copy of the *Oxford Dictionary of American Quotations* sent to my mother so that we can flip through it when I visit her for her 81st birthday. One of the best merit badges I've ever attained in my life—they actually quote me! Here it is, I think (haven't actually seen the precise page yet):

> "There is no one way the world is because the world is still in creation, still being hammered out."

If there is not one way the world is because the world is still in creation, there is no everlasting scientific theory either. Quantum mechanics will one day meet its demise in one way or other. The point for me for interpreting it (in a way that it ought to be) is to get a safer suggestion for how to take the next step.

22-01-10 *Is the Big Bang Here?* (to A. Zeilinger)

See attached for the Wheeler quotes I promised you. Most of the quotes are from his presentation (which in their own way discuss the question above), but the actual question came from Richard Elvee at the end of the talk. Wheeler answered, "A lovely way to put it—'Is the big bang here?' I can imagine that we will someday have to answer your question with a 'yes'."

> It is difficult to escape asking a challenging question. Is the entirety of existence, rather than being built on particles or fields of force or multidimensional geometry, built upon billions upon billions of elementary quantum phenomena, those elementary acts

of "observer-participancy," those most ethereal of all the entities that have been forced upon us by the progress of science?

At first sight no question could seem more ridiculous. How fantastic the disproportion seems between the microscopic scale, of the typical quantum phenomenon and the gigantic reach of the universe! Disproportion, however, we have learned, does not give us the right to dismiss. Else how would we have discovered that the heat of the carload of molten pig iron goes back for its explanation to the random motions of billions of microscopic atoms and the shape of the elephant to the message on a microscopic strand of DNA? Is the term "big bang" merely a shorthand way to describe the cumulative consequence of billions upon billions of elementary acts of observer-participancy reaching back into the past?

Stepping stone though this question may be to a new outlook, it is beset before and beyond by traps. One trap is a misjudgment of the role of "consciousness." The other is an exaggerated estimate of the category of "time."

and

Guided by these warnings and encouraged by the view that there is nothing at all of physics more elementary than "elementary quantum phenomena," are we destined some coming century to see all of existence derived out of this utterly primitive unit? And on the way; are we not surely destined to find some single simple idea that will lend itself to statement in a single sentence, so compelling that we will all say to one another, "Oh, how simple!" and "How stupid we all were!" and "How could it have been otherwise?"

Have I been making the world sound like a very mysterious place? It is! But amid all mysteries, we remember those great words of Leibniz, "Although the whole of this life were said to be nothing but a dream and the physical world nothing but a phantasm, I should call this dream or phantasm real enough, if, using reason well, we were never deceived by it."

There are many sources of energy. There is solar energy and the energy of fossil fuels, coal and oil. There is the energy of uranium, but a source of energy greater than any of these is the energy of the human heart, the energy that makes us reach for an understanding of the universe and our place in it, our responsibilities, our opportunities, our hopes. No questions are more pertinent to this comprehension than "How did the world come into being?" and "How is the world constructed?" I know of no clue more likely to allow us someday to grasp an understanding of these questions than the quantum.

and

ELVEE: Dr. Wheeler, who was there to observe the universe when it started? Were we there? Or does it only start with our observation? Is the big bang here?

WHEELER: A lovely way to put it—"Is the big bang here?" I can imagine that we will someday have to answer your question with a "yes." If there is any conclusion that follows more strongly than another about the nature of time from the study of the quantum nature of space and time, it is the circumstance that the very idea of "before" and "after" is in some sense transcended.

There are two aspects of this idea. First, Einstein's theory of space and time tells us that in order to predict all of space and time for time to come, we have to know what the conditions of space are now and how fast they're changing. Only then do we have enough information to predict all the future. The uncertainty principle of quantum theory tells us that if we know the condition of space now, we cannot know how fast it's changing. Or if we know how fast it's changing now, we cannot know what the geometry is now. Nature is so built with this complementary feature that we cannot have the information we need to give a deterministic account of space geometry evolving with time.

That deterministic account of space evolving in time is what we mean by spacetime. Everything that we say in everyday language, about time is directly built on that concept. And with determinism out, the very ideas of before and after are also out. For practical everyday matters, this indeterminism, this indefinability of spacetime is of no concern. The uncertainties only show up effectively at distances of the order of 10^{-33} cm. Nobody at present has equipment fine enough to reach down to a distance so small.

What does all this have to do with the big bang? At the very beginning of time we know that—according to Einstein's account—the universe was indefinitely small. Things were indefinitely compact. When we talk about time when the universe itself is so fantastically small, we deal with a state of affairs where the very words "before" and "after" lose all meaning. This circumstance puts one heavy restriction on the usefulness of the word "time." There is another.

When we do our observations in the here and the now on photons, quanta of light, hunks of energy coming from distant astrophysical sources, we ourselves have an irretrievable part in bringing about that which appears to be happening. We can put it this way: that reality is, in a certain sense, made up of a few iron posts of definite observation between which we fill in, by an elaborate work of imagination and theory, all the rest of the construction that we call reality. In other words, we are wrong to think of the past as having a definite existence "out there." The past only exists insofar as it is present in the records of today. And what those records are is determined by what questions we ask. There is no other history than that. This is the sense in which we ourselves are involved in defining the conditions of individual elementary quantum phenomena way back at the beginning of the big bang.

Each elementary quantum phenomenon is an elementary act of "fact creation." That is incontestable. But is that the only mechanism needed to create all that is? Is what took place at the big bang the consequence of billions upon billions of these elementary processes, these elementary "acts of observer-participancy," these quantum phenomena? Have we had the mechanism of creation before our eyes all this time without recognizing the truth? That is the larger question implicit in your comment. Of all the deep questions of our time, I do not know one that is deeper, more exciting, more clearly pregnant with a great advance in our understanding.

25-01-10 *Silly Name Play* (to A. Zeilinger)

Just playing around with words on my flight to Texas. Here are some potential names for your Copenhagen conference.

- Breathing New Life into Bohr
- Breathing New Life into the Copenhagen Interpretation

- Quantum Information's Impact on the Copenhagen Interpretation
- New Perspectives on the Copenhagen Interpretation
- Lifting of the Fog from the North: New Perspectives on the Copenhagen Interpretation
- Reading Bohr, Heisenberg, and Pauli in the Language of Quantum Information
- Bohr's Relevance Today
- The Copenhagen Interpretation of Quantum Mechanics as a Modern Interpretation of Quantum Mechanics
- Teleporting Bohr to Modern Times: Quantum Information and the Copenhagen Interpretation
- Beam Me Up, Professor Bohr!
- Seeking Bohr's Guidance Afresh: How the Copenhagen Interpretation Enlightens Quantum Information
- Seeking the Soul of Quantum Information Theory ... One Bohr, Heisenberg, and Pauli at a Time
- Searching Copenhagen's Soul: Quantum Information and the Future of Physics
- I Like the Copenhagen Interpretation, Why Don't You?
- Bohr 2, Einstein 1 (the poster could show Einstein and Bohr in football clothing kicking qubits)
- Protecting Bohr with Fault-Tolerant Quantum Error Correction
- If Bohr Knew Then What We Know Now (What Would He Say Differently)
- Bohring the Tears Out of Einstein

The "lifting the fog from the north" remark refers to a quote of John Wheeler: "It may be, as one French physicist put it, 'the fog from the north,' but the Copenhagen interpretation remains the best interpretation of the quantum that we have." (I think the French physicist was de Broglie.)

28-01-10 *Morning Time, Cuero* (to D. B. L. Baker)

Getting your note yesterday still strikes me as such a strange coincidence. Everything you said was exactly on my mind—both, about not going home and never really leaving.

Attached is a paper I've been working on (and still have a good ways to go before finishing). [See "QBism, the Perimeter of Quantum Bayesianism," `arXiv:1003.5209v1`.] It is an example of your point on "never really leaving"—there are Texanisms and Cueroisms sprinkled throughout. Little things from our youth. For instance, when I wrote Footnote 7, I kept thinking of [Cindy X]'s dad calling Terry "you common son of a bitch" the night he caught them together. And I thought of a beer joint jukebox when I wrote the "hell hath no fury" line on page 5. There are others, as well. Funny too you write me about the Bible just as I was putting in Figure 2.

And the Ike story. Before coming to Cuero, I had a bunch of books shipped here from Amazon etc. Things that I couldn't get in Canada without waiting a ridiculous time, or having to pay exorbitant shipping costs. One of them was the *Oxford Dictionary of American Quotations*, which I discovered only a couple of weeks ago to really have a quote of mine—I found my name in the index of the Amazon preview of it, as I was buffing up my resume, but that was all I could see. (The dictionary contacted me years ago, asking permission, but as time went on I had forgotten about it, until I was searching for merit badges to beef up my resume to try to get a promotion.) It's really very flattering being there with Jefferson and Emerson and Mark Twain, even if you know it was someone's arbitrary decision. I'm rather proud of it really. Anyway, for a brief few minutes I thought about writing Linda Henderson with the news. But I backed off, thinking something exactly like your Ike Eichholz story.

Tomorrow morning early, I go back to Waterloo to face the cold and the snow. But then in two weeks, I go to Japan for my 10th time. (Nagoya this time; never been there actually.) It still smarts to hear my old brother-in-law from years back, saying, "Why would you want to go over there?"

Funny the synchronicity between us. I do think of you often. As I walked the streets of Vienna and the quiet square of Judenplatz, where there is a little memorial for the 65,000 Austrian Jews killed by the Nazis, I was thinking of the time you brought the Blue Danube into our tent at Boy Scouts. It was one of my first introductions to any of that side of the world. You brought a perspective that I had never seen. You were the only culture I ever knew in Cuero, and there's no doubt the little bit you pulled me into, I fought kicking and screaming. I sometimes wish I had it all to do over again—to try to keep the good with the good from that little town, but reject the parts that gave me such a slow start.

I learned yesterday from my mom that Michael's dad died a few weeks back. I should send Michael a note this morning.

02-02-10 *Permission?* (to C. E. Granade)

I'm working on an article that reviews my research program, and there's a spot in it that one of your neologisms [psi-ontologists] would be perfect for. See footnote 2 (and the paragraph to which it refers) on page 3 of the attached draft:

> Not to be confused with the Scientologists. This useful descriptor was coined by Chris Granade, a PSI student at Perimeter Institute, and brought to the author's attention by R. W. Spekkens, who immediately understood its psychological value.

The article is not actually going to *Physics in Canada*, despite the formatting—I just haven't changed it yet. I'm not yet quite sure where I will send the thing. In any case though, do I have permission to use your beautiful word? If no, then I'll strip it out. If yes, then is there anything you want me to change in the way that I give you credit?

03-02-10 *Three Cheers for Measurement* (to J. Rau)

Thanks for the revised version of your paper. [See J. Rau, "Measurement-Based Quantum Foundations," `http://arxiv.org/abs/0909.1036`.] "We are such stuff as quantum measurement is made on." That is a line that will end one of my own forthcoming compositions. [See "QBism, the Perimeter of Quantum Bayesianism," `arXiv:1003.5209v1`.] I'll attach it as it stands—it still has a good ways to go before being finished, but perhaps you can start to see the outline of things to come. At the end, it will agree with you that the notion of measurement is the very primitive.

03-02-10 *Giving QM and Pragmatism a Chance to Flirt with Each Other* (to R. Schack, D. M. Appleby, H. C. von Baeyer)

The Templeton Foundation has announced two funding opportunities that seem to fit our proclivities. See:

`http://www.templeton.org/what_we_fund/2010_funding_priorities/`

I will be applying for the quantum one, and it looks like the free-will one very much matches up with Rüdiger's discussion with me at Windsor Castle. Maybe everyone might want to take a shot at it?

I have no firm ideas for myself yet, but I think the direction I want to pursue is to find a way to get quantum foundational thinkers to mix and mingle with pragmatist philosophers. The thought I have is that it is the physicists who could use some education, and I want to think of ways to foster that. If anyone has ever seen a model of similar ilk work before or has any ideas along such lines, I'd enjoy hearing.

09-02-10 *Village Voice* (to D. B. L. Baker)

Bakerism 6: *Thanks for attaching a sample of your latest writing. I definitely heard your voice as I read it. I have to admit that the only science journalism I ever read is stuff you forward to me so it is kind of hard to compare it to anything else. How much of what is published is written in such a colloquial, conversationalist style? Even the hard science/technical writing that you send me sounds the same. Maybe it's just that I know you that I hear it so clearly. What do your Ivy League and foreign colleagues say?*

I don't mean to swell your already large sized head but I would compare the experience somewhat to reading Jack Kerouac. Perhaps Ada was wrong and it is not Thoreau you have a feeling for. Even when I read Ginsberg or Burrows it's Kerouac I hear. He just seems/sounds more real so theirs must be borrowed. Maybe it's just a Cuero thing, having to explain things to people who may not be interested or even understand; people who never wanted to leave town or think about anything that doesn't happen there. Hal Ketchum's "Small Town Saturday Night" definitely on the jukebox there. "Lucy, you know the world must be flat 'cause people leave town, they never come back."

PS. You can use "Quantum Kerouac" if you want, though I do enjoy being cited.

Thanks for the nice compliment—the idea of being on the road with Kerouac is nice. But there are lightyears between him and me. The very big difference is that his writing was natural: He typed his first book on a paper towel roll, as I recall! And I don't think it took him more than a few weeks. I pain over every sentence, changing some probably a hundred times before I get it right. It's completely fake with me. Kerouac was the real deal.

But thanks! I'll send you the final version of the paper when it's finished. I got sidetracked with lots of things once I got back to Waterloo. My collaborator Appleby is here from England, and we've been at the chalkboard pretty much nonstop. Those damned consternating SICs.

10-02-10 *Boyle* (to D. Kobak)

Thank you very much for that—it was thought provoking. Soon I will put a paper on the `arXiv` titled "The Perimeter of Quantum Bayesianism" where I expand in more detail on the character and origin of quantum indeterminism. It is a bit as you say, but in place of "divine will" I would write "divine wills". You will see what I mean when I finally release the paper.

Dmitry's Preply

> As I feel that I'd better introduce myself: we met at PI during one of the quantum foundations schools several years ago, and then last year had a brief communication about the infamous anti-Bell works of De Raedt. This time I have a much more pleasant topic.
>
> I have recently stumbled upon a short text about Robert Boyle – an extremely interesting account of his theological thoughts driving his scientific research. Here it is: `http://shkrobius.livejournal.com/189428.html` (don't be discouraged by the domain: it's a blog of a chemist and one of the most educated people I know). In short, he is saying that Boyle – who basically invented modern scientific method and was largely responsible for starting science as an enterprise as we know it – that Boyle did all that trying to disprove the idea of natural physical laws. He didn't believe in laws, he believed in Divine will, and so for example wanted to disprove, and did disprove the "law" that Nature "abhors vacuum". I will stop retelling this story and encourage you instead to read that post.
>
> The reason I think it might be interesting for you, is that it strikes me how similar Boyle's views would be to the Bayesian view of QM, where quantum laws are just conceits of mind and there seems to be no law whatsoever behind an outcome of quantum measurement – nothing but the pure Divine will. Would Boyle be a Bayesian?...
>
> I also wrote this in a bit more detail in the comments section of that post. Actually, before writing to you I made a search for "Boyle" in all your samizdats and found zero results. So I thought you might be interested. If you indeed are, I would be happy to know what you think about it.

10-02-10 *Three Cheers for Measurement, 2* (to J. Rau)

Rau-ism 1: *Given that you are such a philosophically minded person (after all, I owe to you my first encounter with American pragmatism), I was wondering whether you had ever come across the Vienna Circle? I first learnt about this group of philosophers (Schlick, Carnap, Neurath, Frank, ...) when I visited Časlav Brukner and Anton Zeilinger in Vienna last October, and I discovered that their "logical empiricism" is very much in tune with the Copenhagen interpretation of quantum theory. In fact, there was a fruitful exchange between members of the Vienna Circle and Niels Bohr. I attach a little paper discussing this exchange – maybe you'll enjoy it.*

Thank you for the Faye article. I have read him before and find him very interesting. Particularly, I read his book *Niels Bohr, His Heritage and Legacy* in very careful detail about 15 years ago. Particularly it was very important for me in learning about Høffding (which connects to my present infatuation with pragmatism, James and Høffding were correspondents). It would be so nice to read this all again, knowing (thinking) what I know (think) now. Faye and Henry Folse, by the way, are good friends. I visited Henry at his magnificent home in New Orleans in October, and he told me a story of the time Faye lived in his basement there. Anyway, though they are good friends, they have very different readings of Bohr. And for my money, I think there is more truth in Folse's reading—which of course can only mean operationally that Folse's reading agrees with my own reading of Bohr. (I may not reflect it in my writings, but I have put significant scholarly effort into Bohr himself.) Still, the healthiest reading involves both these countering opinions. I will study the article you sent me with care.

11-02-10 *Itamar* (to M. Hemmo)

This hits me like a hammer. It is a sad day. He was a great man, from whom I learned so much.

Meir's Preply

Dear friends,

I am very sorry to report that Itamar died last night. There are no words to express this great loss for all of us.

The funeral will take place tomorrow, Friday 12 February, at 10:00 in Jerusalem.

Meir

11-02-10 *Itamar* (to W. G. Demopoulos)

I had already heard about Itamar from Meir and sent my condolences. It is very tough. Itamar was a great man. I learned all the deep, secret details of Gleason's theorem from him.

My mind this morning keeps coming back to a quote of William James:

> To anyone who has ever looked on the face of a dead child or parent the mere fact that matter *could* have taken for a time that precious form, ought to make matter sacred ever after. It makes no difference what the principle of life may be, material or immaterial, matter at any rate co-operates, lends itself to all life's purposes. That beloved incarnation was among matter's possibilities.

I want say that Itamar's work in quantum theory was a foundation for the same conclusion, having come at it from a more rational side. Matter is sacred.

I will remember him all my life.

15-02-10 *Notes* (to M. B. Ruskai)

Yes, thank you, that would be nice. There is a quote of Primas's that I keep in my computer that I think is very deep:

> It is a tacit assumption of all engineering and experimental sciences that nature can be manipulated and that the initial conditions required by experiments can be created by interventions using means external to the object under investigation. That is, *we take it for granted that the experimenter has a certain freedom of action which is not accounted for by first principles of physics.* Man's free will implies the ability to carry out actions, it constitutes his essence as an actor. Without this freedom of choice, experiments would be impossible. *The framework of experimental science requires this freedom of action as a constitutive though tacit presupposition.*

I'm off to Japan early tomorrow morning.

Mary Beth's Preply

> Don't know if you're familiar with the work of Hans Primas on quantum theory. Going through some papers, I found a set of lecture notes from a course he gave at the ETH about 1970 on
>
> Problem der Interpretation der Quantnemechanik Grosser Molekular Systeme
>
> and I wonder if you might be interested. I also have a few preprints from that time.
>
> If you'd like them, I'll see if Bei Zeng can bring them back to Waterloo.

17-02-10 *Jet Lagged Titular Thought* (to R. Schack, D. M. Appleby, H. C. von Baeyer)

"Institute for Quantum and Freedom"
Better suggestions?

17-02-10 *Strong Radio Silence* (to M. Schlosshauer)

You weren't kidding about "radio silence": I'm the king of it! Not only am I not in Vienna anymore, but last night I arrived in Japan. In Nagoya. And to my surprise this morning, I learned that the meeting starts today, not tomorrow as I had thought! So my head is really in the clouds somewhere.

Let us shoot for early June with respect to my getting the interview paper in.

It must be getting very close to your baby's due date now. I hope everything is going OK in that regard.

On my flight over, I read your paper with Camilleri on Bohr's doctrine of classical concepts. It was quite good, and I learned a lot. Particularly, I did not know about the controversy between Bohr and Heisenberg on the movability of the cut/schnitt. I want to delve into that more carefully as I get a chance. I was quite surprised by this line of Heisenberg's too: "[A] dividing line must be drawn between, on the one hand, the apparatus which we use as an aid in putting the question and thus, in a way, treat as part of ourselves, and on the other hand, the physical systems we wish to investigate." I thought it was Pauli only who went so far as to take the measuring device as a prosthetic hand. That point is crucial for QBism in fact; so clearly I should learn more about its roots.

Attached finally is a bit more careful version of what I brought up with you after the New Year, my little epiphany. I am not completely pleased with the exposition—it remains too sketchy—but it is starting to take shape, and it gives me something to try to do better in a proper article later. The argument starts kicking in at page 5 with the discussion of Wigner's friend, comes back a little again at the end of the Seeking SICs section, and then climbs to a fevered pitch starting at page 16 in the Universal Capacity section.

You'll see that everything has grown a bit since the last version I sent you. I took into account almost all your comments, for instance. And indeed, your comments helped set me up for my New Year's epiphany—so I owe you a lot. One thing I haven't done yet that you suggested is to have a discussion on the subjective-Bayesian nature of unitaries—that's actually crucial now, so it's coming. In the present version, I am a bit harsh on the "quantum-to-classical transitionists."

I hope you will be provisionally tolerant of me and not get too angry. I can work harder to set the tone right and still make my point. Those paragraphs were written on the flight over here; so they're pretty raw. They are like Homer Simpson thinking out loud. Still, I thought I'd go ahead and show them to you now and take into account your reactions (and levels of anger) as they are for real, rather than try to anticipate them.

Scanning over your note again … On your question about Anton: Yes, it seems he is actually going to get one of his teams to do a qutrit SIC demo. So tugging on his shirt was a good thing. In fact, he's now quite interested in MUBs and SICs and will be holding a meeting in Vienna on the subject in July.

My apology again on the long silence. One should not go quiet on friends. But some not-good things happened right after Vienna (an old friend died), and I just ended up shutting up for a while.

17-02-10 *Oh, Repository* (to R. Schack)

Isn't your new "potential schism" the very core of our considerations already? The Law of Total Probability is operative when we expect to actually have an experience E_i. The Born Rule (urgleichung) tells us how to modify that old estimate into something relevant when we don't expect an intermediate E_i experience. It is a postulate of quantum mechanics, over and above coherence considerations.

I'm probably still not getting your point.

Random thought. Just recording it even it's not relevant to the present discussion. Decoherence is really just a cheap way of extending "the self" without recognizing it as a such. It tries to say, "that experience is really there waiting for me to have it" when in fact, all it is doing is lengthening the arm of the agent (with a complicated story in between). In this regard, William James's notion of self is important: "In its widest possible sense, however, a man's self is the sum total of all that he can call his, not only his body and his psychic powers, but his clothes and his house, his wife and children, his ancestors and friends, his reputation and works, his lands and horses, and yacht and bank account."

Rüdiger's Preply

> I hope you made it safely to Japan!
>
> I read the first 10 pages of the paper carefully and have some comments (see below), but when reading the Wigner's friend bit and then the measurement in the sky story, I got hung up on a problem that may turn out to be of central importance.
>
> If I intend to perform the experiment in the sky, I expect to get outcome E_i with probability $P(E_i)$, and I expect that in the case I actually experience E_i my new probability for D_j will be my current $P(D_j|E_i)$. Reflection then gives me the law of total probability.
>
> But what if I only *imagine* performing the experiment? I.e., what if I believe there is decoherence (I can see you shudder!) and I want to use reflection to set my probabilities according to the law of total probability as above. I would have to say my beliefs are *as if* I expected to actually experience E_i. This sounds like vile as-if-ism to me. If I don't expect to actually experience E_i, how to I justify to myself setting $P(D_j)$ according to the law of total probability in one case, and according to the Urgleichung in the other case?
>
> Does this have the potential for a schism?

18-02-10 *Eliot* (to M. Schlosshauer)

This synchronicity thing between us seems to have no end. I was on a plane reading your paper, thinking about how you think, thinking about how you will react, and all kinds of things like that. Then, along the way (as I stop in Dallas), Rüdiger finally sends his QB-decoherence draft. Then, I learn that you and your wife were in Copenhagen participating in the biggest event of your lives.

Many, many congratulations. You will have a strong son; he was born in the land of Niels Bohr.

19-02-10 *Potentially Perfect Potential Aaron Problem* (to A. Fenyes & D. M. Appleby)

The PPPAP. [Notation and equations refer to D. M. Appleby, S. T. Flammia, and C. A. Fuchs, "The Lie Algebraic Significance of Symmetric Informationally Complete Measurements," `arXiv:1001.0004 [quant-ph]`.]

Marcus has known for some time that I keep hoping that the R_r will imply everything we need to know about the J_r. If the raw shape of quantum state space is more fundamental than anything else, then the R_r have to be more fundamental. I still hold out this hope.

This morning as I was putting together my talk for Japan, I was struck that we haven't asked the obvious question. What is the analogue of Theorem 7 for the Jordan algebra induced by the anti-commutator?

In other words, equip the vector space of Hermitian matrices with a symmetric product (the anti-commutator), and let Π_t be a basis for the algebra. (No assumptions about Π_t being a SIC or anything.) Now define a matrix R_r by Eq. (16) in the Lie algebra paper, and suppose the R_r have an analogue of the Q-Q^T property. Namely that the R_r can be written as in Eq. (103), where the $\|e_r\rangle\rangle$ are defined as EXACTLY as in Eq. (116) and the Q_r are rank $d-1$ projectors satisfying Eq. (105). Does it follow in analogue to Theorem 7 that a SIC must exist?

If it does, this will be immensely exciting. How are the Π_t related to this SIC, in analogue to Eq. (164)? And if such a theorem does not follow, then what does? What is the most one can say about the basis Π_t?

Aaron, I think this could be a PSI project for you (or the beginning of one) if you are interested. If you get a positive result, it may not have so many applications to the SIC existence problem as the Lie algebra version might (I say might), but for my money it'll be a deeper result about quantum mechanics itself.

Part of the point is, if there is a result like this, then one has a nice way to start with a Jordan algebra and then define a natural Lie algebra associated with it.

Let me know what you guys think? Marcus, what are your feelings/thoughts?

19-02-10 *Postscript* (to D. M. Appleby)

Applebyism 39: *Hope you are enjoying Japan.*

No enjoyment yet. I've just been writing, working on ONR things, trying to plan (unsuccessfully) my PI colloquium, and trying to get Belavkin and Ozawa to respect us. In the wee hours of the morning when I have my hot bath, I've been trying to think about gravity. The bold proposition is that simply the presence of a quantum system of any kind in an otherwise empty region of space must bend light around it. Just like those beautiful pictures we saw at the colloquium on gravitational lensing. No talk of coupling to the EM field (in the usual sense), no talk of the quantum state one ascribes to it, simply the presence of a system. There has to be an equivalence principle lurking here.

I am very intrigued by what you seem to have found. You are right about the flavor seeming to hint that all SICs are WH SICs or simple transformations of them.

Write as you wish, but there is no necessity. If you prove SIC existence, I'll buy you the next bottle of single malt! And a very, very rare one at that.

21-02-10 *Pierce Quote* (to V. P. Belavkin)

J. R. Pierce (IEEE Trans. Inf. Theory, vol **IT-19**, 3–8 (1973)):

> I think that I have never met a physicist who understood information theory. I wish that physicists would stop talking about reformulating information theory and would give us a general expression for the capacity of a channel with quantum effects taken into account rather than a number of special cases.

21-02-10 *Ways of Expression* (to D. M. Appleby)

Here's the way I expressed it tonight to Gen Kimura: If SICs exist, then there's a beautiful way of thinking of quantum state space that had not been thought of before. It is a union of a bunch of regular simplices, each over d^2 extreme points. "Quantum state space is a union of regular simplices."[216]

22-02-10 *Schelling, Quantum, Creation* (to I. Ojima)

I am very happy about our chance conversation today—now I have another refreshing thinker on nature's creativity to read and think about. Schelling strikes me as very interesting.

Attached is the essay I've been writing at this very meeting. It is still unfinished, but it already demonstrates why I was so interested in my conversation with you today.

Here are a few sentences from my paper that may whet your appetite:

- Page 6, figure caption)
  Measurement devices are depicted as prosthetic hands to make it clear that they should be considered an integral part of the agent. The sparks between the measurement-device hand and the quantum system represent the idea that the consequence of each quantum measurement is a unique creation within the previously existing universe.

- Page 8)
  QBism says when an agent reaches out and touches a quantum system—when he performs a quantum measurement—that process gives rise to birth in a nearly literal sense. With the action of the agent upon the system, the no-go theorems of Bell and Kochen-Specker assert that something new comes into the world that wasn't there previously: It is the "outcome," the unpredictable consequence for the very agent who took the action. John Archibald Wheeler said it this way, and we follow suit, "Each elementary quantum phenomenon is an elementary act of 'fact creation.' That is incontestable."

[216] See Footnote 218 for a technical, but remediable, mistake in the original statement of this.

- Page 14)
  The Quantum Bayesian, however, with a different understanding of probability and a commitment to the idea that quantum measurement outcomes are personal, draws a different conclusion from the theorem. And it is profound: Bell's theorem for the Quantum Bayesian is the deepest reaching statement ever drawn from quantum theory. It is that quantum measurements are moments of creation.

- Page 20)
  To put it still differently, and now in the metaphor of music, a jazz musician might declare that a tune once heard thereafter plays its most crucial role as a substrate for something new. It is the fleeting solid ground upon which something new can be born.

Anyway, those are the sorts of things you'll find argued for in the essay.

Below are my already favorite Schelling quotes:

> Has creation a final goal? And if so, why was it not reached at once? Why was the consummation not realized from the beginning? To these questions there is but one answer: Because God is Life, and not merely Being.
>
> — Schelling, *Philosophical Inquiries into the Nature of Human Freedom*, 1809

and

> Only he who has tasted freedom can feel the desire to make over everything in its image, to spread it throughout the whole universe.
>
> — Schelling, *Philosophical Inquiries into the Nature of Human Freedom*, 1809

22-02-10 *Hilbert-Space Dimension in Second-Quantized Theories* (to N. C. Menicucci & E. G. Cavalcanti)

Menicuccism 3: *Eric Cavalcanti raised a question that I've thought about, as well, in relation to your claim in "Quantum Mechanics as Quantum Information (and only a little more)" that the dimension of a Hilbert space is real: what happens if the dimension is not well defined, as is the case in QED? One can have a superposition of photon-number states, which results in a superposition of number of qubits available and thus a superposition of dimensions of the overall state space (e.g., H/V qubit encoding). Is the answer trivial (e.g., the overall dimension is infinite, which is a real property of the world), or is there something more subtle at work here? Have you (or anyone else that you know of) written about this?*

No I haven't written about this before, but I am just about going to! There'll be a discussion in the attached paper which I am in the process of writing at this very moment. I'll go ahead and send you this much, and sketch very briefly an answer to your present question. The paper helps give the setting, and the precise sense in which I'm thinking of quantum dimension now.

Anyway, to answer your question:

1. If quantum fields really did exist, the answer would be the one you call the trivial one: dimension $= \infty$.

2. Even if they don't exist, one might think of this case as like the moral equivalent of an infinite heat bath: a limiting case or approximation.

3. But in fact, I'm starting to suspect the nonexistence of infinite dim Hilbert spaces. This is because I am starting to take this holographic principle stuff more seriously. But I think these guys are misidentifying the principle as giving an entropy bound (how could you do that with a subjective quantity?). What I suspect it really gives is a dimension bound.

4. In any case, if such is the case, it keeps my "dimension as valence" thinking from collapsing. So, something like that ought to be the case.

These are the things I'll eventually write more thoroughly (and more poetically!) in the completed paper.

I hope you find some food for thought in the paper, even as it stands.

Best wishes from Nagoya, Japan (in the middle of a talk on "nonlocality" ... as if such crap were true).

23-02-10 *Kitaro and James* (to I. Ojima)

I have now read this article on Nishida Kitaro's conception of "pure experience" in contrast to William James's conception of it. [See D. Dilworth, "The Initial Formations of 'Pure Experience' in Nishida Kitaro and William James," *Monumenta Nipponica* **24**(1/2), 93–111 (1969).] Indeed—a bit as you warned—Kitaro does not look like such an interesting philosopher to me.

The article "Nature in American Philosophy," by Stefano Poggi, on Google Books looks to be very interesting. I have just started reading it, but it looks like it does a good job of tracing Schelling's influence on Fechner, and Fechner's influence in turn on James.

26-02-10 *Kitaro and James, 2* (to I. Ojima)

Thank you so much for the papers. I have so far read the first [I. Ojima, "Nature vs. Science," Acta Inst. Phil. Aesth. **10**, 55 (1992)] and 1/4 of the second on my flight back to North America. These are very deep papers, and we are very much on similar wavelengths. Technically, I enjoyed your argument on the nonexistence of (ontic) repeatability in the first paper. You gave repeatability a logical inconsistency (rather than an empirical establishment) that I had not appreciated before. To get repeatability you call for "approximation", and in my own naming scheme, I call it "judgment". But it is much the same thing—certainly our hearts are in the same place.

I look forward to finishing your longer paper as I have a chance.

I have gotten further in the writing of the paper I sent you last week. When it is finally finished, I will surely send it to you.

01-03-10 *My Lectures for You* (to J. Emerson & R. Laflamme)

I plan to work through the night putting the finishing touches on the attached (still slightly incomplete) essay. [See `http://arxiv.org/abs/1003.5209`.] Here's what I'd like to do for my lectures for your course. Let me check that you're OK with this.

Rather than give the students a post-lecture homework assignment of any sort, I would like to give them a pre-lecture suggestion or assignment: That they read the attached essay before I show up next week (tomorrow morning's version more precisely). Then through the week or over the weekend, they can email me any questions or discussion points they would like to be brought up in my lectures. In place of rigid lectures then, I'd try to spend much or most of the time replying to their questions, dodging tomatoes, etc. Similarly with any issues that arise spontaneously in the class. I think they'd get a lot more out of this than "yet another lecture on yet another point of view." I.e., it puts me on the spot, and they (and you) can try to pin me down as much as they (and you) want! The essay was written with an intention of being entertaining and provocative; so it should be quite easy reading for them.

If it's OK with you, I'd like to spend less than one minute tomorrow saying this is how I want to run things for my lecture slots. And I'd put a pile of these papers at the front so that they could pick a copy up. (How many students are there?) Then I'd quickly disappear so as not to interrupt your present lecturer.

Please, let me know, and I'll come prepared to tomorrow's lecture with a pile in hand. And I hope to give you some fun next week.

01-03-10 *Curiosity* (to C. Ferrie)

Thanks for this. It is a deeply thoughtful essay, and I enjoyed it very much. You have no need to worry that you cannot "articulate so well"—it simply is not true. Your message came across loud and clear. Are you a different person than when I met you? Or was I just stubbornly blind/deaf?

Just because I caught them, I'll point to some of your typos: ...

Now, not a typo, just a disagreement:

Ferrie-ism 8: *"Humans possess freedom of will. This is a privilege which the Earth, for example, does not seem to benefit from."*

Want to bet?

02-03-10 *Our Unfinished Universe* (to A. Zeilinger and Č. Brukner)

Well, I have finally finished (within epsilon at least), that essay I was writing on in Vienna—the one in which I try to capture my whole (present) worldview. I hope you will both enjoy and not find the ending sections (which were not yet written in Vienna) too outlandish! If you have any comments on anything you think I should change or add or delete!, please do tell me. I'm hoping to post the thing at the end of the week.

Časlav, in the footnote on Kofler, you'll see that our conversation the last days of the visit very much influenced me.

Brothers in arms for a creative universe!

02-03-10 *Wheelerism Full-Throttle!* (to B. W. Schumacher)

I'm nearly finished with an essay I've been pouring my soul into, and I thought I'd send you a draft before posting since it's chock-full of Wheelerish stuff. I attributed Wheeler's "great smoky dragon" to a paper by he and Warner Miller; do you happen to know whether that is the right one? Anyway, if you see anything that should be corrected or amended, please don't hesitate to say. I'll probably shoot for posting this Friday.

Hope you and Carol and the whole family are well.

Ben's Reply

> I won't be able to read this for a couple of days. Looks fun! The Great Smoky Dragon cartoon appears as Plate 27 (p. 399) of the 1988 *Between Quantum and Cosmos* book. The notes at the end (p. 619–20) give a reference that appears to agree with your Ref. 70.

02-03-10 *Nearly Final Product* (to H. C. von Baeyer)

Attached is the nearly final product; within epsilon it is finished! You will find it has changed substantially since the partial draft you read. Quantum measurement, for instance, is no longer a kick, but a birth! I hope you enjoy and not find the whole thing too outlandish.

From YOU (but only you), editorial comments always welcome! Don't be shy if you see something that really could be improved.

Hans's Replies

> Dear Chris – witnessing a birth is vastly more pleasant than giving or receiving a kick! I am reading carefully, and am only on page ten. Soon I will send you a list of small suggestions. . . .
>
> As I read that the world is not made of [Essence X] I recall a relevant quote by the American poet Muriel Rukeyser: "The world is not made of atoms; it is made of stories."

02-03-10 *Fatherhood/Paperhood* (to M. Schlosshauer)

How are you and your wife making it? Hopefully it's been relatively easy; my recollection is that babies are pretty easy at the beginning.

Attached is an actual (potentially) FINAL version of the essay. I bet you thought you'd never see that coming. I beefed up the quantum-to-classical transition discussion at bit—I hope it helps matters a small amount. Only one thing in your "to do" list that I did not do: I just couldn't bring myself to writing on the subjective meaning of unitaries. I lost steam, and couldn't find an easy place for it to fit into the present structure. If you do think the essay is really lacking because of this, please do tell me, and I'll rethink. A day or two of rest often brings a second wind. I value your input; I hope you know that. And I'll value your criticism as well: If I can't get it right with you, I won't be able to get it right with anyone.

I've got a big talk coming up next week that has me completely frightened: It's part of trying to establish myself a permanent position here. Who would think a 45 year old man could be scared like a little boy? But it happens.

I met one of your colleagues from Copenhagen in Japan, Teiko Heinosaari. He seems to be a good guy. He's even working on SICs now!

Please give my regards to your wife. And say hello to Niels from close up; he's been on my mind again lately.

02-03-10 *Another Attempt To Get You To Call Me a Realist!* (to H. M. Wiseman)

Since I implicate you in this essay, I should probably send it to you before posting! [See "QBism, the Perimeter of Quantum Bayesianism," `arXiv:1003.5209v1`.] I drew one of the figures for you. Seriously, thanks for the great challenges you've given me over the years. Any comments you have for improvement—so long as they're relatively easy to implement—will be welcome.

03-03-10 *My Worldview* (to A. Kent)

Since I implicate you in one of my sly insults, I probably ought to send you this essay before posting it:

> Or take the Everettians. Their world purports to have no observers, but then it has no probabilities either. What are we then to do with the Born Rule for calculating quantum probabilities, the very core of the theory from the experimental perspective? Throw it away and say it never mattered? It is true that much effort has been made by the Everettians to rederive the rule, but to many in the outside world, it looks like the success of these derivations depends upon where they are assessed—for instance, whether in Oxford [9] or Cambridge [10].

I hope you enjoy (some of) it. It is my latest attempt to form a worldview.

I hope you come to PI again soon; it's always a blander place when you're not around.

03-03-10 *A Jaume Stamp?* (to J. Gomis)

I finally finished that essay I was telling you about. [See "QBism, the Perimeter of Quantum Bayesianism," `arXiv:1003.5209v1`.] It's attached. I didn't do as good a job connecting Hilbert-space dimension to mass/energy as I had hoped to, but I do believe there is something much deeper to the analogy between "fungibility of quantum information" and the equivalence principle than meets the eye. Anyway, the essay expresses the direction of thought I'll be exploring.

03-03-10 *Novelty, Creation, QBism* (to L. Smolin)

I haven't seen you in a long time, and I've just written something that I hope will intrigue you. [See "QBism, the Perimeter of Quantum Bayesianism," `arXiv:1003.5209v1`.] It's an essay on my worldview, at least as it stands at the moment. See attached. Section V onward, particularly, is about how my QBism research program mounts onto the idea of a pluriverse in constant creation. I don't know to what extent my "interiority" has a connection to Verlinde's "our starting point was that space has one emergent holographic direction," but I am tempted to think something like this is going on . . . but from a completely different end of the philosophical spectrum. I feel it is a big research program ahead.

I hope to post the essay next week maybe. If you have any feedback on how the draft might be improved or made clearer, I'd much appreciate hearing your thoughts.

04-03-10 *My Worldview, 2* (to A. Kent)

Kentism 9: *Thanks. I haven't had a chance to read yet, beyond searching for the flagged implication. I have to be honest, I'm rather disappointed by it: it seems a cheap and lazy way of avoiding serious discussion, and quite inappropriate for an academic article.*

Guilty. And I misstated when I said "sly"—I forgot the extra *i* and *l*. Silly. But the cheapness of it was meant to be a direct comparison to John Bell's statement. The beginning of the paragraph announced it so. There are some things, we each of us, just do not take seriously. For instance a thoroughgoing epistemic interpretation of quantum states, as Bell didn't (and maybe you, don't). Anyway, much of the remainder of the article is meant to show how one can recover from the sting of Bell's original cheap shot.

The only thing I worry about now is that you won't look at the rest of the article, where I try to explain the mindset that would make Bell's remark a "cheap shot" rather than a "forceful way of conveying the essential point".

04-03-10 *Edits* (to H. C. von Baeyer)

von Baeyerism 59: *Figure 2 is unnecessary, and the inclusion of the ass among the Ten Commandments is wrong.*

See: `http://en.wikipedia.org/wiki/Ten_Commandments`:

> The firstborn of a donkey you shall redeem with a lamb, or if you will not redeem it you shall break its neck. All the firstborn of your sons you shall redeem.

And from another page:

> But the firstling of an ass thou shalt redeem with a lamb: and if thou redeem him not, then shalt thou break his neck. All the firstborn of thy sons thou shalt redeem. And none shall appear before me empty.

But you are right, strictly speaking, it is not one of the 10 Commandments. I'll fix the drawing and caption before posting. It was an attempt at humor; it definitely works in talks, but maybe it would not in the paper ... and it might even be offensive to some. Still, I don't think the discussion is unnecessary: You are the rare physicist who has ever heard of a normative rule. And generally, in both physics and philosophy of science, the Born Rule is thought to be of a character as Maxwell's and Einstein's equations: A statement of what is in the world. A quantum state IS, and the probability it carries with it IS. I want to hammer it home that it should be thought of as a recommendation, nothing more.

I keep drawing myself away from my talk preparations to look at your notes!

04-03-10 *Fuchsianism / Ones For Which* (to R. Blume-Kohout)

I finally put it all on paper, everything in my head. It's empty now. Anyway, you always say that whatever I believe of quantum mechanics is a mystery to you: I hope it won't remain so if you read this paper.

And don't forget:

1. Scaffolding paragraph.

2. "Hilbert-Space Dimension as a Universal Capacity" section

3. And I might as well point out these lines too:

> You see, for the QBist, the real world, the one both agents are embedded in—with its objects and events—is taken for granted. What is not taken for granted is each agent's access to the parts of it he has not touched. Wigner holds two thoughts in his head: 1) that his friend interacted with a quantum system, eliciting some consequence of the interaction for himself, and 2) after the specified time, for any of Wigner's own further interactions with his friend or system or both, he ought to gamble upon their consequences according to $U(\rho \otimes |\psi\rangle\langle\psi|)U^\dagger$. One statement refers to the friend's potential experiences, and one refers to Wigner's own. So long as it is kept clear that $U(\rho \otimes |\psi\rangle\langle\psi|)U^\dagger$ refers to the latter—how Wigner should gamble upon the things that might happen to him—making no statement whatsoever about the former, there is no conflict. The world is filled with all the same things it was before quantum theory came along, like each of our experiences, that rock and that tree, and all the other things under the sun; it is just that quantum theory provides a calculus for gambling on each agent's own experiences—it doesn't give anything else than that. It certainly doesn't give one agent the ability to conceptually pierce the other agent's personal experience. It is true that with enough effort Wigner could enact Eq. (1), causing him to predict that his friend will have amnesia to any future questions on his old measurement results. But we always knew Wigner could do that—a mallet to the head would have been good enough.

05-03-10 *Laws of Nature Conference* (to G. Musser)

I finally finished that essay that I had shown you part of. It's attached. [See "QBism, the Perimeter of Quantum Bayesianism," `arXiv:1003.5209v1`.] Do you think you can cut it with meat cleaver and scalpel into something for Sci Am? Would you be interested? Section V is definitely the antithesis of that David Albert article you had.

05-03-10 *Torture* (to A. Kent)

... like a grain of sand in an oyster shell, you have been with me for the last 24 hours. It makes no pearl with me, but I do come to appreciate the annoyance the little fellow feels.

I do insist on insulting Everett, but your scolding (beside making me feel ashamed) did make me realize that I wasn't getting to the essential point. I try to do that in the present version. I will probably tweak it a hundred times more before posting, but the final result will be something more like this than yesterday's:

> Or take the Everettians. Their world purports to have no observers, but then it has no probabilities either. What are we then to do with the Born Rule for calculating quantum probabilities? Throw it away and say it never mattered? It is true that quite an effort has been made by the Everettians to rederive the rule from decision theory. Some sympathizers think it works [9], some don't [10]. But outside the *sprachspiele* who could ever believe? No amount of sophistry can make "decision" anything other than a hollow concept in a deterministic universe.

05-03-10 *Higher Road* (to R. W. Spekkens)

By the way, I did choose a (slightly) higher road with the insult. Now it targets the idea more than the people. You were right. I also rejigged the footnote on Granade and you to something a little less lame:

> Not to be confused with Scientologists. This neologism was coined by Chris Granade, a Perimeter Scholars International student at Perimeter Institute, and brought to the author's attention by R. W. Spekkens, who pounced on it for its beautiful subtlety.

If you're interested, latest version attached.

05-03-10 *A Wild Shock!* (to O. C. O. Dahlsten)

Thanks. On Dakić and Brukner, I personally don't think "information capacity" is the right idea—it is still too close to treating a quantum system as a bucket into which one can pour a certain amount of stuff—but I felt I should cite them in some way. Maybe I'll leave the reference, but take the quote out. I liked Hardy's (old) way of putting it better. It is just that no distinction of quantum theoretical properties can be made between two systems of dimension N.

I look forward to seeing your draft. In my own way, I might want to see systems dropped as well—that's partly what the mumbo-jumbo about "pure experience" was about at the end. But things are not clear in my mind yet. Extra stimulation would be good!

Oscar's Preply

> Thanks a lot, I enjoyed reading it!
>
> I also take PSI-epistemic view, that PSI represents our knowledge about something out there. I even agree that the Hilbert space dimension seems to be something real out there.
>
> A small remark on the Dakić and Brukner paper which you mention in a footnote, which I otherwise like, is that 'information capacity' may be a strange choice of word. Many other hypothetical systems, including gbits have the same information capacity as a qubit, i.e., one can only communicate one classical bit with them (in the sense that Bob can distinguish at most two of Alice's preparations after Alice has sent him the system). We (Roger, Renato and I) are writing something about these things at the moment, i.e., about different notions of how much information a system can be used to convey.
>
> In my way of thinking of things I am inclined to think that the notion of system itself should actually be dropped. Am writing this up at the moment and will send you a draft in case you have time/interest to look at it.

08-03-10 *Another Attempt To Get You To Call Me a Realist!, 2* (to H. M. Wiseman)

Wisemanism 48: *I've started to reading it, and I like the tenor of it so far. You seem to have taken a deep intellectual breath before writing this time.*

Did I ever share with you my idea of Escher's "Print Gallery" as a metaphor for the measurement problem? The boy is the observer, the picture is what he is observing, the town is the universe. The blur in the middle is the flaw which means we will never be able to solve the problem.

I'll keep my fingers crossed that that lasts! I don't believe you'd ever told me the Escher metaphor. My own favorite metaphor comes from a painting as well: Joan Vaccaro's "Broken Block" which she sent me, and I have hanging in my study at QBism house. It beautifully expresses all the cracks in the block universe idea. You can still see it at Joan's webpage, and attached is a little blurb on the house.

08-03-10 *Lee, from the Inside* (to L. Smolin)

Actually a Google search on the phrase "quantum cosmology from the inside" gives *Precisely* one hit ... and it was one of your papers!

10-03-10 *Meliorism* (to L. Smolin)

I read your essay and enjoyed it very much. We are both meliorists! See Footnote 31, page 19 in the essay I gave you for a bit on the term. (I'll attach a copy anew in case you don't have the essay in front of you.) [See "QBism, the Perimeter of Quantum Bayesianism," `arXiv:1003.5209v1`.] I also like this idea of "merging nature and technology"—it is long deep in my thinking. It is, in a way, why I always draw a quantum measurement device as a prosthetic hand.

I also enjoyed the section on democracy. It reminded me of something I wrote to Carl Caves once, when I sent him Louis Menand's book *The Metaphysical Club* and Richard Rorty's book *Philosophy and Social Hope* as a holiday gift (2003). Digging up the note, I ended it with:

> Anyway, I learned a lot about quantum mechanics from these books. And I learned a lot about true Americanism (i.e., the kind of Americanism we need to strive to get back to ... and actually mould into a more stable, long-lasting form). Done right, I think the two subjects are probably the same thing.

It very much fits with the "republican banquet" ontology I see quantum mechanics hinting at.

Anyway, just first thoughts. I'll read it again when things are less hectic.

10-03-10 *The Great Lotze* (to L. Smolin)

Thinking a bit more on your avowal of human agency as a real element in the world, I thought you might enjoy this passage from William James if you've never seen it. [See long William James quote near the beginning of the 05-01-09 note "What I Really Want Out of a Pauli/Fierz-Correspondence Study" to H. C. von Baeyer & D. M. Appleby.]

10-03-10 *QBism on the Make* (to R. D. Sorkin)

I didn't feel I answered your questions very well today—neither to my satisfaction nor yours. I'd like to get a chance again if you've got some time to chat tomorrow. Attached is the essay I just wrote on the big picture of the QBism program. If you have time to give me some feedback on it, I'd sure appreciate it before I post it: I'm sure there are still plenty of places it can be tweaked for clarity, as well as to make sure the right message is coming across.

If you want a short introduction to the technical part about the SIC rewrite of QM, maybe I could recommend this one: `http://arxiv.org/abs/0912.4252`.

10-03-10 *Lighter Fare* (to L. Smolin)

I feel I didn't answer your questions very well today, at least not to the best of my ability. I'd like to get your questions straight. Would you have any time to chat further tomorrow? At the moment, I'm free all day except 2:00 to 4:00.

Attached is a lighter version of some of the "nonreductionism pieces" in the essay I gave you; it also encompasses some of the things I tried to say in answering your questions. [See 16-10-09 note "The More and the Modest" to L. Hardy.] The point being that QBism sees its rewrite of the Born rule as an identification of a new "active power" inherent in all matter. And that the form of the equations are simple enough that we have strong hope that they alone imply the formal structure of quantum mechanics. That should be first thing they do before we get to the next step beyond quantum mechanics, which I definitely see coming. I want to give a shot at conveying that to you.

Also, if you want a short introduction to the technical part about the SIC rewrite of QM, maybe I could recommend this paper to you: `http://arxiv.org/abs/0912.4252`.

11-03-10 *Lighter Fare, 2* (to L. Smolin)

Lee Smolinism 2: *I thoroughly enjoyed your talk and even felt like I understood most of it.*

Thanks; I was afraid you were put off by the talk.

Lee Smolinism 3: *I can put a query about what you mean by non-reductionism this way; to me strong reductionism is the claim that the properties needed to understand a composite system can always be translated completely into the language used to describe the properties of the parts. Non-reductionism denies this and allows the whole to have properties not expressible in the language used to describe the properties of the parts.*

Your proposal, if I understand it, is that the parts have no properties at all, ie you claim there is no realist microscopic description at all. This seems a denial of more than reductionism.

Am I misunderstanding?

Yes. Or it could be that I used some choice of words that accidentally conveyed this. I certainly would not have meant to! I think the two paragraphs below from my essay directly address your question. (And for fun, I'll leave in a footnote that I had opted to leave out of the actual paper.) Maybe a way of putting it is that the view here is that reality runs deep: It is to be found in a new and unique way at every level.

There may be some small similarity to something you said in your open-universe essay (or at least the wording of it). Let me dig up the line: "a lot of progress has recently been made on approaches to quantum cosmology in which time is fundamental rather than emergent." Reality runs deep in the sense that there is something nontranslatable from every level to every other level. And similarly from every "time" to every other "time". (Though I probably shouldn't be using the language of "level" at all: The view here is that there is no ordering or even overly broad partial ordering (though there may be within islands).)

Maybe another troublemaker is my slogan "Quantum States Do Not Exist." Maybe it is this that is giving you the impression that I am saying "the parts have no properties at all." All the slogan is really meant to convey is that quantum states are not microscopic properties, but rather macroscopic. Namely, a quantum state is a property of the agent who holds it. It is a property of the head of the agent, for it reflects how he will gamble on the consequences of the actions he contemplates taking upon a system.

Two paragraphs below. I hope this helps.

Physics—in the right mindset—is not about identifying the bricks with which nature is made, but about identifying what is *common to* the largest range of phenomena it can get its hands on. The idea is not difficult once one gets used to thinking in these terms. Carbon? The old answer would go that it is *nothing but* a building block that combines with other elements according to the following rules, blah, blah, blah. The new answer is that carbon is a *characteristic* common to diamonds, pencil leads, deoxyribonucleic acid, burnt pancakes, the space between stars, the emissions of Ford pick-up trucks, and so on—the list is as unending as the world is itself. For, carbon is also a characteristic common to this diamond and this diamond and this diamond and this. But a flawless diamond and a purified zirconium crystal, no matter how carefully crafted, have no such characteristic in common: Carbon is not a *universal* characteristic of all phenomena. The aim of physics is to find characteristics that apply to as much of the world in its varied fullness as possible. However, those common characteristics are hardly what the world is made of—the world instead is made of this and this and this. The world is constructed of every particular there is and every way of carving up every particular there is.

An unparalleled example of how physics operates in such a world can be found by looking to Newton's law of universal gravitation. What did Newton really find? Would he be considered a great physicist in this day when every news magazine presents the most cherished goal of physics to be a Theory of Everything? For the law of universal gravitation is hardly that! Instead, it *merely* says that every body in the universe tries to accelerate every other body toward itself at a rate proportional to its own mass and inversely proportional to the squared distance between them. Beyond that, the law says nothing else particular of objects, and it would have been a rare thinker in Newton's time, if any at all, who would have imagined that all the complexities of the world could be derived from that limited law. Yet there is no doubt that Newton was one of the greatest physicists of all time. He did not give a theory of everything, but a Theory of One Aspect of Everything. And only the tiniest fraction of physicists of any variety, much less the TOE-seeking variety, have ever worn a badge of that more modest kind. It is as H. C. von Baeyer wrote in one of his books [*Petite Leçons de Physique dans les Jardins de Paris*],

> Great revolutionaries don't stop at half measures if they can go all the way. For Newton this meant an almost unimaginable widening of the scope of his new-found law. Not only Earth, Sun, and planets attract objects in their vicinity, he conjectured, but all objects, no matter how large or small, attract all other objects, no matter how far distant. It was a proposition of almost reckless boldness, and it changed the way we perceive the world.

Finding a theory of "merely" one aspect of everything is hardly something to be ashamed of: It is the loftiest achievement physics can have in a living, breathing nonreductionist world.[217]

[217] Theories of everything, by contrast, belong to dead worlds, ones whose lives have already been completed. But perhaps I should not go so far as to say.

11-03-10 *Survival* (to R. Schack)

OK, I survived giving this: `http://pirsa.org/10030036/`. Now today, I give the follow on to this lecture (grilling) `http://pirsa.org/10030005/` for Laflamme and Emerson's class, and further write my report for the Navy (due Friday 4:00 PM). Saturday, I finally turn my attention to your reflection/decoherence draft and our Templeton proposal. I'm sorry for all these delays; it's just that I am so damned linear.

11-03-10 *New Footnote* (to C. E. Granade)

Thanks for the question yesterday. You'll find a better answer than I gave you in the discussion starting on page 23, and particularly footnote 44, of this nearly final draft of my essay. [See "QBism, the Perimeter of Quantum Bayesianism," `arXiv:1003.5209v1`.] But that's not the "new" footnote I was referring to in the title. I've rejigged the footnote about you.

> Not to be confused with Scientologists. This neologism was coined by Chris Granade, a Perimeter Scholars International student at Perimeter Institute, and brought to the author's attention by R. W. Spekkens, who pounced on it for its beautiful subtlety.

The whole thing is getting very near posting now.

12-03-10 *Counterexample* (to J. Emerson & R. Laflamme)

Just to follow up on one of my remarks yesterday. Take some finite dimensional Hilbert space of dimension $d > 4$, and imagine performing (sequentially) two *projection* valued measurements on it. Suppose the first consists of n non-rank-1 projection operators P_i. For the second, let it be a PVM with d rank-1 projections Q_j. Further suppose that none of the Q_j commute with any of the P_i.

We can think of this as a single measurement with nd outcomes (i, j), and POVM elements $P_iQ_jP_i$. That is to say, a POVM with nd rank-1 elements: Let's call them G_{ij}. To further simplify notation, let's use lexicographic order to associate ordered pairs (i, j) with a single integer $k = 1, \ldots, nd$. In other words, let us write G_k for the POVM elements.

Now, suppose you hadn't read any of the above, and I walk up to you out of the blue and say, "Joseph, I have a POVM with a these rank-1 operators G_k as its elements. I'd like you to rig up a measurement of it for me." My guess is that your knee-jerk reaction would be to say, "Let me use the Neumark extension theorem to write this as a unitary interaction with an ancilla plus a projection valued measurement on an nd-dimensional Hilbert space."

And I would reply, "Yes, that's one way to think of it, but it is not how I described it to you above. Above, I mapped it out as a sequential measurement."

Similarly, a common technique used by the Zeilinger group and others, is to use extra timing information in their measurements. I would be resistant to call that the introduction of extra Hilbert space. The Steinberg SIC experiment is a bit of an example of that as well. I'll attach Medendorp's QELS abstract. There, a perfect SIC is enacted by a photon running around and around a loop and generally evolving unitarily, except encountering very weak partial beam splitters along the way. Zeilinger will also be doing a qutrit SIC experiment, and in the present plans, he will make use of the Neumark theorem and do it that way, i.e., as a PVM on a 9-dimensional system, but that is not the only way to do it.

I will take you up on those beers when I'm back from the APS meeting.

15-07-09 *To Contemplate* (to R. Laflamme & J. Emerson)

Attached is the vector I showed yesterday from a $d = 6$ SIC. The remaining 35 vectors are generated by acting $X^j Z^k$ on it, for all values of j and k. (X and Z are the usual shift and phase operators.)

And I'll remind you of the interest in dimension 6: No one has ever been able to construct a complete set of mutually unbiased bases in that dimension, and it is widely believed (though not proved) that no one ever will. This says the SIC is the only optimal measurement around in that dimension, and thus shows a divergence of the two concepts, SICs and MUBs.

The Singapore group has done a SIC in $d = 2$. Steinberg has done (something resembling) a SIC in $d = 3$, and Zeilinger will soon be doing a more honest-to-god SIC in $d = 3$ as well. It'd be nice to see IQC do the next interesting dimension, $d = 6$. And I suspect your techniques are much more tailored to the problem anyway.

I'll be back from the APS meeting on the 21$^{\rm st}$. Ray, I'll come by your office the following Wednesday.

27-07-09 *Under Your Belt* (to J. W. Nicholson)

I'm gearing up to write a story about you. See attached, page 11. In preparation for it, may I ask you how many publications you have now? I just want to make a small mention of the number, before I plunge into bar stories. And do you have a webpage? I couldn't find it.

Greetings from 4:58 AM,

28-07-09 *Red Naugahyde* (to J. W. Nicholson)

This still isn't a proper reply to your nice notes—I'll work on that soon. But let me send you the first draft of the Nicholson entry to try on for size. You'll find your entry on page 12 (close to the new one of Asher Peres).

If there's anything you want changed, let me know and I'll consider.

> **Jeff Nicholson:** Whether or not it is acceptable to say so in an academic publication such as this, I'll just record it: Jeff Nicholson was the best beer-drinking buddy I ever had in graduate school or since, and I was proud to be the best man at his wedding. Jeff is currently a research staff member at OFS Laboratories in Somerset, New Jersey and writing papers with titles like, "Continuum Generation Using a Femtosecond Erbium-doped Fiber Laser and a Silica Nonlinear Fiber." We started together as officemates at the University of New Mexico in 1993, and then found ourselves together again at Bell Labs many years later. Jeff is the taller, stronger, and faster of the two of us, with over 170 publications and patents. In the days that were, we had many a good round of philosophy at the ever atmospheric *Jack's Liquor and Lounge* in Albuquerque—red naugahyde seats, and plenty of talk of reality creation. I will well bet that J. W. Nicholson is the only person on earth to have handled a polarization maintaining, dispersion managed, femtosecond figure-eight fiber laser *and* read Richard Rorty.

Jeff's Reply

I love it. ☺

Did I ever actually read Richard Rorty? I can't recall ....

Also, you forgot my Nobel-cited paper of which I am waayyyyy too inordinately proud. ☺

- Brian R. Washburn, Scott A. Diddams, Nathan R. Newbury, Jeffrey W. Nicholson, Man F. Yan, and Carsten G. Jorgensen, "Phase-locked, erbium-fiber-laser-based frequency comb in the near infrared," Optics Letters **29**(3), 250–252 (2004).

12-03-10 *Portland!* (to the QBies)

I came downstairs grumbling about having to go to Portland, thinking, "Why in the hell did I commit myself to going so early in the meeting?" *But then* I Googled "used books Portland" and to my absolute surprise, shock, and pleasure found that the downtown area is chock full of bookstores! And Powell's City of Books (1 million in stock, and the building fills a whole city block!) is just four blocks from my hotel!!

I'm taking an empty duffle along with my suitcase—one would not believe it but there are still many books on the anti-block (universe) that I do not have. I suggest you all do the same!

... Now this trip is worth making.

13-03-10 *Conceptual Barrier!* (to the QBies)

Ever since I first exclaimed to some audience, "SICs are so ________ (beautiful? right? I can't remember the exact phrase) for quantum mechanics that, even if they DO NOT EXIST, they OUGHT TO exist!" ... ever since then, I have been fascinated with what my subconscious was trying to express. And it only got fueled one day when Bob Coecke said, "Yeah, there's some truth to that. It's a game that's worth playing. If you can't prove they exist, you just add them as an axiom." You both have heard my allusions to William James's faith ladder in this context (I reprise the story below), and the power of the SICs as a symbol like the Christian cross.

But today it finally all came together! And no less than in a philosophy of science seminar! I have many times said that I never get much of value from a philosopher of science, but this one was different. It was at Mark Wilson's seminar at UW. His abstract is below, but it gives no great hint of the depth of the talk. It seemed to be based on his book *Wandering Significance: An Essay on Conceptual Behavior*, which I am certainly going to buy.

His main lesson was this: There has never been any stabilized, finished thing called Maxwell's theory of electromagnetism. Instead, the meaning of all the terms in it have been subtly changing since the beginning (and even before). Meanings have been modified for "parts" of the "theory" in light of this and that for other "parts." Moving away from Maxwell's theory he had a nice example in Dedekind cuts. Finally he landed with the lesson of the definition of a Riemannian manifold. It was an analogy that I really took to heart. The point he emphasized was that one uses a structure that is not quite right as the basis for getting the structure one really wants. He had a beautiful picture of a curvy manifold with tangent spaces tacked on everywhere: The manifold is the limiting thing that the collection of tangent spaces is not.

[Next day. I started the note above before Kiki and I went to Jazz at the Bistro last night.]

Lesson: There is nothing wrong in using a structure that is not quite right to build up one that is more satisfactory for this or that purpose. So here is what I mean when I say we will *make* SICs exist: If SICs exist, the Born Rule

$$Q(D_j) \,=\, \mathrm{tr}\,(\,\hat{\rho}\,\hat{D}_j\,)$$

is allowed to take the form of the urgleichung

$$Q(D_j) \,=\, (d+1)\sum_{i=1}^{d^2} P(H_i)P(D_j|H_i) - 1\;.$$

We know that the Born Rule has that privilege in at least 67 dimensions; we know that the quantum-state space has the privilege of being a "maximal consistent set" in at least 67 dimensions. In 67 dimensions, the Born Rule represents the simplest modification one can imagine to the Law of Total Probability for taking into account the counterfactuality of the sky path vs the ground path. If living counterfactuality is the message quantum theory is trying to tell us, it has to find a simple expression somewhere in the theory. In at least 67 dimensions, quantum mechanics is isomorphic to "SIC mechanics," but if SICs don't exist generally within the usual quantum formalism, so much the worse for quantum mechanics: It means that quantum mechanics is not quite right. Close, but not quite right. There was never a commandment written in stone that the stories we tell of quantum phenomena must be written in the language of linear operators.

It is hard for me to express how liberating I found this thought yesterday. We have identified an essentially simple core to quantum mechanics in the urgleichung—and it is this that must be saved at all costs. For physics should be built on the conceptually simple. It is only our habit of thinking in terms of orthogonal bases that makes the SICs look difficult. If God had given us "SIC mechanics" to begin with, we would be finding it similarly difficult to establish "orthonormal bases" for representing the theory, and our nearby colleagues would be wondering why we would even want to. For though we would know that we could do it in dimensions 2 through 67 at least, we would not be able to hide the fact that the expression of these bases always look exceedingly complicated in terms of their original "SICs." It would just be our faith that for every extreme point in the set there should be a measurement for which it gives certainty that drives us forward and makes us slave to find such a structure.

One technical question for everyone to think about: Let us not try to build up a maximal consistent set one point at a time, but d^2 points at a time. That is, let us try to build it up one regular simplex at a time (what in quantum mechanical terms would amount to demanding that every pure state be an element in at least one SIC). Let us build a maximal consistent set by taking a maximal union of simplexes, subject only to the urungleichung. Is there now, modulo rotations, one unique set? If so, then under the assumption of SIC existence, that structure would be isomorphic to quantum state space.[218] And if SICs do not always exist, what physical phenomena would recommend that we not pass from the one theory to the other? Maybe we wouldn't be able to find a reason at all.

James's faith ladder and Wilson's abstract below.

> Faith uses a logic altogether different from Reason's logic. Reason claims certainty and finality for her conclusions. Faith is satisfied if hers seem probable and practically wise.
>
> Faith's form of argument is something like this: Considering a view of the world: "It is *fit* to be true," she feels; "it would be well if it *were* true; it *might* be true; it *may* be true; it *ought* to be true," she says; "it *must* be true," she continues; "it *shall* be true," she concludes, "*for me*; that is, I will treat it as if it *were* true so far as my advocacy and actions are concerned."

[218] We now know that, even if SICs do exist, quantum state space *is not* generally a simple union of regular simplexes. Rather, on the supposition of SIC existence, it is the *convex hull* of a union of regular simplexes. This is because there are quantum states for all $d \geq 4$ which are not expressible as a convex combination of SIC elements for any SIC.

Obviously this is no intellectual chain of inferences, like the *Sorites* of the logic-books. You may call it the "faith-ladder," if you like; but, whatever you call it, it is the sort of slope on which we all habitually live. In no complex matter can our conclusions be more than *probable*. We use our feelings, our good-will, in judging where the greater probability lies; and when our judgment is made, we practically turn our back on the lesser probabilities as if they were not there. Probability, as you know, is mathematically expressed by a fraction. But seldom can we *act* fractionally—half-action is no action (what is the use of only half-killing your enemy?—better not touch him at all); so for purposes of action we equate the most probable view to 1 (or certainty) and other views we treat as naught.

"How 'Wave Front' Found its Truth-Values"
Mark Wilson, Department of Philosophy, University of Pittsburgh

Scientific theories rarely serve as islands entire of themselves. Such hidden connections sometimes force novel readings upon venerable doctrines, dramatically altering our understanding of their basic "subject matter" in the process. Conventional Maxwellian electromagnetism underwent an upheaval of this type in the mid twentieth century. The case (which will be recounted in non-technical terms) offers interesting insights for both philosophy of language and philosophy of science, for it supplies a portrait of semantic stabilization unfolding in a different manner than conventional "natural kind" models suggest.

13-03-10 *All the More Reason* (to R. Schack, D. M. Appleby, Å. Ericsson)

Let me add one more reason for wanting the technical question in the last note to work out. It has to do with the axiom Rüdiger and I called "the availability of certainty" in the QB Coherence paper. I've never really liked it, and the footnote attached to our statement of the axiom explains why:

> In several axiomatic developments of quantum theory—see for instance [Goyal08] and [Hardy01]—the idea of repeated measurements giving rise to certainty (and the associated idea of "distinguishable states") is viewed as fundamental to the whole effort. The usual justification is that the existence of such kinds of measurement is nearly a self-evident necessity. However, from the quantum-Bayesian point of view where *all* measurements are generative of their outcomes—i.e., outcomes never pre-exist the act of measurement—and certainty is always subjective certainty [Caves07], the consistency of adopting a state of certainty as one's state of belief, even in what is judged to be a repeated experiment, is not self-evident at all. In fact, from this point of view, why one ever has certainty is the greater of the mysteries.

Couple that with something I said in the last note:

> If God had given us "SIC mechanics" to begin with, we would be finding it similarly difficult to establish "orthonormal bases" for representing the theory, and our nearby colleagues would be wondering why we would even want to. For though we would know that we could do it in dimensions 2 through 67 at least, we would not be able to hide

> the fact that the expression of these bases always look exceedingly complicated in terms of their original "SIC". It would just be our faith that for every extreme point in the set there should be a measurement for which it gives certainty that drives us forward and makes us slave to find such a structure.

That is, the reason we'd be driven is that we would be working to *establish* the availability of certainty as a *theorem*. And that is indeed the way it should be from a QBist perspective. That any certainty at all could come out of quantum theory *should* be a theorem. If something is the "greater of the mysteries" it really shouldn't have a comfortable spot as one of the very axioms.

So now I really find myself hoping the "union of simplexes" idea carries a lot of power.[219] It would be a very clean foundation for quantum theory.

13-03-10 *The Tetra Pak* (to H. C. von Baeyer and D. M. Appleby)

Yesterday I wrote these lines down:

> Ever since I first exclaimed to some audience, "SICs are so ________ (beautiful? right? I can't remember the exact phrase) for quantum mechanics that, even if they DO NOT EXIST, they OUGHT TO exist!" ... ever since then, I have been fascinated with what my subconscious was trying to express.

Today, it dawned on me that maybe there really is some kind of subconscious tug on me in this regard. As I was sitting on a bench in the shopping mall where Marcus gets his groceries here, I remembered my brother coming home one evening in 1968 or '69, when I was 4 or 5, with a small tetra pak of coffee creamer from a diner or Dairy Queen or something. (Look up `http://en.wikipedia.org/wiki/Tetra_Pak` if you don't know what I mean.) He put it in the refrigerator, but I walked behind him and took it out. I thought it was the most fascinating shape I had ever seen. In fact, it was in the refrigerator for some time, and whenever I would open the door, I would have a look at the little thing. Today was the first time my memory has ever gone back to that.

The Tetra Pak ... Pauli's fascination with the Tetractys ... and the hope that quantum state space is *nothing but* a grand union of simplices (subject only to the restriction of the urungleichung).[220] Today is one of those days when I can't seem to stop myself from thinking about the SICs and the Tetragrammaton in the same thought.

13-03-10 *Comments* (to H. C. von Baeyer)

von Baeyerism 60: *p. 22 footnote 37. Magnalium is showing off. I had no idea what it was, and it certainly doesn't matter. Didn't he use other, more common materials as well, like maybe brass?*

Cool! Just looked through; there is indeed new stuff. Thanks a million, million!

Magnalium isn't showing off—it is what he used, and I had never heard of the stuff either. In the first paper where I make a comparison between dimension and mass, I wrote in the acknowledgements:

---

[219] See Footnote 218 for a technical, but remediable, mistake in the original statement of this.

[220] See Footnote 218 for a technical, but remediable, mistake in the original statement of this.

This paper is dedicated to Alexander Holevo on the occasion of his 60th birthday. I thank Osamu Hirota, Chris King, Masahide Sasaki, and Peter Shor for useful discussions, and especially Greg Comer for keeping me close to gravity. I thank Ken Duffy for teaching me about magnalium.

Hans's Reply

Many years ago I started a column on absolute zero (an impenetrable barrier in physics) this way: "The other day, as I was having morning coffee in my solarium, seventeen yellow waxwings crashed into the window and dropped dead into the flower bed below." This sounded ridiculous, so I changed it to seven, and then to three. That's how it was published.

But, Chris, seventeen was, indeed, the truth. Sometimes, in writing, you have to lowball in order to appeal.

14-03-10 *Sadness and Opportunity* (to G. Bacciagaluppi)

I'm so very sorry, but this time I'm going to have to miss the meeting for sure. It's a shame, I really would like to show my support for you and reach out to the UK audience once again. The meetings in Hull and Belfast were very important for me; they shaped my research life really. But July is just too full a month for me. I have to go to Brisbane for a 19 to 23 meeting, and Vienna for a 27 to 31 meeting. And in June there's the Växjö meeting as well, 13 to 18, of which I'm already committed to speaking.

On another subject, I can't tell you how much I enjoyed your recent article with someone (can't remember the name) on Heisenberg's schnitt argument. It was very thought provoking for me. I wish I had it in front of me while writing you (I'm on my way to Portland to show off my students at the APS March meeting): There was a quote by Heisenberg and I think Born on the meaning of probability surviving the transition from the classical venue to the quantum venue that might have come from my own mouth. Attached is a new essay where I say as much (and hopefully a lot more), that I plan to post Wednesday (before Thursday's talk in Portland). Time is short, but if you have any feedback I may be able to take it into account. At the very least—come to think of it—I may be able to cite your new article at some appropriate spot.

14-03-10 *Beginnings of Subconscious* (to the QBies)

Ev'rybody's talkin' 'bout
Bagism, Shagism, Dragism, Madism, Ragism, Tagism
This-ism, that-ism, ism ism QBism
All we are saying is give peace a chance ...

Sing it with me boys! Over the weekend, I've gotten quite taken with the technical question below. [See 13-03-10 note titled "Conceptual Barrier!"] Now a question for you guys to contemplate. Do you think there's any way we might check it numerically for $d = 3$? Or check any aspect of it? Could quantum state space be built up one simplex at a time?

See you in Portland.

14-03-10 *Shunning Certainty and Recovering It* (to L. Hardy)

I thought you might enjoy the notes below that I launched off yesterday to the guys in the crew. [See the 13-03-10 notes to the QBies titled "Conceptual Barrier!" and "All the More Reason."] I think they capture another distinction of direction where the path I'm following seems to take me away from your original axiomatic scheme. Ultimately I'd like to get away from taking the notion of distinguishable states as a primitive for the theory, and rederive that there are some as a consequence of other structures. Below starts to flesh out how that might go, and why I would want to go that way.

It seems to me a rather pretty fact that quantum-state space in SIC representation is exactly a union of regular simplexes.[221] And a maximal union as well, the addition of even one more point would make my urungleichung violated. Only recently has it struck me however that that might be a significant postulate in itself.

16-03-10 *Landed in Portland* (to M. Schlosshauer)

You flatter me through and through. And you make it hard for me to function in the REAL world, where no one likes the sound of anything I say. It's much easier to read Max's notes over and over and then take a nice nap.

Anyway, thank you, thank you so much for your feedback. And then thank Eli and Kari for me, for letting you go for a while to spend some time reading and composing notes. I fully realize that this is a very busy time of your life.

[I wrote the lines above Sunday evening; it is now Tuesday morning.]

But OK, beyond all the nicety, you pushed me: I couldn't stop myself without an effort to do your requests all the way through. Come to think of it, it was the opposite of reading your note and then taking a nice nap! You are subtle—a man who will go places. Let me rush this off to you so that it gets to you before you are asleep. I really want to post the thing tonight or tomorrow morning come hell or high water. Aside from making a couple cross references, and placing the figures more properly it should be done! See footnote 22 on page 13.

On another occasion (soon) we'll talk more about *measuring* dimension. As for the paper, I'll just leave it with the one reference to Scarani for the time being.

More later.

16-03-10 *Progress Report* (to Å. Ericsson)

Six books so far, but the two most notable are:

1) A picture book of alchemical symbols,

2) A book with a serious Jamesian style argument for human immortality

So far, I've only gotten through the first third (plus epsilon) of Powell's philosophy section. Following that I've got about four other bookstores to go to in town!

Haven't seen Hoan, Gelo, and Matthew yet. I'm staying at about the fanciest hotel I've ever stayed at (paid for by the APS)—beautiful lobby I'm writing you from, rich wood everywhere. The other guys on the other hand are probably staying at a dump. It makes me feel guilty.

[221] See Footnote 218 for a technical, but remediable, mistake in the original statement of this.

Not one note from anyone on my weekend epiphany—I thought I had made a great conceptual leap. It has kind of disappointed me. But still I have plodded on thinking about unions of regular simplices.

16-03-10 *Sadness and Opportunity, 2* (to G. Bacciagaluppi)

Bacciagaluppism 3: *Thanks for the appreciation of the Heisenberg article (my co-author is Elise Crull, currently finishing her PhD with Don Howard at Notre Dame). Is the quote the one about the 'quite usual probabilities'? It is actually not clear to me what picture of probabilities Born and Heisenberg have in mind (if they have a single one in mind!), and I suspect it is something like a propensity view (so I am actually wondering whether a quote would be out of context!).*

The issue is not Bayesian vs. Frequentist probability (Heisenberg and Born, at least in that quote, seem to be treating probability frequentistically, not propensitistically), but that whatever notion is chosen is stable under the transition from classical to quantum. Certainly not everyone believes that—they (and Feynman) did. Both emphasize a rule change for *calculating* probabilities when comparing a "factual" to a "counterfactual" (though they didn't say it that way). They both emphasized that the *notion* of probability itself does not change. What I particularly enjoyed about Born and Heisenberg is that they say explicitly this entails no break from the usual probability calculus: The quantum mechanical rule is rather an addition to it!

Attached is a modified draft where I reference you. See footnote 19 on page 12. Please share with Elise if you wish.

The final version of the paper should be posted Wednesday.

17-03-10 *We Are the Small Axe . . .* (to M. Schlosshauer)

I didn't get back to you today as I had hoped, and now I'm a bit drunk from the TGQI "executive" dinner (as if I could be the executive of anything). Blame John Preskill (even though he doesn't drink, funny all the causal connections). So I'll keep it short. It's no payment for all the help you've given me, but I thought I'd make you an "honorary" member of the group by spewing to you like I spew to all the rest of them. (I'm listening to Bob Marley as I write you this; do you know the song in the title? I am no executive, but I might be a small axe.) Below are two notes capturing a good experience I had at the end of last week. [See the 13-03-10 notes to the QBies titled "Conceptual Barrier!" and "All the More Reason."] I don't seriously believe that QM doesn't always contain the SICs, but even if it *does* contain them properly, I now understand that the urgleichung is truly the more basic structure: QM, at best, is secondary. Either way, the equations already tell us that we must *make* these damned SICs exist. I hope you enjoy James's faith ladder; I suspect that you more than anyone else in the group will feel it intuitively.

Just sharing with you, and trying to thank you in the deepest way I can for the ends you've pushed me to. The paper is way better because of you. I will finally post it tomorrow morning! It will be so good to get it off my chest.

I hope all is well with you and Kari and Eli.

17-03-10 *Bob Marley Words* (to Å. Ericsson)

Just heard a lovely phrase in a Bob Marley song, "mighty God is a living man." (I've known it for a long time, but hearing it again brought it to mind.) Anyway, isn't that what I've been saying myself?

I'll give you a better report tomorrow, but it looks like 17 books so far. More tomorrow!

18-03-10 *Very Final Version* (to R. W. Spekkens)

Here is the very final version of the paper, the one that'll be posted Friday. I looked at footnote 37 on Wootters' kid:

> That is, every piece of the universe had better be hard-wired for the contingency that an agent might experience it somewhere, somehow, no matter how long and drawn out the ultimate chain might be to such a potential experience. Does this mean even "elementary" physical events just after the Big Bang must make use of *concepts* that, to the reductionist mind, ought to be 15 billion years removed down the evolutionary chain? You bet it does. But a nonreductionist metaphysic need make no apology for this—such things are in the very idea. John Wheeler's great smoky dragon comes into the world biting its own tail.
>
> W. K. Wootters tells a lovely story of an encounter he had several years ago of with his young son Nate. Nate said, "I wish I could make this flower move with my mind." Wootters reached out and pushed the flower, saying, "You can. You do it like this." From the perspective here, this is an example of an interaction between two nonreductionist realms. Each realm influences the other as its turn comes. There is a kind of reciprocality in this, an action-reaction principle, that most reductionist visions of the world would find obscene.

One aspect of what it says is the very idea you were trying to defend against Tumulka: That "no operational distinction" should correspond to "no ontic distinction." Tumulka would say, "What business does ontology have in knowing what you, a high level agent, can or cannot distinguish?" "Ontology was written down before agents were ever thought of; their limitations are of no consequence for ontology." I imagine him saying. "You have the conceptual flow going the wrong way."

There is a bit of William James in you yet.

18-03-10 *We Are the Small Axe ..., 2* (to R. W. Spekkens)

Here are some of the other things I was telling you tonight, about how I should have answered Lee. [See 13-03-10 note "Conceptual Barrier!" to the QBies.]

Hierarchies of theories are all well and good, but when it comes time to modify quantum mechanics, I suspect it's going to be something much more subtle than just jumping to the next level in one's premade class. One of the things that struck me when I came across the thought below is that I actually found it believable—for the first time I felt the tug of why one would even think of modifying QM. Though as I wrote Max:

> I don't seriously believe that QM doesn't always contain the SICs, but even if it *does* contain them properly, I now understand that the urgleichung is truly the more basic structure: QM, at best, is secondary. Either way, the equations already tell us that we must **make** these damned SICs exist.

19-03-10 *Dimension Witnesses* (to V. Scarani)

Thanks. I was just about to post the thing today, but then was thwarted by some upgrade they've made to their system. Now, with my travels, it probably won't be until next week that I'll be able to figure the new `arXiv` system out. So I attach for you the near-posted version. [See "QBism, the Perimeter of Quantum Bayesianism," `arXiv:1003.5209v1`.] The language near the end of the paper is very close to some things I note in Nicolas Gisin lately (quantum events as moments of creation, etc.), but I suspect he would never accept of any of my starting points or the reasoning that led me to these similar conclusions.

I enjoyed meeting you in Japan, and hope to see you again in the decent future.

Valerio's Preply

Here are a few articles beyond ours on dimension witnesses:

- `http://arxiv.org/abs/0812.1572` (where it is proved that even with binary outcomes you can have dimension witnesses for any d, just by changing the number of measurement settings);
- `http://arxiv.org/abs/0901.2542` (relating dimension witnesses to evolution)

19-03-10 `arXiv` *New submission* → *1003.3223 in* `physics.hist-ph` *from* `jgus@tds.net` (to J. R. Gustafson)

That's great news! Attached is something I'm just on the verge of posting myself. (I tried to post it today, but they thwarted me with a new system that's incompatible with my old version of LaTeX! So, now I'm the beginner again!)

John's Reply

I am enjoying your new "bigqbism" article that you sent to me, making me think of some Pauli quotes I had inserted into my dissertation . . . roughly pages 137 and 138 of the PDF file that is now posted to arXiv (excerpt appears below). Pauli's remarks imply to me he may have been thinking of issues we now relate to quantum entanglement. Now I'm motivated to dig further into his later writings. Here's that excerpt.

> In any case, Pauli saw in the concept of synchronicity a direct link to Arthur Schopenhauer's philosophy, which he made clear in a letter to Jung of June 28, 1949:
>
> > The idea of *meaningful coincidence*–i.e., simultaneous events not causally connected–was expressed very clearly by Schopenhauer (1788 – 1860) in his essay . . . . There he postulates an "ultimate union of necessity and chance," which appears to us as a "force," "which links together all things, even those that are causally unconnected, and does it in such a way that they come together just at the right moment."

To my knowledge, Pauli never connected his exclusion principle to sychronicity. He did talk about his exclusion principle and "action-at-a-distance," however, in a course on *Wellenmechanik* at the Federal Institute of Technology (ETH) in Zurich in 1956-1957, according to notes taken by his students:

> From a superficial consideration of the exclusion principle, it might be thought that a sort of action-at-a-distance is being postulated, as a result of which even two widely separated particles are aware of one another ("sign a contract"). However, this is not so, because the exclusion principle is valid only as long as the wave packets of the two particles overlap.

Still, Pauli later called for a unification of physics and psychology, which would have entailed both his exclusion principle and the concept of synchronicity.

19-03-10 *Lunchtime Guilt* (to R. W. Spekkens)

You won't get this note until I can drop it off at the airport, but I compose it at the famous Rocco's, caddy-corner to Powell's. I just want to say I've been walking around the city feeling ashamed and guilty since my outburst the morning. Ostensibly, it was initially meant to be a kind of biting joke ... until I could see the hurt on your face. But the more I've examined the moment in my meanderings through the streets, the more I've become convinced that its real source was a rather deep bitterness in me. Looking back on it, I think I can even identify that I had an image of Travis Norsen in my mind as I lashed out at you. I could be fooling myself, but it feels very palpable at the moment. The sad fact is, like Pavlov's dogs, I carry associations in my mind, and the association you inadvertently provoked my reaction to was between those who give up on Einstein locality and those who call me solipsist. The latter has indeed been a thorn in my side for many years. But you—of all people!—in no way deserved that reaction from me. Even though we at times disagree about the future direction of physics, I *do* recognize that you think harder and more deeply about quantum mechanics than anyone else I know. And I don't say that lightly; I mean it. So, I hope you will accept my apology. It's useful for me to recognize my demons, but there is no reason for my friends to be the targets of my primal screams.

I got quite a lot out of our dinnertime conservation the other night. Some stuff of lasting thought. I want to continue that from time to time without your fearing that I'll crack.

Please don't forget to send me your spellcraft talk. Emma will be thrilled to see it.

19-03-10 *Counterexample, 2* (to J. Emerson)

Sorry it's taken me so long to get back to you. I've been in Portland all week and this meeting has dulled all my senses. (Though I am presently writing you from a nice Argentinean restaurant.) To give a short reply, let me just say we should discuss this paper by Oreshkov and Brun in the context of your framework: `http://arxiv.org/abs/quant-ph/0503017`. I think it gives a formal account of what I was claiming about Aephraim's SIC-POVM technique. Particularly, it shows a way of trading off continuous interaction for ancilla.

My general philosophical beef is this. If one must recognize measurement as a "primitive" in the QM framework, then I see no reason to prefer one kind of primitive (PVM) over another kind of primitive (POVM). One can think of the PVMs as a subset of the POVMs, or one can think of the POVMs as a subset of the set of all possible two stage thingies (unitary coupling to ancilla plus PVM). Since POVMs are formally powerful, that tips the scale for me. Furthermore for a given POVM there is no unique Naimark-extension way of thinking of it: The POVM corresponds to an equivalence class. And where there is such "gauge freedom" I say, one has the wrong object—one should mod out the freedom, and find the mathematical object that remains.

In any case, in my truest philosophy, a POVM is *nothing other than* a collection of conditional probability distributions. See footnote 22 on page 13 of this (still unposted!) paper attached. [See `http://arxiv.org/abs/1003.5209`.] If one takes that point of view, the unitary + ancilla + PVM take on POVMs is rather unnatural way of thinking. That's my truest philosophy, independent of the Oreshkov-Brun stuff. I just threw it out by way of ammunition (on the suspicion that you won't find my identification of a POVM with a set of $P(D_j|H_i)$ as compelling as I do).

I'm getting primed for those beers you offered.

22-03-10 *Pong* (to R. Schack)

Sorry, the March Meeting turned out to be more taxing than I had imagined. I'm back home now and getting back on track. Today I plan to get my email box thoroughly cleaned out and get to work on two things: 1) Templeton proposal, and 2) Research statement for PI. I have no intention of letting Templeton slip through my fingers.

Quick answers to some old items:

Schackcosm 125: *Did we ever make progress on communication?*

No we didn't, or at least no great amount. And I don't think much of what we did talk about is in the correspondence. I am now much happier with my presentation of Wigner's friend. But it leaves communication out other than to speak of it as another quantum measurement. This leaves much, much to be desired. There is no doubt we have to come back to this.

Schackcosm 126: *I feel strongly that Wigner's friend, communication, counterfactuals and reflection should be coming together in one coherent story . . .*

Yes, I couldn't agree more. In most ways, we're just at the beginning of this project.

Schackcosm 127: *You still haven't given me any feedback at all on the reflection draft paper. It would help me enormously to discuss it with you.*

I understand this. I know so much that I must get on it and help you out. I did read the full draft in Portland, and I must get that conveyed to you. But my guess is, with honesty, we're going to have to knock Templeton out of the way first.

Schackcosm 128: *I have been reading, pondering, and rereading your two notes. There is lots in there which I like a lot. Most of all I like the idea of coming up with a theory that is different from quantum mechanics. I am not sure the urgleichung is sufficiently compelling to warrant such a departure, but there are other reasons to want it. . . . If the new theory derived in a world in which SICs exist only as approximations, or only in small dimensions, had features that make a block universe look unnatural, this would be marvelous.*

My guess is that a departure will not be required—my guess is that SICs actually DO exist always. That aside, what I was hoping to express is that my mind is now prepared for what should be done on the off chance that they do not. In my bones, I do feel the urgleichung is sufficiently compelling, but there is no doubt that must be articulated further: For what we already have, in a way that has never been seen before (certainly not from Gleason's theorem, or the raw injunction of a linear rule as in Hardy or Barnum, Barrett and Wilce, etc.), shows that the Born Rule *is* a rule connecting probabilities to probabilities—between counterfactual and factual. It is the "engaged observer" in crystal clear form, and one that pulls the essential factor to the very front of the equation. We need a more metaphysical story to shore it up with, but that's why the equation already feels completely right to me as the foundation of things.

Schackcosm 129: *A more important one is that some aspects of quantum mechanics make it very hard not to be driven to a many-worlds view. The church of the larger Hilbert space can be regarded as simply a mathematical convenience, but any defender of Everett can claim that it is extremely suggestive.*

You should watch this talk or read the associated `arXiv` paper: `http://pirsa.org/10020070/`. It is a bit frightening how much power "purification" can have as an axiom. (As I write this, it starts to strike me that there might possibly be a connection between it and our "posteriors equal priors" postulate. Very slippery thought, but something we might think about.)

Schackcosm 130: *That is my vision at the moment. To come up with a theory that makes the agent dependence explicit in a far stronger way than quantum mechanics does it. To derive quantum mechanics from the requirement that the theory rules out a block universe.*

I am certainly very sympathetic to deriving the existence of certainty in some way. Maybe even finding that certainty only exists in the approximate theory called quantum mechanics.

And I derive a small amount of satisfaction from the fact that you have finally come round to my way of phrasing maximality and abandoned building up maximal consistent sets point by point.

This is important! I had not realized you proposed this. Clearly my memory is not infallible. What was the context of your earlier proposal? What were the sorts of things we were thinking about at the time?

Schackcosm 131: *Are you somewhere out there? Do you want to give me a ring? What time zone are you in?*

If it's OK with you, let me try to stay away from the phone for a couple of days. I'm working from my study in the house today, and trying to avoid contact with other humans (even the best of the other humans). My social spring got stretched beyond its elastic limit at the March meeting.

22-03-10 *A Line I Shall Use in Templeton* (to R. Schack)

Below is a note I had gotten from one of the students, Ian Hincks, in the Emerson-Laflamme quantum foundations class after my first lecture. His last two sentences are a lovely testimonial to what you and I are up to:

> "I like your theory because it returns to me as much freedom as I feel that I have. Such freedom is lost or partially lost in other interpretations."

I'm going to try to find some way to use this as a testimonial in our Templeton proposal.

22-03-10 *Haeccity Through and Through* (to G. Smith)

Wiki says this of it:

> **Haecceity** (from the Latin *haecceitas*, which translates as "thisness") is a term from medieval philosophy first coined by Duns Scotus which denotes the discrete qualities, properties or characteristics of a thing which make it a particular thing. Haecceity is a person or object's "*thisness*".

Thisness would be easier to say. Anyway, it imbues my philosophy of things through and through, and looking back on it, maybe that's why I liked John's lockboxes. Attached is the new paper that I've had trouble posting with the new `arXiv.org` system. [See "QBism, the Perimeter of Quantum Bayesianism," `arXiv:1003.5209v1`.] The haeccity business becomes quite apparent in Section VI. You might enjoy the big eyeball as well.

24-03-10 *Your Discussion with Tumulka* (to R. W. Spekkens)

Coming back to the point I wrote you about earlier, about why the psi-ontologists generally do not find your notion of noncontextuality so compelling (as you reported of Tumulka). Previous note pasted below. [See 18-03-10 note "Very Final Version" to R. W. Spekkens.] I was just cutting and pasting the footnote mentioned there for something else and discovered that I had originally started to write a follow-on footnote as well, but apparently decided not to use it in the paper. Since it's relevant, let me at least use it in this note:

> It is perhaps worthwhile contrasting this to the "hidden-variable vision" of the quantum world, say of the Bohmian pilot-wave theory mentioned previously. The implication of a hidden variable is that it is not directly experienceable, and to the extent that it does ultimately trickle into experience, it is only so that it props up the quantum mechanical equations.

24-03-10 *Notes on the Open Future* (to L. Smolin)

I had a chance to read your draft on "The Philosophy of the Open Future" again. Attached are some notes on it.

Notes on Lee Smolin's 15 February 2010 draft of
The Philosophy of the Open Future

With the APS March Meeting behind me, I've gotten a chance to reread your draft on the philosophy of the open future. It's got some big ideas in it, and I like it very much for the message it's starting to formulate.

I've got nothing very deep to say in response at the moment, but I'll react to a few points in your draft.

First a very general thing. Of the philosophers I have read, the thoughts in your essay sound to me the most like John Dewey's. I say this not to mean that "it's all been said before," but that you two might make good conversation partners. Particularly, you might find some congenial inspiration in his writings. With regard to the subject matter of your essay, I think his sweep and interests are similar to your own. Dewey's thoughts, of course, will not be informed by today's physics or today's economical issues, but he has nonetheless a well-developed system that might be a good backdrop for your thinking. Picking a nearly random book off my shelf (*Dewey's Logical Theory: New Studies and Interpretations*, edited by Burke *et al.*), I find this key point about what Dewey was thinking:

> Dewey begins from a Darwinian premise of interaction. On this view, experience is "an affair of the intercourse of a living being with its physical and social environment" and thus an affair "primarily of doing." Experience then is not a receiving and filtering sensory data from an external world. It is rather an *exchange*, a *transaction*, between an organism and the physical and social factors within its environment: "When we experience something, we act upon it, we do something with it; then we suffer or undergo the consequences. We do something to the thing and then it does something to us in return."
>
> Dewey's placement of experience in the interactions and transactions between an organism and its environment is further augmented with the recognition of a stabilization propensity characteristic of living beings. Experience is episodic, punctuated by occasions of disturbance and resolution, of imbalance and regained composure. Thus experience is not only transformational. It also has force and direction, impelled by an innate drive of the living being to maintain its own *well*-being. In short, experience is an activity in and by which an organism maintains integration with its environment.

And here's another way the point was made in an article on Sidney Hook's intellectual debt to John Dewey:

> In Dewey's naturalistic metaphysics, a contextual and empirical account of the origin and function of human knowledge recognized man's quest for adaptation to and control of his environment. This emphasis upon human adaptation and control characterized the recognition within pragmatic philosophy of its debt to Darwinism in the development of its theory of mind's place in nature and of the nature of human knowledge.
>
> The thesis that human beings were capable of transforming the natural environment and the seemingly "given" facts of nature was a feature of Deweyan naturalistic metaphysics that was relevant for the pragmatic theory of knowledge. Hook followed Dewey in stressing the connection between a naturalistic metaphysics and the identification of human knowledge as an instrument in transforming the real nature of Nature. Significantly, this feature of naturalistic metaphysics heightened the pragmatic emphasis upon the capacity of human agency to function as an activist transformer of the natural environment. To a significant degree, what was natural, whether in the sphere of the universe or the sphere of human affairs, could be considered in the idiom of pragmatism not so much as a "given," but as a possibility for a "taken." The theme of human transformation of the natural environment carried Hook from the initial interest in the metaphysics of pragmatism to the possibilities of pragmatism as a philosophy which could apply scientific method for social change.

When I read your sentences,

Lee Smolinism 4 : *The problem requires not a choice between nature and technology but a reorientation of their relationship to each other.*

Lee Smolinism 5 : *As long as we have the capability to do it, we must prevent or moderate major changes in the climate, for the same reason we must look out for and destroy asteroids that might* *collide with earth. Once we have resolved this emergency we will be committed to a continuing regulation of the climate to keep it in a range where human beings can thrive. This means melding our technologies with the natural cycles and systems that already regulate the climate.*

Lee Smolinism 6 : *The economy and the climate will not be two things, they will be aspects of a single system. Thus, to survive the climate crisis we have to conceive of and bring into existence a novel kind of system, which will be a symbiosis of the biological processes which determine the climate with our technological civilization.*

I hear an echo of the Dewey above. For, like you, Dewey saw these transactions with nature occurring at all scales, from simple organisms to large societies, nations, and economies. It is particularly the last quote of you that I was thinking of when I said that your essay contains some big ideas—the economy and the climate as two aspects of a single thing. I liked your way of phrasing the issue.

Dewey called his philosophy "instrumentalism," but by that he meant something *not at all like* what most modern philosophers of science (Harvey Brown, Richard Healey, Jeff Bub, and the like) mean when they say instrumentalism. The common, modern definition goes something like this: "instrumentalism is the view that a concept or theory should be evaluated by how effectively it explains and predicts phenomena, as opposed to how accurately it describes objective reality" (wiki), or "instrumentalism can be formulated as the thesis that scientific theories—the theories of the so-called 'pure' sciences—are nothing but computational rules (or inference rules)" (Popper). For Dewey, a scientific theory is a good instrument to the extent that it can be used to mold the world to our needs—some of that might be about prediction, but much of it is not. It is all about the actions we can reasonably take upon the world in our present stage of development. Here is the way William James put it, but this strain is certainly in Dewey too:

> [I]f you follow the pragmatic method, you cannot look on any such word as closing your quest. You must bring out of each word its practical cash-value, set it at work within the stream of your experience. It appears less as a solution, then, than as a program for more work, and more particularly as an indication of the ways in which existing realities may be *changed*.
>
> *Theories thus become instruments, not answers to enigmas, in which we can rest.* We don't lie back upon them, we move forward, and, on occasion, make nature over again by their aid.

The purpose of a good theory is not to draw an accurate image of a pre-existent static world, but to be like a hammer, saw, or screwdriver: It is a thought structure that helps us to participate in the inevitable flow and change of the world as best we can. And as we evolve/devolve/change such laws evolve/devolve/change as well (and reciprocally so).

Certainly I believe this of quantum mechanics—that it is a hammer we use in light of the world possessing a certain active, life-breathing power—for I think this is much of its very message. (I probably believe the hammer metaphor of other theories as well, like classical mechanics and general relativity, but there it is not so "in your face" as it is with quantum mechanics.) Maybe it's worthwhile putting it like this. In your essay and my own, one common theme comes out: Human agency matters. "We can on occasion make nature over." Though I myself like to emphasize that agency matters from everything so large as the ecosystem and climate, to everything so small as a quantum measurement.

If you would like to borrow my copy Dewey's *Reconstruction in Philosophy* (a good introduction to his thought), or most anything else for that matter that he's written, let me know.

Now on to more specific matters.

Lee Smolinism 7: *This hierarchy applies also to the natural/artificial divide, in that the natural is valued over the artificial because it is closer to absolute perfection, and therefor closer to timelessness.*

Typo.

Lee Smolinism 8: *But if the search for knowledge is essentially the task of remembering truths which have been ever-present, then the possible solutions to any problem already exist in fixed menus of possibility, and novelty is an illusion. A world without time is a world with fixed categories and fixed possibilities that cannot be transcended.*

I like that phrase "fixed menus of possibility" and can see myself using it. Is the phrase your invention? Or Unger's or Kauffman's or still someone else's?

Lee Smolinism 9: *To fully realize the conception of a time bound world, we need to invent a notion of truth which removes the equation of truth with timelessness and replaces it with a notion of truth that is no less objective, but which has room for surprise, invention and novelty.*

Somewhere—and I have not been able to pinpoint where this morning—William James makes the point that the pragmatic theory of truth he was involved in developing was only a secondary aim for him. It might be written somewhere in *The Meaning of Truth* or *Essays in Radical Empiricism*. Instead James's main aim was something very much like what you say here: One needs more looseness than a correspondence theory of truth allows if one is going to have a malleable, creative world. Truth has to have a different meaning in a world that is "ever not quite." If I can dig up a reference, I'll send it to you.

[Time elapsed.] Aha, I found it! It's in the conjunction of two prefaces—that for *The Will to Believe* and that for *The Meaning of Truth*. Let me quote the relevant pieces:

> Were I obliged to give a short name to the attitude in question, I should call it that of *radical empiricism*, in spite of the fact that such brief nicknames are nowhere more misleading than in philosophy. I say 'empiricism,' because it is contented to regard its most assured conclusions concerning matters of fact as hypotheses liable to modification in the course of future experience; and I say 'radical,' because it treats the doctrine of monism itself as an hypothesis, and, unlike so much of the half-way empiricism that is current under the name of positivism or agnosticism or scientific naturalism, it does not dogmatically affirm monism as something with which all experience has got to square. The difference between monism and pluralism is perhaps the most pregnant of all the differences in philosophy. *Primâ facie* the world is a pluralism; as we find it, its unity seems to be that of any collection; and our higher thinking consists chiefly of an effort to redeem it from that first crude form. Postulating more unity than the first experiences yield, we also discover more. But absolute unity, in spite of brilliant dashes in its direction, still remains undiscovered, still remains a *Grenzbegriff*. "Ever not quite" must be the rationalistic philosopher's last confession concerning it. After all that reason can do has been done, there still remains the opacity of the finite facts as merely given, with most of their peculiarities mutually unmediated and unexplained. To the very last, there are the various 'points of view' which the philosopher must distinguish in discussing the world; and what is inwardly clear from one point remains a bare externality and datum to the other. The negative, the alogical, is never wholly banished. Something—"call it fate, chance, freedom, spontaneity, the devil, what you

> will"—is still wrong and other and outside and unincluded, from *your* point of view, even though you be the greatest of philosophers. Something is always mere fact and *givenness*; and there may be in the whole universe no one point of view extant from which this would not be found to be the case. "Reason," as a gifted writer says, "is but one item in the mystery; and behind the proudest consciousness that ever reigned, reason and wonder blushed face to face. The inevitable stales, while doubt and hope are sisters. Not unfortunately the universe is wild,—game-flavored as a hawk's wing. Nature is miracle all; the same returns not save to bring the different. The slow round of the engraver's lathe gains but the breadth of a hair, but the difference is distributed back over the whole curve, never an instant true,—ever not quite."
>
> This is pluralism, somewhat rhapsodically expressed. He who takes for his hypothesis the notion that it is the permanent form of the world is what I call a radical empiricist. For him the crudity of experience remains an eternal element thereof. There is no possible point of view from which the world can appear an absolutely single fact. Real possibilities, real indeterminations, real beginnings, real ends, real evil, real crises, catastrophes, and escapes, a real God, and a real moral life, just as common-sense conceives these things, may remain in empiricism as conceptions which that philosophy gives up the attempt either to 'overcome' or to reinterpret in monistic form.

And

> Most of the pragmatist and anti-pragmatist warfare is over what the word "truth" shall be held to signify, and not over any of the facts embodied in truth-situations; for both pragmatists and anti-pragmatists believe in existent objects, just as they believe in our ideas of them. The difference is that when pragmatists speak of truth, they mean exclusively something about the ideas, namely their workableness; whereas when anti-pragmatists speak of truth they seem most often to mean something about the objects. Since the pragmatist, if he agrees that an idea is "really" true, also agrees to whatever it says about its object; and since most anti-pragmatists have already come round to agreeing that, if the object exists, the idea that it does so is workable; there would seem to be so little left to fight about that I might well be asked why instead of reprinting my share in so much verbal wrangling, I do not show my sense of "values" by burning it all up.
>
> I understand the question and I will give my answer. I am interested in another doctrine in philosophy to which I give the name of radical empiricism, and it seems to me that the establishment of the pragmatist theory of truth is a step of first-rate importance in making radical empiricism prevail.

Lee Smolinism 10 : *A new philosophy is needed which anticipates the merging of the natural and the artificial by achieving a consilience of the natural and social sciences, in which human agency has a rightful place in nature. This is not a relativism in which anything we want to be true can be. To survive the challenge of climate change it matters a great deal what is true.*

And here I have to say you led my thoughts back to F. C. S. Schiller's paper, "Axioms as Postulates." It is just a wonderful paper. Schiller emphasized that *methodologically* it is important to start by supposing the world to be plastic and malleable to the fullest extent imaginable (i.e., that we *can* have anything we want), and only in exhaustion—when the world does not yield it after our impassioned tries—to accept otherwise.

Let me quote him at length; I think you'll find it fun:

[M]y fourth and most important point is that the world is *plastic*, and may be moulded by our wishes, if only we are determined to give effect to them, and not too conceited to learn from experience, *i.e.* by trying, *by what means* we may do so.

That this plasticity exists will hardly be denied, but doubts may be raised as to how far it extends. Surely, it may be objected, it is mere sarcasm to talk of the plasticity of the world; in point of fact we can never go far in any direction without coming upon rigid limits and insuperable obstacles. The answer surely is that the extent of the world's plasticity is not known *a priori*, but must be found out by trying. Now in trying we can never start with a recognition of rigid limits and insuperable obstacles. For if we believed them such, it would be *no use* trying. Hence we must assume that we can obtain what we want, if only we try skilfully and perseveringly enough. A failure only proves that the obstacles would not yield to the method employed: it cannot extinguish the hope that by *trying again* by other methods they could finally be overcome.

Thus it is a *methodological necessity* to assume that the world is *wholly plastic*, *i.e.* to *act as though* we believed this, and will yield us what we want, if we persevere in wanting it.

To what extent our assumption is true in the fullest sense, *i.e.* to what extent it will work in practice, time and trial will show. But our faith is confirmed whenever, by acting on it, we obtain anything we want; it is checked, but not uprooted, whenever an experiment fails.

As a first attempt to explain how our struggle to mould our experience into conformity with our desires is compatible with the 'objectivity' of that experience, the above may perhaps suffice, though I do not flatter myself that it will at once implant conviction. Indeed I expect rather to be asked indignantly—'Is there not an objective nature which our experiments do not make, but only discover? Is it not absurd to talk as if our attempts could alter the facts? And is not reverent submission to this pre-existing order the proper attitude of the searcher after truth?'

The objection is so obvious that the folly of ignoring it could only be exceeded by that of exaggerating its importance. It is because of the gross way in which this is commonly done that I have thought it salutary to emphasise the opposite aspect of the truth. We have heard enough, and more than enough, about the duty of humility and submission; it is time that we were told that energy and enterprise also are indispensable, and that as soon as the submission advocated is taken to mean more than rational methods of investigation, it becomes a hindrance to the growth of knowledge. Hence it is no longer important to rehearse the old platitudes about sitting at the feet of nature and servilely accepting the kicks she finds it so much cheaper to bestow than halfpence. It is far more important to emphasise the other side of the matter, viz. that unless we ask, we get nothing. We must ask often and importunately, and be slow to take a refusal. It is only by asking that we discover whether or not an answer is attainable, and if they cannot alter the 'facts,' our demands can at least make them appear in so different a light, that they are no longer *practically* the same.

For in truth these independent 'facts,' which we have merely to acknowledge, are a mere figure of speech. The growth of experience is continually transfiguring our 'facts' for us, and it is only by an *ex post facto* fiction that we declare them to have been 'all along' what they have *come to mean for us*. To the vision of the rudimentary eye the world is *not* coloured; it becomes so only to the eye which has developed colour 'sensitiveness': just so the 'fact' of each phase of experience is relative to our knowledge, and that knowledge depends on our efforts and desires to know. Or, if we cling to the

> notion of an absolutely objective fact of which the imperfect stages of knowledge only catch distorted glimpses, we must at least admit that only a final and perfect rounding-off of knowledge would be adequate to the cognition of such fact. The facts therefore which *we* as yet encounter are not of this character: it may turn out that they are not what they seem and can be transfigured if we try. Hence the antithesis of subjective and objective is a false one: in the process of experience 'subject' and 'object' are only the poles, and the 'subject' is the 'positive' pole from which proceeds the impetus to the growth of knowledge. For the modifications in the world, which we desire, can only be brought about by our assuming them to be possible, and *therefore* trying to effect them.

Lee Smolinism 11 : *What is needed is instead a relationalism, according to which the future is restricted by, but not determined from the present, so that genuine novelty and invention, while rare, are real and possible.*

Why relationalism? I don't see a connection between (what I know of) that word and much of the rest of your essay.

Lee Smolinism 12 : *The notion that truth is eternal and lies outside of the world we experience is not only a religious idea. It is in science as well, as is exemplified by the Platonic view of mathematics.*

You remind me here of a point that Richard Rorty once made forcefully. Unfortunately, I seem to have lost my copy and I haven't been able to get hold of the full paper online (titled "Pragmatism as Anti-authoritarianism"). But here is a part of the abstract for your enjoyment:

> There is a useful analogy to be drawn between the pragmatists' criticism of the idea that truth is a matter of correspondence to the intrinsic nature of reality and the Enlightenment's criticism of the idea that morality is a matter of correspondence to the will of a Divine Being. The pragmatists' anti-representationalist account of belief is, among other things, a protest against the idea that human beings must humble themselves before something non-human, whether the Will of God or the Intrinsic Nature of Reality. Seeing anti-representationalism as a version of anti-authoritarianism permits one to appreciate an analogy which was central to John Dewey's thought: the analogy between ceasing to believe in Sin and ceasing to accept the distinction between Reality and Appearance.

Lee Smolinism 13 : *This view is not popular among philosophers due to a powerful and commonsense objection to it, which is that to the extent that mathematical objects live in a separate realm outside of time and space, there is no way for human beings to gain access to or knowledge about them.*

Typo? "gain access to or have knowledge" maybe?

Lee Smolinism 14 : *This was the view of Einstein and many 20th Century philosophers (although, one of them. the logical positivist Carnap, recounts conversations in which Einstein regretted the loss of a place for the present moment).*

Typo: period after them. Also, it is not completely clear that the word "regretted" should be used here. Here's the Carnap quote,

> Einstein said that the problem of the Now worried him seriously. He explained that the experience of the Now means something special for man, something essentially different from the past and the future, but that this important difference does not and cannot occur within physics. That this experience cannot be grasped by science seemed to him a matter of painful but inevitable resignation.

On the other hand compare that to what he wrote to Michele Besso's widow,

> In quitting this strange world he has once again preceded me by just a little. That doesn't mean anything. For we convinced physicists the distinction between past, present, and future is only an illusion, however persistent.

Just a question: Does "painful resignation" imply "regret"?

Lee Smolinism 15 : *This field is as much speculative metaphysics as science. A lot of its literature is taken up with issues that can have no bearing on experiment, such as how probabilities are to be defined in an infinite and timeless realm . . .*

Funny, this is just about the same thing I would say of the Everettians.

Lee Smolinism 16 : *There is a powerful if unconscious attraction to theories in which time plays no role. It gives theorists the impression of standing outside the world, in a timeless realm of pure truth, against which the time and contingency of the real world pale.*

I love the way Arthur Lovejoy puts a similar point in his book *The Great Chain of Being*:

> Some examples of metaphysical pathos in the stricter sense ought . . . to be given. A potent variety is the eternalistic pathos—the aesthetic pleasure which the bare abstract idea of immutability gives us. The greater philosophical poets know well how to evoke it. In English poetry it is illustrated by those familiar lines in Shelley's *Adonais* of which we have all at some time felt the magic:
>
> > The One remains, the many-change and pass,
> > Heaven's light forever shines, earth's shadows fly . . . .
>
> It is not self-evident that remaining forever unchanged should be regarded as an excellence; yet through the associations and the half-formed images which the mere conception of changelessness arouses—for one thing, the feeling of rest which its *innere Nachahmung* induces in us in our tired moods—a philosophy which tells us that at the heart of things there is a reality wherein is no variableness nor shadow that is cast by turning, is sure to find its response in our emotional natures, at all events in certain phases of individual or group experience. Shelley's lines exemplify also another sort of metaphysical pathos, often conjoined with the last—the monistic or pantheistic pathos. That it should afford so many people a peculiar satisfaction to say that All is One is, as William James once remarked, a rather puzzling thing. What is there more beautiful or more venerable about the numeral *one* than about any other number? But psychologically the force of the monistic pathos is in some degree intelligible when one considers the nature of the implicit responses which talk about oneness produces. It affords, for example, a welcome sense of freedom, arising from a triumph over, or an absolution from, the troublesome cleavages and disjunctions of things. To recognize that things which we have hitherto kept apart in our minds are somehow the same

> thing—that, of itself, is normally an agreeable experience for human beings. . . . So, again, when a monistic philosophy declares, or suggests, that one is oneself a part of the universal Oneness, a whole complex of obscure emotional responses is released. The deliquescence of the sense—the often so fatiguing sense—of separate personality, for example, which comes in various ways (as in the so-called mob-spirit), is also capable of excitation, and of really powerful excitation, too, by a mere metaphysical theorem. Mr. Santayana's sonnet beginning "I would I might forget that I am I" almost perfectly expresses the mood in which conscious individuality, as such, becomes a burden. Just such escape for our imaginations from the sense of being a limited, particular self the monistic philosophies sometimes give us.

Of course, when he goes on to opine about my own pathos (the voluntaristic one), I'm not so enamored with his sharp tongue!

Lee Smolinism 17 : *We live in a world in which it is impossible in principle to anticipate and list most of the contingencies that will arise in the future. Neither the political context, nor the inventions, nor the fashions, nor the weather nor climate are specifiable in advance.*

Nor the outcome of a single minuscule quantum measurement. All these instances, if you ask me, are cut from a single cloth. Where quantum mechanics has pedagogical value in comparison to the others, however, is with its shock value. For it is in fundamental physics that one *previously* would not have expected such a thing. Most importantly, it gives a sense that the issue is central to our world.

Lee Smolinism 18 : *Moreover, the higher level laws can and often do influence the lower levels of description. There are molecules which only exist on Earth because they are components of biological systems and hence byproducts of evolution. Suppose we wanted to know how many hemoglobin molecules are present on Earth. Hemoglobin is just a big molecule, completely describable by the laws of quantum mechanics. But there is no way the question of how many exist at a given time could be arrived at just by solving the laws of quantum mechanics. To explain why there are any hemoglobin molecules on Earth, and to estimate their number, one must reason in terms of higher order laws which apply to animals and are not completely reducible to quantum mechanics.*

In my present stage of thought, I myself would never say "hemoglobin is a big molecule **completely** describable by the laws of quantum mechanics." As I wouldn't say it of humans, nor of diamonds (see Section VI in my essay), I wouldn't say it of hemoglobin. It is the "completely" thing that contradicts my own nonreductionism. For me, quantum mechanics is *additive* to whatever is particular in an object/concept. Be that as it may, there are definitely similarities in our thinking here. Here's a little passage and footnote from my essay:

> The metaphysics of empiricism can be put like this. Everything experienced, everything experienceable has no less an ontological status than anything else.
>
> Footnote: That is, every piece of the universe had better be hard-wired for the contingency that an agent might experience it somewhere, somehow, no matter how long and drawn out the ultimate chain might be to such a potential experience. Does this mean even "elementary" physical events just after the Big Bang must make use of *concepts* that, to the reductionist mind, ought to be 15 billion years removed down the evolutionary chain? You bet it does. But a nonreductionist metaphysic need make no apology for this—such things are in the very idea. John Wheeler's great smoky dragon comes into the world biting its own tail.

> W. K. Wootters tells a lovely story of an encounter he had several years ago of with his young son Nate. Nate said, "I wish I could make this flower move with my mind." Wootters reached out and pushed the flower, saying, "You can. You do it like this." From the perspective here, this is an example of an interaction between two nonreductionist realms. Each realm influences the other as its turn comes. There is a kind of reciprocality in this, an action-reaction principle, that most reductionist visions of the world would find obscene.

Lee Smolinism 19 : *The best that theory may be able to do is describe what complexity theorist Stuart Kauffman calls the adjacent possible, that is discern some of the very next forms that may emerge. Or there may be singularities where not even this is possible.*

I've always been intrigued by this passage from Henri Poincaré's essay, "The Evolution of Laws," in his *Dernières Pensées*:

> Mr. Boutroux, in his writings on the contingency of the laws of Nature, queried, whether natural laws are not susceptible to change and if the world evolves continuously, whether the laws themselves which govern this evolution are alone exempt from all variation. ... I should like to consider a few of the aspects which the problem can assume. ...
>
> In summary, we can know nothing of the past unless we admit that the laws have not changed; if we do admit this, the question of the evolution of the laws is meaningless; if we do not admit this condition, the question is impossible of solution, just as with all questions which relate to the past. ...
>
> But, it may be asked, is it not possible that the application of the process just described may lead to a contradiction, or, if we wish, that our differential equations admit of no solution? Since the hypothesis of the immutability of the laws, posited at the beginning of our argument would lead to an absurd consequence, we would have demonstrated *per absurdum* that laws have changed, while at the same time we would be forever unable to know in what sense.
>
> Since this process is reversible, what we have just said applies to the future as well, and there would seem to be cases in which we would be able to state that before a particular date the world would have to come to an end or change its laws; if, for example, our calculations indicate that on that date one of the quantities which we have to consider is due to become infinite or to assume a value which is physically impossible. To perish or to change its laws is just about the same thing; a world which would no longer have the same laws as ours would no longer be our world but another one.

Your remark about singularities brought that to mind.

Lee Smolinism 20 : *The first person to ask this question cogently seems to have been the founder of the American pragmatist school of philosophy, Charles Sanders Pierce. He wrote "The only possible way of accounting for the laws of nature and of uniformity in general is to presume them results of evolution".*

Typo: should be Peirce. With regard to Peirce being the first, I suppose it depends upon what you mean be "cogently." Peirce wrote those lines in "The Architecture of Theories" in 1891. On the other hand Émile Boutroux published his book *The Contingency of the Laws of Nature* in 1874. And then there was Bergson, whose books started appearing in 1889. James in his essay, "On the Notion of Reality as Changing," writes:

> Volumes i, ii, and iii of the *Monist* (1890–1893) contain a number of articles by Mr. Charles S. Peirce, articles the originality of which has apparently prevented their making an immediate impression, but which, if I mistake not, will prove a gold-mine of ideas for thinkers of the coming generation. Mr. Peirce's views, tho reached so differently, are altogether congruous with Bergson's. Both philosophers believe that the appearance of novelty in things is genuine. To an observer standing outside of its generating causes, novelty can appear only as so much 'chance'; to one who stands inside it is the expression of 'free creative activity.' Peirce's 'tychism' is thus practically synonymous with Bergson's 'devenir réel.' The common objection to admitting novelties is that by jumping abruptly in, *ex nihilo*, they shatter the world's rational continuity. Peirce meets this objection by combining his tychism with an express doctrine of 'synechism' or continuity, the two doctrines merging into the higher synthesis on which he bestows the name of 'agapasticism' (*loc. cit.*, iii, 188), which means exactly the same thing as Bergson's 'évolution créatrice.' Novelty, as empirically found, does n't arrive by jumps and jolts, it leaks in insensibly, for adjacents in experience are always interfused, the smallest real datum being both a coming and a going, and even numerical distinctness being realized effectively only after a concrete interval has passed. ...
>
> I can give no further account of Mr. Peirce's ideas in this note, but I earnestly advise all students of Bergson to compare them with those of the french philosopher.

Thus, I myself, would probably credit the three as a triumvirate.

Lee Smolinism 21 : *This provides further motivation for believing in the reality of time and the openness of the future. If the selection of the laws of nature that determine what elementary particles exist and how they interact is a result of evolution analogous to natural selection, then there must be a time that this evolution plays out in. And it must be a time that exists prior to the laws, for the laws must have scope to evolve in time.*

Yes, but I wonder whether there might not *in principle* be as many "reality of times" as there are agents (more broadly, objects)—time being single valued only to the extent that groups of agents interact and "synchronize." My QBist program already captures a bit of an image like this. Wheeler had his "many-fingered time," I need a good name for mine.

Lee Smolinism 22 : *The big bang may even be an event that brought into being a novel form of organization in which particles move in space; if this is so then the laws we probe with particle accelerators like the LHC emerged then.*

I'm not sure I understand how to parse this sentence. I.e., there's something about it that confuses me; I'm not sure what it means.

Lee Smolinism 23 : *But we also have evolved the capacity to think quickly and act decisively at the snap of a twig.*

Nice; immediately gave me imagery of early man huddled in the night.

Lee Smolinism 24 : *Fundamentalist communities and open communities can be distinguished by their understanding of time and the possibilities for knowledge of the future. Fundamentalists believe that the future already exists, and are prone to believe that time is altogether an illusion. They believe in mythological stories according to which the ever changing world we perceive is an illusion that hides a true timeless reality.*

This took my mind back to the fact that Travis Norsen, beside calling me a solipsist at every turn just because I say "quantum states do not exist," also happens to be a follower of Ayn Rand.

Lee Smolinism 25 : *Open communities teach that the future is not yet real, what is real instead is time and the processes by which the future unfolds and emerges out of the present. For a fundamentalist, human agency is an illusion, for a member of an open society human agency is the necessary means of constructing a future that will not otherwise exist.*

I might as well end things with another long quote—Richard Rorty and William James this time:

> By way of conclusion, I want to offer a gloss on the passage from William James which supplied the title for this conference. James writes
>
> > What really exists is not things made but things in the making. Once made, they are dead, and an infinite number of alternative conceptual decompositions can be used in defining them. But put yourself in the making by a stroke of intuitive sympathy with the thing and, the whole range of possible decompositions coming at once into your possession, you are no longer troubled by the question of which of them is the more absolutely true. Reality falls in passing into conceptual analysis; it mounts in living its own undivided life-it buds and burgeons, changes and creates. Once adopt the movement of this life in any given instance and you know Bergson calls the *devenir réel*, by which the thing evolves and grows. Philosophy should seek this kind of living understanding of the movement of reality-not follow science in vainly patching together fragments of its dead results.
>
> There are various things wrong with this passage .... But if you read this passage as a meditation on the relation between history and philosophy, it takes on a non-metaphysical meaning, and says something important: namely that the human future will always, with a little luck and a lot of imagination, be so different from the past that it is pointless to look for a set of concepts that will cover both. Bergson was right to think that the metaphysical attempt to see things under the aspect of eternity was a failure ....
>
> Reading James in this way lets one draw the moral: do not think that making the past ideas coherent with one another will ever enable you to find a substitute for imagination. Do not think that philosophy will ever succeed in its attempt to trump poetry and the arts. Do not look to philosophers for anything different than the sort of inspiration that you get from poets, painters, musicians, and architects. For their ability to find coherence will never be more than a perspicuous archival arrangement of the imaginative products of the past. They will never provide authoritative guidance for the imagination of the present.
>
> John Rajchman describes James as preoccupied with "the problem of novelty"—the problem of how to deal with "things in the making", how to see and respond to the emergence of things for which we have no preset manner of seeing or responding. I do not think that there is a solution to this problem, and therefore, as a good verificationist, I do not see it as a problem. The thing to do with novelty is just to be grateful for it, and to create the socio-political conditions which will ensure that there will be a lot more of it. There is a political problem about how to encourage novelty without weakening communal solidarity and social order, but this is a problem to be solved

> ambulando, experimentally, and democratically. All that philosophy can do to help out with this political problem is to keep reminding us of what is likely to happen if the past is allowed to dictate terms to the future.

For a good bit of the point of your essay is in "reminding us of what is likely to happen if the past is allowed to dictate terms to the future."

Thanks for sharing your essay and giving me the opportunity to think a little. I hope it's well-received wherever you send it.

24-03-10 *Revealing* (to D. M. Appleby, R. Schack, and H. C. von Baeyer)

I've just had a little exchange with Adrian Kent on my lines,

> What are we then to do with the Born Rule for calculating quantum probabilities? Throw it away and say it never mattered? It is true that quite an effort has been made by the Everettians to rederive the rule from *decision theory*. Some sympathizers think it works [Wallace09], some don't [Kent09]. But outside the *sprachspiel* who could ever believe? No amount of sophistry can make "decision" anything other than a hollow concept in a predetermined world.

from the new paper.

My guess is that you'll really enjoy the contortions in his reply, so I'll share it with you:

> It seems to me that (a) we can sensibly discuss the preferences of agents in a multiverse — i.e. what successor states they might prefer if they had freedom to choose amongst them — and so that it isn't ridiculous to formulate a decision theory in this context. But also that (b) the project of trying to recover Copenhagen predictions from such a theory ultimately fails. Maybe we disagree on (a)?

Just look at that lovely counterfactual! "what successor states they *might* prefer if they *had freedom to choose* amongst them"!!! No, we wouldn't dare say outright that they *have* freedom; we only talk about what they would do if they *had* freedom! What a sad statement on the common philosophies of our time!

25-03-10 *Very, Very Final Version* (to the QBies & C. Ferrie)

You may be interested in Howard Barnum's posting this morning: "Quantum Knowledge, Quantum Belief, Quantum Reality: Notes of a QBist Fellow Traveler," `http://arxiv.org/abs/1003.4555`.

Also, attached is the very, very final version of my own screed. [See "QBism, the Perimeter of Quantum Bayesianism," `arXiv:1003.5209v1`.] I'm posting the thing today finally. Since the version you've all read, the very important Footnote 22 has been added.

25-03-10 *Possible?* (to Å. Ericsson)

Åsa-ism 1: *If you should assume everything to be possible because you have no proof of the opposite, wouldn't that lead you to assume just anything "to be the case" (or whatever one should* *say without using the word "true") for which there is no proof of the opposite? But there cannot really be any such rigorous proof. And we cannot live like that. We form beliefs from our experiences, which leads us (at least me!) not to believe in* [just] *anything and also not to believe everything is possible for us.*

If we did not believe that we could prolong human life with better technologies, we as a society would not invest in medical research. But we do. And what is the limit of the prolongation? How far can we go? Can we make people last 100 years on average? 150? Why should there be any end in sight? We console our personal selves to the idea of eventual death because the alternative is not within reach now—not within our expected lifetimes. And that is as we should do. But if death is a *necessary* end, why worry about the difference between 80 and 100 years? *Methodologically* (as Schiller says), we are behaving as if eventually it can be completely overcome. All our industry is geared toward that, one step at a time. First we wipe out HIV, then we wipe out heart disease, then we wipe out cancer (all cancers!). There is no end to the process. And we should not believe that there is one.

25-03-10 *Torture and Relief* (to A. Kent)

Thanks for your note.

(1) OK, I back off on the label "sympathizer." The insult now reads:

> Or take the Everettians. Their world purports to have no observers, but then it has no probabilities either. What are we then to do with the Born Rule for calculating quantum probabilities? Throw it away and say it never mattered? It is true that quite an effort has been made by the Everettians to rederive the rule from *decision theory.* Of those who take the point seriously, some think it works `\cite{Wallace09}`, some don't `\cite{Kent09}`. But outside the *sprachspiel* who could ever believe? No amount of sophistry can make "decision" anything other than a hollow concept in a predetermined world.

You were right to call me on that, for all I had really meant was, "of those who take the point seriously." My plan is to finally post the darned thing today.

(2) Because I don't really. For me it is not that the Everettian interpretation is "bizarre" (as many people say) or carries too much "ontological baggage" (as others say), but that it is simply empty of content. It is a great effort full of sound and fury, in the end signifying nothing. When I heard David Wallace once admit (at the MWI meeting you organized here at PI) that one *could* give an Everettian interpretation of classical Liouville mechanics, that capped it all off for me. His defence was only, "but there is no great need in that case." And so I say of QM anyway. But the essential point is, one can play the MWI game with *any* probabilistic theory. And when done, it is a "more or less arbitrary appendage" to the theory.

(3a) I have to admit getting a really good laugh from this part of your sentence:

Kentism 10: *[W]e can sensibly discuss the preferences of agents in a multiverse – i.e. what successor states they might prefer if they had freedom to choose amongst them ...*

For the Everettians, each one of them, are great monists at heart; in a different century they would have been Hegelians. The real thing behind their motivation is that paper thin. They contemplate a world with no true counterfactuals from within, but then to make sense of this world they invoke a counterfactual at the outset, "what successor states they might prefer if they had freedom to choose amongst them." When I read your sentence, a little sarcastic voice in me came out fighting, "No, we wouldn't *dare* say outright that they *have* freedom; we only talk about what they would do if they *had* freedom!"

Kentism 11: *Obviously, though, I'd be intellectually unhappy with the suggestion that there isn't anything substantive to discuss.*

My psychoanalysis is that this is why my first version of the Everettian insult stung you, when I had intended you to be "on the good side of it". I am sorry about that—I don't mind insulting people at times if I think it might help shake a nut or bolt loose, but I did not want to insult you. On the other hand, I can't hide what you suspect—that I do believe there is not too much substantive to discuss in the MWI view *at this stage in our thinking.* (There once was, even for me, before I had wholly given up on psi-ontology. But now I think it is time to move on.)

One technical point related to this about my present attitude on the Born Rule. It is that it is not something to be *derived* (in Wallace's way, or Gleason's way, or any other way). Rather my present feeling is that it is the fundamental statement of what quantum mechanics is about—it is a rule that takes probabilities in, and gives new probabilities back out. (See the attached "press release" on my house; what I mean in the last sentence is made formal by the "pretty equation" at the bottom of it. Rüdiger and I call it the urgleichung.) Two further notes below on this "attitude" in case you're interested.

I'd love to come to Cambridge again (if you still want me after the note above). Thanks for the invitation. Maybe sometime this Fall.

25-03-10 *What Bayesians Expect of Each Other* (to G. Chiribella)

This is the paper I was talking about. [See M. J. Bayarri and M. H. DeGroot, "What Bayesians Expect of Each Other," J. Am. Stat. Assoc. **86**, 924–932 (1991).] It'd be nice to get a quantum version of this theorem. If you'd like to discuss and think about this, let me know. It'd be great if we could get something solid.

26-03-10 *Templeton OFI* (to R. Schack)

There is very little on paper so far, but I have been thinking much in my head. Fear not: It will come together!

Any preference on these potential titles?

- That the World Can Be Otherwise: The Essence of Quantum Theory
- That the World Could Be Otherwise: The Essence of Quantum Theory
- That the World Has the Power to Be Otherwise: The Essence of Quantum Theory
- The World's Power to Be Otherwise: The Essence of Quantum Theory
- The Essence of Quantum Theory: That the World Can Be Otherwise
- Quantum Theory's Essence: That the World Can Be Otherwise

26-03-10 *Title* (to R. Schack)

"That the World Can Be Shaped: Quantum Mechanics, Counterfactuality, Free Will"

26-03-10 *Thinking, Scheming* (to S. Weinstein & D. Fraser)

Rüdiger Schack and I are working on a Templeton Foundation proposal, and I find myself trying to think big. At the moment, I am playing with, "That the World Can Be Shaped: Quantum Mechanics, Counterfactuality, Free Will," for its title. Anyway, the reason I write you is that I am also playing with the idea of using part of the money to hire a QBism-pragmatism-Cartwrightism sympathetic philosopher as a two-year postdoc. (Beware!) But one of the things I'm bumping into is the space limitations at PI and the "second-class status" of our "associate postdocs" (those that are housed at PI but have funding coming from external sources). Which leads me to the following idea: How receptive would the UW philosophy department be to a postdoc freebie of this variety? There is the space issue already mentioned, but also I'm thinking it might be healthier for the person to be around there more than here anyway. He/she and I could have weekly meetings, lunch, etc., but otherwise it'd probably be good for the person to mingle more closely with proper philosophers.

A couple of questions if this is a possibility. What is the standard salary of a philosophy postdoc at UW? And how much overhead would your department require? (Templeton will give up to 15%. But of course the smaller the percentage I can get away with the happier I'd be.)

Just some thoughts.

By the way, if you don't know what I mean by QBism see the attached new paper and "press release" on my house. [See "QBism, the Perimeter of Quantum Bayesianism," `arXiv:1003.5209v1`.] Particularly the connection between QBism and pragmatism / "Cartwrightism" is described in Section VI, starting page 19.

26-03-10 *QBist Double Slit* (to M. A. Graydon)

Graydonism 1: *Question: Have you written anything on a QBist interpretation of Young's experiment? In the text-book explanations we find references to free-particle wavefunctions in infinite dimensional Hilbert spaces . . . so does this mean that one cannot translate the math into SIC language?*

The Mach-Zehnder interferometer captures the essence of that, and it is a finite dimensional system. Gelo is looking at this in detail at the moment—you might get his take on that.

With regard to infinite dimensional systems more generally, I really don't know how the answer is going to go: It could be that SICs do after all have an infinite dimensional limit, but it could be that they don't. Gutwise, I kind of hope that they don't have an infinite limit. So much the worse for infinite dimensional Hilbert spaces, I say. Physics has been wrenching with the difficulties of field theory and (the absurdity of) renormalization for so long, that maybe it is time for worldview re-adjustment. Infinite dimension might be like infinite inertial mass—a handy approximation to make at times, but ultimately not something that is ever really true.

In general I advocate what Jaynes calls the "the cautious approach policy":

> **Our "Cautious Approach" Policy**
>
> The derivation of the rules of probability theory from simple desiderata of rationality and consistency in Chapter 2 applied to discrete, finite sets of propositions. Finite sets

are therefore our safe harbor, where Cox's theorems apply and nobody has ever been able to produce an inconsistency from application of the sum and product rules. Likewise, in elementary arithmetic finite sets are the safe harbor in which nobody has been able to produce an inconsistency from applying the rules of addition and multiplication.

But as soon as we try to extend probability theory to infinite sets, we are faced with the need to exercise the same kind of mathematical caution that one needs in proceeding from finite arithmetic expressions to infinite series. The "parlor game" at the beginning of Chapter 15 illustrates how easy it is to commit errors by supposing that the operations of elementary arithmetic and analysis, that are always safe on finite sets, may be carried out also on infinite sets.

In probability theory, it appears that the only safe procedure known at present is to derive our results first by strict application of the rules of probability theory on finite sets of propositions; then after the finite set result is before us, observe how it behaves as the number of propositions increases indefinitely. There are, essentially, three possibilities:

(1) It tends smoothly to a finite limit, some terms just becoming smaller and dropping out, leaving behind a simpler analytical expression.

(2) It blows up, i.e., becomes infinite in the limit.

(3) It remains bounded, but oscillates or fluctuates forever, never tending to any definite limit.

In case (1) we say that the limit is "well behaved" and accept the limit as the correct solution on the infinite set. In cases (2) and (3) the limit is ill-behaved and cannot be considered a valid solution to the problem. Then we refuse to pass to the limit at all.

This is the "Look before you leap" policy: in principle, we pass to a limit only after verifying that the limit is well-behaved. Of course, in practice this does not mean that we conduct such a test anew on every problem; most situations arise repeatedly, and rules of conduct for the standard situations can be set down once and for all. But in case of doubt, we have no choice but to carry out this test.

In cases where the limit is well-behaved, it may be possible to get the correct answer by operating directly on the infinite set, but one cannot count on it. If the limit is not well-behaved, then any attempt to solve the problem directly on the infinite set would have led to nonsense, *the cause of which cannot be seen if one looks only at the limit, and not the limiting process.* The paradoxes noted in Chapter 15 illustrate some of the horrors that have resulted from carelessness in this regard.

28-03-10 *Game Theory and Quantum Mechanics* (to D. H. Wolpert)

Wolpertism 1: *There's been a lot of stuff on applying game theory to situations where the game players have quantum-mechanical apparatus to play with. "Quantum games" it's called. IMO, it's physicists looking for something to do.*

There's also been work where people somehow try to modify the Nash equilibrium concept to be "quantum mechanical". The point of which eludes me.

Both of these are simply importing physics into game theory. Yawn.

Now there's another set of ideas, which nobody has managed to run to ground, which would be truly profound, and (I think) related to what you're talking about. This is importing game theory *into physics, rather than vice-versa. Basically, can one cast various physics scenarios in terms of particles that are "players in a game" in some sense.*

I like the sound of such an idea. A bit like exporting "agency" to the "inanimate" world.

29-03-10 *Symmetry of Quantum State Space* (to A. Fenyes)

A SIC measurement allows a one-to-one correspondence between $d \times d$ density operators (positive semi-definite matrices with trace 1) and probability distributions over d^2 points. The result is an affine transformation from one set to the other. Affine transformations preserve various convexity properties (like mixtures, extreme points, and maybe some other things), but they don't necessarily preserve geometric symmetry. For instance, we can get from an ellipsoid to a sphere by an affine transformation. And here is a nice symmetry property of the sphere that a proper ellipsoid doesn't share: The sphere (the ball really) can be thought of as a union of *regular* simplexes each of full dimension.

If SICs exist, then the space of density operators has that property as well—quantum state space can be thought of as a union of regular simplexes.[222] In either representation, I guess: I.e., represented as complex matrices or as probability distributions.

I've always thought of the SIC-induced affine mapping as the best way to "straighten out" out the space of quantum states. For instance, if for a qubit we do not use a SIC, but some other informationally complete POVM to induce a mapping from quantum states to probability distributions, we will not get a sphere, but an ellipsoid. That's a kind of trivial change, of course, but I don't know the full implications of the change in higher dimensions. Maybe there are better reasons to resist "ellipsifying" the sphere there. (Given my remarks above, if SICs exist, quantum-state space is already "straightened out" in a way. I.e., the density operator formalism already captures this nice symmetry—one doesn't have to map on to the probability simplex to see it. If on the other hand, SICs don't exist—then I think one must always "ellipsify" the Bloch ball when transforming from density operators to probability distributions via an informationally complete POVM with rank-1 elements.)

Anyway, I didn't know how sensitive $\mathrm{sym}(x, S)$ was to affine transformations when I wrote my first note to you—I hadn't really looked at the paper to any depth. But now, looking over the paper, I guess Proposition 3 caps off this question. [See A. Belloni and R. M. Freund, "On the Symmetry Function of a Convex Set," Math. Programming **111**, 57–93 (2008).]

Still though, one can ask whether better knowing the structure of the function $\mathrm{sym}(x, S)$ for the set of quantum states might give any clues on SIC existence or nonexistence, or even just reveal some nice features of the state-space that we hadn't known before.

I like your question of comparing the scaling of S to that of a simplex as dimension grows. Also, what is the symmetry value of a sphere of the same dimension? (I'm bad: When I say sphere, I most always mean ball.) I guess it's 1.

29-03-10 *Premature QBism!* (to N. D. Mermin)

To reply:

Merminition 185: *1. Of the three examples at the end of page 1, the second (spontaneous collapse) is more than an interpretive strategy, since it alters the quantitative predictions of the theory. Of course it's motivated by an implicit interpretive strategy.*

[222] See Footnote 218 for a technical, but remediable, mistake in the original statement of this.

Agreed, it is "more than," but I had meant to cover that with this: "The trouble with all these interpretations as quick fixes for Bell's hard-edged remark is that they look to be just that, *really quick fixes*. They look to be interpretive strategies hardly compelled by the particular details of the quantum formalism, giving only more or less arbitrary appendages to it." Looking back at the draft, I see I had cut out the appendage part in the small version of the paper. I hope you'll give me a pass on this one: I'd rather not complexify the issue too much in a "quick introduction."

Merminition 186 : *2. Remark on pilot-wave theories on upper left of page 2. Do you really mean "pretending" (and not, for example, "presenting")? It's a peculiar use of "pretend" and I don't understand what it means here. The term veneer is already disparaging enough. And what is it about counting angels on the head of a pin that is supposed to resemble pilot-wave theories. (When Pauli used the image in his letter to Born he was illustrating worrying about things you can't know anything about.)*

You're right. I was worried there was something wrong with that sentence, but could never quite put my finger on it. Is this better (basically what you suggest):

> If there were no equations to give the illusion of science, this would have been called counting angels on the head of a pin.

And yes, it is precisely the Pauli point. There is a fun exchange between Bill Unruh and Roderich Tumulka during one of the PIAF meeting panel discussions a couple years back. Tumulka said something like, "Bohmian mechanics allows one to calculate answers to some questions that all the other interpretations can't even formulate. For instance, the amount of time a particle is on the inside of a potential barrier." Unruh said, "That's not true! My interpretation allows it. Every particle stays in every potential barrier precisely seven seconds." Tumulka said, "But this is nonsense. We're not just making some number up; we have a scientific theory." Unruh said, "Your theory is every bit as scientific as mine."

Merminition 187 : *3. Remark about Bell on upper right of page 2. You attribute to Bell a fear that is not in the quotation you cite on page 1 but in your own broader remarks in the paragraph that follows it. I'm see no evidence that Bell feared that the conceptual weakness of the theory might lead to a breakdown in its empirical validity.*

Not a fear of a breakdown in QM's empirical validity, but that physics is way, way on the wrong track because of its seeming need to invoke the observer. I've always interpreted Bell as thinking along the lines of something Einstein said:

> It may appear as if all such considerations were just superfluous learned hairsplitting, which have nothing to do with physics proper. However, it depends precisely upon such considerations in which direction one believes one must look for the future conceptual basis of physics.

Merminition 188 : *And I'm not sure what you mean when you say that the only thing to fear is that particular fear itself, regardless of whom you attribute it to. Are you saying that we should take QM as correct and try to understand it better?*

Yes. Or more accurately that the observer is essential in formulating quantum mechanics, and we should try to understand that better. FDR: "The only thing we have to fear is fear itself."

Merminition 189 : *Finally, I don't see anything "shrill" in Bell's rhetoric, and I don't see why your simple resolution of his worry about the collapse of the wave-function of the universe warrants calling his concern "the least of his worries."*

In that spot, I had originally written:

> The real substance of Bell's fear is just that—fear itself. To succumb to it is to block the way to really understanding the theory. Moreover, the harsher shrills of Bell's rhetoric are the least of the worries:

Upon which, Hans Christian von Baeyer who read the draft wrote:

> I don't think shrill is a noun. For "hasher shrills" I would put "shriller notes."

I just basically followed through with his suggestion. But you're right, "shrill" is too strong. How about simply,

> the harsher notes of Bell's rhetoric are the least of the worries:

Merminition 190 : *This leads the reader to expect an even bigger problem — not the solution to the problem.*

Because that is basically where Asher would have left it ... never trying to make his view of quantum mechanics completely consistent.

Merminition 191 : *4. Still upper right, page 2. I'm not sure how you get from antibodies in some of the elderly to the antibody itself being elderly. And I'm not sure you want to call it ineffective, when it's the direction you want to move in.*

Right again: Strange for me to call the antibody itself elderly. How about simply,

> But this much of the solution is only a somewhat ineffective antibody. Its presence is mostly a call for more research. Luckily the days for this are ripe, and it has much to do with the development of the field of quantum information

Merminition 192 : *Nothing else for now.*

The bigger paper is a better paper, but of course inherits many of the bad word choices you mention above.

The only trouble with your being right with your remarks, is that now I'll have to repost the damned thing! And frankly I'm frightened of that.

I hope you'll still read the big paper, even though you've read the little one—it contains a load of mini-epiphanies for me. For instance, Footnote 44, where I turn "the quantum-to-classical transition" around. I'd like to hear whether you think the paper makes any progress toward something else you said:

Merminition 193 : *I suppose it's ineffective in that it hasn't convinced everybody, and is not yet sharply enough developed.*

30-03-10 *Quantum Bayesianism* (to J. Wright)

This is a very late reply; I'm sorry about that. Let me just respond to two points.

Wrightism 1: *My concern is that on one hand the Bayesian view takes a very forward stance, saying so much as "quantum states are not real" and then you said in your lecture that you'd be willing to accept other interpretations on pragmatic grounds — in the sense of electromagnetic fields.*

and

Wrightism 2: *It was an example used in jest but then moments later you talked about the problem of quantum channels and how you wouldn't stand against an interpretation if thinking in that manner provided a solution to such a problem.*

The root of these blurbs is not an inconsistency in my thinking or a religious reliance on pragmatism, but a politician's way of negotiating—a way of demonstrating the possibility of compromise. I give a criterion for what *would* move me toward their views. And I'm honest about that. But it is a bit hollow nonetheless: For I make this "bargain" in very strong confidence that they won't be able to deliver the goods. 50 years of history already shows a world of difference between electromagnetic potentials and the Bohmian trajectories. Potentials, though unobservable except through the forces "they give rise to," are used every day in the aid of hundreds of problems in electromagnetism classes. Bohmian trajectories, even if assumed unobservable except through the measurement clicks "they give rise to," are *nearly never* used. The only exceptions I know of are in the demo problems invented to make them look like a healthy option (like the question of how long in a potential barrier). No actual practical problem is ever helped by their aid.

I hope that makes my strategy a little more understandable, even if a bit slimy.

30-03-10 *That Old Shoe* (to S. Lloyd)

I nearly forgot: I believe I thanked you for the first time in a paper. Have a look at the end of `http://arxiv.org/abs/1003.5209`; the wording might amuse you. The paper is my latest attempt to verbalize a worldview that's been growing in me. Apparently that '92 lecture of yours left a lasting impression on me. (Though in the text of Section VI, I transformed your shoe into a diamond to fit the rest of the story. It deserved to be a diamond anyway!)

30-03-10 *I Knew He'd Just Call Me Solipsist Again, and he did* (to N. D. Mermin)

I made a probability one assignment, and the world complied to what I believed with all my heart. Does that synchronicity call out for further explanation? I made the probability assignment because all my experience thus far had pointed me in just that direction. I compacted all that I felt and saw around me, all my previous dealings with people and *particular* people, my choice of words while writing, and everything else in my memory into a singular supremely strong probability assignment. And the world complied: The action I took in posting my paper to `arXiv.org` led another part of the world to a reaction that I was quite sure I could see in advance.

I suppose it'd be no solace to Travis to know that I really do believe in his autonomy—that he is more than the sum total of my provocations. See below.

With a smile of satisfaction,

Original note from Travis Norsen, "Bell, locality, etc," dated 30 March 2010

I've just read the short QBism paper you put on arxiv the other day, and skimmed the longer one, and thought I'd write and just say hi and register a couple of very quick comments. First, I appreciated the compliment in the footnote of the longer paper, even if it was, well, somewhat qualified! =) More seriously, I think there is a kind of deeper disagreement between us (or between you and Bell) on this stuff than you acknowledge. Let me try to explain what I think the issue is.

I think that, from the very beginning, you are just on the premise of understanding probability statements as referring to subjective degrees of belief (or something in that neighborhood). And, on that basis, your reaction to (for example) the passage from one of my papers that you quote in that footnote, is completely understandable. If you understand probability statements to be, in principle, about degrees of belief, and then you see $P(a) = 1$, then you are absolutely right: that just means that somebody believes "a" with all their heart. It doesn't necessarily mean or warrant some further claim about there being some real element of reality, "a", out there independent of human intervention, awareness, etc.

So on that part we agree. But where we disagree is about whether that's what the probabilities in this particular context actually mean. As a perfectly uncontroversial factual/historical matter, that (i.e., subjective degrees of belief) is *not* what Bell meant by the probabilities he writes down in his various papers. He is just coming from a very different place. He's taking for granted what I've elsewhere called "metaphysical realism" (i.e., that there is some kind of physical world out there independent of us, which it is the goal of candidate physical theories to describe). Then the specific concern which brings probabilities into the discussion is the desire to avoid *assuming* that determinism is true. That is, he very carefully and deliberately sets things up so that we are open, in principle and from the very beginning (and here I'm mostly talking about his formulation of "local causality" from, e.g., "la nouvelle cuisine"), to candidate physical theories (i.e., candidate descriptions of external physical reality) which involve irreducible stochasticity. So he gives, for example, a mathematical definition of "local causality" that is a statement about certain probabilities – and then literally from there (plus the additional assumption of "no conspiracies", aka "freedom") you can run the EPR argument for the existence of certain things, which then run afoul of experiment via Bell's inequality.

Now the key point here is just that the probabilities that are in the mix here – that is, the ones in Bell's definition of "local causality", because that's the premise from which everything else follows – are *not* subjective degrees of belief. They are rather the "irreducible dynamical probabilities" of some candidate theory. In particular, they are the probabilities assigned by the theory to certain physical happenings, not on the basis of anyone's subjective and perhaps-incomplete knowledge of various goings-on, but rather on the basis of a complete description of physical goings-on in some relevant spacetime region. (And note here that both the "complete" and "physical goings-on" parts of the previous sentence mean: according to, i.e., relative to, some particular candidate physical theory. So there simply is no place here where anything relating to knowledge or subjective belief or *anything like that* enters *at all*.) And so, given *this* understanding of the probability statements that are in the mix here, you can surely see why it would be quite inappropriate to say "Just because $P(a) = 1$ doesn't mean there's some fact of reality out there corresponding to 'a'." Yes, it does mean that, because (with this alternative understanding of probabilities in place) "$P(a) = 1$" literally just means that, according to some particular candidate physical theory, the physical fact corresponding to "a" definitely happens. And that means: really happens, out there in reality (according to this theory). And that is all that is needed for the whole argument to go through.

Now, don't get me wrong. I'm not saying "Well, Bell meant something different by probabilities, and so you just have to accept his view." I appreciate that you could – and I'm sure do – disagree with Bell. That is, I suspect you think that Bell's whole way of understanding probabilities is just wrong, and that it just doesn't make any sense to interpret probability statements as propensities (if that is the right terminology for Bell's view) rather than subjective degrees of belief. Fine. But then you should I think more openly acknowledge that you have this more basic disagreement – instead, I mean, of writing as if you and Bell and everybody obviously just agree that probabilities have to mean subjective degrees of belief, and then pointing to the end of some argument (like the one you quote from me) and saying "obviously this conclusion doesn't follow". Because doing that makes your argument into a kind of petty straw man sort of thing, right?

Let me also say that – *if* you really accept what I called "metaphysical realism" above, as I believe you *claim* to do – I don't see how you can possibly argue that it is meaningless/nonsense to talk about probabilities in Bell's "propensity" sense. If you think there's a physical world out there, and you think that in principle its fundamental laws might be stochastic rather than deterministic, then you just have to accept the possibility of candidate physical theories like the ones Bell contemplates. And so I have the very strong suspicion – or perhaps I should say this strengthens my very strong suspicion – that (your own protestations to the contrary notwithstanding) you actually reject "metaphysical realism". Because, frankly, it is only if you reject that, that I think it then makes any kind of logical sense to insist that *all* probability statements *must* just refer to subjective degrees of belief. And that, of course, would just make you a **solipsist**.[223] Which I know you vehemently deny. But in your heart of hearts, come on – you must understand why you keep hearing this accusation.

Let me also just say that I haven't forgotten that you owe "me" (really, the world) some kind of more explicit and careful QBist analysis of (in particular) Bell's formulation of "local causality" from "la nouvelle cuisine". This is what you thought you were going to talk about at PIAF, right, but then you ended up going in a different direction? Anyway, I'm being tongue in cheek in saying "you owe me" – the point really is just that if you want to have a serious and possibly-productive discussion about Bell, locality, QBism, etc., I think this is going to have to be a central part of the discussion.

OK, enough for now.

30-03-10 *I Knew He'd Just Call Me Solipsist Again, and he did, 2* (to M. Schlosshauer and R. Schack)

You two might enjoy this one as well, given your own previous run-ins with Travis Norsen. [See 30-03-10 note to David Mermin titled "I Knew He'd Just Call Me Solipsist Again, and he did."] I've got a good racket going: I post a paper; I get called a solipsist. If I could only figure out how to bottle this stuff and sell it for profit!

[223] My emphasis!

30-03-10 *Soliciting Your Thoughts on Intro to Our Steering Paper* (to H. Barnum)

Barnumism 18: *I meant to ask you this earlier… but when writing the intro to our steering paper, I said "The Bohrian notion of complementarity, for example, can be understood in terms of one type of knowledge about a system precluding another." I felt a bit uncomfortable about this… I thought one or both of you might object based on the idea that what one acquires in a measurement is not really "knowledge about a system" but "knowledge about the outcome of my just-completed interaction with a system". There is a similar issue with the next sentence, about information-disturbance relations.*

I wonder if that's right… and if either of you can think of a better way of pithily summarizing complementarity that still relates it to information/information processing in the way we want to in our intro.

Let me think on this for a bit. I'm not sure at all about how I would approach trying to say something about "complementarity". As for "steering" being such a prominent component, its real essence (from a QBie perspective) must be about the possibilities for conditioning. I keep thinking there must be a deep connection between it and the axiom that Rüdiger and I toy with: That in our urgleichung set-up, any posterior for the sky could have been taken as a prior for it. It's this that sets up a duality between states and measurements in our scheme. But I can't quite put my finger on how this and "steering" (god I hate that name) should amount to the same thing.

30-03-10 *Qbism Questions* (to C. Ududec)

Wow! I just read this all again. I feel I can't even begin to answer you. Would you hold it against me for a still further while? Question 1, for instance, is a research project in itself. Maybe we should just "talk" more. How about we get together sometime next week for an oral version of this?

Cozmin's Preply

> [Concerning a draft I handed out at the Laflamme-Emerson quantum foundations course and became "QBism, the Perimeter of Quantum Bayesianism," `arXiv:1003.5209v1`.]
>
> Sorry for being so late with this, but I didn't get a chance to look at your essay until this Friday. I have a few long winded (and probably still confused) questions and comments. Id like to think about the following more, so maybe this should be a kind of first draft of what I'd like to ask and comment on.
>
> 1) In section three, you argue that since probability does not exist, quantum states do not exist. Presumably this also means that CP maps do not exist. I'm inferring this since if teleportation (which I think you used in an older paper) can be used to argue that quantum states do not exist, then gate teleportation can be used to argue that CP maps do not exist. So what about tensor product decompositions of a Hilbert space, do they exist? There is a version of the Choi-Jamiolkowsky isomorphism (introduced by Matt Leifer in 2006) which shows that specifying a bipartite quantum state ρ_{AB}, and two POVMs, M_A, N_B (which commute), is equivalent to specifying an initial state on A (given by an M_A preparation), and a CPTP map from A to B. So if one agent says that he is working with a bi-partite system and an entangled state, another agent can say he

is working with one system which is mapped to another by some CP dynamics. This is analogous to how specifying a joint probability for two random variables $P(X,Y)$ is equivalent to specifying a pair of $(P(X), P(Y|X))$ where $P(X)$ is now understood as a distribution for X at some initial time, and $P(Y|X)$ is a channel, taking $P(X)$ to $P(Y)$ at a later time.

Also, would it be worth your discussing at least that CPTP maps do not exist in class? Is this implicit in your Wigner's friend argument?

2) Could you comment a little on someone like Leslie Balletine's views on the issues from section III, and his best argument for his views and how you understand them? This may be a strange request, but I think it's interesting to see how people with opposing views evaluate and argue against each others' best arguments. I think of it as a kind of second order evaluation of two positions, with the first order being just looking at both and evaluating them personally.

3) On page 7 you discuss the issue of "Whose information? Information about what?", as well as Pauli's statement that "the results of [an observation] are objectively available for anyone's inspection." Would you still say that the fact of an observation/intervention are objectively available for anyone's inspection? I'm not sure if this is right, but I had the thought that maybe the strong reactions you get to your answer to the information about what question is partly based on confusion over the difference between a statement about the consequences (for me) of my actions on a system, and the consequences of my actions on the system, on someone else's beliefs, or alternatively, the difference between the result of an observation/intervention, and the fact of that intervention. Talking about 'the fact of' an observation already seems to be presuming the answer here, but I'm not sure how to phrase this better right now.

4) In the convex sets, or general probabilistic theories framework which Luca, Howard, Lucien, myself, and others are constantly going on about, we often talk about equivalence classes of preparation devices, and often say (maybe imprecisely) that a 'state' is something like a concise representation of — everything that is statistically relevant about — this equivalence class, i.e., it's a collection of probabilities for the outcomes of future measurements, conditional on the system being prepared by a device from this equivalence class of procedures. From this point of view, statements about unknown quantum states become statements about unknown quantum preparation devices or more generally unknown quantum interactions between the system of interest and another piece of the world. So an agent using some quantum state, is equivalent to (?) it making a statement about the past history of the system of interest. Could you comment on this, and how it fits with your view of quantum states, the quantum de Finetti theorem, and the discussion of the 'right' quantum state?

5) Regarding your comments about the elementary notion of what it means to be two objects rather than one, you say that if one gives up the autonomy of one system from the other, it surely amounts to saying that there were never two systems there after all, and ask why the quantum formalism would engender us to formulate our description in terms of a tensor product of two four dimensional Hilbert spaces, rather than simply a raw 16 dimensional Hilbert space. The conceptual distinction that the tensor product brings in is purely at the operational level, while the question of the autonomy of systems seems to have a much more ontological flavor. The tensor product is a structure we use within quantum theory (which you've argued is a manual that any agent can use to make wiser decisions) given certain other assumptions about some physical situation and what statistics we expect to see (i.e. No-Signaling statistics). My

question (1) above also seems very relevant here, but I'm not sure how to phrase things properly in relation to that ....

For example, I can imagine a world where at some basic ontological level, there are objects in the world, which after interacting with each other in a precise way no longer claim an existence independent from each other. However at the operational level, the level with agents and preparation and measurement boxes, it appears as if — the statistics of various measurements show that — they do have an existence independent of each other. So the agents in this world, would use something like a tensor product decomposition for their description of the statistics of their experiments.

6) A warning about the following: this is partly my attempt to understand the various issues surrounding things like scientific explanation, causation, Bell's theorem, and last but not least, Bell's theorem Qbism style.

I don't think it would be controversial to say that probability theory conceived of as a calculus of consistency in the face of uncertainty (or language for dealing with uncertainty coherently?) does not have the structure or syntax to express the concept of causation. For example, the syntax of probability theory does not allow us to express the statement that "symptoms do not cause disease". There is nothing in the joint distribution of symptoms and diseases to tell us that curing the former would or would not cure the latter.

Why am I bringing this up? Well, I would argue that research in most areas of science such as physics, and biology, as well as in engineering, law, economics, and immunology, is not statistical but is causal in nature. Many questions in these fields are not just about discovering correlations between different variables, but are questions about the process by which the data was generated. They are questions of an explanation of the data, or of what caused or generated the data. We can look at the world, and the things in it as black boxes whose internal workings we can't directly observe. What we want to do is open the black boxes and expose their inner mechanisms.

Why should we care about this notion of explanation through mechanisms? Many laws or statements in physics do not express causal relations, but just regularities. Some examples are A) the daily regularity of the tides, and their correlation with the positions of the sun and moon in the sky, B) the ideal gas law, which relates pressure, volume, and temperature for a given sample of gas, and C) Kepler's laws of planetary motion which describe relationships between various parameters of the orbits of the planets.

There are also many laws or theories which do express causal relations. For example, the increase in pressure of a gas when we change the volume with a piston is explained causally by postulating particles which collide with the walls of the container more frequently when the volume is decreased. So we have a noncausal regularity which we explain on the basis of some postulated underlying causal mechanism. Similarly, Newton's laws of motion and gravitation explain such regularities as Kepler's laws, as well as the tides. The theories (not just in physics) which postulate some causal processes and explain some observed regularities tend to be more precise or powerful (and let us sleep better at night). They also tend to come with more baggage, like postulated particles or fields, and their dynamics.

Now, it seems to me that the way Bell's theorem is usually presented is as a statement about causality, or about the structure (the functional relationships between various postulated variables) of physical theories which explain certain correlations in certain well specified experiments. I say explain, rather than account for, since in a sense quantum theory already accounts for the correlations, i.e., given a belief about how a bipartite system was prepared, and some beliefs about the structure of two further interactions with the systems, the correlations between the outcomes of the interactions are predicted by the theory. Quantum Theory seems more like the examples A, B, C than say General Relativity or Statistical Mechanics. So the way I see the ontological model's program, and more specifically, Bell's theorem, is as an attempt to find a mechanism for the observed correlations, i.e., to find a General Relativity for the Kepler's laws of Quantum Theory.

Given the above, I'm worried that analyzing Bell's theorem purely from a "probability theory conceived of as a calculus of consistency in the face of uncertainty" doesn't do justice to it. So I'm curious what you think of the above considerations of explanation and causation.

You also argue that a probability-one assignment lays no necessary claim on what the world is. Most scientific theories have many probability-one assignments, and they do seem to make claims about the way the world is. I'm wondering how you would rephrase those theories (like classical Electromagnetism, modern genetics, and chemistry experiments where catalysis is important) and the claims they make, to be more consistent with the "probability theory conceived of as a calculus of consistency in the face of uncertainty" point of view. Also, how would you look at a statement like $Pr(X = i|B, T)$, i.e., "Given background knowledge B, and postulated theory T (with all the extra variables, and functional relationships between variables which it postulates), the value of observable X will be i, with probability one"? It seems to me like the quote in your footnote 27 has the structure of a statement like the above, rather than a statement like "this probability one assignment for variable X (given background knowledge B), necessarily implies the world is such and such …".

Do you think that Bell's theorem (or maybe some slightly weakened version of it) could be formulated without something explicitly or implicitly equivalent to the EPR criterion of reality? In other words, is taking something like that criterion a necessary condition for Bell like no-go theorems?

Finally, do you mind sending me an electronic copy of the Qbism essay?

31-03-10 *An Important Message from the QBomancer* (to the QBies)

(OK, I need a better name for myself or my role in this group. "Cubomancy" is defined as "divination by throwing dice." … Given that that's what I've been doing all my life, it seemed a little appropriate. QBomancy—divination by performing quantum measurements.)

Anyway on to more serious matters: […]

31-03-10 *Bell, Locality, Etc.* (to T. Norsen)

Thank you for your note. I have studied it carefully, and plan to study it still more carefully on second and third passes. But your remark, "I've just read the short QBism paper … and skimmed the longer one," coupled with your second-to-last paragraph where the S-word is mentioned, made me smile and reminded me of an encounter I once had with Leslie Ballentine at a meeting in Sweden. Leslie had sent me his previous conference proceedings a bit before my travel to the new meeting, and we met in the coffee line the first morning. I had skimmed his paper, and to outward appearances, it looked to have no innovations over his previous discussions; so I left it at that. But as you can guess, at coffee the conversation very quickly came to the issue of quantum probability.

Leslie said, "Did you read my new paper?" I said, "No, actually." He crisply turned 90 degrees and said as he walked away, "Then we have nothing to discuss."

Much of Section VI was written with your inevitable challenge at the back of my mind. Your image arose fleetingly as I composed Section V, but it was the composition of Section VI that more than once brought me back to thinking of you. (Maybe it was the big eye in Figure 5 that did it.)

When you have read the whole paper, like I have read your whole note, we can discuss.

31-03-10 *Erwin Schrolipsism* (to N. D. Mermin)

Merminition 194: *As one of the earliest people to accuse you of solipsism (do a search for the word in our correspondence, if you're well enough organized to do that — it was a very long time ago) and as one who understands how wrong-headed that was of me, I can only sympathize.*

Well you called Erwin Schrödinger a solipsist long before you called me one! That note dates from 25 January 2000:

> P.P.S. Have you seen a little book by Schrödinger called "My View of the World"? It contains two extended essays on the nature of objective reality, one in 1925 (before his Equation!) and one in 1960. They're surprisingly similar. They turn upside down the notion that objective reality is a valid inference from the fact of intersubjective agreement. He argues instead (I think) that intersubjective agreement is a manifestation of the unity of all consciousness, which is also what creates [the illusion of] objective reality. A kind of global mass-solipsism. But very beautifully put. Makes me think I should read Spinoza, which I never have done. So the IIQM is being tugged in one direction by QIP and quite another by goddamed mysticism. It's really delicious that Schrödinger is the hero of those who believe Bohr abandoned hard-headed rationality.

31-03-10 *I Knew He'd Just Call Me Solipsist Again, and he did, 2* (to N. D. Mermin)

Merminition 195: *On the other hand I'm sympathetic to Travis's complaint that you owe the world the critique you promised but never delivered on Bell's analysis of what counts as an explanation of correlations in distant places, that I commended to you in his essay on the new cooking (and in Bertlmann's Socks). I remember pressing Rüdiger on it when I visited him in London several years ago, and the best he could come up with was to shrug his shoulders and say something like, "Why should correlations have to have explanations?" I still regard the absence of a better rejoinder than that as the weakest point in our battle against the purveyors of nonlocality.*

The key issue is this: WHAT QUANTUM MECHANICS, AS A SINGLE-USER THEORY, IS TALKING ABOUT ARE NOT IN *DISTANT* PLACES. They ARE wherever the agent is whenever he performs the action (you'll see what I mean when you read Sections III and V). Of course, I am using William James's notion of 'the self':

> "In its widest possible sense, however, a man's self is the sum total of all that he can call his, not only his body and his psychic powers, but his clothes and his house, his wife and children, his ancestors and friends, his reputation and works, his lands and horses, and yacht and bank account."

But I'd never get you to write nice things about me in recommendation letters if I told the world the real source of all my ideas!

31-03-10 *Bell, Locality, Etc., 2* (to T. Norsen)

Norsenism 1: *Your point is fair and well taken. For what it's worth, I actually have skimmed the whole paper – that is to say, I was already aware that there was significant explicit discussion of the S-word in these later sections. But you're absolutely right that there's no point discussing it until I've read those sections fully and carefully. I'll be trying to get around to that in the next few days, and so I'll just let you know what I think afterwards.*

That said, though, and to try to explain further why I wrote what I did yesterday even before having read the whole paper carefully, let me say this: the subjective probability I assign to my coming to believe that your sections 5 and 6 address all of my concerns, is very low.

Don't think that I myself didn't already assign a subjective probability of nearly one to this proposition long before reading it this morning!

Travis's Reply

> I figured you did. More precisely, I assigned a subjective probability near one to the proposition that you did.
>
> By the way, despite really loathing your solipsism and even more the fact that you're in denial about it, I love and respect your openness and sense of humor.
>
> OK, maybe some serious discussion in a couple days …

31-03-10 *Truth and Happening* (to N. M. Boyd)

I'm looking forward to your seminar on "truth" that was just announced. Just to throw in a vote: I hope you will have the time to say a few words (pro or con) on the notion of truth in American pragmatism (particularly William James's and John Dewey's) and that this important notion from a century past will not get lost in the shuffle. Here's one of my favorite sentences of all time by William James:

> The truth of an idea is not a stagnant property inherent in it. Truth *happens* to an idea. It *becomes* true, is *made* true by events. Its verity *is* in fact an event, a process: the process namely of its verifying itself, its veri-*fication*. Its validity is the process of its valid-*ation*.

Attached is a page of something I wrote to Lee Smolin a few days ago in response to reading one of his drafts. [See 24-03-10 note "Notes on the Open Future" to L. Smolin.] It says a bit of why this notion of truth is important to me. The relevant discussion is between Smolinisms 9 and 10. It says that this notion of truth is important for making possible a certain kind of ontology. The reason that in turn is important to me is that it happens to be the kind ontology I myself am aiming for. If you have any interest in my motivations, you might skim the last three sections of my recent essay: [See "QBism, the Perimeter of Quantum Bayesianism," `arXiv:1003.5209v1`.]

As I say, looking forward to hearing some discussion on the important issue of "truth" at PI.

31-03-10 *Working Glossary* (to the QBies, R. Schack & N. D. Mermin)

I thought it'd be useful to update our group glossary. Please bring any omissions of words we have used before to my attention. Creativity is welcome as well; though I reserve final say on quality control. Particularly, I'd like a good word for myself or my role in this group. Matthew suggested QBoss or QBishop, but that feels a bit too aggrandizing for me to use as a description of myself—I need something a little more Chris-safe. (Of course, you can call me anything you want in private! Even QBastar. . . .)

Also it'd be a nice to find a grammatically correct nickname for Joan Vaccaro's painting *Broken Block* that I think illustrates so well the inevitable cracks in the block universe conception of things.

QBism – the quantum foundational program of quantum Bayesianism; see `http://arxiv.org/abs/1003.5209`.

QBist – a practitioner of QBism.

The QBies – C. A. Fuchs, along with his group of three grad students (Hoan Dang, Matthew Graydon, Gelo Tabia), PI associate postdoc Asa Ericsson, and PI visiting researcher Marcus Appleby.

QBism House – 49 George Street, Waterloo, Ontario; see attached "press release".

The QBibbo Angle – 60 degrees; see Assumption 7 and Equation 24 of `http://arxiv.org/abs/0912.4252`.

The QBicle – the office of the student QBies, PI room 415.

QBic Equation – the most important equation underlying the shape of quantum state space; see Equation 19 of `http://arxiv.org/abs/1001.0004` or Gelo's beautiful rendition of it in $d = 3$:

$$\sum_i p(i)^3 \;-\; 3 \sum_{(ijk)\in Q} p(i)p(j)p(k) \;=\; 0$$

where Q consists of all lines in the affine plane,

$$\begin{array}{ccc} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{array} \qquad \text{I.e.,} \qquad Q \;=\; \begin{array}{ccc} (123) & (456) & (789) \\ (147) & (258) & (369) \\ (159) & (267) & (348) \\ (168) & (249) & (357) \end{array}$$

QBissel – one who is intrigued by QBism but not yet convinced (compare German word "bissel").

QBicity – the quality or state of being properly oriented with respect to quantum interpretational issues (compare "cubicity" and "state of nirvana").

QBomancy – divination through quantum measurements (compare "cubomancy").

QBomancer – one who divines with the help of quantum measurement (compare "Raussendorf-Briegel model of quantum computation")

QBalla – ??

01-04-10 *Too Short an Answer* (to T. Norsen)

This is no answer to your nice note — I won't be able to do that for a few days. (I am not so quick as you.) But I want to try to make one point very tersely, in case it might open up some understanding. It is related to your Ballentine bullet.

With regard to the issue of quantum states (and probabilities) being "epistemic" (broadly construed), there are two points that must be addressed:

1. Are they? I.e., are they "epistemic" (broadly construed as "in your head rather than out there")? My stance, and Ballentine's (possibly, since he also will say things like "a hydrogen atom ground state is no one's degree of belief") and Einstein's and Peres's and Peierls's and Spekkens's (all to varying degrees of consistency), is that they are.

2. But epistemic about what? There is more than one possibility here, and that seems to be one of the things getting in the way of your seeing where I am coming from. The epistemic states could represent uncertainties about hidden/ontic variables completely external to the agent—that is the common story of Einstein's take on it, and it seems to me what Ballentine must be talking about implicitly. (Though as I say you never know about Ballentine.) It is definitely Rob Spekkens's desired interpretation of the epistemicity of quantum states. But it is not mine. My whole paper is about exploring a different view: That they are an agent's epistemic states for his own potential experiences *under the premise* that those experiences will arise as a consequence of his actions on ("interactions with" is too loaded of a term for me to want to use it here) the world external to him.

The imprint of the character of the external world (and the world as a whole, including the world before man)—this is an idea that approaches your definition of "metaphysical realism"—does find its way into the formalism (in my view), but when it does it does so as an additional normative rule for the agent's gambling attitudes on those potential experiences. Where "normative rule" does not mean that one must adopt this or this or this *particular* probability assignment, but that one should try to make all of one's gambling attitudes (for all kinds of things) mesh together according to a certain scheme. In the case of quantum phenomena (when made explicit with SIC language), the Born Rule is seen as a normative rule for meshing together beliefs between "a one-step factual measurement" and "a two-step counterfactual one."

I'll leave it at that for now, and just ask that you mentally readdress your questions, issues, and reading of the paper with distinction number 2 at the forefront of your mind. It is the predominant thing that sets QBism apart from the "epistemic-state, ontic-variable program." And it is underneath everything I say about the locality issue: For the quantum state, on this view, is only calibrated to what the agent believes he himself will experience (which in common language one might say as "happens in his vicinity").

I'll come back to your many other issues at the end of Easter.

I'll cc this note to Rob Spekkens since I impute a definite statement onto him, and he may disagree. (I'd cc it to Einstein, Peierls, and Peres too, but they're dead.)

01-04-10 *Strange Anton Dream* (to A. Zeilinger & H. C. von Baeyer)

Since H. C. von Baeyer is convincing me more of the importance of dreams, I'll record this one from the night before last. You (Anton) were visiting Waterloo, and I had had some house work done a week or so before your visit. There was a fresh concrete sidewalk laid and some concrete steps leading up to my house. The concrete was dry and hard—it was already a week old. When you arrived at my house, there was some melting snow on the ground; the new sidewalk was a bit wet. We started discussing matters quantum mechanical on my porch, or maybe at my chalkboard at the wall. I told you that there is some pattern you must understand—it was a very important thing. The pattern was apparently on a piece of paper or a leaf, or "both" if you can figure out what that means. (I have conflicting images of both.) But the wind had blown it away. I walked into my yard looking for it in the snow, but finally found it wet and crumbling on the new sidewalk.

I knew that it could not be recovered without destroying it if I tried to peel it from the sidewalk. I became very sad at the loss, and I tried to peel it anyway. It did indeed tear into a hundred pieces, or was a bit like oatmeal as I tried to pull it up. But to my astonishment the pattern had been transferred into the concrete—the concrete now had etchings and lines and bumps. And it was a bit surreal even; I seemed to be able to see it more clearly now than I could before. I said, "Anton, Anton, you must see this!" You walked over and we studied it very carefully, more excited about the transference than about the original pattern that I had thought was so important. Then I looked up and down the sidewalk and steps and found all sorts of other things recorded in it. For instance, on one of the steps, there was a very deep footprint (I think yours) showing every detail of the underside of your shoe. I thought, "But this is finished concrete; how can this be?" And what struck me again, was the surreality of it: The edges were extremely crisp, almost as if the shoe had been pressed into a kind of plastic. I thought, this is so much like the *Magic Eye* books, where when the 3D image finally becomes visible it is always strangely crisper and clearer than it should be.

And that is all I remember. (See `http://en.wikipedia.org/wiki/Magic_Eye` if you don't know what I mean by the *Magic Eye* books.) Of course, I have no real idea what it means (if anything), but I wonder if it is not connected to an excited note I wrote to my colleagues a couple weeks about about the SIC problem. I'll append part of that below for completeness.

On a not unrelated matter: Did you ever make contact with Karl von Meyenn about the funding issue? I continue to worry that Pauli's work on dreams and alchemy will be lost forever to the broader audience if von Meyenn does not complete his project.

01-04-09 *Beyond QT?* (to M. A. Graydon)

Graydonism 2: *I've been thinking harder these days about more conceptual issues (must be the hot weather), and I wonder if you might agree with the following:*

The reality underlying quantum theory consists of systems, and those systems are defined exclusively by a single, objective, ontic property denoted by D. Of course, the QBist need not posit that the whole of physical reality may be described in these terms, for the QBist is primarily concerned with an interpretation of the quantum theory. In QBism, there are no mathematical symbols in the quantum formalism that point to any other ontic property other than D. In particular, the quantum state represents one subjective agent's degrees of belief regarding the outcomes of future measurement interactions with an objectively existent external physical system. An 'agent' is one in the world who may identify systems, contemplate their dynamics, and participate in measurement interactions. A 'measurement interaction' involves an agent and a system. Operationally speaking, the agent passes the system through some measuring device and learns that one of n outcomes has occurred. But then it seems that, at least for the QBist — measurement interactions cannot change the (quantum) ontic nature of the system, for the system's only property is D. Would you agree? Must we remove the '(quantum)' and look for a deeper theory?

Pretty darned good summary. I was with you all the way until the last two sentences. I think my best reply is to suggest re-reading Section VI in my recent long paper "QBism, the Perimeter ..." on `arXiv.org` now. I think you'll see in that how your last two sentences contradict what I'm thinking. I'm prepared to think that quantum measurements (like any human action) change the world in a very deep way. I'll send you some supplementary material in a minute, but do reread Section 6 (and 7 and 8 as well).

01-04-10 *Explanatory Note* (to M. A. Graydon)

"More to Read x" where $x = 1, 2, 3, 4$. They're all about how "measurement" changes the world. Happy Easter!

I was just reading your note again before filing it. [See 01-04-09 note "Beyond QT?" to M. A. Graydon.] Part of me wants to say "broader" is a better term. But I do get where you're coming from in the last question. Absolutely, there must be a "next step" in physics. My own favorite dream is that whatever "quantum measurement" is, the world is made of it—it was a dream instilled in me by John Wheeler long ago. QBism, as it presently exists, has for me always been preparatory work for getting at that deeper question. (There, I used "deeper" myself.) John's sense was that quantum measurement has more to do with all kinds of things than many imagine (for instance, "the big bang").

So, getting back to D. I view it as a quantitative measure of "one aspect" of everything. But what is that aspect? That's the broad question we're gearing up to with QBism. The aspect I think has to do with is "whatever quantum measurement is."

02-04-10 *More to Read 5* (to M. A. Graydon)

[See 01-04-10 note "Strange Anton Dream" to A. Zeilinger and H. C. von Baeyer.] Here is my interpretation at the moment. That the urgleichung is the "imprint" in the concrete (world), and that QM and SICs were the original "pattern" that I was trying to tell Anton about. The imprint is surreally crisper than the original.

02-04-10 *The Quantum Bayesian Glossary – Some Updates* (to N. D. Mermin and R. Schack)

Boys, it's just like the old days! Remember when we put so much effort into constructing:

Mechanica Quantica Lex Cogitationis Est

Makes me feel young again!

02-04-10 *The Friday Philosopher* (to Å. Ericsson)

I'm sorry: It's turned out to be such a pleasant day outside, that I think I'll just stay home. In fact, just a little while ago, I wrote Max Schlosshauer the lines below.

It's funny, earlier today I was thinking I would ask you if would be interested in going to see *Clash of the Titans* with me at the 1:30. (I figured you wouldn't be so interested—none of my girls were—but I thought it'd be worth a shot.) Then I went outside for breakfast, and it was just so pleasant, it rearranged my whole mentality.

If you want a reading suggestion, for something to print out and take under a tree, here's what I'm dipping into from time to time today (I've already told you about it before):

http://en.wikisource.org/wiki/Personal_Idealism/Axioms_as_Postulates.

02-04-10 *Congratulations!* (to J. Emerson)

Emersonia 4: *Thought you might be happy to hear, Quantum Bayesianism won the vote in class today for "favorite interpretation"! Well done! PS: Many worlds got zero votes... So the tides may be turning!*

That is great news! What were the other interpretations on the table? And what was the margin? Definitely let's get some beer Wednesday.

02-04-10 *Congratulations!, 2* (to the QBies)

Joseph Emerson just wrote me this:

Emersonia 5: *Thought you might be happy to hear, Quantum Bayesianism won the vote in class today for "favorite interpretation"! Well done! PS: Many worlds got zero votes... So the tides may be turning!*

Those of you in the class, tell me more about this! Was there much of a margin or was it slim? What were the other interpretations on the table?

Hoan's Reply

QBism got 8 most-favorite votes and 3 least-favorite votes, resulting in +5 (we could have got +6 had Gelo had not to leave for Europe).

If I remember right, ensemble and operationalism both got +4. Many-worlds got -9, Bohmian mechanics got -3.

There were totally 8 or 9 interpretations on the table, but some of those we never studied carefully so most of the people didn't vote on those.

02-04-10 *Congratulations!, 3* (to the QBies)

Who voted "least favourite" for QBism. Do you know the names of anyone? I won't throw eggs at their houses: I'm just curious. It'd be interesting to learn their reasons.

Hoan's Reply

I think they were all undergrads, but I didn't recognize them. One thing I remember is that when they raised their hands to vote QBism as the least favorite, one other undergrad (who voted most favorite for QBism) shouted out "come on, it's not solipsism!"

03-04-10 *The Quantum Bayesian Glossary – Some Updates, 2* (to M. Schlosshauer)

Schlosshauerism 22: *Q'ran (noun) – the Holiest of Holy Scriptures telling the story of QBism from the ground up. (This is of course nothing but a thinly veiled attempt at letting the idea of a book on QBism resurface. Honestly, I've been thinking about writing something, sometime. But it remains a ridiculously vague plan for now.)*

Now, that's an idea I like! You do the writing, and I'll do the praising! I say, find a way to make it a less vague plan! One of my own troubles is that I don't know where the ground is yet. Also, I don't have the broad perspective that you do: I've been a QBist-in-the-making since the beginning, with all kinds of petty prejudices against other directions since the beginning. With honesty, I know that I've never given most of the other foundational programs a fair shake. What the program really needs is someone who can give it a reasonably careful comparison to the other extant programs. Someone too who can more detachedly discuss QBism's weaknesses.

And I'm getting good at "praising." I wrote something for the back of Schumacher and Westmoreland's new book. And I just wrote this a few days ago for the Nielson and Chuang's 10th anniversary edition:

> Nearly every child who has read Harry Potter believes that if you just say the right thing or do the right thing, you can coerce matter to do something fantastic. But what adult would believe it? Until quantum computation and quantum information came along in the early 1990s, nearly none. The quantum computer is the Philosopher's Stone of our century, and Nielsen and Chuang is our basic book of incantations. Ten years have passed since its publication, and it is as basic to the field as it ever was. Matter will do wonderful things if asked to, but we must first understand its language. No book written since (there was no before) does the job of teaching the language of quantum theory's possibilities like Nielsen and Chuang's.

Don't know whether the editor will let me keep it in this form (or make me make it more technical), but anyway, just imagine what'd I'd write for you!

As far as the glossary term Q'ran goes, though, I know you've recognized that it breaks the B rule. QBie's already taken (that's what I call my group members.) And QBest was sweet, but David Mermin already beat you out:

> QBlue – a fanatical, unshakeable QBist; codename for C. A. Fuchs.

I'll think about QBitter. How about this variation:

> QBitter – despair experienced by a QBist every time he is called a solipsist (again!); not to be confused with QBiteer (see next term).

03-04-10 *QBar!* (to M. Schlosshauer)

Schlosshauerism 23: *Here's another one:*

> QBar (or QBa/QBah) – the cocktail lounge at QBism house, serving exclusively mix drinks from Havana and the rest of the forbidden island.

Oh, bad, bad, bad. I stop now.

OK, that was bad! But it did inspire me to think that we need a LaTeX symbol `\qbar`, analogous to `\hbar`. It is QBism's version of Bohr's "finite quantum of action." I'm thinking here of the value `\qbar=2` for Eq. 12 (and discussion following) in the new paper. Appleby when he writes a lower-case `q` vector on the chalk board, always puts a line through the tail. That's the sort of thing I'm imagining. The value `\qbar=2` corresponds to 60 degrees for the QBibbo angle.

Thanks! I wanted to respond to your science of philosophy note, but I finally got into my hotel room and am getting a bit sleepy. It might wait until after a nap, i.e., you'll have some morning reading. (The family is in Buffalo today and Niagara tomorrow, and while the girls have been out shopping, I've been working in the hotel lobby. We're having the Easter egg hunt in the hotel room tomorrow morning.)

03-04-10 *Philosophys* (to M. Schlosshauer)

Schlosshauerism 24: *Namely, have* you *ever considered crossing over to a philosophy department?*

Too many times. But the philosophers never wanted me.

John Preskill and I once worked to get Caltech to make a joint physics/philosophy position for me through a very broad "information department" initiative. Attached are my proposals for that. [See 12-02-04 note "The House Philosopher" to J. Preskill and H. Mabuchi.]

Now a nap. More later on how at times, I have actually gotten something from the philosophers. I exaggerated a bit in that sentence you quoted. (And I should be careful before samizdatizing it.)

03-04-10 *The Science of Philosophy – 2* (to M. Schlosshauer)

Now to this:

Schlosshauerism 25: *It was a nice coincidence that you again appended your note "Conceptual Barrier!" to your email. After reading it the last time, I was struck by these words of yours: "I have many times said that I have never once gotten anything of any value from a philosopher of science ..."*

I'm glad you did mention Arthur Fine's name, because it reminded me that there are many ways to get "something of value" from people. And from Arthur, I got quite a lot from his historical work on Einstein and Schrödinger. A lot of *The Shaky Game* was quite good for me.

Also his "Do Correlations Need to Be Explained?" (or a similar title) gave lots of food for thought for me, particularly with his discussion of "the hidden hand." Did I ever recommend Bruno de Finetti's "Probabilismo" to you? He has a lovely discussion on this: Suppose you make a probability-nearly-one assignment and then upon looking at the event you find that it did indeed happen. Do you then have the right to be surprised? Do you then have the right to declare that the fact of the outcome actually occurring was a great mystery, needing more explanation than it already had? Well, "correlation" is just a two-variable version of that, and Arthur came so close to the point. If he hadn't gotten confused with frequentism, he would have had it. So, looking back, I should recognize that he likely planted a seed in my mind that would help me better appreciate de Finetti when that later time came.

Also, I remember reading Richard Rorty say that Arthur Fine was his favorite philosopher of science. And that means something to me. I have gotten so much from reading Richard Rorty. If there are some confluences in their thoughts, then more familiarity with Fine might do me some good.

Another example is Bas van Fraassen. There's been very little I've gotten from him, and for instance, when I sat in his seminar with Halvorson on the philosophy of quantum information, I thought both of them so amazingly confused and far from clear thinking that I wondered how they could be bestowed with the credential of "philosopher" in the first place. *But* Bas's "reflection principle" within probability theory is a *golden nugget*. It has turned out to be the key to a QBist's understanding of why everyone *thinks* (i.e., gets confused) that decoherence *precedes* the registration of a measurement outcome (and thus seeks out detailed measurement models to make that turn out to be the case). Decoherence as a *physical process* does not precede registration: It is only the agent "reflecting" in van Fraassen's sense that causes him to gamble *as if* it had been so. And if *Ruediger* and I ever write this up, we will owe Bas an immense intellectual debt.

Finally, there is no doubt that Jeff Bub, Bill Demopoulos, Richard Healey, Wayne Myrvold, Huw Price, Allen Stairs, and Chris Timpson have provided a kind of tension in my conversations with them that I have found extremely useful for organizing my thoughts.

So now I qualify myself, I should never say "never once gotten anything of any value from a philosopher of science."

06-04-10 *In Reverse* (to M. Schlosshauer & H. C. von Baeyer)

I'll send this to Hans Christian too.

We're back home today, and I've really got to kick in the work the next nine days. But I want to first record an experience that quite knocked me for a loop yesterday. It has to do with your remark [concerning my 01-04-10 note to A. Zeilinger and H. C. von Baeyer titled, "Strange Anton Dream"]:

Schlosshauerism 26: *That's an impressively surreal dream you've had there! I'm also flabbergasted at the amount of detail you could remember.*

Sometimes I get a little too close to dreams. And vice versa. I'll try to make the story short and simple; I suspect nothing I write will convey the impact those few minutes had on me.

It was yesterday, early afternoon and we had been walking around the cheesy part of Niagara for a couple of hours—that is, the amusement-park looking area, with wax museums, haunted houses, a Harley-Davidson memorabilia shop, etc. We started by taking a ride on the big Ferris wheel, letting the girls buy a couple of postcards, and ended with a walk through a park closer to the Falls. When it was time to go, we trudged back up the hill toward where our mini-van was parked. I remember well holding Emma's hand for about the last block of the walk, and just as we neared the car I gave it a firm squeeze before letting go. Kiki said with a bit of triumph, "All right, we're back." The kids went straight to the car door on the sidewalk side, and I went to the street side of the car to get into the driver's seat. Nothing out of the ordinary you would say.

There was a bit of traffic, so I waited for a second to open the door. I did note to myself, "Funny that Kiki didn't unlock the door with the clicker. I guess she had left it in the car." I inserted the key, used the button to unlock everyone else's doors, and looked up. There was no one with me! No one behind the car, no one near it, and all of this happened within the small flash of a second. Everyone was gone. I walked back onto the sidewalk, and looked into four nearby store fronts—no sight of them. I can't describe the feeling of how disorienting this was. I even came to the car to look in and see if I hadn't missed them somehow. It was an absolutely strange experience. I thought to myself, "Have I been living in a dream for months? Was this happy family life and all of today just a dream? Could it be that Kiki left me long ago, and I've been living on my own and out of my head?" I was in shock. I looked down at my clothes and thought, "They look clean, not like the clothes of a transient." I looked in all the stores again, this time more thoroughly, and nothing. My mind kept coming back to the image of the firm squeeze I had given Emma just before we parted—I remembered it vividly. I had this really palpable fear that I had been living a dream and just become conscious. I started to look for some evidence of the reality of my life. I went into the shade under an awning and pulled out my digital camera. To my great relief, there were images of the morning. Still I waited a lifetime—or so it felt—and they never came. The fear kept nagging me.

Finally I went back into a store and started to pull out my digital camera as I asked a lady at the front, "Have you seen a woman in a blue coat with two young girls in the last few minutes?" She said, "No, but you might check downstairs; sometimes I don't pay attention to everyone coming and going." Sure enough, just as I turned to the stairs, Kiki and the kids emerged from the lower floor. I nearly cried with relief, and it took me much of the time driving home to completely recover.

With hindsight, what I find most interesting about this is the question of why my mind was so susceptible to the theory that I might have just become conscious from a dream. There is a little bit of a cheap answer in that we had just watched the movie *50 First Dates* with Drew Barrymore and Adam Sandler two nights before. It is the story of a man who romances a woman that had suffered a head injury: Each night when she falls asleep, her short term memory disappears. Each day he must romance her again, and eventually, with the help of a growing video montage, becomes her memory. They marry, and in the last scene of the movie, he introduces her to their 10 year-old daughter. It was a cute movie and must have been in the recesses of my mind. Also there is another Hollywood precedent in my mind, a movie I saw 21 years ago: *Dad* starring Jack Lemmon, Ted Danson, and Olympia Dukakis. Lemmon had two completely separate lives that he had been sustaining for years—one in a dream, and one in the real world, and only when he became quite ill did he realize that there were these two separate lives and he was one person. The memory of that movie flashed through my mind yesterday as well.

But neither of these thoughts feel like they go deep enough to explain my susceptibility. It's absolutely freaky that I "freaked out" to the extent described above. So, I record the story here with you two because you have been involved in my dream thoughts lately (in all kinds of ways), and I continue to think about what this might mean in the wider context.

06-04-10 *QBism Glossary* (to the QBies and Other Friends)

The long awaited QBism Glossary is near completion. If you have any suggestions for improvement, or any terms so good that they'd knock some of the existing ones off the page, now's your time to speak up: I will finalize and post on my door soon.

I'm not all that happy with the look of the present QBar. Better might be to have a q with an extended tail and a bar through it, but I couldn't figure out how to do that with LaTeX. If anyone has any ideas on how to improve the symbol, please say so.

Luca Mana's Reply

There could also be QBismillah, from bismillah … Good for quantum fundamentalists.

06-04-10 *QBism Glossary* (to M. Schlosshauer)

Schlosshauerism 27: *Love it!*

And thanks for the credit – which I don't even deserve, since it looks like none of my suggestions made the cut anyway. (Which is absolutely fine I hasten to add: I wasn't too electrified myself about my submissions.)

That is not true: You directly inspired QBar. One of the most important concepts in the whole list. Attached is Åsa's variant: When blown up like this, it's beautiful:

$$\underline{q}$$

Unfortunately it doesn't work so well in small font.

07-04-10 *Paper and Glossary* (to D. B. L. Baker)

I never did send you a final version of the paper. You might enjoy the obscenities in the closing paragraphs of Section VIII. [See "QBism, the Perimeter of Quantum Bayesianism," `arXiv:1003.5209v1`.] (It starts with "mount" and goes downhill from there.) More than that though, you might enjoy the further glossary of terms, fresh off the keyboard this morning.

07-04-10 *SICs, Counterfactuals, and Other Stuff* (to O. Cohen)

Cohenism 1: *Secondly, I wanted to mention that I have been following your recent work on Quantum Bayesianism with interest. I think that the SIC structure is very elegant and compelling. I am still digesting the longer of your two recent postings on* `quant-ph`*, and may get back to you in due course with some comments, if that's OK with you. Your formulation in terms of counterfactual vs actual measurements is of particular interest to me right now as . . .*

Thirdly, I have been drafting up some recent musings of mine, which were triggered after re-visiting some of Bell's papers. I have been mainly concerned with looking at Bell/CHSH from a different perspective, which focuses on the actual vs counterfactual relationship when viewed from a local perspective. I think there may be a connection with your formulation, though I haven't had time to explore this yet. I am attaching a draft of my paper, which I am thinking of posting on `quant-ph`*, though I am a bit tentative as it's possible that what I have done is trivial and/or nonsense. If you are able to give any comments or feedback, that would be great and I would really value your opinion. But if you are too busy to spend time looking at the work of amateurs like me, that's also fine and I fully understand!*

Well, I certainly like this line in your paper, "By exploring possibilities such as this, as a means to unravel Bell's theorem, we are moving the focus away from locality and on to counterfactuals." I've only skimmed your paper just a little, but that philosophical or programmatic position seems to be on the right track to me.

Hopefully I'll get a chance to look at your paper in seriousness in a couple of weeks, after I get some grant proposal things cleared off my desk. Also, I hope you don't mind, but I'm going to encourage Howard Barnum, our seminar chair, to invite you to give us a talk on the subject.

07-04-10 *Templeton* (to H. Price)

Pricey Quote 3: *Dean and I are putting together a proposal for the Templeton Foundation, to try to get money for a series of three conferences (and a postdoc). One of them is intended to be a "motivations for thinking that physics needs a flow of time" meeting. You'll see the general line, in the attached printout of our draft from their online application page. Can we list your name, as one of our intended participants/collaborators?*

Absolutely. Thanks: It's nice to be called, even if implicitly, one of "the world's leading philosophers and physicists of time." You might consider Lee Smolin as well, since he now writes things like,

> This provides further motivation for believing in the reality of time and the openness of the future. If the selection of the laws of nature that determine what elementary particles exist and how they interact is a result of evolution analogous to natural selection, then there must be a time that this evolution plays out in. And it must be a time that exists prior to the laws, for the laws must have scope to evolve in time.

It would seem the meeting you wish me to play a role in has a little bit to do with this gem of a book I found in Portland: *Incompatibilism's Allure*, `http://metapsychology.mentalhelp.net/poc/view_doc.php?type=book&id=4752`. Just what is this allure of Chris and others to something *you* cannot even formulate a meaning for? ☺

Anyway, maybe we'll get a chance to play north and south pole within the Templeton Foundation. Rüdiger Schack are at the moment writing a proposal, "That the World Can Be Shaped: Quantum Mechanics, Counterfactuality, and Free Will" and you know me well enough to guess where that's going!

07-04-10 *Yet Another Workshop* (to Č. Brukner)

Unfortunately I think it is going to be almost impossible for me to attend this, as I must be at QCMC in Brisbane, and its dates are July 19-23.

This is really sad, because you know your meeting's topic is much closer to my heart! To your title question, you would do me honor to read one paragraph from my paper in one of the discussions.

"What exists in the quantum world?" Tell them, "Everything!" and read:

> Physics—in the right mindset—is not about identifying the bricks with which nature is made, but about identifying what is *common to* the largest range of phenomena it can get its hands on. The idea is not difficult once one gets used to thinking in these terms. Carbon? The old answer would go that it is *nothing but* a building block that combines with other elements according to the following rules, blah, blah, blah. The new answer is that carbon is a *characteristic* common to diamonds, pencil leads, deoxyribonucleic acid, burnt pancakes, the space between stars, the emissions of Ford pick-up trucks, and so on—the list is as unending as the world is itself. For, carbon is also a characteristic common to this diamond and this diamond and this diamond and this. But a flawless diamond and a purified zirconium crystal, no matter how carefully crafted, have no such characteristic in common: Carbon is not a *universal* characteristic of all phenomena. The aim of physics is to find characteristics that apply to as much of the world in its varied fullness as possible. However, those common characteristics are hardly what the world is made of—the world instead is made of this and this and this. The world is constructed of every particular there is and every way of carving up every particular there is.

If you were to say that, it'd be like my being at the meeting anyway! For, in spilling those I would already exhaust all my thoughts up to this date! (Though I miss a chance to learn from all of you.)

07-04-10 *Is the Compromise Worth It?* (to N. D. Mermin)

Waking up in the middle of the night, I'm torn worse than earlier. Åsa wrote me this,

> Mermin's comment makes sense for someone with a broad knowledge. But I believe your response is correct. When it comes to understanding these words I don't think I am much worse than many others at PI. The glossary looks good now. With footnotes it will likely look cluttered. To make the 'Compare "____"' not stick out as much, I suggest you use 'cf. ____', perhaps in parentheses or with ; before instead of starting a

new sentence (but this is perhaps incorrect, I don't know rules for semi-colon). The "
can be taken away if the words are italicized instead.

My gut feeling is that she's more right for the common folk and that your opinion, though more pure (and godlike for it, I emphasize), will lose me too much of an audience.

Your QBit was different. The QB here is to emphasize "Quantum Bayesian" and the two letters come as a package. Moreover, you were fighting the long usage of qubit. In contrast, before QBism there was no QBism!

Of course, you are right about "consistency." If I had not been driven by insane consistency, I would not have arrived at QBism as it presently stands. I would rather have ended at a sort of ugly halfway house, like Peres and Ballentine did, each in their own way. Thus, if I were to revert, I should give QBlue a "compare" as well.

Well, I will try to go back to sleep in spite of these deep troubles, and hope that a solution comes in the morning.

07-04-10 *Up Front* (to Å. Ericsson, N. D. Mermin, and R. Schack)

My three most trusted consultants,

I think the attached is my own favorite version: I decided to put the cognate words right up front. In my mind that somehow diffuses David's criticism . . . but I don't know, he might find it even more annoying now. I'll listen to all your opinions carefully. Clearly this is something I want to get right!

Glossary of Quantum Bayesianism

(with contributions from the QBies, Kiki Fuchs, N. David Mermin, Rüdiger Schack, and Maximilian Schlosshauer)

QBism – the quantum foundational program of quantum Bayesianism; see "QBism, the Perimeter of Quantum Bayesianism," `arXiv.org:1003.5209v1`.

QBist – adjectival form of QBism and a practitioner thereof.

QBlue – cf. *true blue*; a fanatical, unshakeable QBist; codename for C. A. Fuchs.

QBies – everyone supported by ONR grant N00014-09-1-0247: QBlue, along with graduate students Hoan Dang, Matthew Graydon, and Gelo Tabia, PI associate postdoc Åsa Ericsson, and PI visiting researcher Marcus Appleby.

QBism House – 49 George Street, Waterloo, Ontario, "where the ghosts of pragmatist philosophers past listen to how their ideas of an unfinished, malleable world take a more exact form with the help of quantum theory."

QBicle – cf. *cubicle*; the office of the student QBies, PI room 415.

QBuki – cf. *kabuki*; the theater of the QBies' weekly group meeting outside PI office 355, Fridays 1:00–3:00 PM.

QBicity – cf. *cubicity*; the state of being properly oriented on quantum interpretational issues. "Along with nirvana, one should strive for QBicity."

QBar – the QBist's *elementary quantum of action*, $\underline{q} = 2$. When $q = \underline{q}$, the generalized urgleichung

$$Q(D_j) = \left(\frac{1}{2}qd + 1\right) \sum_i P(H_i) P(D_j|H_i) - \frac{1}{2}q$$

becomes the usual Born Rule if SICs exist.

QBibbo Angle – cf. *Cabibbo angle*; maximum angle $\theta_{\rm QB}$ between quantum states in a QBist representation. See Assump. 7 and Eq. (24) of "A Quantum-Bayesian Route to Quantum-State Space," `arXiv.org:0912.4252v1`,

$$\cos\theta_{\rm QB} = \frac{q}{q+2} \ .$$

When $q = \underline{q}$, $\theta_{\rm QB} = 60$ degrees.

QBissel – cf. Bavarian *bissel* and *N. D. Mermin*; one who is intrigued by QBism but not yet convinced.

QBisl – cf. Yiddish *bisl*; one who is intrigued by QBism but is too busy studying the Talmud to give it the time it requires.

QBitz – cf. *kibitz*; a common social interaction between a QBist and a QBissel—QBist as the QBitzer of course.

QBic Equation – most important equation underlying the shape of quantum state space; see Eq. (19) in "The Lie Algebraic Significance of Symmetric Informationally Complete Measurements," `arXiv.org:1001.0004v1`,

$$\frac{d}{2} \sum_{ijk} R_{ijk}\, p(i) p(j) p(k) = \frac{d+7}{(d+1)^3} \ .$$

QBomancy – cf. *cubomancy*; divination through quantum measurements, as with the Raussendorf-Briegel model of quantum computation.

QBosh – cf. *kibosh*; rare moment when a QBist, by force of argument, gets the holder of an alternative quantum interpretation to flinch. *Inside the Perimeter* headline: "QBist Puts the QBosh on Visiting Everettian!"

QBlah – cf. Islamic *kiblah*; the direction QBists face when contemplating the beauty of SICs—inward!

QBalah – cf. *kabalah*; mystical practice of demanding SICs to exist in all dimensions, or, if mathematics won't yield, that quantum mechanics be scrapped in favor of "urgleichung mechanics." See "Quantum-Bayesian Coherence," `arXiv:0906.2187v1`.

07-04-10 *Finished Product* (to J. Rau)

Rau-ism 2: *Many thanks! I really enjoy the wit and clarity with which you expose your scientific and philosophical point of view. I was wondering, actually (and asked this question to Rüdiger who didn't know the answer) whether your acronym QBism was intentionally close to cubism, and whether you would like to become the Picasso of quantum mechanics?* ☺

Thanks for the papers. On your questions, I have quite wondered how I might use an association with cubism to further my agenda, but so far I have fallen short. On the other hand, you might enjoy a few of the other words in the QBism Glossary. See attached.

07-04-10 *Mid Conversation Frustration* (to T. Norsen)

Norsenism 2: *Anyway, running with the photocopy metaphor, I see our dispute this way. We both look at something and agree: this is definitely a photocopy. I say "there's got to be an original somewhere, let's start working on finding it". You say, "ah, but maybe this photocopy is only a copy of another photocopy, in which case we don't have to talk any longer about originals and all the genuinely foundational issues (though not some interesting technical ones) evaporate."*

I know that you like to think that you are a careful reader, but all the evidence I have ever gathered from interacting with you shows that the thing you read best is your own mind.

If we had agreed, why would I have written these (unnoticed?) lines in the paper?

> A fairer-minded assessment is that the accusation springs from our opponents "hearing" much of what we do say, but interpreting it in terms drawn from a particular conception of what physical theories *always ought to be*: Attempts to directly represent (map, picture, copy, correspond to, correlate with) the *universe* ...
>
> Quantum Bayesianism sidesteps the poisoned dart, as the previous sections have tried to convey, by asserting that quantum theory is just not a physical theory in the sense the accusers want it to be. Rather it is an addition to personal, Bayesian, normative probability theory. Its normative rules for connecting probabilities (personal judgments) were developed in light of the *character of the world*, but there is no sense in which the quantum state itself represents (pictures, copies, corresponds to, correlates with) a part or a whole of the external world, much less a world that *just is*. In fact the very character of the theory seems to point to the inadequacy of the representationalist program when attempted on the particular world we live in.

Part of me sometimes wants to say, "Oh, why don't you stop talking so much, and just go out and find an equation that someone will believe?"

But I hope my frustration will eventually wane, and I'll get back to "fairer-minded assessment" mode. Maybe indeed much does depend on what you mean by the phrase "physical world out there independent of us." As I read you, if I don't mean by the phrase *exactly* what you mean, then the view *must* collapse into a belief in no external world at all. It's probably a useful strategy for starting a church, but it's a waste of your time (trying to straighten me out) if your aim really is to find a bigger, better equation that will pass the tests of other physicists' notice. (If you're not worried about it passing the test of other practitioners finding it useful in some way, then you're the solipsist, not me.)

What is the thing you truly want to accomplish in life? And are your energies really turned to it?

07-04-10 *And After a Deep Breath* (to T. Norsen)

More nicely,

That the external world is at times resistant to my actions upon it, and participating in the consequences of my actions upon it, is enough of a notion of "independence" for me. It is a view that gives both conceptual players (agent and world) an autonomy that doesn't take away from the other's. Indeed, I suspect that this is not what you mean by "physical world out there independent of us." Rather what I can tell of your view is that the world underneath us acts upon us insofar as we are part of its great cog, but that there is no meaningful reciprocity (for we are parts, and it is the whole). This is the kind of thing I call "monism" in the paper, in distinction to "pluralism." Solipsism, as far as I can tell, is a monism, just a monism at the other end of speaking: for, the agent is now the whole, rather than a part.

If you want some philosophical literature to rip into, I would suggest this paper by F. C. S. Schiller: `http://en.wikisource.org/wiki/Personal_Idealism/Axioms_as_Postulates`

Calmer wishes,

07-04-10 *Second Deep Breath* (to T. Norsen)

This is an example of what I find so frustrating in trying to discuss things with you. My paper says this:

> The metaphysics of empiricism can be put like this. Everything experienced, everything experienceable has no less an ontological status than anything else. You tell me of your experience, and I will say it is real, even a distinguished part of reality. A child awakens in the middle of the night frightened that there is a monster under her bed, one soon to reach up and steal her arm—that *we-would-call-imaginary* experience has no less a hold on onticity than a Higgs-boson detection event would if it were to occur at the fully operational LHC. They are of equal status from this point of view—they are equal elements in the filling out and making of reality. This is because the world of the empiricist is not a sparse world like the world of Democritus (*nothing but* atom and void) or Einstein (*nothing but* unchanging spacetime manifold equipped with this or that field), but a world overflowingly full of variety—a world whose details are beyond anything grammatical (rule-bound) expression can articulate.

And then it goes on, I think rather clearly and carefully, to say that "dimension" is a numerical *quality* common to all pieces of the physical world, first prefacing it with

> Physics—in the right mindset—is not about identifying the bricks with which nature is made, but about identifying what is *common to* the largest range of phenomena it can get its hands on. The idea is not difficult once one gets used to thinking in these terms. Carbon? The old answer would go that it is *nothing but* a building block that combines with other elements according to the following rules, blah, blah, blah. The new answer is that carbon is a *characteristic* common to diamonds, pencil leads, deoxyribonucleic acid, burnt pancakes, the space between stars, the emissions of Ford pick-up trucks, and so on—the list is as unending as the world is itself. For, carbon is also a characteristic common to this diamond and this diamond and this diamond and this. But a flawless diamond and a purified zirconium crystal, no matter how carefully crafted, have no such characteristic in common: Carbon is not a *universal* characteristic of all phenomena. The aim of physics is to find characteristics that apply to as much of the world in its

> varied fullness as possible. However, those common characteristics are hardly what the world is made of—the world instead is made of this and this and this. The world is constructed of every particular there is and every way of carving up every particular there is.

And yet you say,

Norsenism 3: *you* claim *to believe in reality (and say some things always at the end about how maybe at the end of the day we'll learn about the dimension of the hilbert space of some system, which you take to be as far as I can tell the one-and-only external fact that exists or that we might get access to in the near future, etc.), . . .*

Where in THIS paper did it say that dimension is the one-and-only external fact? Two objects have *this* quality; five objects have *another* one. But dimension is something that they all seemingly have—it is a quality, and I would say the only one that quantum theory identifies. But I was not born with this answer in my head; I have been working the idea out slowly, and this paper represents the present status of formulation. What you write above may refer to an inarticulate way in my previous expression from the 2002 paper, but I thought the issue at hand was what is in this paper.

07-04-10 *Me, Me, Me Again!* (to N. D. Mermin)

You always delight me!

Merminition 196: *14R. I was surprised to read that "quantum measurement outcomes" are personal. I had thought the probabilities of those outcomes were personal. I will peruse the earlier sections to see if you really meant this. It sounds (ahem) like solipsism.*

It goes back *at least* to the attached note to YOU (and Rüdiger) in 2003 [titled "Me, Me, Me" and dated 12-08-03], and the idea has been in every one of my papers since then!

Here is the way I put it to Norsen in yet the latest attempt to get at the two-level personalism of QBism. [See 01-04-10 note "Too Short an Answer" to T. Norsen.] (He in his oh-so-careful reading didn't even notice the personal bit, and couldn't figure out the distinction between Ballentine and me. At least you noticed it!) *Even* Einstein recognized that the probability statements of QM might refer to "personal outcomes"—that was the reason for that very long quote!

07-04-10 *LNC Section 6.8* (to N. D. Mermin)

Merminition 197: *There are no probabilities of 1 in the argument in LNC* [J. S. Bell's article "La Nouvelle Cuisine"]. *(Indeed arguments of that type were originally developed explicitly to avoid using probability-one assignments, which were held to be unphysical idealizations of the probabilities one could assign to the outcomes of actual experiments.) No agent is certain about anything.*

> That ordinary quantum mechanics is not locally causal was pointed out by Einstein, Podolsky and Rosen, in 1935. Their argument was simplified by Bohm in 1951. . . . Each of the counters considered separately has on each repetition of the experiment a 50% chance of saying "yes". But when one counter says "yes" so also always does the other, and when one counter says "no" the other also says "no", according to quantum mechanics. The theory requires a perfect correlation of "yeses" or "nos" on the two sides. So specification of the result on one side permits a 100% confident prediction

> of the previously totally uncertain result on the other side. Now in ordinary quantum mechanics there just is nothing but the wavefunction for calculating probabilities. There is then no question of making the result on one side redundant on the other by more fully specifying events in some space-time region 3. We have a violation of local causality.
>
> Most physicists were (and are) rather unimpressed by this. That is because most physicists do not really accept, deep down, that the wavefunction is the whole story. They tend to think that the analogy of the glove left at home is a good one. If I find that I have brought only one glove, and that it is right-handed, then I predict confidently that the one still at home will be seen to be left handed. But suppose we had been told, on good authority, that gloves are neither right- or left-handed when not looked at. Then that, by looking at one, we could predetermine the result of looking at the other, at some remote place, would be remarkable. Finding that this is so in practice, we would very soon invent the idea that gloves are already one thing or the other even when not looked at.

QBISM BLOCKS THAT MOVE RIGHT THERE. QBists would not go with EPR and Bell and declare "ordinary quantum mechanics is not locally causal" just because of that. And it is not by a quick assumption of action-at-a-distance, but because for the QBist, probability-1 carries no force in truth assignments.

Yet, the QBist, might have gone *partially* with EPR and said,

> They decided that the wavefunction, making no distinction whatever between one possibility and another, could not be the whole story.

I.e., the QBist might have said, "Yet it gets me into no trouble to provisionally accept that my probability-1 assignment does imply that I actually believe in a pre-existent truth value." And that is where Bell's reasoning shows him a contradiction. So long as the QBist holds on to locality (and he can because of the blocked move above), he *cannot* entertain that his "probability-1 assignment for a measurement outcome implies that he actually believes in a pre-existent truth value for it."

The issues are exactly the same in the algebraic version of it all that I gave in the paper.

Bell and Norsen (and most everyone else but the three QBists) rely on the same crutch when they say that raw, ordinary quantum theory is "not locally causal".

Geesh!

07-04-10 *Me, Me, Me Again!, 2* (to N. D. Mermin)

Merminition 198: *What, for example, does it mean to make a bet that the reading will be 0 when the Dutch bookie I'm placing the bet with, watching the same measurement gate, may disagree? Do you need this additional layer of looseness to get rid of "the measurement problem"?*

Rüdiger is always careful to point out that Dutch-book coherence really is always an internal requirement (i.e., not in last analysis a two-person adversarial thing). It is really only that probabilities be consistent with logic. I'll cc him on this in case he wants to send you something he's written on this take of it.

07-04-10 *Births and Preclusivity* (to R. D. Sorkin)

By the way, I much appreciated your talk yesterday; I got a lot out of it and it helped clarify things to me. (You're on my mind because of a current email debate I'm having with Travis Norsen.)

There is certainly a broad way in which our two research programs overlap: it is that quantum mechanics is ultimately about events being born, and that what we presently call "measurement" should be considered instances of such, though that is not the exclusive provenance of such events. Or at least this is what I thought I understood from you.

Where the programs seem to part is in 1) the manner in which that broad statement above is implemented, and 2) the exact usage/meaning of probability within QM.

For more personal (or petty) reasons I was quite happy to see your *axiom* of preclusivity laid out so explicitly and so honestly. For, by recognizing it as an axiom, you show that you implicate it (at least in the case of your "quantum measures") as *no* logical necessity. You take preclusivity as an axiom connecting the measures to truth values. Nothing wrong with that, but it is an axiom—in principle, one can take it or leave it. Of course, you tried to motivate this by an analogy to old-time probability theory—but my guess is that you would admit that preclusivity is really an axiom there too. I don't know; am I wrong? Anyway, it was useful for me to see these things. For in my program of QBism, one of the key points is that preclusivity is not a logical necessity in personalist Bayesian probability theory either (though I haven't yet used the word "preclusivity"). In fact, the whole approach is based on trying to get some interpretative traction by going the opposite way from you on this issue! For instance, it is the point of Footnote 29, page 18, of my recent posting, `http://arxiv.org/abs/1003.5209`, where I take Norsen and Bell's nonlocality on.

I've just printed your new paper out and will be studying it.

08-04-10 *Me, Me, Me Again!, 3* (to N. D. Mermin)

Merminition 199: *Do you need this additional layer of looseness to get rid of "the measurement problem"?*

In a word, yes. That's what the section on Wigner's friend is about. If quantum theory is a "user's manual" for one's personal experiences, then there is no measurement problem. Each of us uses it, each of us get the consequences of our actions upon the world, but we never let our own uses of the manual be dictatorial over others' experiences.

08-04-10 *Me, Me, Me Again!, 4* (to N. D. Mermin)

Merminition 200: *What, for example, does it mean to make a bet that the reading will be 0 when the Dutch bookie I'm placing the bet with, watching the same measurement gate, may disagree?*

And it's not that he would disagree, but that "to see what I have seen" he would have to interact with me. An old and metaphorical idea: No two poets see the same world. But seriously. It is the point of Footnote 35 and the text to which it is attached.

Sorry I didn't catch this yesterday.

08-04-10 *Your Weltanschauung* (to N. D. Mermin)

Merminition 201: *So I don't think you should have been surprised at my reaction to 14L in the context of your paper, though I really have to take more time to inspect the document before deciding that I should have been reading you more carefully. But my present view is that my confusion on this point is at least as much your fault as mine.*

All fair enough. But I think I was referring to a conversation that I had had with you when I talked about shooting myself in the foot in the passage below (I was never completely sure, but someone definitely said it):

> The answer to the first question surely comes as no surprise by now, but why on earth the answer for the second? "It's like watching a Quantum Bayesian shoot himself in the foot," a friend once said. Why something so egocentric, anthropocentric, psychology-laden, myopic, and positivistic (we've heard any number of expletives) as *the consequences (for me) of my actions upon the system*? Why not simply say something neutral like "the outcomes of measurements"? Or, fall in line with Wolfgang Pauli and say:
>
>> The objectivity of physics is ... fully ensured in quantum mechanics in the following sense. Although in principle, according to the theory, it is in general only the statistics of series of experiments that is determined by laws, the observer is unable, even in the unpredictable single case, to influence the result of his observation—as for example the response of a counter at a particular instant of time. Further, personal qualities of the observer do not come into the theory in any way—the observation can be made by objective registering apparatus, the results of which are objectively available for anyone's inspection.
>
> To the uninitiated, our answer for *Information about what?* surely appears to be a cowardly, unnecessary retreat from realism. But it is the opposite. The answer we give is the very injunction that keeps the potentially conflicting statements of Wigner and his friend in check,[224] at the same time as giving each agent a hook to the external world in spite of QBism's egocentric quantum states.

I hope you didn't take my exclamation marks yesterday too seriously. I resonated deeply to what you said with, "I have trouble enough keeping a grip on my own Weltanschauung, so it's not surprising that I can't hang on to yours." It demands too much of a QBissel. And Carl worked like hell to suppress drawing direct attention to it—to the extent that he could do so without speaking an untruth—in the paper on "quantum certainty" that you refereed for us ... which could have better prepared the ground for you. That is why that paper marked our last-ever joint conceptual-writing project together. (I leave open the possibility that we could write something technical together again. But something where words are particularly important, no.)

I'm glad your daughter is coming by for a visit.

08-04-10 *Your Weltanschauung = My Weltanschauung–Epsilon?* (to N. D. Mermin)

You mean 14R (should have told you that earlier). "Outcome" seems to be too loaded of a term, for you and probably for others as well. Would "experience" in the caption to Figure 1 have alleviated some of your pain? I use it in the figure itself, but I had not in the caption: "consequence = experience" the figure says. Similarly for Figure 5. Read the caption to Fig 5 with "experience" in place of "outcome."

[224] Pauli's statement certainly wouldn't have done that. Results objectively available for anyone's inspection? This is the whole issue with "Wigner's friend" in the first place. If both agents could just "look" at the counter simultaneously with negligible effect *in principle*, we would not be having this discussion.

As a long exchange with you once taught me to stop using the word "knowledge" for quantum states (that's where "belief" came from), maybe you are teaching me that I should be more honest and forthright with the word "experience." For it is definitely where I am heading—that the world before man, after man, in between and everywhere, is a patchwork of "pure experience" (as James called it). See 27L and 27R for this said rather explicitly.

In some ways, this strikes me as a lot in the spirit of your old "correlation without correlata" — that the world becomes, like Noah filled the arc, bipartite by bipartite (instead of the more unary "event by event" for instance). But to get at the ultimate idea, one must jettison the notion of quantum state in its formulation. That is what always clouded me away from your earlier program—it made explicit use of quantum states. But if one strips away the earlier technical formulation, there might be some of your spirit in this present stage of my thinking. Though still another difference might be my emphasis on "becomes." It is the same thing I meant when I told Rob Spekkens that his hoped for view was not "sexual enough" in the attached pages [see note to Rob Spekkens titled "The Helping Hand" and dated 24-09-03.]. With him, the idea of true becoming, is a non sequitur (he embraces the block universe conception of things). With you, I haven't been so sure, but I always felt your "correlation without correlata" at least in those days leaned in that direction.

Does this sound credible to you? Are we making progress?

08-04-10 *Too Silly?* (to N. D. Mermin)

Merminition 202: *Yes, they're too silly. CVs should be concise. People spend a lot of time reading them. You don't want to waste their time with ephemera, however entertaining they might be. But breaking up the writings into categories is a good idea. It's surprising how many people don't.*

This is a good word to know actually. "Ephemeron" and "Ephemera". The world "becomes" ephemeron by ephemeron. Doesn't capture the bipartite by bipartite part of it though.

Thanks for the advice.

08-04-10 *Starting It Over* (to N. D. Mermin)

Your last hatching system was confusing too me; line breaks got deleted or something. So, I'll just respond to your responses directly.

Merminition 203: *So even you, whose writing I admire, use the redundant "of"! Then the battle is lost.*

Not really: I had thought there was something strange in what I wrote—I recognized that, but couldn't figure out what it was.

Merminition 204: *Are you willing to say up front that different agents can experience different readings of a single measurement gate at a single moment.*

To paraphrase William James,

> In its widest possible sense, however, an agent is the sum total of all that he can call his, not only his body and his psychic powers, but his clothes and his house, his wife and children, his ancestors and friends, his reputation and works, his lands and horses, and yacht and bank account.

See footnote 35 on 20R. More seriously, if "two" agents are part of a single common experience, then they are "one" with respect to the experience. Quantum theory as a "single agent's user's manual" only has two slots: one for the agent and one for the system. The theory as it stands, gives no tool for even posing what it means for "two different agents to read a single measurement gate at a single time." In a way, that's been the conundrum since the very beginning of the theory—QBism is just an attempt to embrace that as positively as possible.

Merminition 205: *If so, then you ought to spell out explicitly why QBism requires this.*

I thought I had done that with the Wigner's friend discussion on 5R through 8L. What's lacking there?

Merminition 206: *Yes indeed. And also in the spirit of that Physics Today column on reifying abstractions — and the talk I gave at PI last October.*

I definitely want to watch that again after Templeton. I remember liking it, and also the column, because you did use the word "experience."

Merminition 207: *but now I lose you. The correlata are the unary experiences, which belong to me, but not to physics. What's bipartite here? Is the pair experience-outcome?*

Maybe so (i.e., you lose me), because I'm wanting to put the experiences out into the world as its atoms. That is to say, to put it into physics. See the Dupré quote on 19L and the thing on Bohr in Footnote 34 on 20L. Bipartite refers to the way we usually think of what is happening in quantum measurement—one part is the agent, one part is the system. A clearer view might get rid of the cut. William James would say, the cut is *additive* to the pure experience; it is something placed on top of it. I'm still working out how far I can go with that. But all of this is far down the road for me. The first step is to understand what the QBist's "elementary quantum of action" QBar is telling us in the usual (bipartite) picture. At the very least, when I put an experience into spacetime, it becomes bipartite.

08-04-10 *UNC Visit* (to Y. J. Ng)

I'm just about to remove some silly lines that I had provisionally put in my CV, but I thought you might enjoy seeing them first. They're the two entries just above the "Awarded and Endowed Lectures" section on page 2:

> A true-to-form conversation with Terry Rudolph on the meaning of quantum mechanics is immortalized in Louisa Guilder's history of quantum entanglement, *The Age of Entanglement: When Quantum Physics was Reborn*, (Alfred A. Knopf, New York, 2008), pp. 332–336.
>
> Still Sillier Things: Academic Lineage — F. S. Exner, F. Hasenöhrl, K. Herzfeld, J. A. Wheeler, K. S. Thorne, C. M. Caves, C. A. Fuchs. Erdös number — 3 (but who doesn't have one). Einstein number — 3 (Einstein–Rosen–Peres–Fuchs). Wolfgang Pauli number — 4 (Pauli–Einstein–Rosen–Peres–Fuchs).

Looking at it, they're too silly. But maybe they'll give you some material for my intro! Exner was Schrödinger's advisor, and actually is someone who embraced indeterminism even before quantum mechanics. And Herzfeld (according Mehra and Rechenberg's history) was the first person to coin the term "quantum mechanics."

08-04-10 *What I Mean* (to P. G. L. Mana)

Yes, I like the Truesdell quote very much.

Luca's Preply

Physics is a kind of art, like painting (C. A. Truesdell):

> A theory is a mathematical model for an aspect of nature. One good theory extracts and exaggerates some facets of the truth. Another good theory may idealize other facets. A theory cannot duplicate nature, for if it did so in all respects, it would be isomorphic to nature itself and hence useless, a mere repetition of all the complexity which nature presents to us, that very complexity we frame theories to penetrate and set aside.

and

> If a theory were not simpler than the phenomena it was designed to model, it would serve no purpose. Like a portrait, it can represent only a part of the subject it pictures. This part it exaggerates, if only because it leaves out the rest. Its simplicity is its virtue, provided the aspect it portrays be that which we wish to study. If, on the other hand, our concern is an aspect of nature which a particular theory leaves out of account, then that theory is for us not wrong but simply irrelevant. For example, if we would analyse the stagnation of traffic in the streets, to take into account the behavior of the elementary particles that make up the engine, the body, the tires, and the driver of each automobile, however "fundamental" the physicists like to call those particles, would be useless even if it were not insuperably difficult. The quantum theory of individual particles is not wrong in studies of the deformation of large samples of air; it is simply a model for something else, something irrelevant to matter in gross.

09-04-10 *Starting It Over, 2* (to N. D. Mermin)

Merminition 208: *But now you're telling me that the two agents can't both assign probabilities to the readings of one and the same measurement gate when it interacts with that system?*

That's right: The agent IS the measurement gate. The prosthetic hands are crucial to Figure 1.

Merminition 209: *That not only are the probabilities personal to the agent but so is the event to which the agent assigns those probabilities?*

Well, it is shared between him and the system. So, in a sense it's personal to the system as well.

Merminition 210: *If they can then we're back to my original question — can one experience 0 while the other experiences 1?*

Right, I'm trying to nullify your original question.

Merminition 211: *If they can't, what does it mean for them both to place bets on that reading?*

I don't think it means anything within the quantum formalism. If they want to discuss both seeing something from the same system, they have to "talk" to each other and that is another quantum measurement—one shared between the two of them: From one point of view, agent and system, and from another point of view, system and agent.

I don't want to infuriate you, but this is the way I'm seeing it. And I recognize that these questions are good for me.

09-04-10 *Moving Along* (to N. D. Mermin)

Merminition 212: *since for Bohr (and for me, and I had thought for you) communication between agents was at an entirely different level.*

No, for me, every action an agent takes on the external world (which can be putting an SG device in front of an electron or talking to another agent) falls within the framework of a "quantum measurement". Please see Footnote 46, the paragraph to which it is attached, and the one before that on page 24. Whacking a baseball is a quantum measurement from this point of view.

Here's where I hope you'll say that "strikingly original" phrase again. It is that quantum mechanics is "additive" to the classical world.

Give that little bit of reading a shot, and I'll try to fill the further head-scratching it might engender.

Glad to hear you're not infuriated (and I hope not appalled either).

09-04-10 *And Coming Back a Bit* (to N. D. Mermin)

Merminition 213: *But now you're telling me that the two agents can't both assign probabilities to the readings of one and the same measurement gate when it interacts with that system?*

That not only are the probabilities personal to the agent but so is the event to which the agent assigns those probabilities?

Thinking upon this, you may not realize, but it is why I have always been fascinated with Pauli rather than Bohr. I never felt Bohr's position was consistent, and I tried very hard to believe that it was (and read nearly every philosophical thing he wrote). It is in exactly whether the measurement device is a prosthetic hand, rather than a piece of equipment in the laboratory separate from the agent, that the two men disagreed. This is why the old book is *Notes on a Paulian Idea*—this very issue is the deep part of THE Paulian Idea. (OK, so Pauli himself is not completely consistent, and I take him to task in the present paper, but he came closer to consistency than Bohr, I always felt.) In a way, it means you never quite took me seriously on this "detail." (Quotes because who would take this seriously as "just a detail.")

Actually, I'm sorry I didn't realize that we weren't communicating on this for all this time! Wow, I'm feeling idiosyncratic at the moment! It makes me wonder how many people who think they follow me (to some extent at least, like Max) don't realize how radical I (and Pauli) get.

I deeply appreciate having you as a reader!

09-04-10 *QB Decoherence* (to M. Schlosshauer)

I talked with Rüdiger, and he was OK with my showing you the draft as it stands. As I wrote to him, "Max's feedback may well spur us on to finish the thing and make it an easier paper to write in the long run."

Let me try to sketch a bit of the idea. When von Neumann was not using "Type 1 process / Type 2 process" language for collapse and unitaries, but rather discussing "measurement models" he described it as the two-step process you described nicely in your paper with Camilleri. First there is entanglement between the system and device (and with the addition of Zeh and Zurek, entanglement with the environment), and then—mysteriously—selection. (Of course the Everettians try to drop that last step, but they're not my target here.) You can probably guess that I would say, "von Neumann's setting the issue of measurement in these terms was the great original sin of the quantum foundational debate," and I would. The question is, what would a QBist put in its place and what connection, if any, is there to the previous notion of decoherence occurring before the magical selection step?

For a QBist, the only *physical* process in a quantum measurement is the selection step—i.e., the part the decoherence program tries to ignore—the whack, the action/reaction, the data that leads to a new state of belief about the system. Decoherence? There's no room for it, no role for it in this picture ... or is there? See attached photo (of my chalkboard before it was painted). The ghostly arrows represent the vN-Z-Z way of looking at measurement: We go from an initial quantum state and a specification of a "measurement interaction" (using something closer to my own terms, I have it written the specification as a set of completely positive maps Φ_i) to a decohered quantum state to a selected final quantum state (one of the ρ_i with probability $p(i)$). The arrows are ghostly because for us, that's all imaginary. What happens in reality is the dark upper arrow labeled "whack." It would appear that the decohered state ρ_w is never the state of belief of anybody. And in a way, that is true. For though the usual story is that the outcome of the measurement is "out there" simply unknown to the agent, and so he should adopt this as his new state of belief, we QBists reject that: There is no outcome for the agent except in his own experience. Like the thing John Wheeler used to say about the umpire, "They ain't nothin' till I calls 'em."

Nonetheless, one can imagine a situation in which an agent would adopt ρ_w for his gambling attitudes. It has to do with van Fraassen's reflection principle. Suppose I know that I'm going to whack the system *tomorrow morning* and that consequent to it I will adopt one of the ρ_i for my future beliefs. But you, Dutch bookie, offer me a lottery ticket *today* for a second whack that I'll perform *tomorrow afternoon*. What should I regard as a fair price for the ticket? The reflection principle requires I adopt ρ_w, or I can be Dutch booked.

And that from the QBist side of the world is the story of decoherence. Decoherence doesn't come conceptually before a "selection," but rather is predicated on the possibilities for the next quantum state. Decoherence comes conceptually *after* the recognition of the future possibilities (i.e., what used to be called "selection"). This is why I've been going around for a year saying that Zurek has it exactly backwards.

10-04-10 *Introduction, Pure Experience, Quantum Bayesianism* (to D. C. Lamberth)

First off, let me say that I am a great fan of your book on James and the metaphysics of pure experience, as well as your contribution to the *Cambridge Companion to William James*. Both writings influenced me deeply, and I think it is time I met you (electronically at least).

I am a physicist at the Perimeter Institute for Theoretical Physics in Waterloo, Canada with a deep interest in pragmatism and radical empiricism. You can read about Perimeter here if you care: `http://www.perimeterinstitute.ca/`. As well, I attach my CV, so that you will have some evidence that I'm not a lunatic coming out of the woodwork.

I also attach a recent paper on the research program into the foundations of quantum theory that I head (Quantum Bayesianism, or QBism), and a "press release" on my research group and the pragmatism library I have built up for everyone. I don't expect you to be aware much of quantum theory, but my guess is that the last three sections of the paper should still be quite readable to you nonetheless (because of their broader nature). Most importantly, they give some hint of why I am so interested in James's notion of pure experience, and why I cite you. My feeling is that this phenomenon in my field called "the quantum measurement problem" is as close to an expression of pure experience as we have ever encountered in physics. Moreover, that thinking in these terms will ultimately delete the word "problem" from the phrase "measurement problem" and open up great new vistas of physical exploration.

That is the general reason I contact you—to ultimately set up a dialogue on this subject. I think much progress can be made, but it will require a dialogue between physicists and the right kind of philosophers (pragmatists).

The more specific reason that I contact you now, rather than say three months from now, is that I am working on a pre-proposal for the Templeton Foundation for their call on research in quantum theory (due Thursday, April 15). The title of the proposal (if it gets invited) will be, "That the World Can Be Shaped: Quantum Bayesianism, Counterfactuals, Free Will," and the research it describes will have a large component in making the things I mentioned above more concrete. Below is the "Executive Summary" I have written for it, and it may give you some hint of what I am aiming for. With my reputation, I believe the pre-proposal has a strong chance of being invited as a proposal and then ultimately fly as an honest-to-god grant.

You will note that I mention "two international workshops" in the summary. I am thinking of something fairly intimate, with approximately 15 people for each. One will be targeted for the Alps near Zurich in the land of Wolfgang Pauli and his particular contributions on this subject (along with his interactions with Carl Jung). But for the other workshop, I would like to devote it to "Quantum Theory and Pure Experience" and make it a dialogue between physicists, philosophers, and theologians. Since you are my favorite contemporary thinker on pure experience, it seems natural to apprise you of this, and test whether you might have any interest in being involved. We have excellent conference facilities at Perimeter Institute, but I would likely try to hold it in a more inspiring setting.

Involvement only means spiritual involvement, organizational involvement, intellectual involvement. I would provide all of the funds for this workshop if it materializes.

A student wrote me recently (and it is certainly a line I will use in the proposal), "I like your theory because it returns to me as much freedom as I feel that I have. Such freedom is lost or partially lost in other interpretations [of quantum mechanics]." I hope the same point will help cause you to take notice of what I am writing you here.

> <u>Executive Summary</u>
>
> Speaking on scientific theories, the philosopher William James once said, "If you follow the pragmatic method, you cannot look on [a completed theory] as closing your quest. You must set it at work within the stream of your experience. It appears less as a solution than as a program for more work, and more particularly as an indication of the ways in which existing realities may be changed. Theories thus become instruments, not answers to enigmas. We don't lie back upon them, we move forward, and, on occasion, make nature over again by their aid." On this conception, a theory is not a statement about what the world is, but is a tool, like a hammer, to aid in making the world what we want it to be. The world may resist, but to some extent it is plastic.
>
> The research program of Quantum Bayesianism (or QBism) is a take on the quantum interpretation problem that reveals with mathematical precision, not poetry, that such

plasticity is quantum theory's greatest lesson. With every quantum measurement set by an experimenter's free will, the world is shaped just a little; and so of every action of every agent everywhere.

To further develop QBism and explore its broad implications, we request funds for two postdocs, two international workshops, and regular travel for collaborators.

11-04-10 *QBism Comes to Life!* (to C. Ferrie)

Ferrie-ism 9: *I wanted to play around with the website below and the first dialogue that came to mind was the one in your paper:* `http://www.xtranormal.com/watch/6389801/`*. What do you think?*

QBism already was alive! It's the most living interpretation of quantum mechanics there ever was!

But I'm very proud that that was the first dialogue that came to your mind! You flatter me. What do you think about this one from 2000?

> In the first frame God starts to speak to Adam at a time just before Genesis, "Adam, I am going to build you a world. Do you have any suggestions?"
>
> **Adam**: Mostly I don't want to be alone. I want to have friends ... and enemies to spice things up ... and generally just plenty of people to talk to.
>
> **God**: Done. I'll give you a world populated with loads of other people. But you ask for a bit of an engineering feat when you ask to be able to talk to them. If you want to communicate, the world can't be too rigid; it has to be a sort of malleable thing. It has to have enough looseness so that you can write the messages of your choice into its properties. It will make the world a little more unpredictable than it might have been for me—I may not be able to warn you about impending dangers like droughts and hurricanes anymore—but I can do that if you want.
>
> **Adam**: Also God, I would like there to be at least one special someone—someone I can share all my innermost thoughts with, the ones I'd like to keep secret from the rest of the world.
>
> **God**: Now you ask for a tall order! You want to be able to communicate with one person, and make sure that no one else is listening? How could I possibly do that without having you two bifurcate into a world of your own, one with no contact whatsoever with the original? How about we cut a compromise? Since I'm already making the world malleable so that you can write your messages into it, I'll also make it sensitive to unwanted eavesdropping. I'll give you a means for checking whether someone is listening in on your conversations: whenever information is gathered from your communication carriers, there'll be a reciprocal loss in what you could have said about them otherwise. There'll be a disturbance. Good enough? You should be able to do something clever enough with that to get by.
>
> **Adam**: Good enough!
>
> **God**: Then now I'll put you in a deep sleep, and when you awake you'll have your world.

> **Adam**: Wait, wait! I overlooked something! I don't want an unmanageable world, one that I'll never be able to get a scientific theory of. If whenever I gather information about some piece of the world, my colleagues lose some of their information about it, how will we ever come to agreement about what we see? Maybe we'll never be able to see eye to eye on anything. What is science if it's not seeing eye to eye after a sufficient amount of effort? Have I doomed myself to a world that is little more than chaos as far as my description of it goes?
>
> **God**: No, actually you haven't. I can do this for you: I'll turn the information-disturbance tradeoff knob just to the point where you'll still be able to do science. What could be better? You have both privacy and science.
>
> So Adam fell into a deep sleep, and God set about making a world consistent with his desires. And, poof(!), there was QUANTUM MECHANICS.

Or this version of it from 2010:

> Strictly speaking, meliorism is the doctrine "that humans can, through their interference with processes that would otherwise be natural, produce an outcome which is an improvement over the aforementioned natural one." But we would be reluctant to take a stand on what "improvement" really means. So said, all we mean in the present essay by meliorism is that the world before the agent is malleable to some extent—that his actions really can change it. Adam said to God, "I want the ability to write messages onto the world." God replied, "You ask much of me. If you want to write upon the world, it cannot be so rigid a thing as I had originally intended. The world would have to have some malleability, with enough looseness for you to write upon its properties. It will make your world more unpredictable than it would have been—I may not be able to warn you about impending dangers like droughts and hurricanes as effectively as I could have—but I can make it such if you want." And with that Adam brought all host of uncertainties to his life, but he gained a world where his deeds and actions mattered.

11-04-10 *Templeton, Schlosshauer* (to A. M. Steinberg)

Steinbergism 2: *Obviously, we'd be very happy to have any of your turncoats around. Does sound like philosophy or IHPST are the natural homes for him, but the more he interacted with us in Physics, the happier we'd be. I believe I could pretty easily secure him a (shared) postdoctoral office if all else fell through, but that might not be his first choice.*

Thanks on Max. With regard to Templeton, not to worry: *Everyone* I know is applying for this. There's no real competition between us unless you too are calling to make connections between quantum theory, William James's notion of "pure experience," and Wolfgang Pauli's interest in alchemy and Jungian psychology. You aren't ... are you? Though I could imagine an experiment or two that'd tidy up some of those connections ...

12-04-10 *Truth and Happening, 2* (to N. M. Boyd)

Thanks, I enjoyed that!

I'm glad you mentioned Richard Rorty. I think there's just a wealth of good stuff in his writings (though I don't follow him on many things). I have a long quote of him, that at least indicates what I find most useful to cherry-pick from him, in this pseudo paper: "Delirium Quantum," `http://arxiv.org/abs/0906.1968`.

12-04-10 *QB Glossary* (to the QBies)

By the way, here's the finalized version of the QB glossary.

QBlue signing off!

12-04-10 *Notes on a First and Second Reading* (to D. M. Appleby and H. Barnum)

Last night, I read Marcus's note "quantum belief and quantum reality" for the first time and Howard's paper for the second. Call me pigheaded, but my reaction was like that of a Japanese friend who wrote recently, "I do not understand your long sentence."

In the part that I take issue with (i.e., *not* the part about meatiness, where I do believe there is much work to be done, see Footnote 46 in my recent posting), I only felt that I saw two laments—one of five thousand words, and one of ten thousand—that boiled down to saying a single sentence, "In some cases, there *should* be a notion of a *right* probability assignment independent of the agent's personal mesh of beliefs." Why? "Well there should be." Why? "Well there should be!"

I continue to think such a notion is only trouble, a cloud that keeps us from seeing over the hill. Why would I adopt it when I can do everything your gut tells you that you need to do without it? 1) I walk into a lab, make a judgment about this or that piece of equipment; the experimentalist tells me that I'm "wrong." Fair enough: But, he does that based on his personal mesh of beliefs. 2) I use *my* mesh of beliefs to extract a probability-1 statement about some potential experience. I wait for the experience, and it does not happen. I say to myself, "That was stupid; I was wrong!" Fair enough: But "wrong" comes *after* the fact, and only then can I see that I should readjust my mesh of beliefs.

Particularly, the "wrong" does not come before the actual event. And, for me, that point is crucial for breaking the block. The block universe. What I see in your laments is a feeling that the probabilities should be right or wrong beforehand, and right or wrong based on something impersonal.

I accuse that idea of being a cloud. When it comes to quantum mechanics particularly, it is a cloud that keeps us from having a solution to Wigner's friend already in hand. And it leaves us with an action-at-a-distance that I find unacceptable (block issue again). Howard admits as much with his last sentence:

> We seem on solid ground if we wish to maintain that the fact about how Alice should bet is not a fact about how things are at Bob's site. It's not reasonable to say that quantum physics recommends that Bob should immediately change his betting behavior to the one it recommends for Alice. (Though I suppose it does claim that he'd be better off if he did.)

And I tried to make this point at length on page 5, right column, and footnote 7, of my last big paper. Furthermore, the issue has nothing to do with no-signalling or incompatibility with Lorentz invariance for me: It is all about the issue of the block. See page 18L.

Finally I'll say Marcus sizes me up wrong in the part of the discussion about my old phrase "(and only a little more)". I agree with William James that "the trail of the human serpent is over everything." Every statement of the form "I hypothesize the world to be made (in part) of stuff X" without doubt exhibits the trail of the human serpent. But still such statements have a function, and that function can be better or worse served by different choices of X. My *only* claim is that if one invokes a statement that boils down to "I hypothesize that the world is made (in part) of probability" (as you two seem to me to be doing) one does oneself no favor.

With regard to the trail of the human serpent, I believe that I agree with this paper of F. C. S. Schiller to a great extent: `http://en.wikisource.org/wiki/Personal_Idealism/Axioms_as_Postulates`. Reading it might help diffuse the repeated accusal of my believing otherwise.

13-04-10 *After Hans, 1* (to H. C. von Baeyer)

Opening section now reads:

> Of scientific theories, the philosopher William James once said, "You cannot look on [a completed theory] as closing your quest. You must set it at work within the stream of your experience. It appears less as a solution than as a program for more work, and more particularly as an indication of the ways in which existing realities may be changed. Theories thus become instruments, not answers to enigmas. We move forward, and, on occasion, make nature over again by their aid." On this conception, a theory is not a statement about what the world is, but a tool, like a hammer, to aid in making the world what we want it to be. The world may resist, but to some extent it is malleable.
>
> The research program of Quantum Bayesianism (QBism) is an approach to quantum interpretation that reveals, with mathematical precision not poetry, that quantum theory's greatest lesson is the world's plasticity. With every quantum measurement set by an experimenter's free will, the world is shaped just a little; and so of every action of every agent everywhere.
>
> To develop QBism's mathematics, amalgamate its philosophical implications, put it before a wider jury, and write a book on the subject, we request funds for two postdocs, two international workshops, and regular visits from collaborators.

13-04-10 *A Worry* (to H. C. von Baeyer)

von Baeyerism 61: *The opening quote by James is wonderful, BUT the key phrase, for which you selected it, is in brackets, giving the impression that YOU supplied it to make it fit your purpose. Maybe James was talking about something different from a theory! Is there a way to use more of his own phrasing here, fixing it up with brackets only minimally?*

I guess strictly speaking, he was talking about "metaphysics" just before those sentences, but a couple of paragraphs down, he goes on to say:

> One of the most successfully cultivated branches of philosophy in our time is what is called inductive logic, the study of the conditions under which our sciences have evolved. Writers on this subject have begun to show a singular unanimity as to what the laws of nature and elements of fact mean, when formulated by mathematicians, physicists and chemists. When the first mathematical, logical, and natural uniformities, the first laws, were discovered, men were so carried away by the clearness, beauty and simplification that resulted, that they believed themselves to have deciphered authentically the eternal

thoughts of the Almighty. His mind also thundered and reverberated in syllogisms. He also thought in conic sections, squares and roots and ratios, and geometrized like Euclid. He made Kepler's laws for the planets to follow; he made velocity increase proportionally to the time in falling bodies; he made the law of the sines for light to obey when refracted; he established the classes, orders, families and genera of plants and animals, and fixed the distances between them. He thought the archetypes of all things, and devised their variations; and when we rediscover any one of these his wondrous institutions, we seize his mind in its very literal intention.

> But as the sciences have developed farther, the notion has gained ground that most, perhaps all, of our laws are only approximations. The laws themselves, moreover, have grown so numerous that there is no counting them; and so many rival formulations are proposed in all the branches of science that investigators have become accustomed to the notion that no theory is absolutely a transcript of reality, but that any one of them may from some point of view be useful. Their great use is to summarize old facts and to lead to new ones. They are only a manmade language, a conceptual shorthand, as some one calls them, in which we write our reports of nature; and languages, as is well known, tolerate much choice of expression and many dialects.

> Thus human arbitrariness has driven divine necessity from scientific logic. If I mention the names of Sigwart, Mach, Ostwald, Pearson, Milhaud, Poincaré, Duhem, Ruyssen, those of you who are students will easily identify the tendency I speak of, and will think of additional names.

That he could have been talking strictly of "scientific theories" in the passage from my Executive Summary follows from this line in the paragraphs above:

> Their great use is to summarize old facts and to lead to new ones.

Thanks for worrying. But I'm not quite sure what to do.

13-04-10 *Possibly Final Version of Section 2* (to H. C. von Baeyer)

I turned you into a writer and added one more Jamesian phrase at the very end. 0 characters remaining:

> QBism is an interpretation and technical development of quantum theory due predominantly to C. M. Caves, C. A. Fuchs and R. Schack, with early contributions from N. D. Mermin and A. Peres and historical roots in an eclectic mix of the thoughts from W. Pauli, J. A. Wheeler, and B. de Finetti.

> Three characteristics set QBism apart from other existing interpretations of quantum mechanics. First is its crucial reliance on the mathematical tools of quantum information theory to reshape the look and feel of quantum theory's formal structure. Second is its stance that two levels of radical "personalism" are required to break the interpretational conundrums plaguing the theory. Third is its recognition that with the solution of the theory's conundrums, quantum theory does not reach an end, but is the start of a great journey.

> The two levels of personalism refer to how the "probabilities" and "measurement events" of quantum theory are to be interpreted. With regard to quantum probabilities, QBism asserts that they be interpreted as personal, Bayesian degrees of belief. This is the idea that probability is not something out in the world that can be right or wrong,

but a personal accounting of what one expects. The implications of this are deep, for one can see with the help of quantum information theory that it means that quantum states, too, are not things out in the world. Quantum states rather represent personal accounting, and two agents speaking of the same quantum system may have distinct state assignments for it. The second level of personalism appears with the meaning of a quantum-measurement outcome. On this QBism holds with Pauli that a measurement apparatus must be understood as an extension of the agent herself, not something foreign and separate. A quantum measurement device is like a prosthetic hand, and the outcome of a measurement is an unpredictable, undetermined "experience" shared between the agent and external system. Quantum theory, thus, is no mirror image of what the world is, but rather a "user's manual" that any agent can adopt for better navigation in a world suffused with creation: The agent uses it for her little part and participation in this creation.

The project we propose is to further develop this point of view, both mathematically and philosophically, by way of our own efforts as well as getting a wider community involved in its consideration. On the mathematical side, much work remains to develop a formalism that most crisply expresses QBism's worldview. Fuchs already has a group of six at Perimeter Institute tackling this head on–a key issue is understanding the structure of symmetric informationally complete (SIC) positive-operator measures. For with them, quantum theory takes the cleanest possible expression in terms of probabilities. A key collaborator D. M. Appleby lives in England–travel and accommodation expenses would allow him to become more intimately involved with the group. Co-investigator Schack would advise a postdoc in developing the notions of "quantum randomness" and "private information" from a purely Bayesian point of view. Its mathematics, we believe, particularly will take us to the next stage of understanding the "interiority" (Pauli) of quantum phenomena. Fuchs would advise proposed postdoc M. Schlosshauer in writing a full-length book on QBism, much like his well-recognized book on decoherence. On the philosophical side, we would organize two 10-day workshops. The first, with the help of Pauli scholar H. Atmanspacher and writer H. C von Baeyer, would be devoted to meshing Pauli's prosthetic-hand notion of measurement with modern developments. The second, in conjunction with the William James Society, would explore J. A. Wheeler's idea that "the big bang is here all around us" with each quantum measurement, which in the hands of QBism starts to look like a modern and promising version of James's ontology of "pure experience" where creation comes "in spots and patches."

14-04-10 *Final Cut?* (to H. C. von Baeyer)

Thanks a million! (But quit telling me to break a leg! The imagery is too vivid.) On point number 1, you're right: It's funny how many times I've had a little battle with my conscience before showing you something, and then when I do, you come out as "the good" voice that had already been in me but not listened to. Anyway, it's stripped away! On 2, I modified it to this:

> QBism is an example of the unexpected places to which striving for consistency can lead. When Quantum Bayesianism started 15 years ago, all it attempted initially was to view quantum states as knowledge to dispel some foundational conundrums. But the urge for consistency kept pushing it further, all the way to the two-level personalism we have today. The full implications of this are starting to sink in: From an original reductionist disposition, we arrived at a NONreductionist view of one of the most

fundamental theories of physics! See http://arXiv.org/abs/1003.5209. We now see the many efforts to derive the "quantum-to-classical transition" proceeding backward. Instead, quantum theory should be seen as "additive" to common experience–the union of the two make something greater. This turns the traditional debate on its head. The proposed JTF project is part of a greater goal to develop the view until other physicists feel it in their bones and use it themselves to reshape physics.

Now, if I can get Rüdiger's CV turned into .doc format without too much distortion, I'll be done!

14-04-10 *Willing Free Will* (to D. Rideout)

If I understood you correctly on our walk to the bus stop, you think "free will" is a presupposition for science. In any case, I certainly do! See for instance the left column, page 18, of http://arXiv.org/abs/1003.5209.

In case you're interested, attached is the thing I proposed to the Templeton Foundation today (actually it was a web form, but I weakly TEXified it—that's what I'm sending to you). Honestly, I was rather impressed with John Templeton's Donor Intent; see:

http://www.templeton.org/what_we_fund/donor_intent/philanthropic_vision/.

Let's talk about this again some time. It's my favorite subject on earth.

16-04-10 *Dangerous Jaynesian Tendencies* (to C. Ferrie)

I sent Rüdiger your term paper yesterday, and he replied thusly:

Schackcosm 132: *I just read his term paper. There is some very nice stuff in it. He seems to have dangerous Jaynesian tendencies, though.*

Beware those Jaynesian tendencies!!

16-04-10 *QBies Activate!* (to the QBies and R. Schack)

Today, 1:00 group meeting. It sounds like the big discussion will be on linear dependencies. And never forget these lines from Henry V'th:

This day is call'd the feast of Crispian.
He that outlives this day, and comes safe home,
Will stand a tip-toe when this day is nam'd,
And rouse him at the name of Crispian.
He that shall live this day, and see old age,
Will yearly on the vigil feast his neighbours,
And say 'To-morrow is Saint Crispian.'
Then will he strip his sleeve and show his scars,
And say 'These wounds I had on Crispian's day.'
Old men forget; yet all shall be forgot,
But he'll remember, with advantages,
What feats he did that day. Then shall our names,

Familiar in his mouth as household words—
Harry the King, Bedford and Exeter,
Warwick and Talbot, Salisbury and Gloucester—
Be in their flowing cups freshly rememb'red.
This story shall the good man teach his son;
And Crispin Crispian shall ne'er go by,
From this day to the ending of the world,
But we in it shall be remembered—
We few, we happy few, we band of brothers;
For he to-day that sheds his blood with me
Shall be my brother; be he ne'er so vile,
This day shall gentle his condition;
And gentlemen in England now-a-bed
Shall think themselves accurs'd they were not here,
And hold their manhoods cheap whiles any speaks
That fought with us upon Saint Crispin's day.

We will break this SIC problem one day! With Rüdiger in the list, we are all seven here!

17-04-10 *QBism's Foster Home* (to G. L. Comer)

I was just about to listen to your new recording, but I think I've got a "better yet." I'll listen to it tomorrow evening in The Carolina Inn. I'll be in Chapel Hill for the first time in 10 years, to give the physics colloquium and a seminar Monday and Tuesday. I'll listen to QBism from the old foster home (where the ideas were first fostered in me from reading a paper by Braunstein and Caves).

17-04-10 *World Elements* (to M. Schlosshauer)

For a couple of days I had been planning to write you on the "pure experience" idea, but your last note, replying to "Reasons Why" stole the thunder. You're on the right track, and what you wrote is about all I was going to write you anyway.

But this is all so sketchy at the moment. You wrote:

Schlosshauerism 28: *And I suppose this is where your link to James' "pure experience" comes in—provided I understand correctly what may be meant by this term.*

I think the way to treat James here is only as giving the hint of a hint. And the major part of the synthesis will have to be done by us ourselves, informed by the actual structure of quantum mechanics. This idea of "pure experience" (broadly construed) being the stuff of the world runs wide and deep in the particular lot of people I have taken the time to study over the years. It can be found in the writings of James, Pauli, and Wheeler. A good bit of the hidden Pauli, for instance in his personal letters to Fierz, Jung, and von Franz, was devoted to understanding this "neutral stuff" that quantum theory is the first indication of and dreaming of a "neutral language" to describe it all in. Also, there's some of Bohr even in this regard—revisit the Folse quote I used in the last paper.

But still, much of this only starts to click for me now: It took me nearly 26 years to get this far—i.e., the part where I start to get the hint of the hint and to see that it actually is in context (fitting for quantum mechanics). The clock started when I met John Wheeler and first read things like the quote you quote.

Anyway, I feel like I need to make a big push on reading everyone who has contributed to the neutral-stuff idea. And the group is bigger than I had previously imagined. For instance, have a look at the preface and introduction to Erik Banks' book *Ernst Mach's World Elements* on Google Books. Also, I've recently learned that Bertrand Russell embraced good bits of the Jamesian idea in his two books *Analysis of Mind* and *Analysis of Matter*. And too Ralph Barton Perry's "New Realism." Also Shadworth Hodgson. I feel like I need to get really coordinated on this, and go at it systematically for a bit, before I try to combine it with all this talk of dimension as a kind of valence.

That's where it stands at the moment. Tomorrow morning I fly to Chapel Hill, North Carolina to give the UNC colloquium and a seminar. Greetings to Kari and Eli as well.

Max's Preply

> Well, it had already dawned on me over the past few days that my query could have something to do with the Jamesian conception of "pure experience." There are certainly some hints of this in Section VIII of your paper; I did pick up on those earlier, but I feel the gears are only starting to mesh now. For example, there's the Wheeler quote that opens your section:
>
> > Is the entirety of existence, rather than being built on particles or fields of force or multidimensional geometry, built upon billions upon billions of elementary quantum phenomena, those elementary acts of 'observer- participancy'. . . ?
>
> So I suppose that part of the answer to my query would be to refer to exactly this speculation of Wheeler's: that, in fact, there are no other "physical processes" besides creation-by-quantum-measurement, and that the primary "ontology" are these acts of creation. Then there would be no "particles scattering other particles." It would be merely a figurative way of saying that two parts of the world have entered into a relationship by which they give rise to something new, namely, the "experience" that's shared between the two systems.
>
> And so on.
>
> The obvious next question would of course be: what precisely constitutes these "experiences"? How do they affect the future evolution of the world?
>
> And I suppose this is where your link to James' "pure experience" comes in—provided I understand correctly what may be meant by this term. For instance, the *Stanford Encyclopedia of Philosophy* says:
>
> > James's fundamental idea is that mind and matter are both aspects of, or structures formed from, a more fundamental stuff—pure experience—that (despite being called "experience") is neither mental nor physical. Pure experience, James explains, is "the immediate flux of life which furnishes the material to our later reflection with its conceptual categories . . . a that which is not yet any definite what, tho' ready to be all sorts of whats . . . " (ERE, 46). That "whats" pure experience may be are minds and bodies, people and material objects, but this depends not on a fundamental ontological difference among these "pure experiences," but on the relations into which they enter. Certain sequences of pure experiences constitute physical objects, and others constitute persons; but one pure experience (say the perception of a

> chair) may be part both of the sequence constituting the chair and of the sequence constituting a person. Indeed, one pure experience might be part of two distinct minds, as James explains in a chapter entitled "How Two Minds Can Know One Thing."

So, in this way of thinking, one would really close the circle back to the Wheeler quote! (I like it!)

19-04-10 *QBism* (to G. L. Comer)

Boy did that take me back to some youthful experiences in old John Hamilton's dance hall in Cuero TX, when a band would be just freestyle jamming before or after their paid performance and nearly everyone was gone (but old David and me). I have a particular memory in mind, though I can't express it adequately.

No doubt you caught an aspect of QBism—a world with creation all around, near and far. There was something about your licks that had an almost spatial feel, as if I could feel things all around me. That was really cool; thanks!

Things around here are significantly similar to the way they were 20 years ago (though all traces of Jim York are gone). I went into The Cave last night and drank a PBR, and shopped at The Bookshop tonight. Tonight's stash below.

Even Eugen Merzbacher was the same! He's 89 now, and was without doubt my most attentive listener! I have lunch with him tomorrow.

1. Murray N. Rothbard, *Ludwig von Mises: Scholar, Creator, Hero*, PB, 6.50 USD.
2. Edward H. Madden, *Chauncey Wright and the Foundations of Pragmatism*, HC, 8.50 USD.
3. George Herbert Mead, *Movements of Thought in the Nineteenth Century: Works of George Herbert Mead, Vol. 2*, edited with introduction by Merritt H. Moore, PB, 6.50 USD.
4. Robert Avens, *Imagination is Reality: Western Nirvana in Jung, Hillman, Barfield and Cassirer*, PB, 7.99 USD.
5. James Cambell, *Understanding John Dewey: Nature and Cooperative Intelligence*, PB, 8.50 USD.
6. Donald D. Palmer, *Structuralism and Poststructuralism for Beginners*, PB , 5.99 USD.
7. Jim Powell, *Derrida for Beginners*, PB, 5.99 USD.
8. David Baggett and Shawn E. Klein, editors, *Harry Potter and Philosophy: If Aristotle Ran Hogwarts*, PB, 8.99 USD.
9. Maurice Friedman, editor, *The Worlds of Existentialism: A Critical Reader*, HC, 6.99 USD.
10. Philip P. Wiener, *Evolution and the Founders of Pragmatism*, with foreword by John Dewey, PB, 3.99 USD (slated as gift for Lee Smolin).

19-04-10 *Pauli, Fechner, Schelling* (to H. C. von Baeyer)

Good morning. I'm a bit closer to your neck of the woods this morning—I'm in Chapel Hill, NC. (Though there was no gravy for the biscuits this morning: Maybe there are a bit too many souths for my taste.)

I'm reading a very nice book by Michael Heidelberger on Gustav Fechner, *Nature from Within*. Fechner was the father of psychophysics and a philosopher who argued that nature is permeated with souls. I'm halfway thinking I might write a review on this book for you if you're interested in it.

For the moment though, I'm just curious: We know that Pauli read Schopenhauer and Mach, but is there any evidence that he read Schelling, Oken, or Fechner? (Mach was greatly influenced by Fechner.) Anyway, all three of these guys thought nature was alive and in continuous creation, which you can guess intrigues me.

Hans's Reply

> Welcome to the Confederacy. Fechner is the very first reference in Karl von Meyenn's contribution to the Almanspacher/Primas book. (The chapter is entitled "Wolfgang Pauli's philosophical ideas viewed from the perspective of his correspondence.") So, to answer your questions I will hunt for clues in the yellow bible.
>
> The idea of atoms with souls has a history reaching back to Lucretius. Bernard Pullman, in *The Atom in the History of Human Thought*, cites the lovely conception of Denis Diderot (1713-1784) of animate atoms. Diderot hopes that he will be buried next to his beloved Sophie, because his atoms and hers may still retain vestiges of feeling, and may try to mingle with hers. Atoms in love!

19-04-10 *Fuchs_Penta-Chart_2010(2).ppt* (to R. F. Wachter)

Sorry for the delay. It looks pretty good. Here are my answers to your queries. [. . .]

3. *Every* quantum measurement is a little act of creation. Disturbance is too weak of a concept; it goes further than that. In a wispier philosophical mood, I wrote recently: "The research program of Quantum Bayesianism (or QBism) is an approach to quantum interpretation that reveals, with mathematical precision not poetry, that quantum theory's greatest lesson is the world's plasticity. With every quantum measurement set by an experimenter's free will, the world is shaped just a little; and so with every action of every agent everywhere." Do you dare say that in front of your admirals? You might enjoy the attached "Glossary of QBism," particularly with respect to SICs, "QBalah." [See 07-04-10 note "Up Front" to Å. Ericsson, N. D. Mermin, and R. Schack.]

20-04-10 *Fuchs_Penta-Chart_2010(2).ppt, 2* (to R. F. Wachter)

Wachterism 2: *Enjoy this well-known alternative dictionary,*

`http://www.gutenberg.org/etext/972`.

You compare my QBism glossary to the Devil's Dictionary?

20-04-10 *Adam and God Again, Again* (to Č. Brukner)

I just booked my flights to Jeff Bub's meeting. So I'll actually be there. For a bit I wavered because I had waited so long in booking my hotel that the price had jumped up to $272/night. But Spekkens is letting me room with him; so that took the sting out of it. Now I get to witness the fireworks between you and Tumulka first-hand!

On this trip, I've been reading a nice book on the life and thought of the physicist/philosopher Gustav Fechner. (I'm in North Carolina at the moment.) I'm finding many things thought-provoking in it. Here is a little passage on the thought of theologian Christian Hermann Weisse:

> All that is real originates in acts of freedom, originates in "voluntary action in general," either acts of God or acts of his creation. These acts are voluntary because they totally lack subjection to necessity. In creating the world, God willingly limits his own power and thereby continuously establishes the spontaneity and freedom of the beings he created. Spontaneity and freedom of action occur within time and thus make God a historical being, unfolding himself over time. These two traits also restrict his capacity to entirely foresee the future.

It strikes me as hauntingly similar to my Adam/God story. I didn't realize that I'd be branching into reading theology soon!

20-04-10 *My Itinerary for DC* (to R. W. Spekkens)

I've been talking with Eugen Merzbacher today: Wonderful firsthand stories of Einstein, Oppie, Lothar Nordheim (now there's a name for you to search your memory), Wheeler, Rosen, Podolsky, Glauber, Bryce DeWitt, Everett, Wigner, Dirac. Very nice.

21-04-10 *Very Nice* (to Y. J. Ng)

I just finished reading the von Baeyer article. Your idea with Henk was very nice. I am just about to board the plane. I bought six more books last night. Everything fit in one suitcase. Thanks again for all the hospitality—I think that is the best I have ever been treated just for giving a couple of seminars!

(And lobby your department chair to instate a modern quantum information course; it is sad when one of the *few* people at the colloquium to already be aware of generalized quantum measurements was an 89 year old!)

21-04-10 *World Elements, 2* (to M. Schlosshauer)

Now you flatter me too much. Lost wanderers shouldn't get such easy rides; it's not healthy. I just think there is something solid to work on here.

How is your Everettian analysis going? Are you still working on that somewhere on the side? I do hope you'll finish that. This morning I'm going to read Zeh's article, "Feynman's Quantum Theory." Before the Los Alamos fire, I had a copy of the 1957 conference proceedings he discusses, and I was aware of the dialogue he cites (nearly 20 years ago!). I happened upon it at the University of North Carolina in a room that was opened briefly so that an old, mostly out-of-commission copier could be used while the main one was broken. There was an old file cabinet in the room labeled "preprints," so I rummaged through it. Lots of stuff from when Bryce DeWitt was still there, and at the very back was a folder with two copies of this proceedings. One was labeled, “Last Copy. Do Not Take.” But the other one said nothing, and I took it. (I later told Jim York about this, and he took the last copy, ignoring the warning label.)

I had some nice discussions with Eugen Merzbacher, who was the first to *really* teach me quantum mechanics. He’s 89 now, and was actually the most attentive person in my colloquium. He moves slowly, but his mind is as sharp as it was when I first met him, without exaggeration. It was nice to hear so many first-hand stories of Einstein, Oppenheimer, Lothar Nordheim (now there’s a name for you to search for – it was at his house that Wheeler’s much advertised version of twenty questions really happened), Wheeler, Teller, Rosen, Podolsky, Glauber, DeWitt, Everett, Wigner, Dirac, Schlosshauer!, and others. Merzbacher gave me a first edition of von Neumann’s book that he had had bound long ago. It’s in beautiful shape.

21-04-10 *Sci Am* (to H. C. von Baeyer)

We never did write that Pauli article. (My guess at this stage is that, unless I sketch a first draft, it’s not going to happen. But I might be wrong?) Anyway, beside it or on top of it or instead of it, here’s an idea: See correspondence with George Musser from *Scientific American* below, where he writes:

> I’m not sure this paper lends itself to straightforward abridgment for a Sci Am article, though, because the style is that of a manifesto – an effort to rally one’s colleagues, address the misgivings they have, and set them on the right path. A general reader (and I include myself in that category) is coming to this from a very different point of view. We’d need a more straightforward account: here are the mysteries of quantum mechanics; here are the usual responses; here is why those responses fail; here is a better way. I suspect that such a reader will actually be more receptive to the notion that quantum states represent a form of gambling odds than a physicist or philosopher steeped in the subject is; we have less baggage to shed. *But* we *do* share the desire to know ultimately what the information is about and, even if this question cannot be answered, will want to know how the Bayesian approach advances that goal.

Trouble is, I don’t think I know how to write something that is *not* a manifesto—it is a character flaw. That’s where your writing discipline could come in. What would you think about us throwing in together on something like this? Does the idea evoke any emotions in you?

21-04-10 *Book Review Notes* (to H. C. von Baeyer)

Notes from a mid-flight reading below:

At the nine-volume remark, should mention or cite von Meyenn . . . at the very least so that readers who do not know the word “Briefwechsel” will know what to search on.

I’ve never liked it when people say Pauli and Jung “co-authored” a book. It gives the sense that they wrote the two papers together. It is a book of two papers by two distinct authors. They didn’t even write an introduction together, did they?

Planck length: Miller didn’t say that in the context of quantum gravity? Was there a discussion of gravity about?

Your page 100 remark, about Pauli getting to the Born Rule before Born. I have a faint (actually not so very faint) memory that Miller may be close to right on this. Trouble is, at the moment, I can’t remember my source. It was a scholarly article by Fine or someone else (probably not

Fine). Anyway, the point they made was that Born received his Nobel prize so very late because everyone in Copenhagen had already understood probabilities for measurement results as squared amplitudes. It was a vestige of the Bohr-Kramers-Slater theory, and even some Einsteinian work earlier than that. So Born's Nobel-prize referees (surely Bohr was in that lot) were not so very keen to give him a Nobel prize on that in any great hurry. I have a rather strong impression of this. I believe there is a letter from Einstein to Born in their letter collection, where Einstein laments the lateness with which the prize came. But Einstein was not part of the Copenhagen crowd. It'd be interesting to look up what Pauli wrote to Born about the award, and what Pauli wrote to his other friends at about that time.

23-04-10 *WRT Your Talk on Quantum-Bayesianism* (to I. N. Hincks)

I never did get back to you on your queries. I hope you've found some of the answers to your questions in a re-reading of the paper. But I did want to tell you how beautiful I found the closing sentences in your note. In fact, I have made use of them, and I hope you don't mind. Please see the attached proposal to the Templeton Foundation; I quote you in Section 7. If I ever use them again in a more public document, I will certainly cite you by name. Thank you for inspiring me.

Ian's Preply

> Your talk today turned some things up side down for me.
>
> I find the underlying principle of the thing rock solid, at least for now. I have questions of clarification below. (If you have already written down the answers somewhere, please refer me there.)
>
> 1. On the first page of the essay you handed out was a quote from Bell, about the qualifications involved in being an observer (does it need a PhD, etc.). Does your theory have a set of such qualifications? I imagine your response might be (it's fun to put words into other people's mouths) that such a list is not necessary, it is after all, a single-user theory, and that, perhaps, the trick is to use empirical observation to infer that (most) other humans are qualified to be agents. And perhaps an ordinary rock is just as capable an observer, but having no useful way of communicating with a rock, we choose to draw no conclusion. But let's remove the focus from other (potential) observers, or agents, onto ourselves. What I would like to get at is this: your overhead slide with the stick-man with a moustache and fan hands was drawn by you as, well, a stick figure. Was the reason for this iconic, or literal? I can perform measurements with my dial hands. If I get into an accident I can perform (albeit, more slowly) observations with just my left hand. But with no hands, what am I? Well, I get robotic arms implanted to continue with my measurements. My point is that your theory seems, at least to me, that your diagram must have been iconic, simply because it is hard to "nail the soul to the body" in a consistent way. (I had some of Walt Whitman's words, from *I Sing the Body Electric*, running through my head during your talk today: "And if the body were not the soul, what is the soul?")
> 2. This is how I understood one of your points: it is unfair to necessitate the deconstruction of the shoe into its constituents (being "elementary particles"), and call this deconstruction the shoe. Rather, a shoe is a shoe, and an elementary particle is an elementary particle, and when we are lucky, physics will give us relationships

> between the two. This has a tinge of Platonism to me. It seems like "shoeness" must exist in a realm, and it must be the physical realm since this is where our fan hands measure it. Would you agree? And if you substitute "Love" for "shoe", where is Love's realm? The physical realm? These are earnest questions I have, they are not posed as a criticism.
>
> I like your theory because it returns to me as much freedom as I feel that I have. Such freedom is lost or partially lost in other interpretations.

24-04-10 *Implications* (to N. D. Mermin)

How's Berlin? I just wrote the note below to Huw Price, and because of it, I reread the thing I had sent off to Templeton last week. It dawned on me that maybe you should know how I have implicated you in this business! You'll find your name mentioned at the top of Section 3. Thanks for all the good tension over the years!

24-04-10 *Weyl's Book and John Wheeler* (to the QBies)

- 1928. *Gruppentheorie und Quantenmechanik*. transl. by H. P. Robertson, *The Theory of Groups and Quantum Mechanics*, 1931, rept. 1950 Dover.

Wheeler, on the other hand, was born in 1911 and got his PhD in 1933 (having skipped a bachelor's degree). He wrote:

> I first knew Weyl before I first knew him. Picture a youth of nineteen seated in a Vermont hillside pasture, at his family's summer place, with grazing cows around, studying Weyl's great book, *Theory of Groups and Quantum Mechanics*, sentence by sentence, in the original German edition, day after day, week after week. That was one student's introduction to quantum theory. And what an introduction it was! His style is that of a smiling figure on horseback, cutting a clean way through, on a beautiful path, with a swift bright sword. Some years ago I was asked, like others, I am sure, to present to the Library of the American Philosophical Society the four books that had most influenced me. *Theory of Groups and Quantum Mechanics* was not last on my list. That book has, each time I read it, some great new message.

I never realized that Weyl's book was written before von Neumann's. Indeed, it was even written before Dirac's! (von Neumann's was 1932, and Dirac's was 1930.)

And if I'm not mistaken, our beloved Weyl-Heisenberg group goes back to that book of Weyl's. Does anyone know where to find it in there? Despite Andrew Gleason's spirit residing in my copy, he hasn't given me enough hints to find the right section on perusal.

24-04-10 *Saturday Morning Alchemy* (to the QBies)

It's one of those mornings when I find myself thinking that what we're doing is *really*, *really* important. Because it goes to the very heart of what matter is. Lately, I've become fixated on the imagery of "the philosopher's stone" as the root of the right way to think of quantum systems. My daughter Emma was reading to me from a book *The Sorcerer's Companion* about the real-life sources of the things in Harry Potter, and it put me in an extraordinarily sentimental/contemplative mood. "Medieval alchemists like Nicholas Flamel now spoke of producing a new substance—an extraordinarily potent catalyst that when added to common metals would trigger their transmutation ..."

I usually only share this earthy base of my thinking with Marcus, but I'm feeling rather open mouthed this morning. I say "earthy" because of this thing Marcus wrote a couple weeks back:

> One of the difficulties with this programme is that a building has to rest on something. Actual modernistic buildings rest on the same wormy, fungus and bacteria- impregnated earth that the medievals used to build their mud-huts on. With the modernistic structures we build in our minds it is even worse: they don't simply rest on the same soil, they actually rest on the mud hut itself, entire and unreconstructed. Despise the mud-hut at the bottom of the whole thing, as contemporary physicists almost all do, and you are despising the foundations on which everything else depends.

The earthy is definitely welling up in me lately. For instance, here's a blurb I wrote for the back of the new edition of Nielsen and Chuang's book:

> Nearly every child who has read Harry Potter believes that if you just say the right thing or do the right thing, you can coerce matter to do something fantastic. But what adult would believe it? Until quantum computation and quantum information came along in the early 1990s, nearly none. The quantum computer is the Philosopher's Stone of our century, and Nielsen and Chuang is our basic book of incantations. Ten years have passed since its publication, and it is as basic to the field as it ever was. Matter will do wonderful things if asked to, but we must first understand its language. No book written since (there was no before) does the job of teaching the language of quantum theory's possibilities like Nielsen and Chuang's.

I guess I just want to say something nearly the same to you QBies: Believe in the philosopher's stone!

Attached is an extract of the pre-proposal I sent off to the Templeton Foundation last week.

Top of the mornin' to you,

24-04-10 *Weyl's Book and John Wheeler, 2* (to the QBies)

The section in Weyl's book seems to be Section IV.D.14, starting on page 272. I'm not quite sure what it is saying, but it sounds awfully deep. It seems he views the generalized Pauli operators as the very defining feature of a quantum system, and bases everything on the consideration of them. I think it means SICs really do form the right "phase space" for QM.

25-04-10 *The Importance of Gadflycity* (to N. D. Mermin)

Glad Berlin is living up to your dreams. That's one German city I've never been to.

Merminition 214: *I'm honored to be mentioned with Asher as a kind of godfather of Qbism, but I'm not sure what I did to deserve the accolade. I think of myself as more of a gadfly. At best.*

I thought long and hard about putting you in that line, but decided that if I were to say something about Asher, I must also say something about you. Do not underestimate the contributions of a good gadfly—that was exactly your role; you hit the nail on the head. And I'm proud to say it; if it weren't for the tension you (more than anyone else) have given me, QBism would be just another lazy, half-way interpretation of quantum theory. Indeed another line in the proposal was an implicit statement about your gadflycity: "QBism is an example of the unexpected places to which striving for consistency can lead. When Quantum Bayesianism started 15 years ago, all it attempted initially was to view quantum states as knowledge to dispel some foundational conundrums. But the urge for consistency kept pushing it further, all the way to the two-level personalism we have today." The "urge for consistency" was really just "saving face" in light of your queries.

Merminition 215 : *Does Templeton require a religious twist? Is it necessary that Qbism end up pointing the finger at God?*

They do require an applicant to declare the relation between his proposal and "Sir John's Donor Intent." See Section 13 in the thing I sent you. But I enjoyed reading his donor intent, and found it quite liberal and humble. My reading is that it says, in essence, never throw away a possible source of enlightenment—no matter the source. My reading of it didn't sound a lot different (though less thorough and eloquent) from my readings of William James. Anyway, everything I said in this proposal is genuine me, and if that is religious, it is that I'm not going to let the world completely tell me what to do: The world must listen to man (in the end), as much as man must listen to the world. If someone construes that saying agency is real, has something to do with pointing a finger at God, then QBism is already pointing there. That's the thing that spooks Norsen and Spekkens (and Caves?) and the like—they think that if science doesn't reduce mankind's actions to a kind of nothingness, then all hope is lost. But of course, I just think QBism points to agency, NONreductionism, and plasticity: It points to the idea that the world is malleable. I wouldn't call that God.

Merminition 216 : *How did you hook up with Max Schlosshauer? I met him for the first time in Copenhagen last year, and liked him a lot.*

That's a story worth recording on a slow Sunday. My first contact with him was pretty inconsequential; I had just asked him to comment on a Kofler/Brukner paper that I think does the quantum-to-classical transition better than anything the decoherence program had ever dreamed up. Max's reply was predictable (defensive of the status quo) and not enlightening.

It was really my second contact with him that got things going in a positive direction. He wrote me in his capacity as an editor, asking if I would consider writing a book on QBism. In that note, he wrote furthermore:

> First, I'd like you to know that for quite some time I have really enjoyed following the development of the quantum Bayesian program and the intellectual discourse surrounding it. I have found your writings both illuminating and entertaining, and I feel that they have instilled in me an ever-increasing appreciation of the Bayesian viewpoint and of the motivations and philosophical attitudes underlying the approach. You see, I have been doing a lot of work in the decoherence field, and as you know several of the original forces in this area are openly or semi-openly Everettian, sometimes to the point of where one may get the impression that an Everett view is somehow *implied* by the insights brought about by decoherence. Even I had not been immune to this influence for quite some time, though I finally feel some recovery coming on; the fog is lifting.

I thought, "Yeah right, good salesman; you just want me to write a book for this series." And I pretty much wrote it off as a sales tactic.

But then I saw him at the Växjö meeting last year, and gave him a copy of the QBcoherence paper that you refereed. I thought I was just being devilish. (Zurek was there too, and Max was hanging out with him mostly.) To my surprise, throughout the week, I spied Max actually reading the paper during the talks. On my return home, I stopped in London for a night with Rüdiger and reported all this to him, saying how it surprised me and that maybe "he's not a fake" after all. Then, while in Rüdiger's living room, I looked up Max's webpage and found to even more surprise this line: "More recently, I have become interested in information-theoretic axiomatizations of quantum mechanics, quantum Bayesianism, and generalized quantum-like theories." I said to Rüdiger, "Fakes don't put lines like that in their webpages."

Thus we were off to a new start. Sometime later, Max wrote asking for what of William James I recommend he read. Lots of correspondence ensued. I think maybe what really capped off this transition in him was when I said that my vision of the world was not so different than what happens in jazz improv. That seemed to go to his bone. (You know that he's a jazz musician, don't you?) Since then, he's been a good force behind QBism, helping keep me honest, pushing me to expand points and write more clearly, etc. Then at some point he brought up the idea that he write a book on QBism, and I ran with it.

That's the story roughly.

Merminition 217: *I just turned 75.*

Congratulations. You are the most un-reified 75-year-old I have ever met. I'll be happy when you're ready to take up that gadfly role again! The program needs you.

All the best from drizzly Waterloo.

27-04-10 *Midnight Reading* (to H. C. von Baeyer)

Attached are a couple of articles you might be interested in. Particularly the Bernstein article. I like the way you have your review written now, and I wouldn't want you to change it, but midnight curiosity still drives me to find some evidence for what I claimed of Pauli vs Born. (I am not there yet, but I might be closing in ... or giving up ... we shall see what another hour gives.)

Anyway, reading these articles was quite nice for all sorts of reasons for me. Most particularly, I have recently taken an interest in the historical development of our beloved "displacement operators" or "generalized Pauli operators," by which we generate SICs. I had the most pleasant shock the other day: Weyl in his 1928 book declares, roughly, "A quantum system is one for which there are two quantities A and B that satisfy, $AB = e^{i\phi}BA$." I.e., He *defines* a quantum system by the existence of our generalized Pauli operators! (And consequently with hindsight some time from now, if all works out for us, by the existence of SICs.) See Section IV.D.14, starting on page 272, Dover edition, and notes below. I don't have the book with me at the moment, but I *believe* he takes this as the essence of Heisenberg's postulate (he calls it) when it comes to finite dimensions. Thus it was a real surprise to learn that this commutation relation (in "Heisenberg form") is actually Born and Jordan's and inscribed on Born's gravestone!

Of course, it has to be that after all this work of ours we will end up back at quantum mechanics, but it is interesting to see how some of the earliest math in one of the earliest formulations of the theory (Weyl's) came so close to what we are working with today.

By the way, the remark below about Gleason is referring to the fact that, thanks to a chance encounter of one of my students in Powell's Bookstore in Portland (and his reticence to buy it), I now own Andrew Gleason's copy of Weyl's book. He told me the story of the stamp in the book, and I got on the web and bought it right away!

27-04-10 *Questions for Aaron's Consideration* (to A. Fenyes)

Here's a document I hastily threw together this morning. Could we meet to discuss some tomorrow? I will be out of town Thursday and Friday.

> Here are some things I'd be quite interested in knowing the answer to. If anything strikes you, let's work on it. All three questions are geared toward pieces of rederiving quantum-state space from urungleichung considerations. If these question don't lead to directions for progress, and something else strikes you, feel free to modify at will. [. . .]
>
> **3. Building Up Quantum-State Space One Simplex at a Time?**
>
> Let me call a set $\mathcal{S}$ of probability distributions *consistent* if no two points violate
>
> $$\frac{1}{d(d+1)} \leq \sum_r p_r q_r \leq \frac{2}{d(d+1)} \; . \tag{99}$$
>
> (All probability distributions p_r assumed to be over d^2 points.) Let me call such a set *maximal* if no further probability distribution can be added to $\mathcal{S}$ without violating (99), but otherwise the set must be as full as can be. One can prove that all maximal consistent sets must be convex and closed. (See paper with Appleby and Ericsson.) Moreover, quantum-state space is an example of a maximal consistent set.
>
> Tell me as much as you can about maximal consistent sets with the following extra bit of structure: Every extreme point $\vec{p} \in \mathcal{S}$ must be embeddable in some set of d^2 extreme points $\vec{p}_\alpha$ that form a regular simplex.[225] I.e., for every extreme $\vec{p}$ there must exist some set $\vec{p}_\alpha$ of extreme points with $(\vec{c} - \vec{p}_\alpha) \cdot (\vec{c} - \vec{p}_\beta) =$ constant (with $\alpha \neq \beta$ and $\vec{c}$ being the center point of the probability simplex), and $\vec{p} = \vec{p}_\alpha$ for one of the values. That is to say, what happens if we build up a maximal consistent set $\mathcal{S}$ one regular simplex at time? What further properties does it share with quantum-state space? Might it just be isomorphic to quantum-state space?!?

28-04-10 *Stueckelberg??* (to L. Hardy)

Hardyism 6: *Do you know what Stueckelberg did in his paper on real Hilbert space quantum theory? I haven't read it and it doesn't seem to be available on line. In particular, did he come up with the notion of local tomography? Bill and I are hoping to finish our paper in the next few days and it would be good to cite Stueckelberg properly.*

No, Stueckelberg didn't have that notion. He just showed that one could recover "single system" quantum mechanics (or "full system" rather) using a real Hilbert space, plus superselection rule. Particularly demanding that all observables commute with a certain operator J such that $J^2 = -I$.

I think the first person to use a local tomography axiom independently of Bill was Araki. It should be at the end of this paper if recall correctly: H. Araki, "On a Characterization of the State Space of Quantum Mechanics," Comm. Math. Phys. **75**, 1 (1980). He noted the usual problem in fields other than the complex.

Stueckelberg, by the way, went quite insane at some point. I read a story a while back about how he showed up at a conference once thinking (and acting) that he was a horse. He was eventually institutionalized. Maybe it means you shouldn't think about real Hilbert spaces too much!

[225] This appears to be a more careful statement than what I was guilty of so many other times. See Footnote 218, as well as Footnotes 216, 219, 220, 221, and 222.

29-04-10 *Spectra of* $G = \sum_{r=1}^{d} \Pi_r$ (to M. A. Graydon)

Thanks Matthew! Interesting, especially $d = 5$. I've been reading on your Emersonian essay again, with my after-dinner beer. (Demopoulos's essay had more urgency, since I have to meet with him tomorrow. So he got the dinner reading.) I've just gotten to the Wigner's friend part, which I haven't started yet. That'll have to wait for another quiet spell. Eventually, I'll write you up some notes on it. You do a really good job, but I'll nitpick some.

I'm steeling myself for Spekkens' arrival. We're rooming together for this conference; he should arrive in a half hour. Imagine the shear in the spacetime continuum of this room tonight: The left-hand side a block universe, the right-hand side an anti-block! Something strange is bound to happen.

04-05-10 *Gout and Regout* (to W. G. Demopoulos)

It's slowly getting better. I soaked it in Epsom salts water a couple times yesterday. Sunday was absolute misery getting through the airports—from Washington Reagan, I had a connection in Chicago O'Hare. Getting from H12 to G8 was a triumph of human will! But by yesterday afternoon, I was able to stand on it well enough to pull dandelions (of which there has been an explosion here that I can't afford to turn my back on).

I'm glad to hear you're back home safely, and enjoyed my time with you this weekend. I had said that I would be in London for the Saturday talks of Harperfest, but I'm starting to have a few misgivings: There is so much that needs to be done in this yard, and I hate to see another weekend evaporate. (I've been gone the last two for conferences.)

Yesterday, I found Bertrand Russell's *Collected Papers*, Vol 7, which I had ordered ages ago. So, I stopped reading my book on Fechner for the evening to indulge in a little Russellania. The reason I bought this volume is because it contains the only book-sized manuscript that he never published, and it records his transition from being against to being for William James's (and Mach's) "neutral monism" (as Russell called it).

The thing in Schrödinger's *Nature and the Greeks* I was telling you about is what he calls the "principle of objectivation":

> By this [i.e., by "the principle of objectivation"] I mean what is also frequently called the 'hypothesis of the real world' around us. I maintain that it amounts to a certain simplification, which we adopt in order to master the infinitely intricate problem of nature. Without being aware of it and without being rigorously systematic about it, we exclude the Subject of Cognizance from the domain of nature that we endeavor to understand. We step with our own person back into the part of an onlooker who does not belong to the world, which by this very procedure becomes an objective world.

He also goes on about it in a lengthier way in *What is Life?* As I recall, it is all really good reading. Though of course, with my present pragmatism and radical empiricism, I don't much subscribe to the principle, at least when it comes to quantum issues: QBism's view of quantum theory as a normative single-agent "user's manual" leaves the theory necessarily in great part about the agent himself.

I will dig up the Forman article for you, about Schrödinger's and Weyl's and Exner's and others early leanings toward indeterminism, once the library restores my privileges to retrieve things online. (I discovered that I was overdue with some books.)

04-05-10 *Gout and Regout, 2* (to W. G. Demopoulos)

Demopoulosism 39: *Russell's* Theory of Knowledge *ms is somewhat misleadingly titled since it's really more about his theory of propositions and propositional understanding than anything else. I believe the best development of the views of his that you're interested in is in* The Analysis of Matter *(oddly, better than* The Analysis of Mind *on these topics, a book that I regard as something of an abortion that he should have discreetly buried). But there are parts of* Theory of Knowledge *that were published (in* The Monist*, under the title "The Principle of Acquaintance" that deal explicitly with James and Mach and which are likely to interest you, if I'm remembering correctly.*

Indeed, that is the very part of the book that interests me. Also I now have both *Analysis of Mind* and *Analysis of Matter* on my bookshelf. All of this is part of my summer reading program. (And I will keep your criticism of the former in mind as I read it.)

05-05-10 *1003.5209* (to C. H. Bennett)

When you think of me, why is it always prompted by a bad philosophical paper? What do you think about when you see the good philosophical papers? I suspect you never write Scott Aaronson, for instance, saying, "Scott, What do you think of 'QBism, the Perimeter of Quantum Bayesianism' by the physicist Fuchs?" ☺

Scott was at Jeff Bub's annual meeting last week and gave an excellent talk on the "mud fight" (he called it) between himself and Watrous, on the one side of the ring, and you, Debbie, John, and Graeme on the other side. Best talk of the whole meeting, for sure. I had some nice discussions with Scott before and after. He hadn't realized that various assumptions of linearity are pushed upon you nearly automatically by an epistemic interpretation of quantum states. For instance, if you could clone with quantum theory, you would *never* call a quantum state a state of knowledge. Which is the same as saying: If you think there's enough evidence to call a quantum state a state of knowledge, you wouldn't expect that you could clone (even if you didn't yet have a proof in hand). The "linearity trap" is a very happy home for the quantum-state epistemicist.

Attached are two pictures of Spekkens and me at that meeting, sent to me by Michael Seevinck. (The old man with his mouth agape is Charles Misner.)

Yeah—I know you could guess—I don't think much of the Lyre paper: It's the standard 80-year-old fare; no creativity. Quantum measurement problem, humbug. "Quantum theory is in conflict with [Lyre's] CMP," humbug again. My own feeling is that "measurement outcomes" and the world of common experience are just given (i.e., undeniable), but that quantum theory is "additive" to that. It is means of achieving uncommon experience in addition to the usual common stuff. I'd be curious to hear your reaction of pages 22 (right-hand column) through 25 (left column, end of first paragraph) of `http://arxiv.org/abs/1003/1003.5209`.

Well, it's a work in progress: There's no pretense that it's a final story. I am absolutely enamored, however, with Eq. (8) on page 12. If these SICs always exist they give a very pretty way of thinking of the Born Rule for calculating probabilities. I joked with Scott (about my friend Hardy and others), "If your axioms for quantum theory only took you a few months to construct, then it's too cheap a solution."

Things are going well here. My little group is discovering all kinds of things about these SIC measurements. I.e., even if we can't see how far down the beach they go, each one seems to be pretty in its own right, and every now and then one comes across two that have something in common. For instance, we just discovered something very nice in dimensions divisible by 3!

06-05-10 *The Urgleichung as a Normative Rule* (to R. Schack)

Your note from yesterday confronts the central issue, and makes it clear that we have much to discuss and work out in Zurich (what better place than where the whole thing was born!) and Växjö. My feeling is that when we adequately answer the issues you bring up, we will at the same time understand the precise reason for *this* modification to the LTP rather than some other—i.e., why the urgleichung takes the precise form it does. I may comment a little more later after I get some things cleared off my desk.

Rüdiger's Preply

For the last few weeks, I have spent a lot of time thinking about the status of the Urgleichung. Regarding it as an addition was a stroke of genius. What I am struggling with is where exactly between the normative and the empirical it is located.

It is clearly not normative in the Dutch book coherence sense, i.e., it is not a completely internal rule. It says something about the world. It gives an agent who uses it an advantage. A piece of the world has a new property, dimension. Suppose I measure a system with dimension d. Then I can analyze the measurement in terms of a particular counterfactual measurement, one that is appropriate for dimension d. The Urgleichung tells me how my betting odds for the counterfactual measurement should relate to those for the actual measurement.

What happens to me if I use different betting odds, i.e., odds that violate the urgleichung? One possible answer, which is problematical and not really what I want, is that if I violate the urgleichung, I will not be well calibrated. One way in which this might work is sketched below. Do you have any thoughts on this? This is tied up with the very definition of dimension, of course. If the definition of dimension is that it enables an agent to set probabilities according to the urgleichung, then one simply could not have a system of dimension d and not use the urgleichung. But that is begging the question.

One way to bring in calibration is through a game in which the agent announces probabilities for the ground both for the case that the measurement in the sky is counterfactual and the case that the measurement in the sky is factualized. An opponent then chooses if the measurement in the sky is performed. The statement would be that if this game is repeated many times, this creates two subsets of outcomes. The statement would be that the agent cannot be well calibrated for both subsets unless he uses the urgleichung.

Several things are wrong with this construction. If a measurement is an extension of the agent, how could an opponent choose which measurement is performed? Also, for this construction to work one would have to ascertain that the measurement in the sky is an actual SIC and not something else, which elevates "being a SIC" to a property of a piece of the world. Bad.

06-05-10 *Växjö Abstract* (to M. Schlosshauer)

Attached is my draft of an abstract for your session. If it fits the bill of what you wanted, let me know and I'll hit "submit" on the registration form. If you don't like it, or you catch any typos, let me know.

Any further word one way or the other on whether WHZ will be there? Morally, I really ought to confront him real-time with this.

Quantum-Bayesian Decoherence
Christopher A. Fuchs and Rüdiger Schack

The usual story of quantum measurement since von Neumann has been that it occurs in two steps: First the quantum system becomes entangled with the measuring device; then, mysteriously, there is a selection of one of the entangled state's components in order to single out an actual measurement result. But the entangled wave function alone (with its freedom to be expressed in any basis) cannot say how it should be decomposed so that the selection can even be effected. The theory of quantum decoherence, developed by Zeh, Zurek, and others, attempts to shim up this deficiency in the von Neumann story by supplementing it with a further story of interaction between the device and an environment: The idea is that the specific form of the interaction with the environment specifies how the system+device state ought to be decomposed. But then what of the mysterious selection? Decoherence theorists usually leave that question aside, implicitly endorsing one variety or another of an Everettian interpretation of quantum mechanics.

In contrast, the Quantum Bayesian view of quantum theory developed by Caves, Fuchs, Schack, Appleby, Barnum, and others, leaves most of the von Neumann chain aside: Instead of unitary evolution, it takes the idea of common experience as first and foremost. In this view, quantum "measurement" is nothing other than an agent acting upon the world and experiencing the consequences of his actions—the very same thing he was doing before quantum theory was even thought of. A quantum measurement is most generally an agent's "whack" upon the external world and its unpredictable consequence for him. To say it still differently, the Quantum Bayesian story is the preface and conclusion of the von Neumann one, without the dramatic artifice of unitary evolution, entanglement, and decoherence in between: selection is the consequence of a whack and nothing more.

Thus, it would seem there is no foundational place for decoherence in the Quantum Bayesian program. And that is true. Nonetheless, one can identify a two-time gambling situation (gamble now on the outcome of a measurement in the future, given that an intermediate measurement will be performed in the nearer future) for which consistent gambling behavior mimics a belief in decoherence. The consistent gamble makes use of a quantum version of van Fraassen's reflection principle, and explains to some extent the seduction (but misleadingness) of the decoherence program. This work builds on [1], [2], and [3], where the Born Rule is viewed as an empirical addition to probability theory and quantum theory is seen as "additive" to common experience, rather than "underlying it" in a reductionistic sense.

06-05-10 *Växjö Abstract, 2* (to M. Schlosshauer)

Schlosshauerism 29: *Judging from the abstract and what you've told me before, you surely have a point: the final step of "selection" is the notorious achilles' heel of the decoherence program. But at the same—I'd say—the program (understood properly!) never claimed to remedy this worry. Instead, it assumed that one would tack on in the end whatever interpretation of QM one wanted, in order to effect selection. In other words, decoherence (again, properly understood) assumed that one works in a picture where selection happens at some stage of the vN chain.*

Understood. But the way I said it was this:

> But then what of the mysterious "selection"? Decoherence theorists usually leave that question aside, implicitly endorsing one variety or another of an Everettian interpretation of quantum mechanics.

And you have to admit that that is *usually* the case. Furthermore, the Oxford Everettians think that decoherence is precisely the remedy—that selection is never needed and decoherence is precisely the missing link.

In any case, I'll make this claim: It may be true that, logically speaking, the decoherence program is noncommittal on the interpretive program, but my suspicion is that, for all those who take it seriously as a foundational ingredient, the die is loaded. That von Neumann Type 2 (unitarity) is considered the more *natural* thing for physics to be talking about than von Neumann Type 1. The assumption is, unitarity is no mystery—that's the starting point.

Schlosshauerism 30: *Now, to my mind, the new aspect that the QBist approach is bringing to the table is to say: all unitaries are subjective. So the whole entanglement business of decoherence appears in a much less physically relevant light. I think most (if not all) other interpretations would ascribe some sort of objective character to unitaries (and thus the process of entanglement à la vN), and thus there'd be a real place for decoherence in this picture.*

06-05-10 *Movie Title?* (to S. Savitt)

It was good talking to you again. May I ask you to send me the movie title you mentioned that brought up some imagery of the Jamesian theory of truth? I'd like to watch that.

I read the Gerard Manley Hopkins poem: It is indeed powerful! I wish I could read it with the same verve you demonstrated the other night!

Steven's Reply

> The movie is *Playtime*, which fans on the IMDB say should be watched only in a theatre in the 70mm version, which one never has a chance to do. Every film by Tati is wonderful in its own way.

10-05-10 *The Urgleichung as a Normative Rule, 2* (to R. Schack)

[Here's the completion of the note I had started last week.]

You do have several good points in this note. [See R. Schack's Preply to note titled, "The Urgleichung as a Normative Rule," dated 6 May 2010.] And I do think that Zurich is going to be a grand time to think about it deeply. Here are some shorter, preliminary replies at the moment.

Schackcosm 133 : *What I am struggling with is where exactly between the normative and the empirical it is located.*

My answer at the moment is that I don't want to see it as "between" at all. The urgleichung is a normative statement, full stop. It is that a normative statement (a recommendation for behavior) has been latched onto for empirical reasons. The usual vision of a physical law is that it is a) intended to be descriptive (in a correspondence sense) and b) empirically motivated. What we QBists do is simply replace a) by "intended to be normative."

Schackcosm 134 : *One way to bring in calibration is through a game in which the agent announces probabilities for the ground both for the case that the measurement in the sky is counterfactual and the case that the measurement in the sky is factualized. An opponent then chooses if the measurement in the sky is performed.*

Yes, like you, I don't like this. It is similar to Itamar's way of posing coherence in `quant-ph/0208121` and `quant-ph/0510095`. As you always emphasize, coherence should be posed as a purely internal criterion. That's a first consideration, but then there is also this further crucial point that you make (specific to quantum theory): "If a measurement is an extension of the agent, how could an opponent choose which measurement is performed?" And finally, on calibration, I'd say we can't waiver: "Probability is single case or nothing!"

My feeling is that if we get an argument for the specific form of the urgleichung, we'll at the same time start to understand what the agent is supposing of his world so that he would view any other connection between the probabilities as ill-advised. And for this, we're going to have to dig deep into our souls again. I wrote this to Max yesterday:

> Rüdiger and I are now set for Växjö. We're in Zurich the week before, and then we transfer to Sweden, via Copenhagen, on Sunday, June 13. At the moment, we're scheduled to stay in Växjö 'till the end, because I'd like to talk with Anton if he does actually show up. But on the guess that there's a significant chance that he'll be a no-show with only a few days notice (as he often is at conferences), we're contemplating uprooting to Copenhagen for a day or more. Two weeks of sublime thought! I'm really looking forward to it. The main project on the table is to find a convincing motivation for the urgleichung. Consistency, like always, should carry the day! It's just a question of following its instructions.

It must be that there is something in our conception of quantum measurement that pushes us to the urgleichung (or at least the linear form of it).

I wish I had more to say, but at the moment, I don't.

10-05-10 *Reference and Weyl* (to W. G. Demopoulos)

Demopoulosism 40 : *I'll be copying the Weyl today and should be able to put it in the mail very soon. Do you have the page number for your quote from Feynman about the atomic hypothesis?*

I wish I had marked that page number down! For, this morning, I haven't been able to find it. However, I am quite certain I found it in that book—I believe I pulled it off my shelf and tracked it down when I was writing that section of the paper. Anyway, a web search this morning shows me that it can (also?) definitely be found in *The Feynman Lectures on Physics*, Volume 1, beginning Section 1-2. Unfortunately, I cannot see the page number on that. . . . Wait! I can do better, that

IS the page number, 1-2 (that's the convention of the book). The Section is titled "Matter is Made of Atoms."

... Interesting. Just as I was putting my copy of *The Character of Physical Law* back on the shelf, I noticed that it was sitting exactly beside Gerald Feinberg's book, *What is the World Made Of?* It's been about 30 years since I've read that one, but my guess is, his answer wasn't, "The world is made of this and this and this. The world is constructed of every particular there is and every way of carving up every particular there is."

10-05-10 *1003.5209, 2* (to C. H. Bennett)

Beautiful article on pre-mineralarian mineralarianism! On Rob, I think he was just temporarily knocked for a loop. I had just commented that I swallowed six pills at once. He seemed surprised, "Six at once!?" I said, "No gag reflex; I'd be great in the porn industry." Then I was so tickled with myself, I couldn't stop laughing. Rob had difficulty recovering himself as well.

I'm jealous of your visit to Seven Pines. You and I were there together previously in 2004.

The 200th anniversary celebration sounds perfect. Kiki and I would have loved to have come (i.e. we would definitely have done it), if I weren't already scheduled for Europe on the same day. I'll be in Zurich on the 12th just finishing Renato Renner's meeting, and then traveling to Sweden on the 13th for Max Schlosshauer's special session on "quantum decoherence" at the annual Växjö meeting. So, from Zurich to Zurek for me. See attached trouble-making abstract. [See 06-05-10 note "Växjö Abstract" to M. Schlosshauer.] I get to confront Wojciech directly with this.

Charlie's Preply

> I think of you often, and not mainly in connection with bad philosophical papers. I suspected it was bad, just needed you to tell me. I am at a conference on decoherence in Minnesota with, it turns out, a lot of talk about quantum foundations, the Seven Pines Symposium, sponsored by a wealthy gentleman physicist whose hobby is refurbishing 1910 era cars, especially Mercedes-Benz. Others include Bill Unruh, Amit Hagar, Phil Stamp, Hans Briegel, David Wallace, and Alastair Rae. In the pictures you sent, why is Rob holding his book upside down? Is that part of the SIC-POVM philosophy? In reading the suggested part of your latest tract, I especially liked the new uses of diamonds and the ability to calculate the additional attraction of a hungry child toward an apple.
>
> I have been waging a quixotic battle of my own, trying to persuade the curator of the Museum of Hoaxes to correct his site's entry on Mineralarianism, where he says minearlarians eat rocks. In fact they eat synthetic chemicals made from rocks (and air and water), but most people are surprised to hear this is possible. I have found an amazing number of otherwise well educated people who think that human nutritional requirements are so complex that a person could not possibly survive on an all-chemical diet—surely there must be some undiscovered substances in natural foods without which humans would sicken and die, just as they do when deprived of known vitamins or essential amino acids. In the course of this I uncovered a piece of research done by NASA exploring just this kind of diet. See attached article.
>
> Theo and I are celebrating the 200th anniversary of our house in June—see attached invitation. It's maybe a bit far for you and Kiki to come, but I think it's the sort of event you would enjoy.

12-05-10 *Correct Woody Allen Quote* (to the QBies)

You might want to know the correct quote as well:

> "I hate reality, but, you know, where else can you get a good steak dinner?"

12-05-10 *Today's Colloquium* (to the QBies)

Today's colloquium speaker Verlinde strikes me as potentially interesting: He strikes me as having a good "idea for an idea" (but it probably shouldn't be thought of as more rigorous than that). Anyway, the talk might give you some food for thought in relation to QBism, or "additionism" as Marcus calls the broader program.

12-05-10 *Definitely Over the Limit* (to M. Schlosshauer)

Schlosshauerism 31: *I discovered [this album] just the other day: it's pianist Jacky Terrasson with vibes player Stefon Harris locked in spontaneous interplay. Another great example for how standards are just some very vague foil for creating something entirely new.*

And so too of space itself. See this talk we just had at PI today, `http://pirsa.org/10050022/` (it's not posted yet, but should be by tomorrow morning my time . . . or probably by the time you read this note). Space, like the jazz standard, is the foil in the background—or at least that's a thought that intrigues me. You can also see this paper by Verlinde, `http://arxiv.org/abs/1001.0785`. It's all vague and hand-wavy at the moment (dimensional arguments really), and from the wrong philosophical point of view, but I can't help the feeling that there is something really deep here. It says that space is the stuff on the "outside," and I quite like that. It is connected (I think or hope) to what I meant in the last paper when I said that QBism "tinkers with spacetime."

But on to the music! There is deep stuff here as well. I loved this line in the album you suggested: "Our two instruments became one instrument with four hands." That, I think, is the right way to think of Alice and Bob in most quantum information protocols. When in collaborative communication, two (ostensible) agents are really one with respect to the concerns of personalist, Bayesian probability theory. I must have sent you William James's notion of the self before:

> In its widest possible sense, however, a man's self is the sum total of all that he can call his, not only his body and his psychic powers, but his clothes and his house, his wife and children, his ancestors and friends, his reputation and works, his lands and horses, and yacht and bank account.

Thanks a million again for the suggestion. It pushes me to new thoughts, and for that I am always grateful.

13-05-10 *Contact from the Stellenbosch Institute for Advanced Study* (to H. B. Geyer)

It looks like it's been seven years since we've "seen" each other! Great to hear from you. It sounds like a lot has been happening down there.

Thanks for the flattering remarks on my latest paper. I am intrigued by your proposition, but let me try to understand it better. Are you wondering whether I would be interested in an existing project? Or are you asking whether I might consider being a "project leader" (phrase you used)?

It is true that I look for every opportunity possible to promote progress on understanding these magical quantum measurements, the symmetric informationally complete (SIC) positive operator valued measures. (See all the references in this paper by Scott and Grassl, if you want to get a sense of the breadth of the problem: `http://arxiv.org/abs/0910.5784`. You might also get a laugh out of the "press release" on my group's involvement with these things; attached. And here's a meeting I organized on the problem a couple years back: `http://pirsa.org/C08025`.) Would a program like that be something of interest to STIAS?

It would indeed be nice to give you a shorter visit and see what it is like there. Thank you for the invitation. But with all the travel I'm already committed to this summer, I couldn't possibly do it before September or October. Would something like that work for you?

Hendrik's Preply

> A voice from the past – you may recall that you helped guide Robert Schumann 10 years ago through a thesis on Quantum Information Theory which I supervised; I think we sporadically exchanged a few e-mails after that.
>
> Much has happened here since; I/we managed to establish a National Institute for Theoretical Physics in South Africa, funded by the SA Dept of Science and Technology. Neil Turok will be able to tell you something about it; amongst other things Neil was instrumental in getting Stephen Hawking here in 2008 at the inauguration (see `http://www.nithep.ac.za/`).
>
> My own career has recently somewhat diverged from theoretical physics; I am presently the director of the Stellenbosch Institute for Asdvanced Study (STIAS) – see `http://www.stias.ac.za/`. (Lenny Susskind has been a long time supporter, by the way, and spent time here in 2009 – `see http://www.stias.ac.za/news.html`). STIAS has an ambitious programme covering all disciplines, with a focus on inter-/transdisciplinary projects. Finding projects within, or primarily rooted in, the natural sciences proves to be quite a challenge.
>
> I recently read your papers on Qbism, Perimeter etc., finding them stimulating, became aware of your work at Perimeter and wondered whether you would be interested to explore a quantum information related project at STIAS. Such projects typically entail that a project leader and a group of researchers identified by/in consultation with him/her are invited as STIAS Fellows who then spend time here simultaneously – from one to several months (not unlike the Kavli Institute setup, but on a smaller scale of course).
>
> Perhaps you would consider first coming to STIAS on your own to get a feel for the place. I can invite you as my guest for a week or two (or longer, if your programme would allow it). This will also provide an opportunity to interact with people at NITheP, apart from whoever is here as STIAS Fellows at the time.
>
> Please give it a thought, and let me know.

14-05-10 *Definitely Over the Limit, 2* (to M. Schlosshauer)

Schlosshauerism 32: *As for considering Alice and Bob as one agent: do you then look at this agent as possessing two independent prosthetic hands with which "he" can perform two different—and potentially synchronous—actions upon the world, at different points in space?*

Your question on Alice and Bob is good one, a deep one, an important one. I promise you an answer in Växjö! Monday, I go back to DC, this time to report on the QBies to ONR. So I'm scrambling once again!

14-05-10 *Qutrit SIC POVM experiment* (to L. A. Rozema)

Rozema-ism 1: *Is there anything that makes the 3d sic povm more interesting than the 2d sic?*

There's a quote by Richard Feynman that goes: "A poet once said, 'The whole universe is in a glass of wine.' We will probably never know in what sense he said that, for poets do not write to be understood. But it is true that if we look in glass of wine closely enough we see the entire universe."

Similarly one can say of the qutrit: The whole of the probabilistic structure of quantum mechanics is already in it. What I mean by this less poetically is that Gleason's theorem, which underlies the Born Rule for quantum probabilities, makes crucial use of the qutrit in its proof. Particularly, Gleason shows that if the theorem is true in dimension three, then it is true in all dimensions (even infinite dimensions), and as it turns out, the hard part of the proof is precisely the dimension-three part. So everything stands or falls on the qutrit case.

Now, we Quantum Bayesians want to take the "quantum law of total probability" (i.e., the Born rule written in SIC language) as a new foundation for quantum theory. So, it is just nice to see it firmly established (experimentally) in dim=3, and by way of this, one can make a direct comparison (in word and deed) to Gleason's theorem when advertising the new point of view.

That is to say, Gleason (effectively) shows the QLTP as a *theorem* in dim 3. (I say "effectively" because he didn't know of SICs at the time, and thus could not rewrite the Born Rule into that language.) We on the other hand want to take the QLTP as an axiom. So, it really ought to have some experimental grounding. And showing that it has experimental grounding in dim 2 is of no great interest, because Gleason's theorem doesn't even work there: I.e., the QLTP has no competition from Gleason in dimension 2. All the direct competition is in dim 3.

Finally, let me attach one of Gelo's very pretty equations. See Eq. (2) in the attached file. The "QBic equation" along with the "Bloch-sphere-type" equation uniquely specifies which probability distributions for SIC outcomes correspond to pure quantum states. Only in dimension 3, so far as we know, does the QBic equation take such a simple and beautiful form. If simplicity unlocks secrets, it's going to be found there. Still another reason for looking at qutrits. (And once again, another reason that qubits are too trivial. In the qubit case, only the Bloch sphere equation is active—for the QBic equation reduces to it in that case. Quantum life only becomes interesting in dimension 3.)

Hope that helps some.

17-05-10 *Chris and the Navy* (to D. H. Wolpert)

Wolpertism 2: *Navy? Related to things like quantum computing/encryption?*

No, quantum foundations. They fund my QBism (Quantum Bayesian) effort. Specifically, the technical part of it—to develop a *clean* formalism for quantum theory that dispenses with quantum states and instead uses probabilities only. The key part of the apparatus is the SIC (symmetric informationally complete) positive operator valued measures—an object we believe (but have not yet proven) to exist in all finite Hilbert-space dimensions.

See attached glossary. [See 07-04-10 note "Up Front" to Å. Ericsson *et al.*]

20-05-10 *Civil War Times* (to D. B. L. Baker)

Yesterday, on my drive between Shepherdstown, West VA and Dulles Airport, I took a small side jaunt to the Antietam Battleground. The view was breathtaking; I wish you could have been there. Such a beautiful place, juxtaposed with the idea of so much killing. I cried a bit before getting back in the car.

20-05-10 *My Weyl Quote* (to H. Price)

I'll show you mine; now you show me yours ...

Unfortunately, I don't know the original source (where Weyl wrote it). I do know however that I got this from Paul Forman's article, "Weimar Culture, Causality, and Quantum Theory, 1918–1927: Adaptation by German Physicists and Mathematicians to a Hostile Intellectual Environment." Presumably (hard to remember, it being 11 years since I copied this down) the phrase "[regarded as a four-dimensional continuum of events]" was Forman's addition (i.e., not mine, but I can't guarantee it at the moment).

> Finally and above all, it is the essence of the continuum that it cannot be grasped as a rigid existing thing, but only as something which is in the act of an inwardly directed unending process of becoming ... . In a given continuum, of course, this process of becoming can have reached only a certain point, i.e. the quantitative relations in an intuitively given piece $\mathcal{S}$ of the world [regarded as a four-dimensional continuum of events] are merely approximate, determinable only with a certain latitude, not merely in consequence of the limited precision of my sense organs and measuring instruments, but because they are in themselves afflicted with a sort of vagueness ... . And only "at the end of all time," so to speak, ... would the unending process of becoming $\mathcal{S}$ be completed, and $\mathcal{S}$ sustain in itself that degree of definiteness which mathematical physics postulates as its ideal ... . Thus the rigid pressure of natural causality relaxes, and there remains, without prejudice to the validity of natural laws, room for autonomous decisions, causally absolutely independent of one another, whose locus I consider to be the elementary quanta of matter. These "decisions" are what is actually real in the world.

21-05-10 *About Changing the World* (to L. Freidel)

Returning to last night's discussion ... The part about "changing the world" (literally) with the aid of a scientific theory. I expand on some of what I said in Sections 6, 7, and 8 of this paper: `http://arxiv.org/abs/1003.5209`.

But more directly, you might enjoy reading the first few paragraphs of the attached proposal I wrote for the Templeton Foundation. It says it all a bit more flowingly, and I was pretty upfront about it with them. I.e., I actually believe this stuff!

21-05-10 *Workshop Talks* (to O. C. O. Dahlsten)

Let's give it the following provisional title:

"Some Properties of QBist State Spaces, whichever Ones Rüdiger Schack Does Not Cover"

How does that work for you?

21-05-10 *A Third Way* (to M. Gleiser)

I was reading your piece in the *Harvard Divinity Bulletin* from 2005. I just want to quickly respond to these lines of yours near the beginning:

> After reading hundreds of creation myths I realized they all fall within a simple classification scheme, based on how each answered the question "Did the world come to be at a specific moment in the past?" That is, "Was there a moment of creation?" The answer can only be "yes" or "no." A "yes" means the universe has a finite age, just as we do; it appeared some time in the past and is still around today. A "no" can mean two things: either the universe has existed forever, an eternal, uncreated cosmos, or it is created and destroyed in a cyclic succession that repeats itself throughout boundless time.

But there is a third way to envision things ... at least, and probably more than that, but one I care about. It is that creation comes in "spots and patches" as William James puts it:

> Our acts, our turning-places, where we seem to ourselves to make ourselves and grow, are the parts of the world to which we are closest, the parts of which our knowledge is the most intimate and complete. Why should we not take them at their facevalue? Why may they not be the actual turning-places and growing-places which they seem to be, of the world—why not the workshop of being, where we catch fact in the making, so that nowhere may the world grow in any other kind of way than this?
>
> Irrational! we are told. How can new being come in local spots and patches which add themselves or stay away at random, independently of the rest? There must be a reason for our acts, and where in the last resort can any reason be looked for save in the material pressure or the logical compulsion of the total nature of the world? There can be but one real agent of growth, or seeming growth, anywhere, and that agent is the integral world itself. It may grow all-over, if growth there be, but that single parts should grow *per se* is irrational.
>
> But if one talks of rationality—and of reasons for things, and insists that they can't just come in spots, what *kind* of a reason can there ultimately be why anything should come at all?

I like it because it tracks with what I think is going on with quantum measurement. But we can discuss.

I can't wait until this meeting is over, so that I get a chance to read some of these writings of yours that I just discovered!!

22-05-10 *The Coffeemaker Revisited* (to L. Hardy)

I just got the coffee brewing this morning and imagined the following. A devotee of Sarah Palin says, "God created the world just as it is. All the complexity, all the detail you see, to its last detail, was in God's great plan." And that of course, includes the bad Sunbeam coffeemaker design I deal with everyday (the carafe always drips onto the counter). A devotee of Daniel Dennett says, "The way to understand the world is as Conway's Game of Life. All the complexity, all the detail you see, to its last detail, was in the game's initial condition." And that of course, includes the bad Sunbeam coffeemaker design I deal with everyday (the carafe always drips onto the counter).

26-05-10 *Invitation to Speak at Science and Nonduality 2010* (to S. E. Sobottka)

I have been thinking hard about whether I might take you up on your invitation—the conference distinctly intrigues me—but in the end I must say "no." It is not that I am not sympathetic to *some* aspects of what I read at the conference website. In my own opinion, quantum theory might well imply, or at least hint at, a kind of pantheism. But when so, it does as a kind of pluralism (something along the lines of ideas in William James's book *A Pluralistic Universe*). So, it would be a kind of spiritualistic universe, but not one of "oneness"—instead a kind of "manyness," a pluriverse. However, that's just a line of thought and research—one that I'm sure will take me several years and several developments in the formalism to see through clearly. Not something written in stone—but a research direction—and ideally it might be good for the general public to know something about this.

The reason I say "no" to the invitation is what I perceive as the hodgepodge nature of the meeting and the speakers there. The ideas I read are really all over the map: It feels to me like a million stories by a million lonely souls. Take F. David Peat, Stuart Hameroff, Amit Goswami, and me. The *only* thing we'd really have in common is the *word* "quantum"—there's no common substance beyond that. Goswami's website contains nearly the opposite of everything I'd say. There's nothing wrong with debate of course: But a debate at the service of a pre-established cause (say "nonduality") troubles me. Moreover, I worry about the level, or to be more honest, lack, of serious critical thinking in many that I see in the speaker list.

In all, I think the conference is just not the right forum for me. At Perimeter Institute, I carry a coffee cup that says, "Life is not about finding yourself, but about creating yourself." All the evidence in front of me indicates a conference largely consisting of people who've spent years "finding themselves" rather than ones who've jumped into the stream of life and contributed to making the world "go." In the end, I'd likely be pretty uncomfortable there.

But thanks for your consideration, and best wishes.

27-05-10 *Stream of Life* (to J. B. Lentz)

Just yesterday, I turned down an invitation to speak at one of the strangest conferences I've ever been invited to. If you have a look at the other speakers, you'll understand why. See: `http://www.scienceandnonduality.com/speakers.shtml`. (The main page of the conference is `http://www.scienceandnonduality.com/`.) As it turns out, I ended my note to the organizers with these words:

> In all, I think the conference is just not the right forum for me. At Perimeter Institute, I carry a coffee cup that says, "Life is not about finding yourself, but about creating yourself." All the evidence in front of me indicates a conference largely consisting of people who've spent years "finding themselves" rather than ones who've jumped into the stream of life and contributed to making the world "go." In the end, I'd likely be pretty uncomfortable there.

Before meeting Kiki and meeting you, I'm not sure I could have written some of those sentences. The way you live has been an inspiration to me since the beginning: You more than most others I know have certainly "jumped into the stream of life and contributed to making the world go."

Happy 70th birthday Brad! I think now is when life gets really good.

29-05-10 *God Wouldn't Scam, Would He?* (to H. B. Dang & the QBies)

Dangism 4: *I've bought many things on eBay, and this is a principle I've been always followed to avoid scams: if it sounds too good to be true it probably is.* [...]

As Ingemar-Kate pointed out, in $d = 6$, among the 984 normal vectors, we can find sets of 4 vectors whose squared inner products are all 1/3. Moreover, in each such set, those four 6-component vectors span a 2-D subspace, so they indeed form a 2-D SIC. This is very interesting, because one doesn't need to start with a 6-D SIC fiducial. Start from any vector in the Zauner subspace (which we know how to calculate), we will still get the same linear dependency structure and still get 2-D SICs out of it.

The big question is, of course, will this kind of miracle happen in $d = 9$? [...]

In $d = 9$ there are 79767 normal vectors (corresponding to that many hyperplanes), and there are over 3 billion inner products to be checked. Instead of taking a long walk like Ingemar did, I slept, played pool, talked to Chris, etc. while waiting for 20 hours for my desktop and the QBism server to finish the calculation. Indeed, there are pairs of normal vectors that have the right inner product. Those pairs come from 54 normal vectors.

Next small question: among those 54 vectors, can one find set of 9 vectors whose squared inner product between any 2 of them is 1/4? [...]

Last small question: for those set of 9 vectors, do they live in a 3-D subspace?

The answer is yes! So they do form a 3-D SIC!

God? It is *our* efforts and actions that complete nature! You have added to nature, and it has tolerated it. (See one of my favorite William James quotes attached.) [See quote in 05-01-09 note "What I Really Want Out of a Pauli/Fierz-Correspondence Study" to H. C. von Baeyer & D. M. Appleby.]

Mighty good work! This gives me a very happy feeling this morning.

31-05-10 *References* (to N. D. Mermin)

Merminition 218: *I'm refereeing a paper that claims that virtually nobody but Fine and de Munyck dissent from the view that quantum mechanics is nonlocal. Could you send me a few references to published papers by yourself et al. that take issue with nonlocality.*

I'm sorry, I forgot to reply to this one! My "inbox" is an absolute mess. Is this still relevant to you? If so, I'll put a list together a little later in the day. Also, Zeilinger and Brukner and Zukowski emphasize that there is nothing nonlocal about QM. Griffiths and Gell-Mann as well. And I'm sure more names will come to mind if I think harder.

31-05-10 *References, 2* (to N. D. Mermin)

Merminition 219: *Any other names that come to mind (me, for example) should be added to my list.*

With regard to yourself, I'll let you make your own judgements. With regard to me, these three are fairly explicit:

1. C. A. Fuchs and A. Peres, "Quantum Theory Needs No 'Interpretation'," Physics Today **53**(3), 70–71 (2000).

2. C. M. Caves, C. A. Fuchs, and R. Schack, "Subjective Probability and Quantum Certainty," Studies in History and Philosophy of Modern Physics **38**, 255–274 (2007).

3. C. A. Fuchs, "QBism, the Perimeter of Quantum Bayesianism," (2010), `arXiv:1003.5209v1`.

With regard to Brukner and Zukowski, see: `http://arxiv.org/abs/0909.2611`. They tell me they are writing a masterwork on the subject, coming flat out against nonlocality, but I don't see it on the `arXiv` yet. You might contact them directly. Here's an older one by Marek: `http://arxiv.org/abs/quant-ph/0605034`. As I recall, here's one where Duvenhage came out fighting for locality: `http://arxiv.org/abs/quant-ph/0203070`. There were a gazillion things by Peres. Here's one of the later ones: `http://arxiv.org/abs/quant-ph/0310010`. Is that enough to get you started?

It sounds like Griffiths exaggerated, but I concur with the gist of what he was trying to get after. The vast majority of quantum info people, at least, seem to buy spooky action at a distance out of hand.

31-05-10 *Another on the Side of Locality* (to N. D. Mermin)

This one from Itamar Pitowsky: `http://arxiv.org/abs/quant-ph/0510095`.

31-05-10 *And Bill Demopoulos* (to N. D. Mermin)

Also, Bill Demopoulos has a paper coming out that is sympathetic with the side of locality. It's not on the web yet, but I'll cc this note to him and maybe he'll send you the present draft.

31-05-10 *Caves Talk* (to N. D. Mermin)

You might enjoy this talk of Carl's "What are the laws of physics? Resisting reification" at `http://info.phys.unm.edu/∼caves/talks/talks.html`.

31-05-10 *The Gleason-Weyl Thing* (to D. B. L. Baker)

Speaking of bad mental places, sorry I've kept you so long with a reply. This Spring has turned to insanity for me. Some men can't keep their pants on; my problem is I can't stay off a damned airplane. I'll try my best to write you a longer note from Zurich next week; the town is the kind of place that makes me think, and I'll surely be lonely in the soul once again.

I certainly still want to steal away with you, but the demons have me booked up all the way into the Fall. Maybe when (more carefully, if) my position becomes permanent here, I can use that as a good excuse to blow some money on a celebration with you.

When I was in Portland in March, I couldn't keep myself out of Powell's Bookstore. It was the most amazing place I had ever seen. And you want to talk about hippie chicks! First off the town is full of them, but then the concentration at Powell's reaches truly dangerous levels. Nonetheless, I nearly single-mindedly kept my attention on the books: I came home with over $400 worth!

But my best purchase of all from them had to wait until my return home—it came from the internet. When I got home, I asked my three students, "Did you go to Powell's." "Only to the technical book annex a few blocks away from the main store," they responded. I was like, "You losers! You missed the greatest bookstore ever. All the history, art, architecture, philosophy, biography ..." Then I said, "Well, did you buy anything?" They all responded, "Nah." But Matthew, the youngest, said, "Well, I did see an old book on group theory, with a stamp on the first page that said, 'Andrew M. Gleason'." I said, "Which book on group theory?" He said, "An old book by Weyl." I said, "*Theory of Groups and Quantum Mechanics*?" He said, "Yeah, that was it; an old hardcover version of it." I said, "You came across Gleason's copy of Weyl's book and you didn't buy it?!?!" "How much did they want for it?" He said, "$17.95." My jaw dropped. I said, "What on earth were you thinking?" He said, "Well, I didn't know if that was really Gleason's stamp or not; somebody else might have just put it there to sell the book more easily." I said, "Now who would do that?!?! Who on earth besides us even knows who Gleason is?" Well, I got on the internet and found that Powell's had one hardcover copy of the book for $17.95 and bought it immediately. Now, the mingling of Gleason and Weyl's spirits hanging out in my study have been giving me all kinds of inspirations. Report of one such below. (And still further below, John Wheeler's story of how he learned quantum mechanics from Weyl's book when he was 19.) [See 27-04-10 note "Midnight Reading" to H. C. von Baeyer and 24-04-10 note "Weyl's Book and John Wheeler" to the QBies.]

In another note, I'll tell you about who Gleason was and why anyone would care, and I'll record a funny story about the one time I met him.

01-06-10 *SIC POVMs and the Law of Total Probability* (to B. R. La Cour)

I got your note and have read it. Thanks for your interest in these matters. Near the closing, you write,

La Courism 3: *The use of SIC POVM and projection measurements leads to a result which, at first, appears to be at variance with the law of total probability. A more careful examination reveals that the apparent discrepancy is due to ...*

I think, implying that *I* think [sic] that there is some discrepancy between the quantum rule and the law of total probability. But I do not think that. Rather I view the Born Rule as a *supplement* to raw probability theory that allows probability assignments in *one* experiment to be expressed in terms of the probability assignments in another (incompatible) experiment (where there need not have been any a priori connection). Please see Section IV of my paper "QBism, the Perimeter of Quantum Bayesianism," `arXiv:1003.5209v1`. Particularly, the part below Eq. (8) where it says,

> But beware: One should not interpret Eq. (8) as invalidating probability theory itself in any way: For the old Law of Total Probability has no jurisdiction in the setting of our diagram, which compares a 'factual' experiment (Path 1) to a 'counterfactual' one (Path 2).

If you'll be in Växjö, we can discuss then. I'm just getting ready for it, by way of Zurich the week before.

01-06-10 *URGENT QCMC Invited Speakers ABSTRACT* (to QCMC 2010)

Attached is the abstract for my talk, both in LaTeX and as a PDF file.

Charting the Shape of Hilbert Space

The space of quantum states for a d-level system is usually thought of as a smooth, featureless place—simply, a linear vector space $\mathcal{H}_d$ over the complex field. But in fact, the space of quantum states corresponds to the convex set of trace-1 positive semi-definite operators *on top of* $\mathcal{H}_d$: This is a body that is anything but smooth and featureless. And in its shape may lie the key to a deeper conceptual understanding of quantum mechanics—at least this is the point of view of the Quantum Bayesian approach to quantum theory developed by Carlton Caves, Rüdiger Schack, the author, and others [Fuchs10].

The reason for this is that Quantum Bayesianism, or QBism, is based on the idea that quantum theory is best understood as an *addition* to probability theory, not as a theory separate from standard probability theory or one including standard probability theory as a special case. It is an addition invoked in a situation where one wants to analyze a given physical experiment in terms of another, never-actualized (or counterfactual) experiment. As such, the first step to finding a deeper understanding quantum theory is to find a manageable representation of quantum states purely in terms of probabilities, without amplitudes or Hilbert-space operators. In this talk, we review the efforts the Perimeter Institute QBism group has made to find such a good representation.

The best candidate so far involves a mysterious entity called a "symmetric informationally complete positive-operator-valued measure," or SIC (pronounced "seek") for short. This is a set of d^2 operators $H_i = \frac{1}{d}\Pi_i$ on $\mathcal{H}_d$, where the $\Pi_i = |\psi_i\rangle\langle\psi_i|$ are rank-one projection operators such that

$$|\langle\psi_i|\psi_j\rangle|^2 = \frac{1}{d+1} \quad \text{whenever} \quad i \neq j\ . \tag{100}$$

We say mysterious because, despite 10 years of growing effort since the definition was first introduced [Zauner99,Caves99] (there are now nearly 50 papers on the subject), no one has been able to show that SICs exist in general finite dimensions. All that is known firmly is that they exist in dimensions 2 through 67 [Scott09]. Dimensions $2-15$, 19, 24, 35, and 48 are known through direct or computer-automated analytic proof; the remaining solutions are known through numerical simulation, satisfying Eq. (100) to within a precision of 10^{-38}.

What is most intriguing about a SIC is that the probabilities $P(H_i)$ for its outcomes uniquely determine the system's quantum state ρ, and they do so through an amazingly simple formula,

$$\rho = \sum_{i=1}^{d^2} \left((d+1)\, P(H_i) - \frac{1}{d} \right) \Pi_i\ . \tag{101}$$

Making us of this formula, one finds a novel way to think of the Born Rule for quantum probabilities. For instance, consider a von Neumann measurement with outcomes $D_j = |j\rangle\langle j|$ (the vectors $|j\rangle$ forming an orthonormal basis), and let $P(D_j|H_i)$ be a conditional probability for finding outcome D_j if the system had been prepared in state Π_i. Then the probability for D_j given by the standard Born Rule

$$Q(D_j) = \mathrm{tr}(\rho D_j) \tag{102}$$

becomes

$$Q(D_j) = (d+1) \sum_{i=1}^{d^2} P(H_i) P(D_j|H_i) - 1\ . \tag{103}$$

Compare this to the expression one would expect from classical probability theory (i.e., the Law of Total Probability),

$$P(D_j) = \sum_{i=1}^{d^2} P(H_i) P(D_j|H_i) \; . \qquad (104)$$

What a tiny modification to the classical law! In fact, the Born Rule seems to be nothing but a kind of Quantum Law of Total Probability.

Recent work at Perimeter Institute has been devoted much to the SIC existence problem, rewriting the problem in Lie algebraic terms [Appleby10], and trying to see how much of the shape of quantum-state space is implied by the very consistency of Eq. (103) [Fuchs09a,Fuchs09b]. Surprisingly, one can glean quite a bit about the structure of quantum states from the requirement that $Q(D_j)$ always be a proper probability distribution. The talk will end with a list of open problems and avenues for further research.

This work was supported in part by the U. S. Office of Naval Research (Grant No. N00014-09-1-0247).

01-06-10 *Antietam* (to D. B. L. Baker)

Thanks for the lesson. That was great!

It's funny, I know so little about the Civil War myself, but I could still envision a vague sense of the battle. Probably old memories from nearly forgotten movies replaying in my head. But it was real enough at the moment to pull the emotions forth. Things were probably already set in motion by the massive cemetery I drove past in Sharpsburg before getting to the battleground. The weather, dreary and drizzly, was probably conducive as well.

I didn't have much time because I felt I was running late for the airport, but I also stopped at an oak grove in Sharpsburg where Robert E. Lee had camped (for three days I think). It was a beautiful setting—big, massive trees. Very peaceful. It goes to show you the depth of things hidden in the calm airs around us.

01-06-10 *Flattery Will Get You Everywhere* (to J. Ismael)

You flatter me (but I bet you say such things to all the boys). In any case, it worked! I printed out your papers and will be carrying them to Europe with me. I hope to get back to you soon with my thoughts on them.

I too enjoyed our conversation. I feel like I'm learning a lot on Weyl, Ramsey, and the embedded perspective.

Excerpt from the Draft "Volition, Time, and Becoming" Jenann Had Sent

> What makes the world itself appear to be in the process of becoming as it is experienced (rather than simply the otherwise natural idea that we simply have a changing appearance of a fixed reality) is that we observe the results of our own actions. The world partakes in the unsettled, unresolved, remaining to be decided character of volition because what I freely decide to do changes the future course of experience. If we just were just observers of history, there would be no reason that becoming wouldn't be a feature of our experience of time, rather than a feature of time itself. It's the discovery that what happens depends on my will, that makes time itself partake in the contingency of my present and future willings. I can no more regard time itself as a static dimension of which I have a varying appearance than I can regard my own volition that way. Of course there is a transcendent perspective from which both my decision processes and their downstream consequences are part of the fixed, eternal manifold of events. But from any given temporally embedded perspective with a life, as it is being lived, there are any number of futures, any one of which might yet be chosen.
>
> In sum, then, our conception of time differs crucially from our conception of space in that we don't think of ourselves as simply 'viewing' different parts of time in temporal sequence as we think of ourselves as viewing different parts of space. We think of the future as existing only in potential until experienced because the future depends on the movements of my will, and the movements of my will are up for grabs, from my own perspective, up until the very moment of choice.

03-06-10 *Traunkirchen Again* (to the QBies)

On the other workshop, I'm fine with that for anyone who wants to. I myself had to turn down their invitation since I'm going to be in Australia at another meeting. It doesn't look quite so exciting as the second meeting, but it'd be interesting to see how people react to Richard Healey's talk, since he's turning partial QBist. It would give you more time in the Alps to think, contemplate, calculate, get inspired, eat schnitzel, whatever. (The urungleichung, after all, was born in the Alps.)

03-06-10 *Padmanabhan* (to L. Smolin)

I found the talk by your friend yesterday extremely exciting. (And much better/plausible than Verlinde's.) It is hard not to feel that there is something really deep in pursuing this direction.

When he talked about observer-dependent entropy, I wanted to say, "Entropy is *always* observer dependent in a Bayesian understanding of statistical mechanics." I.e., the kind of Ed Jaynes thermodynamics/stat-mech that Caves and I have been promoting all these years. But I was too shy: It was too trivial a point in comparison to the other deep ideas I was hearing.

I feel though that there is something wrong about the "micro-state counting" part of Padmanabhan's picture. What came through loud and clear to me instead yesterday is that an "accelerating observer" is an "agent taking an action upon space" (like in the picture on my office door—it is just that the cube is replaced with empty space). To accelerate is to initiate a quantum measurement (i.e., taking an action on the external world and suffering its consequence).

Anyway, huge foods of thought here!

03-06-10 *Padmanabhan, 2* (to L. Smolin)

Thanks; that was fun! Who could ever say that the standard quantum foundational issues aren't absolutely crucial for issues to do with gravity. The Rindler observer *is* Wigner's friend!

03-06-10 *Gravity and Wigner* (to L. Hardy)

By the way, yesterday you missed one of the best talks I've ever heard coming through the quantum gravity group here. You should watch it as you get a chance: `http://pirsa.org/10060000/`.

The reason I think I'm so excited is that I saw more clearly than previously that one should think of an accelerating observer as one who is taking an *action* (quantum measurement) on empty space (the quantum system). It starts to fit QBist terms for me now, and that always makes me feel happy.

03-06-10 *Elementary Question* (to W. G. Unruh)

I have a probably stupid question, but maybe you have an elementary explanation. As I understand it, a uniformly accelerated observer will see black-body radiation in a case where an inertial observer will see none. People say this arises from the existence of a horizon, blah, blah, blah. But what of the case of an observer standing on the surface of the earth? In the idealized case of a free-falling observer seeing *no* blackbody radiation, would the stationary observer on the surface see some? There's no horizons here, are there? Yet, what I understand of the equivalence principle, it would seem that the fellow stuck on the surface of the earth should see the same thing as the fellow in the elevator.

Confused in Waterloo,

03-06-10 *A (really, really) Recommended Talk* (to G. L. Comer)

Which email address should I use for you now? I'm confused; I didn't see your university one come up in my address book.

Anyway, there is a link to what I thought was a fantastic talk below. And the reasons why I thought it fantastic too. [See notes to L. Hardy and L. Smolin from earlier in the day.] Still one more conceptual link: I saw Bill Unruh give a talk on (your old) dumb holes last month in DC. Afterward I made a comment to him that when two things look too much like each other, one might should stop calling one the analogy of the other. For instance, one should stop thinking of the numerical identification between inertial and gravitational mass as accidental, but rather the consequence of a deep principle. I said, "Maybe you should be looking for your own equivalence principle." He joked that he asks his students, "What do elephants and steam ships have in common?" and then replies, “They both carry trunks. But that doesn’t make them the same thing, does it? Well, it’s amazing how often it works in physics to act as if they are.”

But I think I’m not joking. I think the principle here is that acceleration (through any medium) enacts a quantum measurement upon it. It is an action upon it.

05-06-10 *A Question on Informational Gravitation* (to H. Poirier)

I definitely remember you. And I definitely feel a resonance between Verlinde’s latest turn and my QBism program. See, for instance, this paper of mine: `http://arxiv.org/abs/1003.5209`. See the end of Section VI on page 25; I cite Verlinde’s paper there. Particularly, I am intrigued with the way he treats spacetime as having emerged “outside of the boundary”, while inside the boundary there is not yet such a thing as spacetime.

It is all very early in this stuff still, though. What he seems to have is really more of “an idea for an idea” (as John Wheeler would say) than any truly solid idea, much less an actual “derivation” of Newton’s laws, etc., as he claims in the paper.

Have a look at the papers by this guy, Padmanabhan. For instance,

- `http://arxiv.org/abs/0911.5004`
- `http://arxiv.org/abs/0911.1403`
- `http://arxiv.org/abs/0910.0839`

They support a similar point of view, but I think are much more solid.

I fly to Zurich tomorrow morning, and so may be delayed in my emailing for a day or two, but if you have any further questions, let me know.

05-06-10 *The Consequences of Tommy* (to the QBies)

Saturday morning philosophizing. Thinking about how the urgleichung fits in with Unruh radiation and the principle of equivalence. Listening to The Who’s album *Tommy*. And at this very moment, it’s going by the words:

> Right behind you I see the millions.
> On you I see the glory.
> From you I get opinions.
> From you I get the story.

I like that line, “Right behind you I see the millions.” For I do: It’s one of those days when I feel like we’re doing really very big things. Small, small steps, all on the path toward something really big. And from you guys, “I get the story.”

Let me recommend this interview with John Wheeler for your own Saturday philosophizing: `http://www.bigear.org/vol1no4/wheeler.htm`. Among other things, I think it characterizes well, the role you guys play in my life, or at least it’s what I’d like to strive for:

> **Interviewer:** Do you have some thoughts about educating students?
>
> **Wheeler:** Shouldn’t you rephrase your question? After all, I’m sure that it is really the students who educate me! We all know that the real reason universities have students is to educate the professors. But, in order to be educated by the students,

> one has to put good questions to them. You try out your questions on the students. If there are questions that the students get interested in, then they start to tell you new things and keep you asking more new questions. Pretty soon you have learned a great deal.

Thought of the day in the attachment:

> It is difficult to escape asking a challenging question. Is the entirety of existence, rather than being built on particles or fields of force or multidimensional geometry, built upon billions upon billions of elementary quantum phenomena, those elementary acts of "observer-participancy," those most ethereal of all the entities that have been forced upon us by the progress of science?
>
> — John Archibald Wheeler

07-06-10 *Time Flies* (to J. D. Norton)

Greetings from Zurich, where I happened to bring a few John Norton papers with me (most on historical matters in GR). The physicist in me thinks that before using the words "quantum" and "gravity" in the same sentence, we should take all that we've learned about quantum mechanics and go back to 1907.

Anyway, not quite related to that project, but because I was intrigued, I read your "Time Really Passes" and I enjoyed it very much. I'm glad you've now joined those who believe time flies. For your enjoyment a little story about John Wheeler below drawn from my email collection (it was originally a letter to Greg Comer).

From a 17 December 1997 note to Greg Comer, "It's a Wonderful Life"

> Good holidays to you. This morning, as I was driving to work, it dawned on me that roughly this day 10 years ago, I was conferred my degrees at the University of Texas. Time does fly.
>
> It made me think of a little anecdote about John Wheeler that I heard from John Preskill a few days ago. In 1972 he had Wheeler for his freshman classical mechanics course at Princeton. One day Wheeler had each student write all the equations of physics s/he knew on a single sheet of paper. He gathered the papers up and placed them all side-by-side on the stage at the front of the classroom. Finally, he looked out at the students and said, "These pages likely contain all the fundamental equations we know of physics. They encapsulate all that's known of the world." Then he looked at the papers and said, "Now fly!" Nothing happened. He looked out at the audience, then at the papers, raised his hands high, and commanded, "Fly!" Everyone was silent, thinking this guy had gone off his rocker. Wheeler said, "You see, these equations can't fly. But our universe flies. We're still missing the single, simple ingredient that makes it all fly."

07-06-10 *Time Flies, 2* (to J. D. Norton)

Nortonism 2: *Nice to hear from you and thanks for the Wheeler story. There have been just a few extraordinarily people like Wheeler, full of ideas and able to enthuse students.*

I expect to be excommunicated from the Church of Philosophers of Physics!

Well, in my eyes, that represents genuine progress. Here's the way William James once put it with regard to German philosophy:

> In a subject like philosophy it is really fatal to lose connexion with the open air of human nature, and to think in terms of shop-tradition only. In Germany the forms are so professionalized that anybody who has gained a teaching chair and written a book, however distorted and eccentric, has the legal right to figure forever in the history of the subject like a fly in amber. All later comers have the duty of quoting him and measuring their opinions with his opinion. Such are the rules of the professorial game — they think and write from each other and for each other and at each other exclusively. With this exclusion of the open air all true perspective gets lost, extremes and oddities count as much as sanities, and command the same attention ...

And I must say, I find myself thinking that of the Philosophy of Physics a lot. Extremes and oddities sit side by side with sanities, and it is all tolerated in the forum. Your essay is an example that makes it clear—why should you fear that you'll be excommunicated but that the subject has gone so very wrong. Don't get me wrong, I think I am personally deeply philosophical, and it is a very worthy business, but most of my influences have not come from the clique of philosophy that calls itself Philosophy of Physics.

Thinking of the ending remarks in your essay, it strikes me that the time is right in your life to rethink James's *Principles of Psychology*, particularly the bit on the perception of time, if you haven't read it recently. If nothing else, I'll guarantee that the writing will captivate you.

All the best (and I wish you were here for dinner time discussions as I make a bit of progress in your old papers).

09-06-10 *Appleby's Mud Hut* (to R. W. Spekkens)

With regard to the conversation we just had, here are some excerpts from a ridiculously long email from Marcus to Howard and me:

Applebyism 40: *The usual attitude, which not only drives the Bohmians and Everettians, but is also dominant among physicists generally, is to regard ordinary language/common-sense as a kind of medieval mud-hut. A way of thinking which was useful in the past, but whose day is now gone. Survivals from the past often induce reverence. One seeks to preserve them. And indeed that is the attitude of archaeologists to actual medieval huts found in the course of excavation. However, there are limits. No archaeologist would want to live in a medieval mud-hut, all dank and dark and smelly (except perhaps for a week or two, just to see what it is like). Similarly with common-sense, in the minds of most physicists. It may have a place in the museum. But so far as serious thinking is concerned the only thing to do is tear it down and replace it with some modernistic structure, all glass and polished steel.*

One of the difficulties with this programme is that a building has to rest on something. Actual modernistic buildings rest on the same wormy, fungus and bacteria-impregnated earth that the medievals used to build their mud-huts on. With the modernistic structures we build in our minds it is even worse: they don't simply rest on the same soil, they actually rest on the mud hut itself, entire and unreconstructed. Despise the mud-hut at the bottom of the whole thing, as contemporary physicists almost all do, and you are despising the foundations on which everything else depends.

[...]

The dominant tendency among physicists is to identify physics with the developed mathematical theory. With the equations, in other words. But if you were only allowed to write equations, and *nothing else at all, then I doubt that it would be possible even to get started on the problem of explaining (in response to a question from an undergraduate, for example) just what is so puzzling about quantum mechanics. To get puzzled by quantum mechanics in the first place you have to draw on ideas which reach all the way down to that poor old primitive mud-hut. Dank and dark and smelly it may be. But there is no getting away from it. Trying to get away from it: this would be like a tree trying to pull itself up by the roots. The attempt is unlikely to succeed. But if it did it could only end in disaster.*

Moreover, I don't think it is only quantum foundations which has this dependency on common-sense and ordinary language. I think the same is true of every other area of physical thinking, without exception. Walk along the corridors of any physics department and, though you will certainly see people writing on chalkboards, you will also see them talking and writing, using ordinary words. Moreover if you take the trouble to inspect what has been written on the chalkboards, though you will doubtless see equations, you are likely also to see simple-minded drawings, assimilable at the level of mud-hut thinking. Again, any half-way decent talk includes an attempt to provide background, and intuitive motivation: and those are things which simply can't be done just by writing equations. It takes words. Ordinary words.

12-06-10 *Pauli, Four, and Me* (to R. Renner)

Thanks again for a wonderful, thought-provoking conference. Schack and I are soon to head out to explore the city and the hills nearby.

I wanted to show you one thing that Heisenberg wrote on Pauli in his essay "Wolfgang Pauli's Philosophical Outlook":

> In the alchemistic view "there dwells in matter a spirit awaiting release. The alchemist in his laboratory is constantly involved in nature's course, in such wise that the real or supposed chemical reactions in the retort are mystically identified with the psychic processes in himself, and are called by the same names. The release of the substance by the man who transmutes it, which culminates in the production of the philosopher's stone, is seen by the alchemist, in light of the mystical correspondence of macrocosmos and microcosmos, as identical with the saving transformation of the man by the work, which succeeds only 'Deo concedente.' " The governing symbol for this magical view of nature is the quaternary number, the so-called "tetractys" of the Pythagoreans, which is put together out of two polarities.

If you compare that to what I wrote for the back cover of the 10$^{\text{th}}$ anniversary edition of Nielsen and Chuang:

> Nearly every child who has read Harry Potter believes that if you just say the right thing or do the right thing, you can coerce matter to do something fantastic. But what adult would believe it? Until quantum computation and quantum information came along in the early 1990s, nearly none. The quantum computer is the Philosopher's Stone of our century, and Nielsen and Chuang is our basic book of incantations. Ten years have passed since its publication, and it is as basic to the field as it ever was. Matter will do wonderful things if asked to, but we must first understand its language. No book written since (there was no before) does the job of teaching the language of quantum theory's possibilities like Nielsen and Chuang's.

you might see why I have a fascination with Pauli! (I have a big portrait of him on my wall at PI.)

Anyway, thanks again. Schack and I have done some good science in this city. It seems to bring out the best in people.

14-06-10 *Displacements All the Way Down* (to A. Plotnitsky)

Here is this paper on Weyl that has interested me greatly. [Erhard Scholz, "Weyl Entering the 'New' Quantum Mechanics Discourse," conference contribution to *History of Quantum Physics 1*, Berlin, July 2–6, 2007.] The main reason is that my beloved SICs seem to be the dual structure to Weyl's "phase space." And that phase space goes all the way back to at least 27 September 1925!

I'd like to look up the dates (or narrow the range) of when Heisenberg and, particularly, Born found the unitial commutation relations.

Best wishes from just behind you ...

15-06-10 *Human Observations* (to R. Schack)

BTW, did you notice how the guy from the Austrian Academy of Sciences seemed to insist on invading the space between you and me? What was up with that? When I would rotate toward you, he would reinsert himself between us, only looking toward me, keeping the back of his head more toward you.

Very strange.

15-06-10 *How To Make SICs Exist* (to J.-Å Larsson)

Attached is my spiel on willing SICs into existence. It starts at the heading titled "Conceptual Barrier!" [See 13-03-10 note "Conceptual Barrier!" to the QBies.] (You'll see that I'm not crazy ... just very close to being so.)

15-06-10 *Gravity as Thermodynamics* (to F. De Martini)

Following on from our conversation on the bus this morning: The guy I was telling you about is Padmanabhan. Here a couple of links to his papers:

- `http://arxiv.org/abs/0911.5004`
- `http://arxiv.org/abs/0910.0839`.

And here is a link to a video of the talk he gave us at PI:

- `http://pirsa.org/10060000/`.

It'll be good to talk more when you're at PI.

21-06-10 *QBist Interference* (to J. I. Rosado)

Rosado-ism 3: *I read with great interest your paper "QBism, the Perimeter of Quantum Bayesianism". I think the ideas exposed in this paper not only are useful to find a QBist explanation of the Born rule but also to explain the fundamental concept of quantum interference.*

Thanks for your continued interest during all these years. I'm glad you are working out some of these ideas yourself. I make a bit of a more thorough analogy to interference in `http://arxiv.org/abs/0906.2187`. You might have a look at that paper if you have some interest.

24-06-10 *Idea This Morning* (to R. Renner)

This morning I was thinking about a proposal I'll be writing to the Templeton Foundation in a month or so, and I had an idea that might involve you if you have any interest. Attached is the pre-proposal I had written for them earlier, and they have given me the go ahead for writing a full proposal. I think my chances for obtaining the funding are quite good, given their mission and my subject matter ... [yeah, right][226].

If you read through this thing, you'll note a certain emphasis on Wolfgang Pauli's thoughts being brought into the modern context. And particularly, in Sections 3 and 6 you'll find mentions of a workshop on Paulian ideas. The tentative title for the meeting is, "A Malleable World? Wolfgang Pauli's Dreams for Physics in the Light of Quantum Information." It doesn't say so in the proposal yet, but I've been thinking I'd like to have that meeting in Switzerland, perhaps in a place like the small village where Harald Atmanspacher lives, Amden. (Beautiful setting.) The point is to have an inspiring setting, and I'll make the argument we'll more easily get some Pauli scholarly work going in Switzerland than anywhere else. I.e., that this is the natural place for such a meeting.

The idea I had this morning is this: Might the Pauli Center have any interest in being involved in sponsoring such a workshop? Or at least lending its name to the proposal, even if no dollars? As I say, I think my chances of getting this funding are already fairly good, but it never hurts to get as much legitimacy as possible before pursuing these things. And who knows, maybe the Pauli Center would even get something out of my efforts in return.

Just an idea. I'd welcome your thoughts pro and con and even sideways.

26-06-10 *We're in the Top Ten!* (to the QBies)

Have a look at this old blog entry of Scott Aaronson's:

`http://scottaaronson.com/blog/?p=112`

Particularly, look at the rules in Number 10. It was fun to learn that already in 2006 someone voted our research subject one of the "ten most annoying questions in quantum computing."

26-06-10 *Things to Read* (to P. Wells)

Here are a couple of the blogs I was telling you about, by Perimeter-style thinkers, even if some are not presently at Perimeter:

- Scott Aaronson's "Shtetl Optimized":

  `http://www.scottaaronson.com/blog/`.

  Scott had been a postdoc with us some years ago; now he's a professor at MIT. (Funny too: I was pleased to learn in flipping through it a few minutes ago, as I retrieved the address for you, that my group's main research problem was voted one of the "ten most annoying questions in quantum computing." Quite an honor!)

[226]Not in original note; addition for the purposes of this samizdat.

- Michael Nielsen's blog:

  `http://michaelnielsen.org/blog/`.

  Michael wrote the major textbook in quantum computing, was a professor at U. Queensland, and finally on faculty at Perimeter until he decided to drop out of physics entirely.

- John Baez's "This Week's Finds in Mathematical Physics" can be found here:

  `http://math.ucr.edu/home/baez/`.

  John is a cousin of Joan Baez the singer, as I was telling you, and apparently is just about to make a career change as Nielsen did. (Unrelated, but did you know that Olivia Newton-John is a granddaughter of the great physicist Max Born, one of the founders of quantum mechanics? I learned recently that he had his beautiful equation

  $$pq - qp = \frac{h}{2\pi i}$$

  carved into his gravestone.)

- Sabine Hossenfelder's BackReaction:

  `http://backreaction.blogspot.com/`.

  Sabine had been a postdoc with us; she works in quantum gravity.

- Finally, let me mention Howard Barnum's "Wine, Physics, and Song":

  `http://winephysicssong.com/`.

  Howard is a visiting researcher with us, on leave from Los Alamos National Lab, and working in the quantum foundations group. He hasn't written on his blog in a while, but some of the entries in it on wine at the Black Hole Bistro are real gems. What amazes me in reading some of these entries, is that I can well remember being with him at the moments the entries describe . . . and to all outward appearances we were having technical discussions about details of quantum mechanics. But in the back of his mind, he was clearly writing up his tasting notes!

I myself am not a blogger, but I do fancy myself something of a writer. In prep for our discussions next week, I might point you to Sections 1 and 6 of this paper:

`http://arxiv.org/abs/1003.5209`

and Section 1 of this one:

`http://arxiv.org/abs/quant-ph/0205039`.

I think they're written in a way that a general reader can get the point from, and they tell the story of why I think quantum foundations is important.

Also, let me attach the intro to my Cambridge University Press book: It tells the story of why I'm in physics in the first place (not for the search of truth and beauty, but for science fiction). You might find it a bit entertaining.

30-06-10 *Two Pictures from Copenhagen* (to the QBies)

The Niels Bohr Institute, one innocent day in June, 2010—what was happening on the outside, and what was happening on the inside. You'll find the eight new isms I think QBism is pointing us to:

1. interiorism
2. agentialism
3. meliorism
4. jazzism
5. nonreductionism
6. empiricism / "the world is not sentence shaped"-ism
7. additivism
8. experientialism

02-07-10 *Version 6, Reply 1* (to H. C. von Baeyer)

OK, organize my thoughts, I need to do. (Spoken like Yoda in my head.) It's not easy!

I liked your lede (except for the little-bit distracting parenthetical detail on Einstein vs Bohr). And I wondered what came next! To make the transition from the (ancient) wave vs particle to the (modern) probability vs click is probably a good way to go for Sci Am readers.

A long time ago when I first thought about writing an article for them, I thought about starting off with something like this:

> In the holiday movie classic *It's a Wonderful Life*, the protagonist George Bailey proclaims in a moment of anguish, "I suppose it'd have been better if I'd never been born at all." It was the very idea his guardian angel Clarence needed to save his soul. "You got your wish. You've never been born." The story develops with George seeing how disturbingly different the world would have been without his presence. As Clarence told it, "You've been given a great gift, George—a chance to see what the world would be like without you." George came to realize how integral his life and his actions were for the very shape of the world around him. There was great wisdom in that movie: For in the 85 years since the advent of quantum theory, we have started to learn that this may be just be its greatest lesson. That our actions and their consequences are so integral to what the theory is about, to try to imagine what the theory is saying about a world without us simply cannot be done.

This certainly was not the vision of science before quantum theory, and is very much the source of why quantum theory often seems to mysterious even today. Science, and certainly physics, was once thought to be *exactly* about what the world is like without *us* playing any active role in its course. A whole cottage industry has developed . . .

Anyway, that's old stuff. As I wrote you at the start of this project, "Trouble is, I don't think I know how to write something that is *not* a manifesto—it is a character flaw." And that remains true. I think you're probably much more right on your track. After getting back from dropping the kids off at the Toronto airport tomorrow morning, I plan to put much more quality time into your old outline and give you some proper feedback, and also to try to figure out what my role can be here—i.e., how I can help you, while letting your seasoned science-writing instinct reign.

Kids off to Texas tomorrow! And as I say, I proper letter back to you tomorrow.

04-07-10 *Idea This Morning, 2* (to R. Renner)

Thank you for your thoughtful message. Maybe it is best not to push the issue too far with the Pauli Center.

Still!, given what you have written, you make my mind turn: I start to wonder whether it might be useful to consider eventually writing a Pauli-Center-specific proposal. Maybe for a follow-on conference for the year after the Templeton one (if that proposal flies). I can easily imagine a theme that a) would be politically safer than the Templeton stuff, but b) still in line with what I think is most worth developing in quantum foundations. For instance, a meeting with a title like "Quantum Contextuality: From Wolfgang Pauli to Kochen-Specker and Beyond." Maybe you'd have some interest even? It could be partially historical, partially philosophical, and partially technical. I write all the time that I think quantum mechanics is just the beginning of something much bigger; the workshop could be on that—giving theorists with good technical skills some better perspective (historical and philosophical) on why they should be pursuing the mathematics that they are pursuing.

Just the "idea this evening"! Let it roll around in your head a bit and see if we might do anything with it in the next year. I, of course, would do most of the legwork if you have any interest. And if you don't have any interest, that is OK too: As always, I'm just trying to see what I can help make happen.

06-07-10 *Comments* (to C. Ferrie)

Ferrie-ism 10: *Are you still around the IQC? If not, this is just an e-mail to remind myself to follow up on your question in my talk.*

Sorry, I'm gone already. Here's the kind of thing I was thinking—please allow me to use a SIC representation of quantum states to get the problem started. Suppose I have a measurement whose clicks are labeled j. Then the quantum probability $q(j)$ given by the Born rule can be written in terms of the SIC basis according to:

$$q(j) = \sum_i \left[(d+1)p(i) - \frac{1}{d}\right] r(j|i)$$

where $p(i)$ is the probability distribution for SIC outcomes and $r(j|i)$ is the probability for a j outcome given that the preparation was the i SIC vector.

In this context, I would call the quantum state corresponding to $p(i)$ "classical" in the case that

$$(d+1)p(i) - \frac{1}{d} \geq 0.$$

for all i. The reason I would call it that is because then $q(j)$ is calculated according to the classic Law of Total Probability for any measurement at all.

This defines a convex set of the $p(i)$. In this case, a regular simplex.

Anyway, I was thinking the "classical states" must always correspond to an affine transformation of that basic set.

07-07-10 *Leipzig* (to Å. Ericsson)

I'm thinking harder of cleaning my schedule of the Leipzig meeting, and you did a fantastic job with your talk in Växjö. I.e., I trust you now. I thought about giving a talk titled, "Probably the Best Statistical Manifold for Quantum Theory," as a play on the Carlsberg beer advertisement, but if you could give a talk expressing the same idea, even if not the same title!, this might be something to consider. Here is a link to the conference venue:

> `http://www.mis.mpg.de/calendar/conferences/2010/infgeo/`
>
> and
>
> `http://www.mis.mpg.de/calendar/conferences/2010/infgeo/program.html`.

Please let me know your thoughts. Is it something you have any interest in going to? Would you "strive to" do an effective sales job on our program while there (not only during your talk, but lunches and dinners and coffee breaks … a bit like I would do)?

11-07-10 *Marley Lyrics of the Morning* (to Å. Ericsson)

Lyrics to "Put It On" by Bob Marley:

> Feel them spirit
> Feel them spirit
> Feel them spirit
> Lord, I thank you
> Lord, I thank you
>
> Feel alright now
> Feel alright now
> Feel alright now
> Lord, I thank you
> Lord, I thank you
>
> I'm gonna put it on, I put it on already
> I'm gonna put it on, and it was steady
> I'm gonna put it on, put it on again
> Good Lord, help me
> Good Lord, help me
>
> I'm not boastin'
> I'm not boastin'
> I'm not boastin'
> Feel like toastin'
> Feel like toastin'
>
> I rule my destiny, yeah
> I rule my destiny
> I rule my destiny
> Lord, I thank you, yeah
> Lord, I thank you

No more cryin'
No more cryin'
No more cryin'
Good Lord, hear me
Good Lord ...

I really like that line about ruling my destiny.

12-07-10 *Dentist Office* (to P. Wells)

It was part of this:

> For my own part, I imagine the world as a seething orgy of creation ... There is no one way the world is because the world is still in creation, still being hammered out. It is still in birth and always will be ...

I think the dictionary only used the middle sentence of that.

12-07-10 *Interpretation* (to Å. Ericsson)

After you left, I had a read through some of the discussion on that Marley song.
One person wrote:

> *his voice sounds "otherworldly" here*

Another one wrote:

> *I know exactly what you mean. I have felt a spiritual presence while listening to his music. It's as if when he sang he became a vessel for something beyond even his own comprehension. This is probably my fav song of his. It's so bare.*

And earlier, still another had written:

> *1 year ago 2 I had just left a graveyard after visiting an old beau's headstone with his mom. I had this song on in the car and felt my seat belt constrict for no apparent reason. The song completely spoke to me and that moment and I realized so much about my relationship with God and my old boyfriend. "Put on the spirit of Christ." The reason I love Bob and reggae! "Good Lord, thank you!"*

12-07-10 *Interpretation, 2* (to Å. Ericsson)

My own interpretation is something like the last one. By "feeling them spirit" and "putting on (something like) Christ" (i.e., like putting on clothing), he could rule his destiny. And like the other commentator, one of my own attractions to the song is how bare it is. I think it is basically a prayer.

12-07-10 *Interpretation, 3* (to Å. Ericsson)

"put it on" = take, receive, try out. "I'm going to wear it." "I'm going to make it part of me."

12-07-10 *Interpretation, 4* (to Å. Ericsson)

Here, actually listen to this version: `http://www.youtube.com/watch?v=McJu3cRcjeo`. (It is slower than some other versions.) Definitely has the sense of a chant or a prayer. I think he was asking for strength and received it.

12-07-10 *QBism, Installments 1, 2, and 3* (to H. C. von Baeyer)

I like your introduction even better now.

I'm not sure how I should tackle giving you feedback. Perhaps recording my "stream of thought" might be the most efficient way to go forward at the moment. At present, I'm finding it extremely difficult to *organize* any thoughts.

1) As you know, I love it when I learn something just from the very act of writing. And I love it too when I learn something from my co-author's very act of writing! These lines were quite thought provoking for me: "The resolution of the incongruity between waviness and graininess was effected by a compromise. Quantum mechanics avoids the description of an electron as a particle or a wave. Instead, it introduces the new, somewhat nebulous notion of the quantum state." I think that is a really good way to put it, and I don't think I've ever quite thought in terms of a compromise before.

2) Whenever/wherever possible, might we use "a quantum state" rather than "the quantum state"? Remember these lines from my introduction of *Coming of Age*:

> Better writing, not just any writing, made for better understanding. ... I started to realize that the major part of the problem of our understanding quantum mechanics had come from bad choices of English and German words (maybe Danish too?) for various things and tasks in the theory. Once these bad choices got locked into place, they took on lives of their own. With little exaggeration, I might say that badly calibrated linguistics is the predominant reason for quantum foundations continuing to exist as a field of research. Measurement? I agree with John Bell—it is a horrible word and should be banished from quantum mechanics. But it is not because it is "unprofessionally vague and ambiguous" as Bell said of it. It is because it conveys the *wrong* image for what is being spoken of. *The* quantum state? That one is just about as bad. Who would have thought that so much mischief could be made by the use of a definite article?

3) I know I've got to fight my manifesto-izing instincts, but I wonder if we couldn't come off more strongly in the closing paragraph of the introduction? I think it would be nice to give the reader a sense that something thunderous is happening in our understanding of the quantum before he plunges into the rest of the article. Somehow I'd like to send a big rush of enthusiasm. Also, I think it'd be good to take a swipe there at the science-fiction solutions to the quantum conundrum the regular readers of that magazine have surely seen. I'm thinking particularly of parallel universes and action-at-distance. Remember, Musser had written this to me just before I thought of proposing the project to you:

> We'd need a more straightforward account: here are the mysteries of quantum mechanics; HERE ARE THE USUAL RESPONSES; here is why those responses fail; here is a better way. I suspect that such a reader will actually be more receptive to the notion that quantum states represent a form of gambling odds than a physicist or philosopher steeped in the subject is; we have less baggage to shed. But we do share the desire

> to know ultimately what the information is about and, even if this question cannot be answered, will want to know how the Bayesian approach advances that goal.

I all-capped the part I was thinking of particularly. I wouldn't want to dwell on those other "responses," but I think I would like to say something to the effect, "those sensationalistic responses are all well and good for a Hollywood movie, but in the end they're not very imaginative (like a Hollywood movie) and don't come close to expressing how really cool/awesome/nifty/exciting/unusual the quantum world really is." The world is wired in such a way that our actions matter; and that is certainly not the world of Banville's left-hand group.

4) I'm OK with 1/2 of Banville's distinction, but I'm not sure his right-hand group is the right way to put where I sit personally. ... [MORE TO COME]

I'll come back to that point in minute. In the meanwhile, let me send this much to you: I'm not sure when you go to bed, and I want to make sure you have *something* from me today before you close your eyes.

Picking back up ...

4) I'm OK with 1/2 of Banville's distinction, but I'm not sure his right-hand group is the proper way to identify where I (or QBism) sit(s) in the spectrum. To pinpoint it, maybe I can say this: I'm not so sure I like to think that a physical theory imposes *order* on an unruly world, so much as it imposes our will (to the extent that it can presently be imposed). Remember the description I gave of William James's view in the Templeton pre-proposal:

> Of scientific theories, the philosopher William James once wrote, "You cannot look on any such [theory] as closing your quest. You must set it at work within the stream of your experience. It appears less as a solution than as a program for more work, and more particularly as an indication of the ways in which existing realities may be changed. Theories thus become instruments, not answers to enigmas. We move forward, and, on occasion, make nature over again by their aid." On this conception, a theory is not a statement about what the world is, but a tool, like a hammer, to aid in making the world what we want it to be. The world may resist, but to some extent it is malleable.

I'm not saying not to work with Banville's distinction or use it as a hook, I'm just pointing the difference of flavor in my own thought.

5) I did however like Banville's phrase (and your use of it) of a "boiling chaos". It's a bit similar to Chris Timpson's description of my view:

> The four-dimensional pattern is too unruly: it does not admit of any parsing into laws, or even weaker forms of generalisation, not even statistical ones.
>
> This, then, is the micro-level we have dubbed unspeakable; to which we are denied direct descriptive access. The picture is of a roiling mess. Fuchs adds:
>
> > For my own part, I imagine the world as a seething orgy of creation... There is no one way the world is because the world is still in creation, still being hammered out. It is still in birth and always will be... (To Sudbery-Barnum 18.8.03)

Part of that quote of me, by the way, made it into the *Oxford Dictionary of American Quotations*. (Surely I've told you this before, but my memory gets worse and worse.)

6) "Mathematically it is described ..." In line with what I said previously, "the function" $\longrightarrow$ "a function"? "can usually not be visualized" $\longrightarrow$ "can almost never be visualized"

7) "Max Born" Worth parenthetically mentioning (grandfather of the pop singer Olivia Newton-John)? Probably not, but I thought I'd throw it in for consideration.

8) “psi should be interpreted in terms of a probability” $\longrightarrow$ “psi is a tool that can be used to calculate probabilities”? The reason I bring this up is because (part of) QBism's contribution has been to emphasize that it is “absolutely nothing more” than probabilities; it has no existence beyond them.

9) “negative or even imaginary” $\longrightarrow$ “negative or even an imaginary number”?

Since I just got a response from you, I'll chop this much off now and send it. Back later with stuff on section 2 and beyond.

Picking up again with the random stream of thought (this time more random and vague than previously).

10) “Atom of Information,” let me just play around that phrase, or use it as a focus, for a while. A journalist from *Science et Vie* this morning wrote me, “what is for you the meaning of information (in a physics sense) — a physical substance?” To which I plan to reply, “God no!” One of the key things I want to stress with him, and I guess with you, is that when Shannon quantified information, he quantified it in terms of “surprise.” To receive a “bit of information” is to say one will be completely surprised by the answer to the relevant question. (Or, in the quantum case, the consequence of the relevant action.) If I write down a 0, as opposed to a 1, on a piece of paper, and then announce to you that I wrote down a 0, when I finally give you the piece of paper you will not receive any bits at all: The paper gives no information because it gives no surprise. Somehow I'd like to see that crucial point worked into the story: Information (in a Bayesian understanding) is not a new fluid that we pour into receptacles.

Still, “atom of information.” It is a phrase I rather like. Particularly because it helped me think of qubit as an “atom of surprise.” No matter how I take an action on it, it always has the ability to surprise me with the response I receive. And that is a crucial piece of QBism.

And maybe too emphasizing that “bit” quantifies “surprise” rather than “substance” or “fluid content” can help make the transition to what Bayesian probability is all about, “disciplined uncertainty accounting.”

11) Actually I wouldn't mind having a small box, not particularly on SICs, but on the urgleichung. A little visual on the sky vs ground measurements, and the simple rule that connects them. It is a statement that one can do without quantum states completely. Instead the Born rule is really about “taking probabilities as inputs and returning probabilities as outputs.” Does it go too far for *Sci Am* to actually show one equation? Kind of in the way that I did in the attached?

But the way, the SIC was brought out of the sky and placed a little closer to the ground a couple weeks ago. See: `http://arxiv.org/abs/1006.4905`.

12) Going back to point 10 above. After laying down what Bayesian probability is about (uncertainty, surprise, not objective features “already there”), maybe then it is a good time to come to the “puzzles of qm” (item 4 in your old outline)? One could contrast their standard accounts with the QBist stories of the same.

13) Maybe I'll leave it at this for now, not giving an unlucky point 13.

After I hear some of your responses, I'll think harder about a more “look ahead” outline.

Time to start heading for home so that I can start heading for the airport to pick up the kids—those wonderful disciplinary resources for keeping old dad working rather than slacking off.

13-07-10 *QBism, Installment 4* (to H. C. von Baeyer)

von Baeyerism 62: *Do you think we should go through the list of current “interpretations” of q.m. in the text, the way you did in “Perimeter”, or should that be a box? I agree that the list is* *necessary, but am on the fence about the issue of a box. Whatever the answer, the list has to come early in the piece.*

14) I tend to think it ought to come in the text directly. This is part of what I was trying to suggest in Point 3 (Installment 1). I think that, with some good planning, one should be able to knock out a couple of them relatively quickly. Or perhaps, another way to go is to put a sentence or two in the text (I would prefer taking a little swipe at them for some spice), but then have a larger box saying a little bit about each mentioning a short-coming: A) Many worlds, the beloved one of science fiction writers, could have been imagined under any physics, and indeed was. Aka, it is contentless, despite all the bluster about it. And even those who think it has content still can't agree whether it can generate probability. B) Bohm. Must have faster-than-light "signals" but yet, miraculously, they cannot be used to actually signal. C) GRW-Flash. The "flash" events can always be adjusted to be just out of experimental reach. Furthermore, as Spekkens emphasizes, the flashes are ad hoc additions that give no unifying power. I.e., supposing them doesn't help us understand the structure of quantum theory in any way. D) Consistent Histories (Griffiths version). Despite its bluster, it doesn't go an inch beyond Copenhagen. E) Decoherence (Zurek version). Many worlds in disguise. Disguised mostly by all the bling it adds to the costume.

15-07-10 *Wednesday Soirée* (to P. Wells)

Similar to Latham, I want to make an addendum to last night's discussion.

Actually a corrigendum. When I went onto the porch for my coffee this morning, I realized to my horror that there was a typo in the equation I wrote for you!

I wrote

$$q(j) = \sum_i p(i) \left[(d+1) r(j|i) - \sum_k r(j|k) \right]$$

when I should have written

$$q(j) = \sum_i p(i) \left[(d+1) r(j|i) - \frac{1}{d} \sum_k r(j|k) \right] \ .$$

Sorry!

15-07-10 *Wheeler's 20 Questions* (to P. Wells)

Here's an extract (less than five pages) from a big, fat document (194 pages) of mine. The first page records Wheeler's 20-questions-in-reverse story, the other pages (pages 183–186) expand on it a little more. It looked like you were interested in the story last night, so I thought you might enjoy reading it in the old man's own words.

> The Universe can't be Laplacean. It may be higgledy-piggledy. But have hope. Surely someday we will see the necessity of the quantum in its construction. Would you like a little story along this line?
>
> Of course! About what?
>
> About the game of twenty questions. You recall how it goes—one of the after-dinner party sent out of the living room, the others agreeing on a word, the one fated to be a questioner returning and starting his questions. "Is it a living object?" "No." "Is

it here on earth?" "Yes." So the questions go from respondent to respondent around the room until at length the word emerges: victory if in twenty tries or less; otherwise, defeat.

Then comes the moment when we are fourth to be sent from the room. We are locked out unbelievably long. On finally being readmitted, we find a smile on everyone's face, sign of a joke or a plot. We innocently start our questions. At first the answers come quickly. Then each question begins to take longer in the answering—strange, when the answer itself is only a simple "yes" or "no." At length, feeling hot on the trail, we ask, "Is the word 'cloud'?" "Yes," comes the reply, and everyone bursts out laughing. When we were out of the room, they explain, they had agreed not to agree in advance on any word at all. Each one around the circle could respond "yes" or "no" as he pleased to whatever question we put to him. But however he replied he had to have a word in mind compatible with his own reply—and with all the replies that went before. No wonder some of those decisions between "yes" and "no" proved so hard!

And the point of your story?

Compare the game in its two versions with physics in its two formulations, classical and quantum. First, we thought the word already existed "out there" as physics once thought that the position and momentum of the electron existed "out there," independent of any act of observation. Second, in actuality the information about the word was brought into being step by step through the questions we raised, as the information about the electron is brought into being, step by step, by the experiments that the observer chooses to make. Third, if we had chosen to ask different questions we would have ended up with a different word—as the experimenter would have ended up with a different story for the doings of the electron if he had measured different quantities or the same quantities in a different order. Fourth, whatever power we had in bringing the particular word "cloud" into being was partial only. A major part of the selection—unknowing selection—lay in the "yes" or "no" replies of the colleagues around the room. Similarly, the experimenter has some substantial influence on what will happen to the electron by the choice of experiments he will do on it; but he knows there is much impredictability about what any given one of his measurements will disclose. Fifth, there was a "rule of the game" that required of every participator that his choice of yes or no should be compatible with *some* word. Similarly, there is a consistency about the observations made in physics. One person must be able to tell another in plain language what he finds and the second person must be able to verify the observation.

— *John Archibald Wheeler*
Frontiers of Time, 1979

16-07-10 *IGAIA III – Missing Titles and Abstracts* (to IGAIA III)

I am sorry to keep you waiting. Here it is.

Title: Rewriting Quantum State Space as a (Nice) Statistical Manifold

Abstract: Recent work in the field of quantum information theory has pointed to the significance of a very special kind of quantum measurement—the so-called symmetric informationally complete quantum measurements (or SIC). This structure is only known to exist for finite-dimensional quantum state spaces with dimension $d = 2$ to 67, but they are widely believed to always exist for all finite dimensions. If they do exist, then quantum state space (i.e., the convex set of trace one positive semi-definite matrices) can be rewritten as a d^2 dimensional (very symmetric) statistical manifold within the d^2 dimensional probability simplex. Furthermore, in this language, the Born Rule for calculating probabilities for all other quantum measurements transforms into a very simple variant of the classic Law of Total Probability. In this talk, I will present all the above in greater depth and list several open questions that the information geometry community may be in a position to answer. Some details can be found at: `http://arxiv.org/abs/0906.2187` and `http://arxiv.org/abs/0910.2750`.

16-07-10 *Where Women Roar and Men Thunder* (to D. B. L. Baker)

It's been a long time since I've written you from a long flight. I've got nothing particular to say, but *it is a long flight* that I am on, and I suppose I hope that this will inspire me to say something. I'm on my way to Los Angeles from Toronto, the first leg of a trip to Brisbane, Australia. I arrive in LA at 9:10 PM, and then depart for Brisbane at 11:30—two hours of misery in a way. My body will be thinking it's between the hours of 12:10 and 2:30, but yet I dare not sleep. At least once I'm on the plane, 14 hours later, I'm in Brisbane.

I believe this is my sixth trip to Australia, though only my second to Brisbane. The other ones have been to Sydney. I'm going to the QCMC conference (Quantum Communication, Measurement, and Computation), where I pick up my \$3K award and make an after-dinner speech. I hate making after-dinner speeches: For some reason they put me on edge like a scientific talk never does. Maybe it has something to do with something Paul Simon said about song writing. He said, in writing a song, he strives to start with a statement of truth; after that everything flows smoothly. Maybe that's why I'm disoriented with the after-dinner thing: I don't know where the truth lies in those contexts.

We were talking about having a walk-about together. I still think that's a good idea. Just got to figure out how to pull it off. I tabulated the other day that I've flown nearly 49,000 miles already since January 1 (46K of it on American Airlines where it earns me free flights more efficiently). Immediately after this trip, I take the family to Munich (separating to go first to a conference in Austria and then a conference in Leipzig). Then in October, I go to Cape Town, South Africa (Stellenbosch, a wine region, actually). And finally in December I go back to Brisbane. So, I plan to have a butt-load of frequent-flyer miles at the end of this year. We just have to do something once I get some of this work cleared out of the way.

My kids took their first great Texas adventure last week. Emma (11) and Katie (8) flew for the first time by themselves. My sister Cathy picked them up in Houston, and then got them back to the airport at the end of the week. Next year, they fly to Europe for the first time without Kiki and me. It's all part of the accelerated growth plan. I was 30 already before I said anything new and useful about quantum mechanics, or natural philosophy more generally. My thinking is that they ought to beat me by at least 10 years.

After reading all the *Harry Potter* books three times, and the *Percy Jackson* series, I've finally bamboozled Emma into reading the *Lord of the Rings* trilogy. She's fought it tooth and nail the last couple of years. But I offered to pay her 10 cents a sentence for every email she writes me about what she's read in the books while I'm away in Australia, and that seemed to tip the scales. She's been saving for an iPod Touch. Ah, priorities!!

Hey, check out this blurb I wrote for the back cover of Nielsen and Chuang's textbook on quantum computing (10th anniversary edition). It made me feel literary when I put it together:

> Nearly every child who has read Harry Potter believes that if you just say the right thing

or do the right thing, you can coerce matter to do something fantastic. But what adult would believe it? Until quantum computation and quantum information came along in the early 1990s, nearly none. The quantum computer is the Philosopher's Stone of our century, and Nielsen and Chuang is our basic book of incantations. Ten years have passed since its publication, and it is as basic to the field as it ever was. Matter will do wonderful things if asked to, but we must first understand its language. No book written since (there was no before) does the job of teaching the language of quantum theory's possibilities like Nielsen and Chuang's.

If Emma hadn't become so fascinated with *Harry Potter*, I'd have never been able to write that. There's so much to learn from our kids. How are your three doing? What sorts of growth and what sorts of mischief have they been up to?

PS. I must say, I still haven't had a vegemite sandwich.

18-07-10 *Where Women Glow and Men Plunder* (to D. B. L. Baker)

It seems my memory failed me yesterday.

Oh well . . . head full of zombie,

20-07-10 *An Honest Attempt* (to C. M. Caves)

OK, an attempt at an actual answer.

It has to do with the trail of thought I've been following since 2001 or so. The only way I know how to express it is in analogy to Newton's law of universal gravitation. Newton's law is that every two masses in the universe attract each other with a force proportional to a product of two numbers intrinsic to each: Their gravitational masses. Newton identified a property common to all matter. But beyond that, it was silent on what is real of the world. It was not a nuts and bolts ontology in the sense that one usually seems to want of quantum mechanics—i.e., that the wave function is real, or the Hamiltonian is real, or the Bohmian trajectory is real, or the multiverse with its universal wave function is the sole reality, etc., etc. All Newton's theory does is say, "Look here. Here is a property common to all matter, in all its manifest and yet to be discovered forms. Every piece of the world has gravitational mass, and the significance of that number is blah, blah, blah."

Now, I think that is the best way to understand quantum mechanics. I.e., to scale back our reductionist dreams for it and say, "It is not at all a theory tailor made for supplying an ontology in the traditional sense. Instead it is like Newton's law in identifying a single, important aspect of all pieces of the world." That aspect, I think, is what we conventionally call Hilbert space dimension, d. Newton's law was a great achievement for physics even though it didn't pretend to be a theory of everything, and the same I say of quantum mechanics. If it can solidly identify one—just one—aspect of this world common to all things, even if it says nothing beyond this, that is enough for me.

So, my whole thought is geared toward pinpointing what the essence of this quantity — dimension — really is.

That is why I am attracted so much to the urgleichung. This is because it displays Hilbert space dimension front and center *as* "deviation from a naive (or unjustified) application of the law of total probability." When we deal with a certain piece of matter, quantum theory advises that we should deviate—by a particular amount, d—from the law of total probability. The more d a system is hypothesized to have, the more we should deviate from a naive application of the LTP in the diagram I always draw. That is something that the usual form of the Born Rule just buries away; it isn't seen at all in the usual complex-Hilbert-space way of writing the rule.

Now, for my reason for pursuing a deep detailed study of the urUNgleichung. These "maximal consistent sets" seem to have a rich enough structure to hint of the possibility that the full structure of quantum-state space might just come from the preservation of the consistency of the urgleichung. In other words: It is that the principle that brings dimensionality out front and center as a deviation from the LTP is the same principle that sets the full structure of quantum state space.

If that *turns out* to be true, then I see it as a great unifying step for QBism. Our thought hangs together better than it used to, and such a theorem would clear out just that much more underbrush. And with that, the hope is we'll be able to see the full forest much better for it.

To a person who wants to build a better gravity wave detector *today*, I would guess all of this will make no difference to his life. But to the person who wants to go the next step in physical theory (say, to talk about gravity and quantum in the same sentence, but not necessarily this), my gut says it will make all the difference in the world. My gut says, despite all the erosions in confidence the live-for-today physicist tries to dole out upon me, that this is the right way to go. At least it is the right way for me. My gut says the fruits of this effort will have lasting value that will long outlive me.

I honestly believe what John said, "Until we see the quantum principle with this simplicity [in one clear, simple sentence] we can well believe that we do not know the first thing about the universe, about ourselves, and about our place in the universe." To the extent of my limited ability, that is what I want to be about. And I feel our emphasized rewriting of the Born Rule is a step in that direction.

20-07-10 *An Honest Attempt, 2* (to C. M. Caves)

Cavesism 84: *Thanks for the answer. I was hoping for something that would, without appealing to the esoterica of quantum gravity, tell me why you're working on this particular program.*

But I wasn't at all appealing to quantum gravity for any kind of justification. I was appealing to the idea of the value of identifying one property common to all things. I.e., nonreductionism. Gravitational mass just happened to be the example.

21-07-10 *Those James Quotes* (to G. J. Milburn)

Here they are. The first concerns how I think you should view your new center, as an addition to your "self":

> In its widest possible sense, however, a man's self is the sum total of all that he can call his, not only his body and his psychic powers, but his clothes and his house, his wife and children, his ancestors and friends, his reputation and works, his lands and horses, and yacht and bank account.

With this new arm, you may do things you had never previously imagined possible.

The second quote concerns German philosophy in the early 1900s, but my experience tells me it is completely apropos of the present-day "philosophy of physics" (considered a professional field).

> In a subject like philosophy it is really fatal to lose connexion with the open air of human nature, and to think in terms of shop-tradition only. In Germany the forms are

so professionalized that anybody who has gained a teaching chair and written a book, however distorted and eccentric, has the legal right to figure forever in the history of the subject like a fly in amber. All later comers have the duty of quoting him and measuring their opinions with his opinion. Such are the rules of the professorial game — they think and write from each other and for each other and at each other exclusively. With this exclusion of the open air all true perspective gets lost, extremes and oddities count as much as sanities, and command the same attention ...

The quote on the self comes from his *Principles of Psychology*. I've never read the whole book, but Scott Aaronson wrote me once: "I'm working through it now. I've decided to recommend it to people as 'the most up-to-date, state-of-the-art book about consciousness' (without telling them the publication date)."

The quote on German philosophy is from his book, *A Pluralistic Universe*.

The first book that really made an impression on me was simply titled, *Pragmatism*.

23-07-10 *Subjectivism in Classical Statistical Mechanics* (to P. G. L. Mana)

A key point (I think in agreement with what you say), is to be found in the second and third paragraphs after Merminition 150 of "Extract for Luca." Also something to think about is Keynes' remark on Ramsey in Extract 2, that the "basis for our degrees of belief ... is ... perhaps given merely by natural selection." [See 08-11-06 note "November 8th" to N. D. Mermin, Mermition 155 now, and the subsection titled "The Projection Postulate as Bayesian Updating" in the 24-06-06 note "Notes on 'What are Quantum Probabilities' " to J. Bub.]

Luca's Preply

This question became more interesting to me after I finally proved to myself that the maximum-entropy principle is just as 'subjective' as the rest of plausibility logic `http://arxiv.org/abs/0911.2197`.

It seems as if there is much to say, and very little to say, about it. The most honest books on statistical mechanics make clear that the various distributions used are just postulated — they are used because they work. Any 'derivation' is only an a posteriori complacency.

Indeed, one could say that we have arrived at them through a sort of historical Bayesian updating: we have tried some until we arrived at those that work, i.e., that are not further updated by new data. This is corroborated by the fact that the usual distributions do not work in some cases, for granular materials e.g., and new distributions are used there — trial and error again.

23-07-10 *What GK Say* (to C. M. Caves)

From G. K. Chesterton's book, *Heretics*:

There are some people—and I am one of them—who think that the most practical and important thing about a man is still his view of the universe. We think that for a landlady considering a lodger it is important to know his income, but still more important to know his philosophy. We think that for a general about to fight an enemy

> it is important to know the enemy's numbers, but still more important to know the enemy's philosophy. We think the question is not whether the theory of the cosmos affects matters, but whether in the long run anything else affects them.

26-07-10 *Just Noticed!* (to A. Kent)

I just noticed the name change:

Centre for Quantum Information and Foundations (formerly Centre for Quantum Computation)

That's great! Congratulations.

03-08-10 *Noncolorable Sets* (to A. Cabello)

Cabello-ism 3: *Would it be interesting to have a finite non-(KS)colorable set of:*
(a) trines
(b) regular tetrahedrons?

Regular tetrahedrons for sure. (Assuming you are talking about for a qubit.) More generally, it would be quite nice to know if in arbitrary finite dimension d, there are always noncolorable SIC sets.

Cheers from Munich (working at my in-laws' house),

04-08-10 *Help* (to C. M. Caves)

Cavesism 85: *I gave a public lecture here the other night on why quantum mechanics is strange and tried to show that it means that things don't have objective properties. Afraid I offended my officemate, Cyril Branciard, who is pointing me to Gisin's work contending that nonlocality is the only assumption in proving Bell inequalities. I don't have time to read and come up with good answers, so give me some help. I will read it, but I'm sure you've thought about it much more deeply than I will.*

Yeah indeed people say that … all the time. Read for instance this "very clear" exposition of Travis Norsen: `http://arxiv.org/abs/quant-ph/0601205`.

My own opinion is that each and every time this claim is made, the claimer is either explicitly or implicitly (and in a roundabout way) assuming the EPR criterion of reality. And an essential piece of that is that CERTAINTY implies TRUTH (in the ontic or correspondence sense).

I'll send you some of my conversations with Spekkens, Mermin, etc., on the subject if I can dig it up.

I think my own best exposition on the subject is Section V (starting page 14) of `http://arxiv.org/abs/1003.5209`. I think that section can be read independently of the rest of the paper.

07-08-10 *Scientific Report* (to M. A. Graydon)

Graydonism 3: *I want to thank you again for making the trip to Traunkirchen possible. I had the pleasure of meeting and discussing physics with some really interesting people while I was there — making the long trip well worth its while. After you left, I gave a short informal talk to a small* *group on quaternion qt and the general Jordan-Banach algebraic structures that have been on my mind lately. Now back home, I am realizing just how beautiful our surroundings were. It's left me with a sense of optimism for the future, both personally and work-wise.*

They were fantastic surroundings. Mother earth is big, and she brings her size and grandeur up front for your inspection in the Alps. I hope you'll use every opportunity like this to see the world from a different angle. There'll be many opportunities in your future. The mind is an amazing connected web of thoughts, plans, feelings and facts, and one shouldn't think for a minute that an emotion in the Alps may not play a role in a mathematical theorem somewhere down the road in Waterloo or anywhere else.

10-08-10 *Whaddya Think?* (to T. Jacobson)

Every new paper like this gives me occasion to recall my wisdom teeth being pulled. No matter how many times it's recalled, it never becomes more pleasant.

Ted's Preply

`http://arxiv.org/abs/1008.1066`

12-08-10 *Slide Permissions Question* (to J. Gleick)

Your publisher sent the note below to me, assuming that you had already written me. I'm not quite sure which slide she is talking about. Maybe you can shed light. Also, it'd be nice to know what your book is about.

I read your *Chaos* book many years ago and enjoyed it much. And your Feynman book has sat on my shelf for a couple years calling me, calling me.

James's Reply

> Oh, gosh. I've been meaning to call or write. Thanks for emailing me directly.
>
> The book is a sort of history of information and information theory. It has Claude Shannon as its core, and goes back to the invention of writing and forward to quantum information science, and meanwhile explores many issues that are more cultural than scientific.
>
> The slide of yours that I want to use, by way of illustration, is attached. Contrary to what Jill says, I don't think a higher resolution version is needed. In the text, I quote something you said in "Quantum Mechanics as Quantum Information (and Only a Little More)"—the passage about holy tumult over quantum foundations, and your comment, "Quantum mechanics has always been about information; it is just that the physics community has forgotten this."
>
> Of course I'll send you the book when it's released. For that matter, would you want to see it in galleys? I'd certainly welcome any comments or corrections you might have. I'd ask only that you keep it entirely to yourself for now.
>
> Thank you also for the kinds words about *Chaos*, and I'm glad the Feynman book has at least made it as far as your shelf.

16-08-10 *Whaddya Think?, 2* (to T. Jacobson)

Sorry for the delay: I wrote you my "smart ass" note just as I was preparing to come home from Europe, and then I needed a few days of "recovery from the vacation" before looking at email again.

I'm going to refer you to Carlton Caves for this one, since he and Rüdiger Schack have a nice paper on the subject:

`http://arxiv.org/abs/quant-ph/0409144`

(I'd refer you to Rüdiger too, but I know he's hiking in France for the next two weeks.)

Ted's Preply

Let's take it out of the cosmology context.

Do you object a priori to the crazy idea that there *are* an infinite number of copies of the system, and that the composite *is* always an exact eigenstate of the relative frequency operator?

If not, that leaves the question whether and in what sense it implies the Born rule for *us* (one of those copies), when *we* do the experiment a *finite* number of times, say 100. A brief perusal of their paper gave me the impression that they were analyzing this latter situation by positing that we sample the infinite number of copies with equal "statistical" probability, so we measure, statistically, the relative frequency operator. But I'm not sure this is what they were saying. And it is suspect, since our 100 repetitions of the experiment either breaks the symmetry between us and the rest of the subsystems, or all subsystems do it, i.e., the whole infinite composite does the experiment 100 times. Then one can ask about the relative frequency operator of just our outcomes, and we know the system cannot be in an eigenstate of this, because that would preclude the 1/sqrt(100)=10% fluctuations that we know QM gives … which suggests that we can't deduce the Born rule after all …

16-08-10 *Slide Permissions Question, 2* (to J. Gleick)

Thanks for the information. (Hee hee.) Sorry to contact you quickly and then leave you high and dry, but I wrote you just as I was traveling back home from Europe … then there was the weekend.

Your new book sounds interesting. Thanks very much for your kind offer to send me a copy! Attached is a little "obituary" I had written on Shannon for the participants of a meeting I was organizing when he died. I wonder now whether you were the author of whatever *New York Times* article I linked to then? [See 27-02-01 note "Claude Shannon's Death".]

And thanks for letting me know which slide you need. I think I can supply you nonetheless with a cleaner scan than the one you have. Just give me a couple of days to dig it up.

Your publisher asked me about "licensing fees" for the slide, but how about we just do this? If you'd cite a couple of my papers on the subject (along with the old one you quote), as well as the upcoming Cambridge University Press reprint of my book *Notes on a Paulian Idea* (in this incarnation it is called *Coming of Age with Quantum Information*), I'd be most appreciative. Attached is a copy of the Introduction to the new edition of the book; you might enjoy some of the character sketches of quantum information figures in it (like Landauer, Bennett, Peres, etc). And the more up-to-date paper I'm thinking for the citing is this one: `http://arxiv.org/abs/1003.5209`. I would think that Section IV sounds particularly relevant to the thing from the old paper that you're already quoting. For instance, this paragraph would seem to indicate so:

> In this regard, no question of QBism tests nature's tolerance more probingly than this. If quantum theory is so closely allied with probability theory, if it can even be seen as an addition to it, then why is it not written in a language that starts with probability, rather than a language that ends with it? Why does quantum theory invoke the mathematical apparatus of complex amplitudes, Hilbert spaces, and linear operators?

Anyway, sound like a deal?

James's Reply

> No need to make a deal. I don't really think you want to charge a licensing fee for the slide, whatever my publisher says, and in any case I cite papers I have consulted and found useful, which includes your wonderful *Notes on a Paulian Idea* among several others. Would you please send me the correct bibliographic information for the CUP book, so that I can update the reference?
>
> Thank you also for the QBism paper; I can see that it's going to cause me to update the book. Luckily it's not too late.

17-08-10 *Hitler's Fireplace* (to D. B. L. Baker)

Thanks for the BBC story. I've been meaning to write you for some time. Particularly, I wanted to write you from Germany, but then things got in my way—I'm certainly not the correspondent I used to be.

What I had wanted to tell you about was my trip to Berchtesgaden, and the emotions it brought with it. Chances are, it's too late to express them properly now. Probably one of those things where you had to be there. It hit me as I was explaining to my girls that Hitler's Eagle Nest (or Kehlsteinhaus) was more than just a place to have a very fancy tea party or to simply impress the visiting diplomats. It was intended to put fear into the hearts of those visiting diplomats as well. It was a subtle way of saying, "Look what the power of this nation can do. Take note. What we can build for ourselves, we can destroy of yours." You really get a sense of this as you drive up the mountain, going through about five tunnels. Then you get to the level where Hitler's Berghof used to be, and you walk into a tunnel deep into the mountain crafted by Italian stone cutters, finally entering Hitler's original (massive) bronze plated elevator to get the rest of the way to Kehlsteinhaus. So, I was really feeling this sense of the Third Reich's strength and power ... when I ran across a picture of Eisenhower and Montgomery viewing a room I had just been standing in. I think it was the room with Hitler's fireplace, now quite damaged from all the chips of marble soldiers had broken from it. There was Eisenhower, standing in the damage, a symbol of America. And I turned to the girls and said, "All that power, and America's in the end was greater." "They put all these stones together on this high, high mountain to show their power and start a war. And we ended the war by putting 14 pounds of plutonium in just the right place. And just 14 pounds! What subtlety. The thousands of beautifully cut stones meant nothing in comparison; power is measured by what you can make happen. 14 pounds in just the right place."

For a few minutes, I was very proud again to be an American and to think of those old victories of mind and industry.

If you want to remind yourself of Hitler's Eagle Nest, this seems to be a pretty good site: `http://www.songsofwar.info/hitlermountain/Kehlsteinhausnew.html`.

Attached are a couple of pictures from the trip. The first is of the whole family, taken at the level of Hitler's Berghof and Goering's home (i.e., not all the way at the top). The second is of

Katie and me at a biergarten back in Munich. (Don't worry: That's an apfelschorle in Katie's hand, not a beer!)

18-08-10 *Your Paper* (to J. I. Rosado)

Congratulations! You did it all without me. *Foundations of Physics* sent me the paper to referee, and I didn't accept to review it: I thought it would be better for everyone if you had impartial reviewers. And it succeeded even without my help. This is a very good sign for the science! [See J. I. Rosado, "Representation of quantum states as points in a probability simplex associated to a SIC-POVM," Found. Phys. **41**, 1200–1213 (2011).]

21-08-10 *The Chartreuse Microbus* (to H. C. von Baeyer)

von Baeyerism 63: *One of the important ingredients of our paper is going to have to be an analogy for the SIC Born rule. Your measurement in the sky or at NIST won't do it, because analogies must not refer back to the concept being explained – quantum measurements in this case. Analogies must be to images that are instantly familiar. Even Fourier series fails on that count, tho it's closer. I'll suggest alternatives later. However, for now, I seem to recall that you wrote a paper with a student about the Fourier analogy but I can't find it in the* `arXiv`*. Does it exist?*

I think you're thinking of the conversation below. [See 11-01-10 note "Analogy?" to H. C. von Baeyer.] The equation numbers must refer to the version of the paper I had sent you just before. I'll re-attach that version for reference.

Just like Fourier expansion is a very special functional expansion (into sine waves), so is a SIC expansion (into a nice set of positive semi-definite operators).

For argument's sake though, I don't think the bureau of standards conception is circular at all. It is more like the Lord of the Rings:

> *Three Rings for the Elven-kings under the sky,*
> *Seven for the Dwarf-lords in their halls of stone,*
> *Nine for Mortal Men doomed to die,*
> *One for the Dark Lord on his dark throne*
> *In the Land of Mordor where the Shadows lie.*
> *One Ring to rule them all, One Ring to find them,*
> *One Ring to bring them all and in the darkness bind them*
> *In the Land of Mordor where the Shadows lie.*
> *He paused, and then said in a deep voice,*
> *"This is the Master-Ring, the One Ring to rule them all."*

I'll expand and explain once I can get my hands more firmly on the keyboard. (I'm presently having cheese and sausage and sliced turkey for lunch—finger food all.)

21-08-10 *One Ring to Bind Them, One Ring to Rule Them All* (to H. C. von Baeyer)

OK, my fingers are clean.

Here's what I meant by saying that the SIC is a bit like the Lord of the Rings. Like all quantum measurements, it is an action that an agent can take on a system with some number of unpredictable consequences for him—so it is not special in that regard, or in any way explanatory of the concept of quantum measurement. However, it does have a special defining feature that sets it apart from all other measurements. It is an action (and the only one) for which the agent can judge the following: That if he contemplates performing it twice on his system (getting outcomes i and j respectively), no matter what his Bayesian probabilities for the first outcome i, he will assign an almost flat conditional probability $p(j|i)$ for the second outcome j. That is, he will assign a $p(j|i)$ of the form $(a, a, \ldots, a, b, a, a, \ldots, a)$, where the value b inhabits the i'th slot of the probability vector, no matter what his prior $p(i)$ was.

And that one simple defining feature—in the end—gives the SIC all its expressive power for the Born Rule for all other measurements. What a nice primitive for a world believed to be indeterministic to its core.

... Ah, now that I've written that I don't feel I've shed the light that I wanted. I'm not getting to the key point in the right way. I may try again later in the day.

22-08-10 *Things from the Middle of the Night* (to H. C. von Baeyer)

Let me think on the new draft. Two broad thoughts at the moment.

1. Something like the red paragraph at the end of Section 2 could work, but it should be re-written to be more in Hans style than Chris style. At present it kind of stands out a bit too obviously (and even when the color was changed from red to black).

2. Section 3 is more sympathetic with frequentism presently than I can personally sign on to. W. K. Clifford once wrote, "It is wrong always, everywhere, and for anyone, to believe anything upon insufficient evidence"—which is not something I subscribe to (give me James's "will to believe" any day). But I do find Clifford's wording appropriate for frequentism: "It is wrong always, everywhere, and for anyone." And that opinion will cause havoc for using the Nagel quote as a pivot as well. In the game of probability, one cannot give an inch without losing a mile. I think these two papers by our friend Appleby make the point better than nearly any other source that I've read:

   `http://arxiv.org/abs/quant-ph/0408058`
   `http://arxiv.org/abs/quant-ph/0402015`.

   "Probability is single case, or nothing."

I shall meditate a bit.

23-08-10 *Probability* (to H. C. von Baeyer)

2:15 AM, at the moment; I had started to become restless at 12:39. I.e., it's another one of those nights.

Thank you so much for this note. I don't think I can adequately express the relief in seeing it. When I finally roused myself from bed five minutes ago, I thought that I would be writing you a small essay that started like this:

A frequentist says probability is long run frequency (always). A Bayesian says probability is judgment *always*. ... A young man has been tossing a favorite coin for a long time, 10,000 trials and has noted the frequency of heads and tails is almost exactly 50/50. Now it comes time to gamble on the next toss—now it comes time to put his observations to use. The young man confidently writes down 50/50 for his probability assignment … BUT WAIT! Just before he's had to act on that assignment he notes the strangest feature of his sequence of coin tosses: By some miracle, it is a binary representation of the digits of π! He uses *Mathematica* to check that there's not one error. How could that be? Is there some hidden mechanism behind the toss? "Hogwash, it can't be," he says, "I've been doing the tossing myself." Still a bookie walks from around the corner, and offers a lottery ticket on the young man's next toss. "Receive $1,000,000 if heads" for the price of $65,000. Will he buy the ticket? Or not? That will depend upon his judgement. He thinks to himself, "It could have been extraordinary luck. If probability is frequency, then this very string of heads and tails was among the possible. But it has no hold over the precise detail of the next coin toss. I will use my study of the frequency to temper myself. It would be foolish to buy such a ticket. That is my salary for a whole year; I would be devastated if I lose that much money." But if instead he judges the finding of π significant, miraculous even—for instance that God is with him in some way in his coin tossing (and I would think myself very likely to judge something like that in such an extreme case)—then he would accept the ticket. All his experience in the past—not just some coarse grained variable like frequency—tells him that it is the right thing to do. He lives by the dictum, "Never throw away information," and proceeds to buy the ticket. Which judgement is the right one? The young man will have time to contemplate that when the moment to buy or not to buy the ticket has passed and the outcome of the next coin toss is in hand.

Moral: A (past) frequency can be used to determine one's (future) probability assignment if one *judges* it to be relevant to that assignment. The judgement, however, is always there in the background; it cannot be gotten rid of. The Bayesian is often considered shrill for pointing this out over and over, but losing sight of it is the great original sin of frequentism. Past frequency is one thing; future gambling (i.e., that which is measured by one's probability assignment) is another.

Anyway, I thought I was going to have to write you an essay like that, but a much more careful one, one that tried to anticipate your every countermove. "But what about this? But what about that?" It would have taken a lot of thought. And then perhaps a long email debate would have ensued—it has happened to me before. … And I must say I was dreading it! BUT you saved the day!!! AND I bet I can fall back asleep now!!!

Hans's Preply

> OK, I see, I'll pour the weak tea down the drain. Somehow I thought that we could define the two prevailing approaches to probability before launching into QBism, but I see now that we must enthrone Bayesian probability before we get to q.m.
>
> Don't bother to save parts of section 3. I'll start it over, taking comfort only in the implication of Appleby that it IS possible to derive probabilities from finite ensembles, the way everybody does, provided only that one admits to sloppy thinking:
>
>> Frequentists are impressed by the fact that we infer probabilities from frequencies observed in finite ensembles. What they overlook is the fact that we do not infer probabilities from just any ensemble, but only from certain very carefully selected ensembles in which the probabilities are, we suppose, constant (or, at any rate, varying in a specified manner). This means that statistical reasoning makes an essential appeal to the concept of a single-case probability: for you cannot say that the probability is the same on every trial if you do not accept that the probability is defined on every trial.
>
> This will take a little longer.

23-08-10 *Probabilismo!* (to H. C. von Baeyer)

I don't know how much prodding to cap off your apparent ascendancy to personalist Bayesianism, but in case you need just a bit more, let me give another reading recommendation. This one is de Finetti's soul-searching article Probabilismo. More than any other thing I've read in the foundations of probability, this article affected me the most deeply. (It took four readings, I should add, before it had this effect on me, but the final result was nonetheless real.)

I hope I didn't cause you too much grief yesterday—as Rüdiger and I know too well, schisms in our thoughts are always painful even if necessary.

23-08-10 *B. Russell You Might Like* (to D. M. Appleby)

I'm having a horribly boring day going through the final proofs of my Cam U Press book, but I came across a quote of Bertrand Russell that I had sent to Bill Wootters in 1999 that you might quite like:

> Physics is mathematical not because we know so much about the physical world, but because we know so little: it is only the mathematical properties we can discover.

Looking forward to your return to Waterloo . . .

24-08-10 *Your Eloquent Point* (to R. W. Spekkens)

I remember you once making the point that to really hope to contribute to quantum foundations, one should know as much of modern physics as possible. And I thought you made the point rather eloquently. Have you ever written that kind of thing down anywhere? I want to use it to help give my student Matthew some guidance on choosing his courses.

25-08-10 *Particle Physics Course* (to M. A. Graydon)

Sorry to keep you waiting. I remembered that my colleague Spekkens had something rather elegant to say on the issue, and I wanted to get that quote from him and send it in my reply to you. But Spekkens has no clue what I'm talking about. So, let me just wing it.

Rob says that one can't really hope to make a deep contribution to quantum foundations unless one has a good working knowledge of all the other things going on in modern physics. (He said it more elegantly.) I think there's some truth in that. And from that perspective, a high energy course would be just the right thing.

25-08-10 *Time for Templeton* (to D. C. Lamberth)

I hope you remember our brief encounter from April. I'll place my original letter of introduction below, as well as your reply to it. You might also go to the Perimeter Institute website `http://www.perimeterinstitute.ca/` if you want to get a picture of me in your head; there happens to be a banner on the homepage at the moment picturing me for a recent award I won.

This time I'm writing you because the Templeton Foundation pre-proposal that I sent you got past their first round of refereeing, and I have been invited to write a full proposal. (I'll attach the pre-proposal again for your convenience.) Thus I'm gearing up to do that—I just started today, and it is due September 15.

In that regard, I'd like to explore again the idea that you join me as a co-organizer in planning a workshop on pure experience and quantum measurement. I presently envision a workshop of about 15–20 people, for about 10 days, in a nice setting. Its participation would consist of a carefully chosen combination of quantum foundational physicists, pragmatist philosophers (possibly a smattering of other neutral monist philosophers), and theologians, with plenty of time for long discussions—a way for the communities to get to know each other and get to know each other's considerations. I am imagining the meeting sometime in 2012, and ideally I think I would like it to be held somewhere in New England, where the spirit of James is particularly strong: Harvard, near Chocorua, don't know.

If you are amenable, I would like to list you among the "personnel" in this proposal, and start up a dialog, even as I write it in the next twenty days, over some of the details of the shape of such a workshop. The only obligation on you with regard to the grant would be in having an active participation in the organization of the workshop. I would try to get enough money from the Templeton Foundation so as to completely cover all the expenses for the meeting. Also, I would of course give you an opportunity to edit any piece of the proposal that has to do with you personally.

I understand it is quite bold of me to contact you like this without either of us knowing each other: But life is short, and I want to make things happen. It is time for physicists and pragmatist philosophers to start talking to each other, and I finally see an opportunity that can give that some possibility of happening.

I hope to hear back from you soon, whatever your opinion.

27-08-10 *Excerpts* (to L. Freidel)

Here's a link to the New York Times article on how the structure of one's native language influences what his attention is drawn to:

> MAGAZINE — August 29, 2010
> Does Your Language Shape How You Think?
> `http://www.nytimes.com/2010/08/29/magazine/29language-t.html?emc=eta1`
> By GUY DEUTSCHER
> The idea that your mother tongue shapes your experience of the world may be true after all.

On the other hand, here is an excerpt from the introduction to my book:

> I started to realize that the major part of the problem of our understanding quantum mechanics had come from bad choices of English and German words (maybe Danish too?) for various things and tasks in the theory. Once these bad choices got locked into place, they took on lives of their own. With little exaggeration, I might say that badly calibrated linguistics is the predominant reason for quantum foundations continuing to exist as a field of research. Measurement? I agree with John Bell—it is a horrible word and should be banished from quantum mechanics. But it is not because it is "unprofessionally vague and ambiguous" as Bell said of it. It is because it conveys the *wrong* image for what is being spoken of. *The* quantum state? That one is just about as bad. Who would have thought that so much mischief could be made by the use of a definite article? So many of these things came to mind as I would strive to be clear and entertaining in my writings to David ...

As I came to realize while talking to you, I think that's why I was so interested in the language article this morning.

Finally another excerpt related to our discussions—this one from one of Rob Spekkens' papers:

> We shall argue for the superiority of the epistemic view over the ontic view by demonstrating how a great number of quantum phenomena that are mysterious from the ontic viewpoint, appear natural from the epistemic viewpoint. These phenomena include interference, noncommutativity, entanglement, no cloning, teleportation, and many others. Note that the distinction we are emphasizing is whether the phenomena can be understood conceptually, not whether they can be understood as mathematical consequences of the formalism, since the latter type of understanding is possible regardless of one's interpretation of the formalism. The greater the number of phenomena that appear mysterious from an ontic perspective but natural from an epistemic perspective, the more convincing the latter viewpoint becomes. For this reason, the article devotes much space to elaborating on such phenomena.
>
> Of course, a proponent of the ontic view might argue that the phenomena in question are not mysterious if one abandons certain preconceived notions about physical reality. The challenge we offer to such a person is to present a few simple physical principles by the light of which all of these phenomena become conceptually intuitive (and not merely mathematical consequences of the formalism) within a framework wherein the quantum state is an ontic state. Our impression is that this challenge cannot be met. By contrast, a single information-theoretic principle, which imposes a constraint on the amount of knowledge one can have about any system, is sufficient to derive all of these phenomena in the context of a simple toy theory, as we shall demonstrate.

It is that point that really drives me: By adopting a way of thinking of quantum mechanics so that it seems to come from a single, very far reaching principle—rather than simply coming out of the blue—I feel we'll more quickly get to the next stage of physics.

30-08-10 *Some Bayesian Crap* (to P. G. L. Mana)

Manalogue 19: *Bayesian crap apart, what still surprises me is how students don't ask "but what determines the individual outcomes?", as any good physicist should do. How many of such questions do you get? Are we just teaching them to become good parrots? Attached is the image of a 'vacuum noise' current measurement, from Leonhardt's book. How can people be happy to know what's the distribution of the peaks without asking why and how it's going up and down that way?*

It still baffles me.

How could Bohr, Heisenberg, and other philosophical clowns have such a big influence?

Well, the philosophical clowns influenced me deeply. I had no illusions that they "had all the answers" or even "most of the answers," but—to me at least—they did have interesting directions of thought. Here is a recent formulation of my own:

> Most of the time one sees Bayesian probabilities characterized (even by very prominent Bayesians like Edwin T. Jaynes) as measures of ignorance or imperfect knowledge. But that description carries with it a metaphysical commitment that is not at all necessary for the personalist Bayesian, where probability theory is an extension of logic. Imperfect knowledge? It sounds like something that, at least in imagination, could be perfected, making all probabilities zero or one—one uses probabilities only because one does not know the true, pre-existing state of affairs. Language like this, the reader will notice, is never used in this paper. All that matters for a personalist Bayesian is that

> there is *uncertainty* for whatever reason. There might be uncertainty because there is ignorance of a true state of affairs, but there might be uncertainty because the world itself does not yet know what it will give—i.e., there is an objective indeterminism. As will be argued in later sections, QBism finds its happiest spot in an unflinching combination of "subjective probability" with "objective indeterminism."

It comes from `http://arxiv.org/abs/1003.5209`.

Appleby as well has some interesting points on the clowns in connection with Bayesianism in the introduction to `http://arxiv.org/abs/quant-ph/0402015`.

31-08-10 *From the Vault* (to A. Kent)

Kentism 12: *But scientifically I'm a little puzzled. I'd thought probably most people at this point would guess that SICs exist in all dimensions. (Am I wrong?)*

No, you're right. It was just one of those things that had been nagging my soul. At the end of a talk I would often get the question, "But what if they don't exist in all dimensions? What of QBism then?" I found that I would always get into apologetic mode, squirming around a bit, and saying something like, "Well, it'd really make no philosophic difference to QBism, but the ultimate formalism would be uglier. The world might have been better, but it wasn't." Maybe the audience couldn't see it, but I'd always shrink a bit inside—sweaty palms and all that. Now instead, I feel I'd rise to the occasion. When someone asks, "But what if they don't exist?" I'll shoot back, "Even better!! Then I'd have a theory—not quantum mechanics—of my very own! I'd be complete in a way Richard Feynman never felt he was!" (From a story in *Surely You're Joking* or somewhere like that.) You get the point.

01-09-11 *Opening the Mind of Max* (to M. Schlosshauer)

BTW, ever since you called my house a palazzo, I've kind of fancied to the term and use it all the time. This morning I coined Palazzo del QBismo and am thinking about modifying the QBism glossary accordingly.

02-09-10 *No Laughing Matter* (to R. W. Spekkens)

OK, I'm procrastinating from my Templeton theological efforts … *but*, two points for me tonight. (I'll make a rule—first person to five gets a free beer.) I looked up the twins story. (1) It wasn't laughs, it was smiles. And (2) Sacks interjected an 8-digit prime. Corroborating passages below.

> The second time they were seated in a corner together, with a mysterious, secret smile on their faces, a smile I had never seen before, enjoying the strange pleasure and peace they now seemed to have. I crept up quietly, so as not to disturb them. They seemed to be locked in a singular, purely numerical, converse. John would say a number—a six-figure number. Michael would catch the number, nod, smile and seem to savour it. Then he, in turn, would say another six-figure number, and now it was John who received, and appreciated it richly. They looked, at first, like two connoisseurs wine-tasting, sharing rare tastes, rare appreciations.

and

> I returned to the ward the next day, carrying the precious book of primes with me. I again found them closeted in their numerical communion, but this time, without saying anything, I quietly joined them. They were taken aback at first, but when I made no interruption, they resumed their 'game' of six-figure primes. After a few minutes I decided to join in, and ventured a number, an eight-figure prime. They both turned towards me, then suddenly became still, with a look of intense concentration and perhaps wonder on their faces. There was a long pause—the longest I had ever known them to make, it must have lasted a half-minute or more—and then suddenly, simultaneously, they both broke into smiles.

03-09-10 *Three Rabbis in a Bar* (to H. C. von Baeyer)

By the way, I have read the document they're wanting comment upon in that question, "The Philanthropic Vision of Sir John Templeton," very thoroughly and twice. I do realize his disciples will know him inside and out, but my reading of that document is that QBism really is on his side (and vice versa) in many, many of the matters expressed there.

But as you say, best not to speak directly of the tetragrammaton.

Still, quoting Sir John himself:

> Possibly, we can become servants of creation or even helpers in divine creativity. Possibly, we are a new beginning, the first creatures in the history of life on earth to participate consciously in the ongoing creative process.

03-09-10 *The Strip Tease* (to H. C. von Baeyer)

Well, Kiki and the kids finally got home from Buffalo. So I guess I have to go now. If I follow your suggestions in the quickest fix way, just stripping out the presumption about Sir J, and rearrange the remark on radical pluralism (see below), that leaves me with 115 more characters to fill in. But now, what to say!?!?

I'll have to think on it, but Kiki's here now. If there's anything that you'd like to see said, suggest away!

> A student who heard the applicant give a guest lecture on QBism in a graduate course on quantum foundations sent an email saying, "I like your theory because it returns to me as much freedom as I feel that I have. Such freedom is lost or partially lost in other interpretations [of QM]." This in fact is the heart of the matter for QBism's development of quantum theory and the heart of the matter, as we see it, with respect to Sir John's Donor Intent.
>
> By solid science, QBism has arrived at a stage of seeing human freedom as no less illusory and no less crucial to quantum theory than an electron's freedom as it "passes through" a Stern-Gerlach device. We feel that we have a window on quantum theory that has never been peered through before. Through the tools of quantum information theory and a sense that Wolfgang Pauli and John Wheeler were on the right track to understand the meaning and significance of "quantum measurement" (our two answers to the two Big Questions of this Funding Priority), we have come to a vision of quantum

theory that finds its most natural expression in the humanistic terms William James used to convey his radically pluralistic ontology.

As we hope to make clear in the more detailed parts of this proposal, what is within grasp through a methodical rewrite of quantum probabilities into Bayesian probabilities is that, at the same time as they bring relief to the quantum foundational conundrums, they indicate a world not "one" in its composition, but "many"–a partial community of partially independent powers, a pluriverse.

Will Durant put it most beautifully, "The value of a [pluriverse] as compared with a universe, lies in this, that where there are cross-currents and warring forces our own strength and will may count and help decide the issue; it is a world where nothing is irrevocably settled, and all action matters."

03-09-10 *The Strip Tease, 2* (to H. C. von Baeyer)

von Baeyerism 64: *I'm sorry, but I still don't really understand what you mean by freedom in your opening passage. Freedom from what? Could your 115 characters help here?*

Freedom of will, of course. The boy was saying QBism rejects the block universe picture of things, and he liked that. No other interpretation of quantum mechanics gives him that, he says. Would it help if I simply put the first and second paragraphs back together (as they were in the preproposal and didn't seem to set of any alarm bells in you then)?

I'm trying to pin down what exactly is confusing you.

Strange morning: For the first time ever, our big golden retriever decided he was frightened of walking down the staircase and wouldn't go done. He wouldn't let himself be dragged either without bringing the house down with him. Even the bribery of food wouldn't work. He was absolutely frightened. Now, where did that come from?

03-09-10 *Putnam Story and Others* (to D. C. Lamberth)

Hilary Putnam was your PhD advisor, wasn't he? I've been looking for a little story I wrote up on him once ... expressing my near horror over his turn toward the Bohmian interpretation of quantum mechanics in 2008 (in a talk at the Bill Demopoulos Fest), but so far I've had no luck. When I find it—if it's nice and joking enough!—I'll send it to you. As I recall, he called information theoretic approaches to quantum theory like my own, "instrumentalism with a postmodern sauce."

Anyway, I like writing stories on people. Attached are some I wrote for the introduction of my Cambridge University Press book. A couple of the stories are about philosophers, I don't know if you know any of these guys—Jeffrey Bub, Allen Stairs, Richard Healey (another student of Hilary's), and Abner Shimony. You might know Abner through proximity. I tried to display his sweetness in a story starting on page 30, and he plays a bit part in the less serious Zeilinger story on page 34.

Hope you enjoy—the Zeilinger story is particularly relevant for my interactions with you:

> Personal anecdotes aside, Anton Zeilinger is certainly a philosophical uncle to the very core of this book, the Paulian idea, and maybe he deserves the title for that alone. Here's the way he put it in a recent interview:
>
> > I call that the two freedoms: first the freedom of the experimenter in choosing the measuring equipment—that depends on my freedom of will; and then

> the freedom of nature in giving me the answer it pleases. The one freedom conditions the other, so to speak. This is a very fine property. It's too bad the philosophers don't spend more time thinking about it.

Simple and clean the notion is: Too bad indeed the philosophers don't spend more time thinking about it!

04-09-10 *House Warming Bubbles* (to H. C. von Baeyer)

Of course I wouldn't want you to enter an empty house! This time I hope I have successfully navigated your concerns.

The references in the Donor Intent section refer to these passages in one of Sir JT's books:

> Although we seem to be the most sophisticated species at present on our planet, perhaps we should not think of our place as at the end of cosmogenesis. Should we resist the pride that might tempt us to think that we are the final goal of creation? Possibly, we can become servants of creation or even helpers in divine creativity. Possibly, we are a new beginning, the first creatures in the history of life on earth to participate consciously in the ongoing creative process. [*Possibilities*, p. 41]

and

> The laws of the spirit refer to patterns of voluntary human behavior, not to the involuntary behavior of physical objects. A person is free to choose to act in accord with these spiritual laws or to try to defy them. This being the case, the patterns which these laws express are not uniformly exhibited by humans at all times. Rather, they represent the ideal patterns to which humans may aspire.
>
> Conformity to the laws of the spirit is a free choice of all responsible humans. So perhaps, to avoid misunderstandings, we should call them spiritual principles. [Possibilities, p. 154]

In the latter case, think of interpreting the Born Rule as a normative rule, and my figure with the tablet of the ten commandments (which I know you still hate). Anyway, they're solid, defensible references for me. In the terminology of Sir JT, QBism says that the Born Rule is a law of spirit or spiritual principle!

06-09-10 *On Dice, Divinity, and Telephone Companies* (to D. M. Appleby)

I walked over to tell Hulya that Rogers (or Bell or whoever you used for your telephone line) said that they'd be by to install it sometime between 11:00 and 2:00 today. She said that she'd be there. Kiki told the telephone people that if for any reason they could not get into your apartment, they should give us a call here at home.

By the way, I reread your paper "Concerning Dice and Divinity" over the weekend. I liked your remark near the end, "By contrast, the epistemic interpretation obliges us to concede to the cat a degree of metaphysical privacy." Looking back, that remark probably had quite some influence on me, expressed today, for instance, in my long rants in Sections 3 and 6 of the long recent QBism paper, `1003.5209`.

08-09-08 *Research Proposal* (to H. B. Dang)

Dangism 5: *Maybe this would cheer you up if I tell you that I start to understand the "ladder of faith" now.*

When I first looked at the Vanier Scholarship it was like "I want this, but this seems hopeless". Then when I read about the selection criteria more carefully: "I do think I have some chance". After I talked to you about it: "I might actually get it". After you submitted your letter: "I ought to get it". I'm not yet at "I must get it", but I will fight for that!

Indeed, James's ideas in use always cheers me up. I am impressed that you paid attention to the faith ladder.

09-09-10 *Your Manuscript LT12790 Medendorp* (to A. M. Steinberg & Z. E. D. Medendorp)

I will return to a civilized state (as opposed to the very furry Neanderthal-ish cave-dwelling persona I've taken on in the last few days), when my full proposal to the John Templeton Foundation has been turned in September 15. (It's on SICs and theology, of course.) In the meantime, maybe someone else will have some useful input on Aephraim's question about how to respond to the instrument matrix thing. Sounds like it's too late to reconstruct it now. It seems the question is now how to find the most positive and politic way to say, in essence, "Well we didn't do it, and we ain't gonna either."

07-09-10 *Agony* (to D. M. Appleby)

In agony over this letter writing (long story that I'll have to make meaningful for you eventually), I can't sleep ... and I can't write either. I turned to the *New York Times* for diversion. Anyway, here is something I just read that struck me as worth recording for myself:

> Science too has its share of mysteries (or rather: things that must simply be accepted without further explanation). But one aim of science is to minimize such things, to reduce the number of primitive concepts or primitive explanations. The religious attitude is very different. It does not seek to minimize mystery. Mysteries are accepted as a consequence of what, for the religious, makes the world meaningful.

In a sense, I think, QBism incorporates religion into science at just that point: Every quantum system is a little core of mystery.

Marcus's Reply

> You rang just as I started to reply to this. I absolutely agree. I think this question of "mystery" and "explanation" is extremely important. People in the Spekkens-Hawking-Weinberg mould invariably regard mystery rather in the way that catholics regard a black mass, as an evil entire and unadulterated. And explanation as a corresponding good. That is a good in the absolute sense. For myself I certainly wouldn't want to reverse the emotional loading. Obviously, explanation is OK in its place, and there are mysteries which are crying out to be resolved (for instance the mystery of why SHW believe what they do). However, it really does need to be kept in its place. The word

"to explain" means, literally, to lay something out flat. The idea being that when one lays it out flat one can see what is going on. Which can often be an interesting and useful thing to do. But of course SHW aren't thinking of just explaining this thing or that thing, in some limited context, as the occasion may arise. They want to explain everything, in some absolute way. EVERYTHING in capital letters. And that I think is a perversion. Laying the entire world out flat: if that were possible wouldn't it mean that the world was very boring? Indeed, the word "flat" is often used more or less a synonym for "boring".

Explanation is certainly a good. But only in the way that food is a good. How would it be if someone got so obsessed with eating that they came to see stuffing their face as the meaning of existence? I think the way SHW regard explanation is similarly pathological.

Incidentally, I think the definition of mystery as something that "must simply be accepted without further explanation" misses the point. The religious attitude of mind is not only willing, it positively desires to contemplate a mystery. Roll it around the mind rather in the way that one rolls wine around the mouth in order to appreciate it. Verbal articulation has a place in this process. Just as Howard will articulate the meaning that a wine has for him, so there are any number of religious writers who will articulate the meaning of a religious mystery. What makes it mysterious is not the fact that it just has to be accepted without further words or thought. Rather it is the fact that it is recognized that there is more to it than words can fully capture. That is obviously true of wine (reading Howard's wine tasting notes is one thing; drinking the wine quite another). Why can we not approach quantum mechanics in a similar spirit? —not as a "mystery" in the pejorative sense that SHW attach to this word, but rather in the way that anyone, them included, appreciates a glass of wine? (it may, incidentally, be apposite to remark that wine is an essential part of one of the central Christian mysteries).

We should talk about this some more, once you have finished your letter and Templeton writing. Also those articles you sent me on language and artificial intelligence. Perhaps over a glass of wine?

08-09-10 *Mixed Signals* (to H. C. von Baeyer)

Uh oh. I thought the guy went out of his way to say *no* manifesto. So when I show him a piece of another manifesto (i.e., a piece of the JTF proposal), I didn't quite expect a reaction like this:

Musserism 29: *Damn, this is great:*

> The research program of Quantum Bayesianism (or QBism) is an approach to quantum theory that hopes to show with mathematical precision that its greatest lesson is the world's plasticity. With every quantum measurement set by an experimenter's free will, the world is shaped just a little as it takes part in a moment of creation. So too it is with every action of every agent everywhere, not just experimentalists in laboratories. Quantum measurement represents those moments of creation that are sought out or noticed. If this vision of quantum theory stands scrutiny, it will mean that modern physics itself already speaks of a humanistic world—a world of hope & struggle & possibility & change. That would be the project's enduring impact.

It almost makes me angry that you haven't written the Sci Am article yet! Because it's going to be a great article.

Maybe he's just bowled over by the ideas.

What are you going to be up to in Spain? How long will you be gone? I don't think I've been to Spain for 12 years, but I still have an overpowering memory of garlic soup, red beef, and Rioja wines.

Bit. Stone. Qubit. Philosopher's Stone. We shall come back to all that after Spain. Have you ever watched the Dustin Hoffman movie, *Mr. Magorium's Wonder Emporium*? My family thinks it's a really wonderful movie, despite all the critics' pans of it. Recommended viewing for all QBies, in fact. Note the similarity between the Congreve Cube and the QBist qubit.

Magorium: Come with me. This, my lovely, is for you.

Mahoney: Thank you. What is it?

Magorium: It's the Congreve Cube.

Mahoney: It looks like a big block of wood.

Magorium: It is a big block of wood. But now, it's your big block of wood.

Mahoney: Thank you. I was just saying last night I don't have enough big blocks of wood.

Magorium: Unlikely adventures require unlikely tools.

Mahoney: Are we going on an adventure?

Magorium: Well, my dear, we're already on one. All I will say is this: With faith… love… this block… and a counting mutant, you may find yourself somewhere you've never imagined.

08-09-10 *Two Dialogues on QBism* (to the QBies)

Both from the movie *Mr. Magorium's Wonder Emporium* with Dustin Hoffman as Magorium and Natalie Portman as Mahoney.

Part 1)

> **Magorium:** Come with me. This, my lovely, is for you.
>
> **Mahoney:** Thank you. What is it?
>
> **Magorium:** It's the Congreve Cube.
>
> **Mahoney:** It looks like a big block of wood.
>
> **Magorium:** It is a big block of wood. But now, it's your big block of wood.
>
> **Mahoney:** Thank you. I was just saying last night I don't have enough big blocks of wood.
>
> **Magorium:** Unlikely adventures require unlikely tools.
>
> **Mahoney:** Are we going on an adventure?
>
> **Magorium:** Well, my dear, we're already on one. All I will say is this: With faith… love… this block… and a counting mutant, you may find yourself somewhere you've never imagined.

Part 2)

Mahoney: Then why are you leaving?

Magorium: It's my time to go.

Mahoney: That's it?

Magorium: What else could there be?

Mahoney: What are we gonna do without you?

Magorium: Run the store.

Mahoney: Sir, I don't know how.

Magorium: That's why I gave you the Congreve Cube.

Mahoney: But it just sits there.

Magorium: What have you done with it?

Mahoney: I don't know what to do with it. It's a block of wood.

Magorium: Can you think of nothing?

Mahoney: Well, I'm sure I could think of a million things to do with it.

Magorium: There are a million things one might do with a block of wood, but, Mahoney, what do you think might happen if someone just once ... believed in it?

Mahoney: Sir, I don't understand.

10-09-10 *Ouch!* (to S. Hartmann)

I was just thinking it'd be nice to have the book on Nancy Cartwright's Phil Sci that you helped edit on my bookshelf . . . and then I saw the price! Ouch; maybe not.

Lately, I've taken an interest in her (never noticed her before) because of my newest thoughts on Hilbert space dimension as a "capacity". In that regard, Sections 6, 7, and 8 of this paper `http://arxiv.org/abs/1003.5209` might amuse you.

By the way, is it true that Cartwright doesn't take email (as it advertises on her home page)? In my files, I do actually have an email from her (turning down a conference invitation). I guess I ask because I am thinking about writing her, but I'd like to understand beforehand how to interpret the silence I'll most likely get in response!!

How are things going in your new chair? You must be getting settled in comfortably by now.

12-09-10 *Interpreting the Universe after a Social Analogy* (to D. C. Lamberth)

I guess because you're on my mind, I reread your article in the *Cambridge Companion* last night. It was as nice as I remembered it to be. I hope you realize from all that I've sent you (especially my last paper, "QBism, the Perimeter . . . ") that your title (that Jamesian phrase)— Interpreting the Universe after a Social Analogy— is exactly what I'm after and what I think our QBistic analysis of "Wigner's Friend" in quantum theory (in Section III) leads straight away to. There's a world of interesting physics in front of us, and the time is ripe—I've just got to muster the resources and sustain the community's attention long enough for this line of thought to sink in!

There's one sentence in your paper that quite captures a distinction between my own approach to quantum foundations and an opposing theme that gets more and more airplay—relationalism (though so far, no one has put much substance behind it). See, for instance: `http://en.wikipedia.org/wiki/Relational_quantum_mechanics`. You pointed out that "James favors a philosophy in which all our dynamic relations in the world are cast (metaphysically) as reciprocal rather than merely relational." Certainly for me. The relational interpretations of quantum theory are all monistic to the core, and all too block-universey for my taste.

I liked your remarks on "compenetration" on page 246 and "novelty" on pages 256–257 as well.

David's Reply

> Thanks for this. I am amused, because this piece has received the most mixed reviews of things I've written, and most readers don't really know what to make of it. The comments you make are right on the mark with what I was after, and what I find remarkable and useful in James's understanding of experience. He had to resort to the language of panpsychism, which is confusing at base because most panpsychists understood consciousness precisely in the way James criticized in his "Does Consciousness Exist." So most have missed the point. This connection, and whether it can be ramified in terms of physics, is what interests me about your proposal here and from the outset.
>
> I expect to be sending you the two documents needed by tomorrow afternoon—I have time mapped out to finish them then

12-09-10 *New Questions* (to D. C. Lamberth)

I've already asked you where you might think a good location for the conference might be (and I hope you'll answer!), but I'm gearing up to write the "conference section" of the proposal, and I'm starting to realize that I'll need more information.

Could you supply me with a list of 5 to 10 or more (the more the better for sure at this stage) people that we can list as potential invitees. Range your mind over:

1. Philosophers of pure experience
2. Philosophers of neutral monism
3. Pragmatists
4. Disciples of the new realists (are there any left?) like R. B. Perry, W. T. Marvin and that lot
5. Panpsychists
6. Interesting Deweyians who have something to say on "experience"
7. Anyone who has anything interesting to say on Mach's world elements (I for instance have been quite taken with Erik Banks' work, maybe there are others)
8. Any Bergsonians?
9. Pragmatists you have ongoing debates with? (Like the trouble-in-river-city guy!?)
10. Any disciples of Russell's neutral monism?

I know plenty of standard philosophers of science who know a little about pragmatism (and even say they are pragmatists or turning pragmatist) like Huw Price, Arthur Fine, Richard Healey, and some others—and they, I imagine, will provide some good connective material for the meeting (go-betweens on quantum and philosophy), but they're not quite optimal for the things I really want to get at.

12-09-10 *I Don't Know That I Had Ever Seen This One Before* (to R. Schack)

Richard Jeffrey, "De Finetti's Probabilism," *Synthese* **60**(1), 73–90 (1984).

12-09-10 *Nor This One* (to R. Schack)

Richard Jeffrey, "Carnap's Voluntarism," in *Logic, Epistemology, and Philosophy of Science IX*, edited by D. Prawitz, B. Skyrms, and D. Westerståhl, (Elsevier, Dordrecht, 1994).

12-09-10 *Books: Free To Good Homes* (to T. Slee)

Slee-ism 5: *We have finally accepted that there are many books on our shelves that we are not going to read again.*

For the next few days these books will be on our driveway at 178 Herbert Street, free to good homes. Please feel free to browse and to take as many as you want.

I just discovered them and gave some Jungian readings (I promise) a good home!

13-09-10 *Pauli's Dreams* (to T. Slee)

I just noticed that I should probably thank Lynne more particularly for the Jung books: I noticed the name Shelagh Supeene is signatured in the front. (A relative? Or another name for Lynne?)

Anyway, on page 116 of the Dreams book, the following line can be found: "The material consists of over a thousand dreams and visual impressions coming from a young man of excellent scientific education."

That young man was Wolfgang Pauli (revealed years later). And I learned from Atmanspacher—one of the personnel in the proposal I'm writing—that another 1,000 pages of Pauli's dreams are soon to be published. (This time, not 1,000 dreams, but 1,000 pages! Or at least that's what he said.) Another one of the personnel in the proposal is my friend Hans Christian von Baeyer. (Maybe you've seen some of his semi-popular books on physics? The one on 'information' is excellent.) I attach one of his articles on Pauli, the man, "Wolfgang Pauli's Journey Inward," in case you're interested.

Thanks to Lynne again!

14-09-10 *The Latest Cleanest Latest!* (to H. C. von Baeyer)

von Baeyerism 65: *The project description reads well. My only negative reaction is to the Timpson bit, which sounds a little immature. After all, when Feynman gave a lecture to physicists,* *he would go out of his way to describe Newton's second law. So to accuse philosophers of science (no less) of not knowing their subject, on the basis of one man's careful definition of terms, seems wrongheaded.*

Well ... as an initial compromise to throw on the table, I took out the "no less!" ... which, after your remark, I started to think was a bit uppity my own self.

... BUT ... BUT ... At the same time I discovered that he had misspelled Peirce (as Pierce). Now what does that tell you about these philosophers of science?

Here's the present version of the passage (I took the liberty of fixing the spelling on Peirce):

> Crucial to our whole effort is fielding the ideas behind QBism more thoroughly in a larger community of expertise. No research effort with a hope to grow and flower can be an island unto itself. But as should be clear by now, QBism is in quite a predicament when it comes to placing itself in a community of appropriate peers. Part of its roots are in quantum information, but how many quantum information theorists have ever read the correspondence between Wolfgang Pauli, Markus Fierz and Carl Jung, where so many of Pauli's ideas on "background physics" were worked out? How many pragmatist philosophers and experts on William James know the distinctions between the frequentist and Bayesian conceptions of probability? How many know the details of quantum mechanics? Vice versa, how many quantum information theorists are there out there who think the philosophy of pragmatism simply means, "Shut up and calculate!"? Maybe to the greatest surprise, it is telling that C. G. Timpson in his review article on QBism in *Studies in History and Philosophy of Modern Physics*—a philosophy of science journal—felt compelled to include a footnote stating, "Pragmatism is the position traditionally associated with the ... American philosophers Peirce, James and Dewey; its defining characteristic being ..." Apparently even the philosophers of science who lay judgment on quantum theory are not particularly familiar with pragmatism!

14-09-10 *From Coleman to Cuero* (to D. C. Lamberth)

Many thanks for this! [...]

It was interesting learning that you were born in Coleman. I know I've traveled near it, if not through it, on the small-road crazy route I used to take between Albuquerque and my own hometown, Cuero. Apparently we were born just 262 miles from each other. And probably temporally close as well; I was born October '64.

The new name I'm toying for the conference is

From Pure Experience to Elementary Quantum Phenomena:
William James, John Wheeler, Quantum Interpretation

and I've tentatively put it "near Chocorua."

14-09-10 *The James Meeting* (to R. Schack)

Lamberth pointed out this place as a possibility for the James meeting: `http://www.asticou.com/` say, in June. (He said tourists don't start coming until July.)

Looking in Richardson's biography of James, I see that I can give as a narrative that it was just after the completion of this time in Maine, at the Northeast Bay, that James brought to a close and bound his notes on radical empiricism.

Or at least that's the general target area, and maybe the prices are typical for something we'd find up there.

> For summer jaunts James went twice in 1906 to Maine. The first time, in July, he went to Northeast Harbor and Mount Desert, and the second time, in August, to Penobscot Bay, Rockland, North Haven, Isle au Haut, and Swan's Island. But it was pragmatism that was on his mind. Between trips he wrote exultingly to Schiller that 'things are drifting tremendously in our direction.' Never hamstrung by modesty, James wrote, 'It reminds me of the Protestant reformation!'
>
> There was one casualty of James's rush toward pragmatism: somewhere along the way he benched radical empiricism. ...
>
> ... Perhaps it was his turning away from what he scornfully called 'technical' work, perhaps it was the force of 'The Miller-Bode Objections,' perhaps it had something to do with his fervid new interest in pragmatism. Whatever the reason, radical empiricism moved to the background as a program and a professional pursuit for William James ...

Actually that latter set of places are much closer to where John Wheeler's home was: High Island, Maine. It might be an interesting theme if we could find a good hotel closer to that region.

15-09-10 *Your Offer Taken!* (to R. Schack)

Schackcosm 135: *I attach my attempt at the budget narrative, at the moment excluding the workshops. Regarding the project timeline and the cost effectiveness sections, they should refer to the outcomes and outputs sections. Do we have such sections?*

Regarding outputs, it's relatively easy. 2 books, say 4 papers each on Jamesian things, crypto and randomness things, SICish things, and 2 workshops.

Outcomes, I am almost tempted to say that it is all towards the one big outcome, a new conception of the world or something like this. The cost effectiveness factor would be something like $720,000 per revolutionary world view, which is a bargain indeed.

I loved that!!!! I laughed and laughed. The family already thinks I'm going crazy because I stood in the yard yelling and wagging my finger at a squirrel the day before last. They almost had a look of horror when I kept laughing and laughing at your "$720,000 per revolutionary world view, which is a bargain indeed."

I dare say I like the idea too! It meshes well with something Hans said, late, just before I went up to bed. Placed below, and cc'd to Hans, so each of you can see each other's thoughts on telling Templeton "we're important."

I'm on my first cup of coffee and getting into the groove ...

15-09-10 *Outcome 1* (to R. Schack)

What will be different and who will be affected:
Mathematical Research:

> QBism is one of the first efforts in quantum interpretation that we are aware of that has said, "A proper interpretation of quantum mechanics should almost close its eyes to the existing mathematical formalism of the theory, and instead IMPLY what

the formalism OUGHT to be." In that regard we have already had some success–our rewriting of the Born Rule is an example of an interpretation-driven change in the very formalism itself–but of course, we want more. In the end, we expect of a Quantum Bayesian interpretation of quantum mechanics that it should actually imply the full mathematical formalism of the theory. An interpretation that did that alone would already be revolutionary in the quantum foundations wars.

Who will be affected? The whole quantum foundations community, for it will hold up an example of how things ought to be done: Interpretation first, quantum formalism next. (Not like, say, the Many Worlds Interpretation views the order of affairs.)

What are the indicators of the difference and the measurable change you expect:

Recently, we got a referee report for a submission to *Reviews of Modern Physics* that had these lines in it, "This is as strikingly novel a way of looking at the quantum theory as Feynman's sum of amplitudes over histories was when it appeared in the late 1940s. Whether it will prove as fruitful and durable remains to be seen, but it ought to be known to a broad audience ...." When we get referee reports like that, we certainly get the sense that we are making a useful contribution to the physics world as a whole.

We want more referee reports like that! And we will strive our best to get them.

But an obvious indicator of how much a scientific result is being noticed is how many times the result is cited per year. We will be watching that closely, but also noticing simply how much "buzz" the view gets as develops ever more.

15-09-10 *Outcome 2 (half of it)* (to R. Schack)

Conceptual Research:

We feel that in the last few years we (QBists) have turned a corner in our understanding by realizing that the deepest import of QBism is that it implies a significantly nonreductionist reading of quantum theory. One of the two great, fundamental theories of physics by its own structure, puts a stop to the reductionist dream that is usually identified with "science itself." This, we feel, instates a humanistic face to physics that has the potential not only to affect physical practice, but also the worldview of even lay scientific enthusiasts (readers of *Scientific American* and such).

Also with the success of this reading of quantum theory, we expect to see the philosophy of physics community for the first time take note of old-style American pragmatism, and perhaps even squeeze their own golden nuggets from it.

Now the question is, what to write for the "indicators" half of this!!

15-09-10 *Outcome 2's INDICATOR* (to R. Schack)

Indicator:

- Count the number of philosophers who stop talking so seriously about Many Worlds (more generally, views that take quantum states as objective properties) and start talking about Pauli's ideas, Bayesianism and pragmatism instead. This is not a joke. It is the method we have used for years to measure the power of our view. We can list (and point fingers to appropriate publications of) philosophers Bub, Demopoulos, Healey, and Stairs, as examples exhibiting themselves as cross-overs in the Bohr-Einstein debate, adopting one or another element close in spirit to the QBist view (even if not remotely the whole QBist package).

We certainly want more of that and will have our eyes open for it and pass on any anecdotal information to JTF.

- More generally the usual markers: invitations to conferences, keynote speeches, citation counts, and reports in the lay press. Also invitations to write articles ourselves for the lay public (as in our recent invitation from *Scientific American*).

15-09-10 *Outcome 3 and Indicators* (to R. Schack)

If you can see anything to add, please suggest.

Workshops:

> The key goal of the two workshops is to get parts of the disparate communities of quantum information physicists, Bayesians, pragmatist philosophers, and Pauli scholars all talking to each other and becoming aware that there is overlap in their interests and concerns. With this, we hope to start to build a community capable of understanding QBist ideas, and even capable of building upon them (at least in spirit, even if not completely in letter). QBism needs a wider community to interact with–to educate and to learn from itself–and the time appears ripe for making this happen.
>
> The conference proceedings arising from this activity will be invaluable resources for the worldwide Bayesian, Paulian, quantum, and pragmatist communities to get to know each other.

Indicators:

- As in the example provided, pre- and post-questionnaires, testing the various community's knowledge of each other is a very good idea, actually.
- Collect anecdotal evidence of friendships and professional ties made at the meetings.
- Collect data six months and a year down the road from the meetings on the network of active email ties between participants.
- Track sales and professional reviews of the conference proceedings.
- Collect data on conference participants starting to take part in one of the other community's conferences.

15-09-10 *Unruh's Talk* (to the QBies)

You can imagine I'm still doing Templeton things—it is literally the hardest grant proposal I've ever written. But I did want to encourage you all to go to Unruh's talk today in my place! The great WG is a man who has made a very deep contribution to physics (that walking through space heats it up), and it's actually rare that we get physicists coming through PI of that stature in nature's eyes.

16-09-10 *The Enduring Impact* (to R. Schack)

> Realistically, we hope the efforts of this project, when all is said and done, will be identified with a small span of history when a tide was turned. It would be nice to change the world fully and deeply in two years, but such things can never be planned for (and perhaps dare not be hoped for). A turning of the tide of this 85-year-old debate on quantum foundations would already be a revolution in itself. QBism points in a direction that says quantum theory's great lesson is not that IT is incomplete (that there is another theory waiting to be uncovered from underneath it), but that the world itself is unfinished—it is still in the furnace of creation. If our efforts contribute to getting our fellow physicists to take this possibility seriously, even if only enough that its residue shapes their work and their questions ever so slightly below the threshold of awareness, then the results of this project will be very pleasing indeed. Physical thought is a collective effect; one physicist affects another in turn with every paper and every experiment. If QBism does point in the right direction, as we believe it does, and if a tide is turned, things will eventually take care of themselves.

16-09-10 *The Final Submission* (to H. C. von Baeyer)

FYI, here's the final thing, warts and all. You'll certainly note, if you care to amuse yourself, that my answers become more and more uncouth as the deadline drew nearer (particularly in the budget justification section, where some of their questions became truly ridiculous). Story below to Rüdiger; I got the thing in just 2 minutes before its deadline!

Wow, what work! And what work for nothing but a chance! Still, there were lessons learned from the exercise, and maybe that's what in the end counts:

1) Let me attach Appleby's letter of support. In it he makes a good point about quantum theory being initially based on a mechanical analogy, and that a wrong turn was taken for interpretation just right there. I liked it and had never quite thought about it that way. It'd be nice if we could squeeze something about that into the *Sci Am* piece in some way.

2) Like with a good joke, I amuse myself sometimes. Here's something I wrote for one of their more worthless fields of questioning:

> QBism is one of the first efforts in quantum interpretation that we are aware of that has said, "A proper interpretation of quantum mechanics should almost close its eyes to the existing mathematical formalism of the theory, and instead IMPLY what the formalism OUGHT to be." In that regard we have already had some success—our rewriting of the Born Rule is an example of an interpretation-driven change in the very formalism itself—but of course, we want more. In the end, we expect of a Quantum Bayesian interpretation of quantum mechanics that it should actually imply the full mathematical formalism of the theory. An interpretation that did that alone would already be revolutionary in the quantum foundations wars.

That really is a key point, and I don't think I've said it that way before. So I should thank the JTF. Or maybe I *have* said it that way. Anyway, the key thing is this. What sets QBism apart from Many-Worlds, say, is that

1. *they* take the formalism as given (they've got no clue why Hilbert space vectors) and try to make up a story for it w.r.t. what it could mean in common life, but

2. *we* take a story, and try to show how it implies the mathematical theory.

There's no doubt our job is harder than theirs: It's easy to make up stories to fit something one doesn't understand. Or another (slightly sophomoric) way to put it: We're doing what physics is all about—noting things, expressing them, and then trying to find a mathematical description that captures their essence—while they're obsessed with a *homework* problem. (Imagine the voice of Darla in *Our Gang*.) "Teacher said 'Hilbert space'. Now we've got to make a story that uses the word five times."

Anyway, like with Appleby, it'd be nice to try to really bring this point home in the *Sci Am* article: I.e., The story has to come first, and then the equations second, or it is not *deep* physics, it's just a homework problem. (Taylor and Wheeler?)

I do hope you're still engaged with QBism and not getting fed up with all my shenanigans. Thanks again (for the near hundredth time) for all the help you've given me. You're teaching me discipline in writing; even Mermin didn't do that; and I do appreciate (even when I stray otherwise). You're my mentor.

Good night, I say, ... as you're probably nearly about to wake up ...

16-09-10 *New Religion* (to D. B. L. Baker)

It's nearly 2:00 AM for me, and I've been celebrating getting this thing (attached) in literally just two minutes before the bloody deadline! (I.e., a wee dram of Scotch and such things.) But, not lying; two minutes. Have a read. Is it just Methodism all over again? Or is it something else? I'd almost like to think it's a new religion. And I've got credentials too ... I'm asking for money! (Not even based in Houston, TX, but I'm asking for money. How else would you define "religion"?) But to Sir John Templeton, I told him it's science.

Religion or science? Not such a clean line is it? Who would expect otherwise from two Cuero degenerates?

17-09-10 *Free Will Saved James's Life* (to the QBies)

William James's Diary Entry, 30 April 1870

> I think that yesterday was a crisis in my life. I finished the first part of Renouvier's second "Essais" and see no reason why his definition of Free Will—"the sustaining of a thought because I choose to when I might have other thoughts"—need be the definition of an illusion. At any rate, I will assume for the present—until next year—that it is no illusion. My first act of free will shall be to believe in free will. For the remainder of the year, I will abstain from the mere speculation and contemplative *Grüblei* in which my nature takes most delight, and voluntarily cultivate the feeling of moral freedom, by reading books favorable to it, as well as by acting. After the first of January, my callow skin being somewhat fledged, I may perhaps return to metaphysical study and skepticism without danger to my powers of action. For the present then remember: care little for speculation; much for the form of my action; recollect that only when habits of order are formed can we advance to really interesting fields of action—and consequently accumulate grain on grain of willful choice like a very miser; never forgetting how one link dropped undoes an indefinite number. *Principiis obsta*—Today has furnished the exceptionally passionate initiative which Bain posits as needful for the acquisition of habits. I will see to the sequel. Not in maxims, not in *Anschauungen*, but in accumulated

acts of thought lies salvation. *Passer outre*. Hitherto, when I have felt like taking a free initiative, like daring to act originally, without carefully waiting for contemplation of the external world to determine all for me, suicide seemed the most manly form to put my daring into; now, I will go a step further with my will, not only act with it, but believe as well; believe in my individual reality and creative power. My belief, to be sure, can't be optimistic—but I will posit life (the real, the good) in the self-governing resistance of the ego to the world. Life shall [be built in] doing and suffering and creating.

17-09-10 *Motivated By Our Pluriverse Discussion* (to the QBies)

`http://en.wikipedia.org/wiki/Universal_set`

20-09-10 *Back from the Mountaintop* (to P. Wells)

Thanks for the article! Sorry to take so long to say "thanks," but when I got your note Thursday I was exhausted, and my writing fingers were broken. Not an easy trip back down from the mountaintop: I had just spent several days in a frenzy trying to get a proposal written for the John Templeton Foundation—toughest grant proposal I had ever written.

I loved your James 1878 quote (and your play on it at the end of the article); where did you get it from? Was it "The Sentiment of Rationality"? I liked too your "read like a forecast of quantum theory." That's the heart of the matter; that's why there's a shrine to him. I was impressed by your sensitivity (at least in my case) to what was going on around you.

Great article.

20-09-10 *Small Vision* (to H. Barnum & R. Schack)

In broadest outline, here's the way I think maybe I can envision how this could become a report.

1) It could start with a section saying, here is how the convex-operational framework is understood. States, effects, linear maps, and all that. Cones, blah, blah, blah. Maybe most of it can be cut and pasted from one of Howard's papers.

2) On the other hand, here's the QBist framework. Not states and effects, but modified law of total probability. No mention of cones directly at all! The QBist hope is that consistency of the modified law alone will imply a significant nontrivial restriction on the parts of the simplex that should be used (i.e., state space), and similarly with the conditional probabilities through the principle of reciprocity.

3) Now show that the QBist framework can be rewritten in convex-operational terms and comes automatically with these statements about the cone of effects.

4) Speculation on next steps.

Enough for a conference proceedings and we'll have a resource for others who are scratching their heads over whether QBism and Coneheadonism have any connections.

21-09-10 *Whitehead on James* (to D. M. Appleby)

I just haven't been able to concentrate so much today, so I took the easy way out reading "people magazines" for the most part.

Here is that quote from the letter Whitehead wrote Hartshorne in January 1936:

> European philosophy has gone dry, and cannot make any worthwhile use of the results of nineteenth century scholarship. It is in chains to the sanctified presuppositions derived from later Greek thought .... My belief is that the effective founders of the renascence in American philosophy are Charles Peirce and William James. Of these men, W. J. is the analogue to Plato, and C. P. To Aristotle, though the time-order does not correspond, and the analogy must not be pressed too far. Have you read Ralph Perry's book (2 vols.) on James? It is a wonderful disclosure of the living repercussions of late 19th century thought on a sensitive genius. It is reminiscent of the Platonic Dialogues. W. J.'s pragmatic descendants have been doing their best to trivialize his meanings in the notions of Radical Empiricism, Pragmatism, Rationalization. But I admit W. J. was weak on Rationalization. Also he expressed himself by the dangerous method of overstatement

And here is another passage I came across; it comes from Whitehead's book *Modes of Thought*. I'll place it below. Personality drivel mostly, but still I wanted to record it, and you seemed like the most natural repository.

> In Western Literature there are four great thinkers, whose services to civilized thought rest largely upon their achievements in philosophical assemblage; though each of them made important contributions to the structure of philosophic system. These men are Plato, Aristotle, Leibniz, and William James.
>
> Plato grasped the importance of mathematical system; but his chief fame rests upon the wealth of profound suggestions scattered throughout his dialogues, suggestions half smothered by the archaic misconceptions of the age in which he lived. Aristotle systematized as he assembled. He inherited from Plato, imposing his own systematic structures.
>
> Leibniz inherited two thousand years of thought. He really did inherit more of the varied thoughts of his predecessors than any man before or since. His interests ranged from mathematics to divinity, and from divinity to political philosophy, and from political philosophy to physical science. These interests were backed by profound learning. There is a book to be written, and its title should be, 'The Mind of Leibniz'.
>
> Finally, there is William James, essentially a modern man. His mind was adequately based upon the learning of the past. But the essence of his greatness was his marvelous sensitivity to the ideas of the present. He knew the world in which he lived, by travel, by personal relations with its leading men, by the variety of his own studies. He systematized; but above all he assembled. His intellectual life was one protest against the dismissal of experience in the interest of system. He had discovered intuitively the great truth with which modern logic is now wrestling.

22-09-10 *The Quote on Sacred Matter!!* (to P. Hayden)

> To anyone who has ever looked on the face of a dead child or parent the mere fact that matter *could* have taken for a time that precious form, ought to make matter

sacred ever after. It makes no difference what the principle of life may be, material or immaterial, matter at any rate co-operates, lends itself to all life's purposes. That beloved incarnation was among matter's possibilities.

22-09-10 *The Tube Alloys Project* (to B. W. Schumacher & M. D. Westmoreland)

I greatly enjoyed our conversation on "pure indeterminism" after your talk. (Ben will understand the allusion in the title; he can explain.)

Attached are two notes from my collection somewhat to do with the issue of "probability + x" that we were talking about. The first one is a (rather nice) note to Abner Shimony introducing the second one. The second one is a rather rabid one to a Princeton professor who annoyed me. (He called me a pansy, basically.) Anyway, it happens to be the one with the key point (starting right after McDonaldism 6). [See 18-10-06 note "Real Possibility" to A. Shimony and 30-01-06 note "Island of Misfit Toys" to K. McDonald. It is McDonaldism 12 in the present compilation.]

I liked Ben's image of the alloy: I think it's much more of the right flavor than the simple "+" I had been using.

22-09-10 *Tube Alloys 3!* (to B. W. Schumacher & M. D. Westmoreland)

Actually I do a much better job on the point in the attached page, drawn from a recent paper. The good stuff is in the left-hand column, particularly Footnote 14:

> Most of the time one sees Bayesian probabilities characterized (even by very prominent Bayesians like Edwin T. Jaynes) as measures of ignorance or imperfect knowledge. But that description carries with it a metaphysical commitment that is not at all necessary for the personalist Bayesian, where probability theory is an extension of logic. Imperfect knowledge? It sounds like something that, at least in imagination, could be perfected, making all probabilities zero or one—one uses probabilities only because one does not know the true, pre-existing state of affairs. Language like this, the reader will notice, is never used in this paper. All that matters for a personalist Bayesian is that there is uncertainty for whatever reason. There might be uncertainty because there is ignorance of a true state of affairs, but there might be uncertainty because the world itself does not yet know what it will give—i.e., there is an objective indeterminism. As will be argued in later sections, QBism finds its happiest spot in an unflinching combination of "subjective probability" with "objective indeterminism."

27-09-10 *Pauli's Eye Quote* (to H. Atmanspacher & H. C. von Baeyer)

Greetings from Stockholm!

Can either of you quickly pin down where I can find an English translation of the nice thing that Pauli wrote Heisenberg, just a bit before Heisenberg found the uncertainty relation? It is something about being able to look through the x-eye or the p-eye, but not being able to open both eyes at once.

I want to use that as a paradigm example that not all great contributions to physics are explicit and based on publication. A lot goes on behind the scenes.

Harald's Reply

It's in P to H Oct 19, 1926 (letter 143, p. 347 in P's corr vol.1), actually in a discussion about collision processes (my translation):

> It's always the same thing: due to diffraction, there are no arbitrarily thin rays in the wave optics of the ψ-field, and it is illegitimate to assign ordinary 'c-numbers' to 'p-numbers' and 'q-numbers' simultaneously. One may then view the world with the 'p-eye' and one may view it with the 'q-eye', but if you want to open both eyes at the same time this drives you crazy.

Note that P does NOT say it is IMPOSSIBLE to open both eyes. He says (in German: "dann wird man irre") that it drives you crazy, or maybe a bit weaker, that it is mind-boggling. [Compare the perception of ambiguous figures like the Necker cube.] The letter was sent to H at Copenhagen, and generated a lot of enthusiasm among H, Bohr, Dirac and Hund who were all there at the time (as H reports in his reply of Oct 28). H's paper "Ueber den anschaulichen Inhalt der quantentheoretischen Kinematik und Mechanik" in ZPhys was received there March 23, 1927.

Another example would be P's postcard of 4 Dec 1930 to the Tuebingen conference on radioactivity where he predicts the neutrino (my translation):

> ... in connection with the 'wrong' statistics of the N and Li6 nuclei as well as the continuous β-spectrum, I hit upon a desperate remedy for saving the 'alternation law' of statistics and the energy law. This is the possibility that there may be, in the nuclei, electrically neutral particles, which I shall call neutrons [later: neutrinos], which have spin 1/2, obey the exclusion principle and, moreover, differ from light quanta by not traveling with the velocity of light. Their mass should be of the same order of magnitude as the electron mass and not greater than 0.01 proton masses. The continuous β-spectrum would then be understandable under the assumption that in β-decay a neutron will be emitted together with an electron, such that the sum of their energies is constant. ... (letter 259, p. 39–40, in P corr vol.2)

29-08-09 *Eight-Port Homodyne Detector* (to M. Sasaki)

I almost forgot, here is the reference I was telling you about `http://arxiv.org/abs/0708.4094`. For myself, it is far too technical to read, but I believe I understand the conclusion: By suitably adjusting the "parameter" mode, one can measure any Weyl-Heisenberg covariant observable. In finite dimensions (up to $d = 67$ at least), one can always construct a Weyl-Heisenberg SIC-POVM by suitably choosing the right fiducial state. (See: `http://arxiv.org/abs/quant-ph/0310075`.) The question then would be, for continuous variables, what sequence of "parameters" would converge to something like a SIC-POVM.

As I say, the Kiukas/Lahti reference is too mathematical for my tastes, but it should have references in it that are more understandable.

29-08-09 *QBism House* (to N. Waxman)

Waxmania 3: *All the best (and remind me to send Kiki pictures of my mom's 150 year old house on a cliff here—it was once an epic fixer upper she would truly appreciate!),*

OK, I'll get in touch with you Monday. And it'll be fun to see the pictures. I myself am thinking about doing a feature for the newsletter if you'll take it, titled "QBism House Open for Business". I'd like to use a couple pictures of our house in it, particularly one showing our porch with chalkboard installed and my floor to ceiling library. I'd explain how my group of six (myself, Appleby, Ericsson, and three grad students) will be using the areas as an annex to PI for research. Say some things about what the research is about, and where we want to go with it. And welcome anyone else who might have an interest in the subject to join us: In good weather, the plan is to have a weekly group meeting on the porch.

You should see the house, if you haven't seen it in a while: It's just about finished on the outside now (except for planting some better grass). And 95 percent finished on the bottom floor. I'm quite proud of it.

Let me know when you're available next week, and we can get together on the webpage stuff.

29-09-10 *Quantum Foundations in the Light of Quantum Information III* (to G. Brassard)

Absolutely! Of course! Yes! Wonderful! Thanks! Please! Cool! Count me in!

29-09-10 *Perfect Contrast* (to H. C. von Baeyer)

I am in the middle of Göran Lindblad's talk, where he had the most lovely (and arrogant) quote by Steven Weinberg. Here's an extension of it that I just dug off the web:

> Bohr had presided over the formulation of a "Copenhagen interpretation" of quantum mechanics, in which it is only possible to calculate the probabilities of the various possible outcomes of experiments. Einstein rejected the notion that the laws of physics could deal with probabilities, famously decreeing that God does not play dice with the cosmos. But history gave its verdict against Einstein—quantum mechanics went on from success to success, leaving Einstein on the sidelines.
>
> All this familiar story is true, but it leaves out an irony. Bohr's version of quantum mechanics was deeply flawed, but not for the reason Einstein thought. The Copenhagen interpretation describes what happens when an observer makes a measurement, but the observer and the act of measurement are themselves treated classically. This is surely wrong: Physicists and their apparatus must be governed by the same quantum mechanical rules that govern everything else in the universe.

The reason I say it is the perfect contrast to us is because QBism rejects exactly what Weinberg takes as unquestionable: "Physicists and their apparatus must be *governed* by the same quantum mechanical rules that govern everything else in the universe." QBism says quantum theory doesn't "govern" anything in the physical world, in the same way that raw probability theory doesn't *govern* anything in the physical world. Quantum theory is something physicists *use*—that was implicit in Bohr's view of QT, as any careful reading of him would show. This is why I say Weinberg is one hell of an arrogant guy when he calls Bohr's view "deeply flawed". He didn't understand a word of it. Humbug!

01-10-10 *Great Minds Think Alike* (to S. Hossenfelder)

Marek reminded me last night of Wigner's remark on von Neumann. I had indeed known that once (long ago), but forgot about it. Sorry I didn't bring it up yesterday. Anyway, it looks like you're thinking like von Neumann. See Footnote 1 in the attached paper. [E. Wigner, "On Hidden Variables and Quantum Mechanical Probabilities," Am. J. Phys. **38**, 1005–1009 (1970).]

03-10-10 *Scaling, of a QBist Flavor* (to M. A. Graydon)

Just a small break from the logistical matters. I think your pushing me on the Hardy axioms has been quite needed. In the following form, I think I might find the composite system law more palatable from a QBist philosophy.

The way I'd like to transform the question is this: For a given number of outcomes in the sky (for a given measure of how much matter we have), how much of a deviation from the law of total probability should we expect in an urgleichung? How does the urgleichung scale with the amount of matter?

We could say as an axiom, β should be multiplicative in those cases when n is multiplicative. And my guess is that that would force upon us the same functional equation Hardy explored.

OK, but now why that particular choice of parameters to assume mutual multiplicativity for? Why not not n and α, for instance? Or could one show that any other choice of pairs for multiplicativity would lead to a contradiction with some other axiom?

I'm reminded of a speculation I've told of Bohr. Somewhere I've read that when Bohr got the idea of quantizing the hydrogen atom, he locked himself away for like three weeks to do the calculations. But you know that it's no more than a night or two of homework to figure out the energy level spacing from Bohr's assumption of simple integer quantization of angular momentum. How could it take Bohr three weeks? I've speculated that at the beginning, he simply didn't know which variable to quantize in terms of simple integer values. And thus he set out on a random walk to find out which scheme would be simple and believable and would give the needed energy level spacing.

Maybe that's the way to approach this problem. "Distinguishable states" and "degrees of freedom" … humbug! (It's nearly hidden-variable talk. Or at least evocative of the imagery.) But "how much stuff" (capacity) and "how much deviation from a naive use of law of total probability"? Now we're cookin'!

05-10-10 *The Old Bayesian Motivations* (to P. J. Lahti)

Thanks very much for your curiosity about my research program. I was very flattered and very much enjoyed my conversations with you.

Let me point you to three papers in case you have any continuing curiosity.

The first really tries to make a connection between the Bayesian motivations and the direction of formalism I seek: `http://arxiv.org/abs/1003.5209`. The second lays out some (provisional) axioms: `http://arxiv.org/abs/0912.4252`. And the third tells something about how to get some of the structure of quantum-state space back out of all of this: `http://arxiv.org/abs/0910.2750`.

Much of it, in the end, will have to do with the story you tell over and over: For the SICs are just a particularly crisp way of simultaneously measuring position and momentum (in Weyl's discrete phase space).

I hope you will view our efforts as complementary!

05-10-10 *Quote of the Day* (to the QBies)

I've rigged Google to give me a "quote of the day" every day now. Here was today's pick:

> Equations are the devil's sentences.
>
> — Stephen Colbert

05-10-10 *Your Newest Book* (to J. W. Moffat)

I read about your new book in the newspaper after getting home from Sweden Sunday (thus I'm not sure which day's newspaper I was looking at). Anyway, it sounds quite interesting, and you can be sure I'll be going to the bookstore once I hear that it is out.

John's Reply

> Yes, there was an article in last Saturday's *Waterloo Record* about me and my new book called: *Einstein Wrote Back*. It will be published by Thomas Allen & Sons, Toronto, about the middle of this month. My first book was: *Reinventing Gravity*, published 2008 by HarperCollins NY and Thomas Allen, Toronto.
>
> Thanks for your interest in my book.

05-10-10 *Galoshes* (to M. A. Graydon)

I won't tell you what I put in my letter, but I will tell you this much: You have some damned big shoes to fill now. I expect to see some really important physics from you.

The more I think about it, the more I'm extremely pleased with the thought direction you've pushed us to. The game is to get in a position of having Hardy's functional equation *without* speaking of composite systems and local measurements. I like having this image in my mind. I throw one rock into a bag and place it on a scale; the scale goes down a bit. I throw two rocks into a bag and put it on the scale, and the scale goes down a bit more. Now I ask myself, if confronted with a bear, do I want to whack it in the head with the first bag, or the second? The second of course—it has more oomph! It's got nothing to do with any local tomographic properties, etc. It's all about how the oomph scales. It's all about how the oomph scales with the stuff.

So, here's a question. Suppose *before* getting to Assumption 6 we make the assumption that n is a function of β. And that when

$$\beta = \beta_1 \beta_2$$

that

$$n(\beta_1 \beta_2) = n(\beta_1)\, n(\beta_2) \; .$$

The sort of thing I'm wondering is, will this allow us to clean up Assumption 6 any? Will it allow us to put something much better in its place?

07-10-10 *Wolfgang Pauli and Alchemy* (to W. R. Newman)

I enjoyed meeting you last night. I feel a bit embarrassed that I was not so coherent in our conversation, but wine does that to me.

I just placed an order with Amazon for your *Promethean Ambitions* book. I look forward to reading it.

Lollygagging away a little time today, I decided to re-read some things in my accumulated notes on the intersection of Pauli and alchemy. I'll share those with you, in case you have any interest. They're in the attached file. Here are the relevant parts:

1) The first quote from Werner Heisenberg's article, "Wolfgang Pauli's Philosophical Outlook" [217].

2) The long quote from Pauli's "unpublished" draft "Modern Examples of 'Background Physics'" [336].

3) "The Influence of Archetypal Ideas on the Scientific Theories of Kepler" [339] (This one is quite good reading.)

4) "Ideas of the Unconscious from the Standpoint of Natural Science and Epistemology" [343].

5) Letters from Pauli to Jung [354].

08-10-10 *History* (to A. Wilce)

Wilce-ism 8: *I still owe you (and the world) a screed. Meanwhile, a question: do you know of a good book on the history of probability theory and/or statistics that talks at any length about early attitudes towards the Normal distribution? Any pointers towards material of this kind would be most welcome.*

Sorry for the delay. Probably the best possible things are Ian Hacking's two books, *The Taming of Chance* and *The Emergence of Probability.* Louis Menand's book *The Metaphysical Club* (one of the best books ever, in any case) has a nice chapter or two on Quetelet and his reception.

12-10-10 *The APS March Meeting* (to G. Chiribella)

Thanks so much taking me up on the invitation to speak. The information on the session is below, and the meeting will be March 21-25 in Dallas, Texas. Anyway, in this, you join some famous company: Lucien Hardy was the invited speaker one year, Rob Spekkens another, and I think Bill Wootters another. [...]

I never could find the right Feynman quote, by the way. It's one about how it takes a generation or two to get used to a new physical theory. The only thing that's really broken in quantum interpretation is just our intuitions, or something like that. If you know which quote I'm talking about, I'd be most grateful if you could send it to me.[227]

[227] R. P. Feynman, "Simulating Physics with Computers", Int. J. Theor. Phys. **21**, 471 (1982): "Might I say immediately, so that you know where I really intend to go, that we always have had (secret, secret, close the doors!) we always have had a great deal of difficulty in understanding the world view that quantum mechanics represents. At least I do, because I'm an old enough man that I haven't got to the point that this stuff is obvious to me. Okay, I still get nervous with it. And therefore, some of the younger students ... you know how it always is, every new idea, it takes a generation or two until it becomes obvious that there's no real problem. It has not yet become obvious to me that there's no real problem. I cannot define the real problem, therefore I suspect there's no real problem, but I'm not sure there's no real problem."

23.13.4: Quantum Information for Quantum Foundations
Organizer: Christopher Fuchs (Perimeter Institute for Theoretical Physics)

Description:

Richard Feynman once famously said, "..." This may or may not be true, but if one supposes it to be getting at the right idea, it behooves us to ask, "Then what would it take to readjust our intuitions so that the discord is alleviated?" Starting with John A. Wheeler, several in the last two decades have suggested that re-exploring the foundations of quantum theory in the language of quantum information may be the first step in a long needed therapeutic process. This focus session will be devoted to assessing the impact of quantum information theory in diffusing the perennial quantum mechanical mysteries, as well as providing novel ways to rewrite the theory in terms of informational structures and functions.

13-10-10 *Congratulations* (to C. G. Timpson)

Timpsonism 14: *Sorry you've not heard anything from me for* ages. *It's been an eventful year: Jane just gave birth to our baby daughter Catherine Jane on 5 August — a most wonderful thing! Such a joy to be a father; though it's interesting trying to teach logic on very little sleep ... Oddly, it seems ok trying to teach QM ... not sure what that says (about QM, or me ...)*

Many congratulations on your daughter; that is wonderful news! Children are the greatest classroom ever for learning about the world. Please give my best wishes to Jane, and of course to Catherine too!

I liked your quip on teaching logic. I think it means logic is forced and strained in our natural humanity, whereas quantum theory is actually a gut feeling we all already have! (It being simply a refinement of everyday life — a story of the consequences of agents taking actions upon the world.) It'd be fun to revive one of F. C. S. Schiller's polemics on logic for a short class reading, like the introduction (as I recall) from his *Formal Logic, a Scientific and Social Problem*. It'll make everyone laugh out loud. (No matter how much inspiration I draw from him, the guy was really and truly a nutcase ... and probably mostly should be kept in the closet.)

13-10-10 *Up in the Air* (to D. B. L. Baker)

Bakerism 7: *I have to admit I haven't been able to completely read your "New Religion" paper. I'm still working on it. Have you seen this entire quote by Samuel Butler?*

> A belief in human progress is a matter of faith. Progress does not necessarily imply a monotonically increased advance, but rather an advance that will eventually occur within the limits of mankind's collective morality and knowledge of its respective environment. It is common to hear both philosophers and non-philosophers complain that philosophy makes no progress. Whether such a complaint is justified depends, or course, on one's understanding of the nature of philosophy, and on one's criteria of "progress". All progress is based upon a universal innate desire on the part of every organism to live beyond its income.

Thanks for the recommendation. Sounds great. Don't worry about the "new religion" thing—it wasn't a paper at all, just a grant proposal ... all geared toward extracting money. (Though I definitely was honest in it with regard to my physical and philosophical beliefs. ... Now, with regard to the "outputs" and "outcomes" that they required me to divine, that might be a different story!)

I didn't know the Samuel Butler quote, and in fact I didn't know about Samuel Butler at all before your bringing him to my attention. So thanks! I just looked him up on Wiki, and will learn more as time goes on. I've got to read more of this guy. The quote certainly resonates with my "meliorist" tendencies. I'll match your Butler with a James or two. I like the little piece that starts in the right-hand column on the first page of "Meliorism 1" at the words, "Free-will is thus a general cosmological theory of promise ..." [See 20-09-07 note "Free Will" to Å. Ericsson.] I also like entry 247 in "Meliorism 2". [See "Pragmatism and Religion" section in 30-06-09 note "A New Name for Some Old Ways of Thinking" to M. Schlosshauer.]

In fact, I just opened up a nice new collector's item this morning that arrived at the door yesterday—a 1933 printing of Henry Call Sprinkle's Yale PhD thesis, *Concerning the Philosophical Defensibility of a Limited Indeterminism: An Enquiry Based upon a Critical Study of the Indeterministic Theories of James, Renouvier, Boutroux, Eddington, Bergson and Whitehead*.

So, the evidence you present to me (and the corroborating evidence I send to you) say that maybe this "new religion" is not so new after all! It's all old stuff really; it's just that science as usually practiced has forgotten it.

14-10-10 *Temporarily Imposed Titles* (to Å. Ericsson, B.-G. Englert, S. T. Flammia, & W. K. Wootters)

Dear Sessioneers!

Since I haven't heard back from most of you, I've gone ahead and made up some tentative titles for you and placed them into the APS system for the purpose of the planning meeting which I leave for tomorrow afternoon: 1) in Steve's case, the title of his last paper on the subject, 2) in Åsa's case, a minor variation of the title she sent me, 3) in Berge's case, the title of his second-to-last paper, and 4) in Bill's case, the title of his last talk on the subject. I.e.,

- The Lie Algebraic Significance of Symmetric Informationally Complete Measurements
  – Steven T. Flammia, California Institute of Technology

- Quantum States as Probabilities from Symmetric Informationally Complete Measurements
  – Åsa Ericsson, Institut Mittag-Leffler

- On Mutually Unbiased Bases
  – Berthold-Georg Englert, Centre for Quantum Tech., National University of Singapore

- States with the Same Probability Distribution for Each Basis in a Complete Set of MUBs
  – William K. Wootters, Williams College

I hope you don't mind me taking this liberty. But please don't forget that these are just tentative titles and can be changed up until November 19. For the remaining speaker, I'm aiming for an *experimentalist* doing MUB and SIC experiments. (I figure if we have an experimentalist, we might just have someone besides ourselves attending the session!) Keep your fingers crossed!

14-10-10 *(Even More Urgent) APS March Meeting Invitation* (to A. M. Steinberg)

I'm the APS March-Meeting program chair for the Topical Group on Quantum Information this year, and I'm presently in the hurried process of planning out three invited sessions for it. On two of them, I've been completely selfless (one theoretical, one experimental), but on one I've been quite self-indulgent (as I have noticed has been the tradition in previous years ... so I don't feel so bad). Anyway, as you might nearly guess, the title of that session will be "Symmetric Discrete Structures for Finite Dimensional Quantum Systems". (A little bit more detail can be found below in the sample invitation I had sent to Berge Englert.)

Here's a listing of four of its five speakers:

- The Lie Algebraic Significance of Symmetric Informationally Complete Measurements
  – Steven T. Flammia, California Institute of Technology

The trouble is, I've been having a hard time thinking of a perfectly appropriate fifth speaker. Most of the guys that come to mind are either already burdened with coming to my Tulane U. "Clifford Lectures" the week before, or too mathematical to really be good salesmen for the subject at the March meeting, or both.

But today I had an idea! (I know, shoot me.) An *experimentalist* in the list would probably be the very best thing we could do for the fame and fortune of the subject! (I.e., that way somebody beside the speakers might actually attend the session.) Would you come and talk on your SIC and MUB experiments?

Please, please, please! (And please let me know as soon as possible. I fly to DC for the planning meeting tomorrow afternoon, and really should have all proposals in the online system before I arrive.)

16-10-10 *(Doubling the Enjoyment* (to A. M. Steinberg)

Read from bottom to top. I got tickled at your email "signature"

> "Shut up and measure." — Jeff Lundeen (after Mermin)

and sent it to David Mermin.

Aephraim's Reply

> To be honest, I would've attributed it to Feynman too, but Jeff used it in his talk with the attribution to Mermin, and the web seemed to agree with him.
>
> I guess the point is that it seems to be what Feynman believed, but in David's words. I have to go back to the original essay ... is that what he was saying?

I should mention that I have a soft spot in my heart for Mermin (whom I've only met about twice, and don't really know personally). I doubt I ever told you, but when in '94 I was first applying for postdoc positions, I wrote a "chain letter" job application, along the lines of "Karl Müller received a copy of this application and forwarded it to 300 colleagues; he received the Nobel Prize the following week. Stefan Schmidt ignored the letter, and his entire division of IBM-Zurich was closed two days later." I sent it to people I knew, and to some people I though might possibly have a job for me but probably wouldn't, and to people I expected would have senses of humor — notably Dan Kleppner & David Mermin, based on their Reference Frame columns. My advisor later ran into Kleppner at some meeting, and Dan said, "Oh, is that your student who sent me this ridiculous email? You should tell him to be careful if he wants people to take him seriously." Prof. Mozart, on the other hand, responded very kindly, and even suggested that I apply for a job with Alex Gaeta, who is indeed an excellent researcher I hadn't previously known about.

I actually really wish I could find that email! Since I never knowingly throw anything (even a backup of the disk from an old computer which probably contains the backup of the disk from an older computer which probably contains all the mailboxes from my 1994 unix account) away, it's hard to believe that I can't find it!

Perhaps it's a WriteNow file unreadable on some disk anyway, since I'm not sure how many of the recipients actually had email addresses at the time!!

22-09-10 *Modal Quantum Theory* (to M. D. Westmoreland & B. W. Schumacher)

This sounds interesting. I'm especially intrigued by your remark, "In fact even if you allow some possible results (in the modal sense) to receive a probability of zero (so that zero probability is not identified with impossible), ..."

The reason, of course, is that the distinction between probability zero and impossibility, and between probability one and truth, is crucial to the QBistic view of quantum theory that Carl Caves, Rüdiger Schack, and I are trying to build up. So the distinction would be crucial (in my mind) for your modal models as well. Here's some of the original reading in case you're interested: `http://arxiv.org/abs/quant-ph/0608190`, and I tried to do a better job of some of the arguments here `http://arxiv.org/abs/1003.5209`, particularly in Section V.

I'll look forward to really understanding your papers once I fight off some of this week's upcoming fires.

Mike's Preply

Ben and I have posted a paper on the material Ben covered in his colloquium talk on modal quantum theory. Here is the `quant-ph` link: `http://arxiv.org/abs/1010.2929`

We should have a paper on the open systems analogues up in two to three weeks.

We are currently in the midst of writing a paper on the quantum analogues to the Kochen-Specker and the Conway-Kochen (Free Will) results. We hope to have that paper posted within a week.

We have also discovered that, at least in some cases, these modal systems cannot be embedded in any probabilistic model. That is, in the mobit model, there is a state and measurements such that no probability distribution on the measurement results can assign a positive probability to the results labeled as possible in the modal system. In fact even if you allow some possible results (in the modal sense) to receive a probability of zero (so that zero probability is not identified with impossible), the only possible probability assignment gives a Popescu-Rohrlich system.

It was great to visit with you last week. I hope it will not be another seven years before we see each other again.

17-10-10 *QBlue's Fall Quantum Information Prize* (to the QBies)

QBies,

I had a wacky idea yesterday in my exhaustion from the March Meeting planning session that I might start instating prizes for little non-SIC puzzles (for God's sake!) that I'd like to see solved. (An effort to broaden us all, if you will.)

So here's my first challenge: Figure out an application for free will. More specifically, consider the lovely nine bases for a $d = 4$ system found by Cabello et al., and described between Eqs. (14) and (17) of my paper `http://arxiv.org/abs/1003.5209`. Challenge: find some quantum information protocol built around these nine bases, and for which these nine bases give the optimal answer. For instance, one can certainly build a quantum crypto protocol of the style of BB84 out of these. But is there any advantage to these 9 bases for that task, rather than some other 9 bases? What is significant about these 9 bases is that they cannot be colored in the Kochen-Specker way. But what is the practical cash value of that observation? Is there any cryptographic use for the way these bases lock together? Is there something unique and interesting about the Gram matrix of the associated 18 vectors? Little questions. Add to the list if you can think of anything.

Anyway, I'll award the finder of the best observation, protocol, or theorem (by my judgement) with some old, nice book on the subject of free will and a good heap of Kiki's cooking.

For the prize and award committee,

QBlue

19-10-10 *Intersections* (to L. Hardy)

Just taking a two minute break (before my nap!). Anyway, when all this writing and politicking is over with, it'd be nice to talk to you about some physics. Most recently (after Matthew's pushing me on the subject), I've been taking your remark from a few months back more seriously—i.e., that maybe we should take an intersection of some of your axioms and some of mine. Below is the note that started the thinking off. [See 05-10-10 note "Galoshes" to M. A. Graydon.]

We've now got a rigorous argument that our modified law of total probability (MLTP) demands that $K_{12} \geq K_1 K_2$. I.e., that that much of your Axiom 4 is not a postulate for us, but required by consistency. Now we're (well, not me really at the moment) trying to see if the MLTP similarly demands that the parameter β (in eq 10 of `http://arxiv.org/abs/0912.4252`) be multiplicative (or submultiplicative or supermultiplicative) as well.

As I say below, the question from the QBism point of view is how the oomph scales with the stuff.

Keeping my fingers crossed . . .

21-10-10 *Genetic Engineering of Nature Itself* (to M. A. Graydon)

Sections 4 and 5 are the relevant parts. [See "The Anti-Växjö Interpretation of Quantum Mechanics," `quant-ph/0204146`.]

22-10-10 *Crazy Talk* (to C. Smeenk)

Thanks for the invitation to the do last night, if you were responsible for it. Immediately after asking my question to Kitcher, I started regretting how I posed it. I should have just asked more crisply, "What would John Dewey have said about Wikipedia?"

Attached is the article from Maclean's Magazine that I was telling you about last night. The reporter sure didn't do me any favours, juxtaposing my thinking with our director's views on the matter!

22-10-10 *Clarence Irving Lewis* (to P. Wells)

I was just forwarding your PI article to a philosopher friend at Western, and I noticed for the first time that you said I had C. S. Lewis on my bookshelf. Not at all! It's C. I. Lewis. Let me introduce you to him:

> `http://en.wikipedia.org/wiki/Clarence_Irving_Lewis`.

22-10-10 *Qualities of Matter* (to C. Smeenk)

By the way, if it's in readable form already, I wouldn't mind getting a copy of your "qualities of matter" paper with Biener. Funnily enough, I've recently adopted a bit of terminology like that for "Hilbert space dimension"—seeing it as a quality or capacity of matter ... not sure which term is best and what all the existing connotations are. Perhaps reading you will help. There's a bit of my present thinking on the matter in Section VI, starting page 19, of this paper: `http://arxiv.org/abs/1003.5209`. And I even give my own—almost surely distorted—view of Newton there. It'd be nice to learn about the real man.

25-10-10 *Paul Krugman's the Man!* (to R. W. Spekkens)

From today's *New York Times*:

> What we do know is that the inadequacy of the stimulus has been a political catastrophe. Yes, things are better than they would have been without the American Recovery and Reinvestment Act: the unemployment rate would probably be close to 12 percent right now if the administration hadn't passed its plan. But voters respond to facts, not counterfactuals, and the perception is that the administration's policies have failed.

25-10-10 *Tentative Title* (to H. B. Dang)

Dangism 6: *The title is actually the hardest line, which I was planning to leave as the last thing to write, with the hope that along the way I will come across a title that best captures this paper.*

You should always write the title long before the writing the paper! I never do otherwise myself.

26-10-10 *A Paper and a Fragment* (to R. Schack)

Sorry for all the silence. I've had a grueling month. Presently I'm hurriedly working on my tenure application and I've finally come to the "Future Research" section ... and thus have started thinking of what I will say in the subsection, "Decoherence and the Classical-to-Quantum Transition (sic)". Anyway, to make a long story short, I discovered the attached paper on the web. It looks useful for our purposes (in case you haven't seen it before): Mitchell S. Green and Christopher R. Hitchcock, "Reflections on Reflection: Van Fraassen on Belief," *Synthese* **98**(2), 297–324 (1994).

Everything is kosher, by the way, with Meir Hemmo. He's waiting on us relatively patiently. I hope to push your draft to the highest possible priority next week while I'm in South Africa getting things set up for a big QBism meeting at STIAS.

26-10-10 *That Old Free Will Again* (to D. M. Appleby)

Yes, I'm still working on the sordid self-aggrandizement exercise—it's up to 45 pages now. But I have a small hope that I will finish it today.

Just writing on Bell-Kochen-Specker stuff ... and came across this reference:

`http://arxiv.org/abs/1002.1410`.

It looks like there's some interesting commentary on your work in there. Were you aware of it?

30-10-10 *Hilbert Space Dimension as an Occult Quality ...* (to C. Smeenk)

I thought you might enjoy a couple of sections near the end of the completed draft (or at least I think I just finished it!) where I speculate on HS dimension as an occult quality! It's a joke of course, but I am a bit serious too. At least to the point that it seems useful for me study some of the historical literature, like your paper, and some other nice looking things I've found on the web.

Once I get a chance to read and think about all this esoteric stuff a bit more deeply, I'm sure to be back in touch!

01-11-10 *And Conway Wasn't Conway* (to A. Karlsson)

You probably learned complex analysis from J. B. Conway's book. The Conway here is John Horton Conway, the very, very powerful mathematician:

`http://en.wikipedia.org/wiki/John_Horton_Conway`

I have a story about Conway and SICs. I told John that it looks like the Welch bound can be achieved in the complex case. He was a bit shocked to learn that—for you know, he knows the real case very well, making very important contributions to it. Anyway, he was very pleased with this new knowledge, thought for a minute, and then declared, "I do believe the bound can be achieved in the complex case, but it would be very difficult to prove it."

02-11-10 *Probable Delay* (to R. Schack)

From New York JFK. Just to warn you: They're presently showing my flight as delayed by 40 minutes. My scepticism says that that'll turn into a much larger delay before it's all over with. Anyway, stay on the lookout so that you don't waste too much time in the airport.

I've been reading some very nice stuff on alchemy this evening. I've learned that Wheeler's "now fly!" metaphor is every bit as old as Aristotle himself. From a 1997 note of mine:

> In 1972 [John Preskill] had Wheeler for his freshman classical mechanics course at Princeton. One day Wheeler had each student write all the equations of physics s/he knew on a single sheet of paper. He gathered the papers up and placed them all side-by-side on the stage at the front of the classroom. Finally, he looked out at the students and said, "These pages likely contain all the fundamental equations we know of physics. They encapsulate all that's known of the world." Then he looked at the papers and said, "Now fly!" Nothing happened. He looked out at the audience, then at the papers, raised his hands high, and commanded, "Fly!" Everyone was silent, thinking this guy had gone off his rocker. Wheeler said, "You see, these equations can't fly. But our universe flies. We're still missing the single, simple ingredient that makes it all fly."

Compare:

> Plato's distrust of the mimetic arts reflects a widespread ambivalence toward imitation in antiquity. This mistrust is rooted in the idea that the painter or sculptor, by producing a replica of something natural, is engaging in a sort of counterfeit. The same attitude existed with regard to the *technai* more broadly. Although they might be clever simulacra of nature, they could not themselves be natural. A clear formulation of this distinction between the products of nature and the products of artifice appear in Aristotle's *Physics*, where the Stagirite distinguishes natural products from artificial ones on the basis of the fact that the natural have an innate principle of movement (or change), whereas the artificial have no inherent trend toward change. For this reason, Aristotle says, "men propagate men, but bedsteads do not propagate bedsteads." The artificial product is static, having received no intrinsic principle of development.

On other matters: The key issue of Weyl's phase space must be that for the measurements associated with it (i.e., X and Z) every SIC vector will give a give a probability distribution for those two observables with identical Rényi 2-entropy. Every SIC vector (WH SIC at least) will generate an entropy of $\log\left(\frac{2}{d+1}\right)$ for either of those measurements. It strikes me that that might well be an axiom we'd want to take. For instance, I have this pet idea (since 4:00 AM this morning) that this might give us the right bound on the number of zero components in a probability vectors. Our bounds previously have been horrible (only saturated in $d = 3$). But this looks like a much tougher constraint to me.

But I cannot get too distracted this week: My purpose is to write, write, write of QBism from the bottom of the world (not derive, derive, derive). And when we all come back next year, we will turn QBism on its head there! That's got to be the purpose of the place.

05-11-10 *Sabbatical in South Africa* (to R. Schack)

I'm now starting to understand what they want: Ideally about 5 people (interdisciplinary) to stay for 6 to 8 weeks and work in their facility. Travel and accommodation covered, as well as a small stipend for food. But no salary support. It is stunningly beautiful here; very nice facilities with nice gardens, vineyard, etc. (Much more my style than Perimeter.) And a very pleasant community with lots of restaurants and cafés.

05-11-10 *Heisenberg's Microscope and Battery* (to H. B. Geyer)

It looks like we were both right. See this excerpt from Cassidy's book:

`http://www.aps.org/publications/apsnews/199801/heisenberg.cfm`

The relevant lines are:

> As the 21-year-old Heisenberg appeared before the four professors on July 23, 1923, he easily handled Sommerfeld's questions and those in mathematics, but he began to stumble on astronomy and fell flat on his face on experimental physics. In his laboratory work Heisenberg had to use a Fabry-Perot interferometer, a device for observing the interference of light waves, on which Wien had lectured extensively. But Heisenberg had no idea how to derive the resolving power of the interferometer nor, to Wien's surprise, could he derive the resolving power of such common instruments as the telescope and the microscope. When an angry Wien asked how a storage battery works, the candidate was still lost. Wien saw no reason to pass the young man, no matter how brilliant he was in other fields.

I do, however, think Cassidy's article is wrong near the end of the webpage. My understanding is that Bohr found his complementarity they same week Heisenberg found his uncertainty principle, and the two of them were in different places at the time.

06-11-10 *QBies for the BQs* (to N. D. Mermin)

Merminition 220: *You've had much more experience with philosophers than I've had.*

Here's a general comment from my draft replies to Max's 17 questions. (He gave me another 15 day extension. I gather you are also delinquent.)

> When I got into this business I had hoped that philosophers would bring to the conversation their historical expertise in the Big Questions. What is the nature of human knowledge? How do people construct a model of the world external to themselves? How does our mental organization limit our ability to picture phenomena? How does our need to communicate with each other constrain the kinds of science we can develop? Those kinds of questions.
>
> But, to my disappointment, it seems to me the professional philosophers prefer to behave like amateur physicists. They don't try to view the formalism as part of a Bigger Picture. On the contrary, they seem to prefer to interpret it more literally and less imaginatively than many professional physicists. Because they are less proficient than physicists in using the tools of physics, they tend not to do as good a job on these narrower matters. Sometimes they strike me as naive and unsophisticated.
>
> So I would say that up to now professional philosophers have not played a significant role in advancing our understanding of quantum foundations. I would not (and could not) discourage philosophers from working in quantum foundations. But I would urge them to keep their eyes on the Big Questions.

So go for somebody who worries about BQs — somebody who brings BQism to QBism.

Oh, I wish you hadn't sent me that! I was only a little way into answering that question, but I was going to make a point much like you. Now, I'll have to think hard so that I don't feel like I'm sounding too much like you.

I was going to base the answer on two recent rants. One to John Norton and one to Max himself. I'll put the rant to Norton below. [See note to J. D. Norton, titled "Time Flies" and dated 07-06-10.]

Here were the words I had constructed so far for my answer to Q14, "What is the role of philosophy in advancing our understanding of the foundations of quantum mechanics?"

> If you catch me on a bad day, I'd say "no role." But I'd be lying if I left it at that. What I mean more particularly is that a large fraction of the philosophers of science who hang out at quantum foundations meetings have never seemed to me to bring much to the table that is forward looking or creative. Except for their willingness to engage in foundational questions in a way most physicists will not, they almost represent an impediment. There is no doubt that my views would not be what they are today if I had not had a sustained interaction with this community, but their role has always been a negative and resistive one; what I have gotten out of the deal is that it has been a kind of whet stone for sharpening my own thoughts. I'd rather say that I've learned something *directly* from them—that my eyes were opened by this one's or that one's considerations—but it hasn't been much so.
>
> The trouble is they advertise that what they are up to is all about the logic of what the physicists present them with, but it has been my experience that it is most often logic used in the service of *their own* prejudices. The manipulations of logic work just as well on false values as they do on truth values . . .

Don't send me any more of your answers!

Off for drive out into the wine regions.

07-11-10 *(Urgent) APS Invitation !!* (to B. W. Schumacher)

I write you (from South Africa!) as a *desperately running late* organizer for the Topical Group on Quantum Information's portion of the APS March Meeting. It's going to be in Dallas, March 21–25.

It's not quite a 10 year anniversary of the old PhysComp '92 meeting we were at, but I did find a way to make it an important anniversary for quantum information. Among the sessions I'm organizing, there'll be one titled "20 Years of Quantum Information in Physical Review Letters" (I used Ekert's QCrypto paper as the excuse) and through it, I'm hoping to draw broad attention to the TGQI by having (somewhat) historical talks about the golden age of quantum information. So far, for that session, I've secured Bennett, Shor, DiVincenzo (who will be at Aachen U by then), and Ekert.

I'm writing . . . *urgently!* . . . to ask if you'd be willing to join the crowd? It'd be a 30 minute talk with 6 minutes of questions. It would be wonderful to have a talk about the origin of the qubit, quantum compression, and quantum channel capacities by you.

In other sessions, so far, I've secured Bill Wootters, Anton Zeilinger, Jeff Kimble, Chris Monroe, Dick Slusher, Richard Hughes (giving a talk titled "27 Years of Quantum Cryptography!"). And present for the executive meeting will be John Preskill and Dave Bacon. I'm sure I'm forgetting others. The main thing I'm trying to impress you with is that you should have some fun people to talk to if you would join us! Oh, and a talk by Till Rosenband on one of the coolest experiments on earth: `http://www.nist.gov/pml/div688/clocks_092810.cfm`. (They can measure GR effects on clock synchronization over just 33 cm!!)

Also there'll be lectures by at least one (and maybe both) of the graphene Nobel prize winners. And since it's a 100th year anniversary of superconductivity, there'll be a special Nobel session with Giaver, Ketterle, Leggett, Mueller, and Wilczek speaking. Finally, David Mermin has said that he might come just to hang out. It'll be a big, buzzing zoo with likely 7,500 attendees (I'm told).

Anyway, I hope you can tell me you'll come! (And I hope you can tell me really *quickly* whatever the answer be. I've really got to get an announcement out to the general membership tomorrow or the next day prodding them to submit abstracts before the Nov 19 deadline, and I want to have just as much firepower as I can by then!)

It is a general policy of APS to not extend travel grants or fee waivers to invited speakers, trying to keep the "exceptional cases" to where the speaker is a nonphysicist or needing to make a transoceanic flight. So far, I've only used this power for Peter Shor because of his maths affiliation. But I don't recall your having a travel grant like all my other guys, so if you need airfare or fee waiver or both, I think I will be able to argue the case (with Ivan Deutsch and Christine Lenihan).

Mostly I want you there! Please let me know just as soon as possible. And at the same time, tell me your financial needs … and your title!

From Stellenbosch,

Chris … (oh, and there'll be a focus session "Quantum Information in the Service of Quantum Foundations" where you and/or Mike your modal stuff for a 12+3 talk)

07-11-10 *Ellis on Time* (to H. B. Geyer)

Here is a short summary of Ellis's view on time that we were discussing yesterday:

`http://www.fqxi.org/community/forum/topic/361`

07-11-10 *Another Meaning of Truth. Or The Usual One?* (to D. M. Appleby)

These lines struck me deeply tonight:

> Everybody loves the sound of a train in the distance
> Everybody thinks it's true

They come from Paul Simon's song "Train in the Distance":

> She was beautiful as southern skies
> The night he met her
> She was married to someone
> He was doggedly determined that he would get her
> He was old, he was young
> From time to time he'd tip his heart
> But each time she withdrew
> Everybody loves the sound of a train in the distance

Everybody thinks it's true
Well eventually the boy and the girl get married
Sure enough they have a son
And though they both were occupied
With the child she carried
Disagreements had begun
And in a while they fell apart
It wasn't hard to do
Everybody loves the sound of a train in the distance
Everybody thinks it's true
Two disappointed believers
Two people playing the game
Negotiations and love songs
Are often mistaken for one and the same
Now the man and the woman
Remain in contact
Let us say it's for the child
With disagreements about the meaning
Of a marriage contract
Conversations hard and wild
But from time to time
He makes her laugh
She cooks a meal or two
Everybody loves the sound of a train in the distance
Everybody thinks it's true
Everybody loves the sound of a train in the distance
Everybody thinks it's true
What is the point of this story
What information pertains
The thought that life could be better
Is woven indelibly
Into our hearts
And our brains

Meliorism is woven into our hearts and our brains.

Greetings from beautiful/ugly, rich/poor, full/empty ... sad/hopeful ... South Africa. This country feels bigger than anything I've ever encountered before.

08-11-10 *Bill's Functionalism* (to W. G. Demopoulos)

Two African meals have passed, and I have finished reading your new version of the paper. It was a pleasure this, as every time before.

I think I caught one typographical error, page 10, 6th line from the top: "to the question whether" $\rightarrow$ "to the question of whether"?

As you can probably guess, I'm still not very sympathetic with (what I view as) your ontological dualism. "Effects are the traces of particle interactions on systems which admit a theoretical description in terms of propositions which belong to them." I don't like the idea of the world consisting of two fundamentally different kinds of entity (in reductionistic character at least). I'm much happier to think “propositions never belong to systems” quantum or classical. If, as opposed to me, you’ll have nothing of agents, then I’d much rather see you develop a view where it’s effects all the way down. A particle’s effect on a device is that its own effects on anything else can now be something that they would not have been otherwise. A world that is “ever not quite” (Benjamin Paul Blood).

My favorite part of the paper continues to be how “a particle’s characterization has the logical form of a function.” A broad suggestion for some next-step explorations/research. It would be nice if you would compare and contrast what you’re talking about here with with some of the (so-far only partially developed) relational views on quantum mechanics. For instance, Rovelli’s `http://arxiv.org/abs/quant-ph/9609002`. What are the differences between Rovelli’s “relationalism” and Bill’s “functionalism”? (It seems your dualism is one thing.) But is there anything in common between them?

Another thing I’d like to hear is a more lingering discussion on, “What are these eternal properties you speak of?” Say, an electron: What are its eternal properties? And is there any connection between the eternal properties and the set of effects a particle can produce.

I liked Itamar’s remark, “The lesson of EPR is not about locality but about how their criterion of reality is insufficient.” However, I don’t agree with one of his lines a few previous to that—that “EPR’s criterion is at best necessary.” That gives it too much credit for me. But that’s all tied up with my personalist Bayesianism even for probability 1.

When you feel like writing again, let me know how you’re doing.

08-11-10 *There and Back Again* (to H. B. Geyer)

I didn’t catch the name of the NITheP director, and I couldn’t find it on their webpage. You might forward this to him. It looks like the Google Swedish tool might be a bit better than the German one after all! Or maybe it’s just that the Swedes have a certain sympathy to Jim’s (old) way of looking at the world.

Here is a passage from a 1968 paper of Jim Hartle’s:

> A quantum-mechanical state, being a summary of the observers’ information about an individual physical system, changes both by dynamical laws and whenever the observer acquires new information about the system through the process of measurement. The existence of two laws for the evolution of the state vector becomes problematical only if it is believed that the state vector is an objective property of the system. Then, the state vector must be required to change only by dynamical law, and the problem must be faced of justifying the second mode of evolution from the first. If the state of a system is defined as [our information of it], it is not surprising that after a measurement the state must be changed to be in accord with [any] new information. The “reduction of the wave packet” does take place in the consciousness of the observer, not because of any unique physical process which takes place there, but only because the state is a construct of the observer and not an objective property of the physical system.

Here it is after Google’s attempt to translate it into German:

> Ein quantenmechanischer Zustand, wobei eine Zusammenfassung der Beobachter Informationen über eine einzelne physische System, Veränderungen sowohl durch dynamische Gesetze und wenn der Beobachter erwirbt neue Informationen über das System durch den Prozess der Messung. Die Existenz von zwei Gesetze für die Entwicklung des Zustandsvektors wird problematisch, wenn man glaubt, dass der Zustandsvektor eine

objektive Eigenschaft des Systems ist. Dann muss der Zustandsvektor verpflichtet, nur ändern, indem dynamische Gesetz sein, und dieses Problem muss zur Rechtfertigung der zweite Modus der Evolution von der ersten konfrontiert werden. Wenn der Zustand eines Systems wie [unsere Informationen davon] definiert ist, ist es nicht verwunderlich, dass nach einer Messung den Zustand geändert werden muss, um im Einklang mit [alle] neue Informationen sein. Die "Reduktion des Wellenpakets" findet statt im Bewutsein des Betrachters, nicht wegen irgendeiner einzigartigen physikalischen Vorgang, der dort, aber nur, weil der Staat ist ein Konstrukt des Beobachters und nicht eine objektive Eigenschaft des physikalischen Systems.

And here it is after Google's attempt to re-translate it back into English:

> A quantum mechanical state, with a summary of information obtained on a single physical system, with dynamic changes in both law and if the observer acquires new information about the system through the process of measurement. The existence of two laws for the development of the state vector is problematic if one believes that the state vector is an objective property of the system. Then the state vector required to change only by law to be dynamic, and this problem needs to justify the second mode of evolution are confronted from the first. If the state of a system like [our information like this] is defined, it is not surprising that change after a measurement the state needs to be in accordance with [any] new information. The "reduction of the wave packet" will take place in the consciousness of the viewer, not because of any unique physical process that there, but only because the state is a construct of the observer and not an objective property of the physical system.

Not so good indeed!

Now, I go through the same process, but with Swedish rather than German. First to Swedish:

> En kvantmekaniska tillstånd, är en sammanfattning av observatörernas information om en enskild fysisk systemet, ändringar av både dynamiska lagar och när Observer förvärvar ny information om systemet genom processen av mätning. Förekomsten av två lagar för utvecklingen av statens vektor blir problematisk endast om det kan antas att staten vektorn är ett mål egendom av systemet. Sedan måste staten vektor måste ändra endast genom dynamiska lag, och problemet måste mötas av att motivera det andra sättet för utvecklingen från den första. Om tillståndet hos ett system definieras som [vår information om det], är det inte förvånande att efter en mätning staten måste ändras för att vara i överensstämmelse med [några] nya uppgifter. Den "minskning av den våg paket" tar plats i medvetandet hos den observatör, inte på grund av unika fysikalisk process som äger rum där, men bara för att staten är en konstruktion av observatören och inte en objektiv egenskap hos det fysiska systemet.

And now back again:

> A quantum state, is a summary of the observers' information about a single physical system, changes to both the dynamic laws, and when the Observer acquires new information about the system through the process of measurement. The existence of two laws for the development of the state vector becomes problematic if it can be assumed that the state vector is an objective property of the system. Then, the state vector must change only through dynamic team, and the problem must be met to justify the other type of development from the first. If the state of a system is defined as [our information

> on it], it is not surprising that after a measurement the state must be modified to be consistent with [any] new data. The "reduction of the wave packet" takes place in the mind of the observer, not because of the unique physical process that takes place there, but just because the state is a construct of the observer and not an objective property of the physical system.

I'm not quite sure, but I think Sweden does a little better!

09-11-10 *The Universe on a Social Analogy* (to P. Cilliers)

I am looking forward to dinner with you all tomorrow evening. At tonight's dinner, I read your paper with Heylighen and Gershenson, "Complexity and Philosophy." Now I understand much better where you're coming from.

You should know that I am quite sympathetic with many things you wrote in your paper. In fact, my foundational effort in quantum theory (which I call QBism) is based on a *denial* of one of the sentences in your paper ... but it is a denial that I think you will be pleased with once you come to understand it:

> While the notion of uncertainty or indeterminacy is an essential aspect of the newly emerging world view centering around complexity (Gershenson & Heylighen, 2005; Cilliers, 1998), it is in itself not complex, and the physical theories that introduced it are still in essence reductionist.

The denial is that actually for quantum theory to make any foundational sense, it must ultimately be read in nonreductionist terms—in fact, it is what QBism is all about! Moreover, it gives some of the main statements within quantum theory a normative reading. You can read about this view in this paper of mine (particularly in Section VI, starting on page 19): `http://arxiv.org/abs/1003.5209v1`. It is written in an entertaining manner and meant to be easy reading, so I hope you'll give it a go.

If I were to organize a project at STIAS, it would be on the themes in this paper, and thus, I think would have quite a natural overlap with your concerns.

I have always been taken with this quote of William James,

> Why may not the world be a sort of republican banquet of this sort, where all the qualities of being respect one another's personal sacredness, yet sit at the common table of space and time?
>
> To me this view seems deeply probable. Things cohere, but the act of cohesion itself implies but few conditions, and leaves the rest of their qualifications indeterminate. As the first three notes of a tune comport many endings, all melodious, but the tune is not named till a particular ending has actually come,—so the parts actually known of the universe may comport many ideally possible complements. But as the facts are not the complements, so the knowledge of the one is not the knowledge of the other in anything but the few necessary elements of which all must partake in order to be together at all. Why, if one act of knowledge could from one point take in the total perspective, with all mere possibilities abolished, should there ever have been anything more than that act? Why duplicate it by the tedious unrolling, inch by inch, of the foredone reality? No answer seems possible. On the other hand, if we stipulate only a partial community of partially independent powers, we see perfectly why no one part controls the whole view, but each detail must come and be actually given, before, in any special sense, it

> can be said to be determined at all. This is the moral view, the view that gives to other powers the same freedom it would have itself.

It sounds similar to some of the ideas in your paper.

Paul's Reply

> I look forward to finally get some time to talk, I have been running around too much. There seems to be a very good basis for a good discussion.
>
> The sentence you "deny" was actually aimed primarily at certain forms of complexity theory, mainly those relying heavily on chaos theory. I have been quite consistent (I hope) in avoiding all reference to quantum theory, mainly because of my own lack of understanding, but also because of a deep suspicion of chicanery when quantum ideas are used by philosophers and other social scientists. This is also something I would like to talk about.
>
> I will probably not have time to read your paper before we meet for dinner, but let us see.
>
> Thanks for taking the trouble to get the discussion going.

13-11-10 *Quantum Foundations at the APS March Meeting* (to J. N. Butterfield)

Word has gotten out that you maintain a mailing list of foundations folks in the UK. May I ask that you distribute the announcement below (along with the showy, crucial attachment of invited speakers) to your list? Nicely, we've already gotten a few European submissions; so it is not out of the question that a European would want to come. Any submission of quality work would certainly help the cause of making foundations a respected field within the broader APS audience.

And a test of your philosophical prowess: What phrase below was snatched from a philosopher, and who was it? Talking about what?

Jeremy's Reply

> Thanks Chris for this! Im afraid I don.t have such a list now, but saw your message go out next day through Bob Coecke.s mail list, which would have covered at least most of my addressees. May I say dear friend: it is: William James on the stream of consciousness?!

13-11-10 *Quantum Foundations at the APS March Meeting* (to B. Coecke)

I agree with Rob, your idea is an excellent idea and long overdue. Having that list would have been very convenient for this year.

In the meantime, I am running out of time to try to get submissions for the present meeting. So if you could forward the announcement below to your existing list, that would be much appreciated. Surprisingly, I have actually gotten a few European and Australian submissions. So, I guess it is not out of the question that Europeans will come.

Please note that the note below and the attachment are slightly different than the previous ones I sent you. Some typos have been corrected, etc. So if you could please use the present versions . . .

This is much, much appreciated. And it'd be great to meet someone from your group (or you!) at the March Meeting!

> ==
>
> **Deadline: 19 November!**
>
> Dear quantum-foundational colleagues,
>
> When Danny Greenberger and Anton Zeilinger first solicited the American Physical Society to form what later became the Topical Group on Quantum Information (GQI), they also intended it to be a representative body for quantum foundations research. Our mission statement makes this explicit:
>
>> The Group is committed to serving as the home within the American Physical Society for researchers in the foundations of quantum mechanics. The Topical Group will promote a continuation of the active and beneficial exchange of ideas between quantum foundations and quantum information science.
>
> I write to you as the chair-elect of the GQI executive committee and 2011 March Meeting program chair to ask you: **PLEASE DO** support quantum foundations in the APS by **SUBMITTING A TALK OR POSTER** on your work for the upcoming March Meeting in Dallas, Texas, 21-25 March 2011.
>
> To stay viable, quantum foundations research must stay visible. It must also contribute to the larger project of physics more generally. Bringing our work to the attention of the APS and showing its respectability is crucial to that project. It helps physics, and it may help create foundations-oriented faculty positions for the younger of us out there.
>
> This year we will have a focus session titled "Quantum Information for Quantum Foundations" with Giulio Chiribella (Perimeter Institute for Theoretical Physics) as our invited speaker. His talk will be titled, "Toward a Conceptual Foundation of Quantum Information Processing." Also, Anton Zeilinger (University of Vienna) will be giving a symposium talk, "Quantum Information and the Foundations of Quantum Mechanics: A Story of Mutual Benefit."
>
> It is very important that we have many other quality submissions to our focus session. I hope that you too will recognize the importance of this meeting and do what you can.
>
> More details of the full program can be found below and in the attached schedule that I have previously sent to the full GQI membership. With all the Nobel prize speakers (6+) and so many of the fathers of quantum information, this promises to be one of the most memorable March Meetings in quite some time.
>
> To register for the meeting and submit an abstract, please go to
>
> `http://www.aps.org/meetings/march/`
>
> and note that the **DEADLINE** for abstract submission is **19 November**, just 6 days away.
>
> Please join us in this "blooming, buzzing confusion" of 7,500 physicists and show them what good quantum foundations work is all about!
>
> Best wishes,
>
> Chris Fuchs

(more details on program below and attached)

==

Dear GQI Membership,

I write to you as the chair-elect of the GQI executive committee and the program chair of our portion of the 2011 APS March Meeting. This coming year the meeting will be in Dallas, Texas, 21-25 March 2011.

We believe we have put together an exciting venue of invited talks and focus sessions. Please have a look at the attachment and you will see. There will be some astounding experiments reported, and you will also have a chance to meet several of the founders of our field. 2011 is a hallmark year for quantum information as a field within physics Also we are pleased to announce that one of our talks will be given by one of the two LeRoy Apker Award winners for "outstanding achievements in physics by undergraduate students."

I should further mention that the meeting will host a talk from one of this year's Nobel-Prize winners for the discovery of graphene, Konstantin Novoselov. (Andre Geim may also speak, but has not yet confirmed.) Moreover, there will be a recognition of the 100th anniversary of the discovery of superconductivity with a session of historical talks devoted to the subject, as well as a Nobel-laureate session on it. Speakers will include Ivar Giaever, Wolfgang Ketterle, Sir Anthony Leggett, K. Alexander Mueller, and Frank Wilczek, and there is word that there may be more.

In all, it should be a more-than-usual memorable meeting, with some quite wonderful GQI invited and focus sessions. The executive committee and I hope the venue will be exciting enough to tip the scales for you if you have been indecisive about attending.

Particularly, we encourage you to submit a talk or poster on your latest research. The better showing GQI makes at this meeting, the greater the chance we have of increasing general APS awareness of our field, the better the chance the topical group may recruit enough members to attain APS Division status, and, **MOST IMPORTANTLY**, the better the chance we have of convincing American physics departments that it is worthwhile to create faculty and research positions for all of us. Your participation is really, truly vital. Quantum information needs you!

> This story shall the good man teach his son;
> And Crispin Crispian shall ne'er go by,
> From this day to the ending of the world,
> But we in it shall be remembered—
> We few, we happy few, we band of brothers;
> For he to-day that sheds his blood with me
> Shall be my brother; be he ne'er so vile,
> This day shall gentle his condition;
> And gentlemen in England now-a-bed
> Shall think themselves accurs'd they were not here,
> And hold their manhoods cheap whiles any speaks
> That fought with us upon Saint Crispin's day.

Please note that the deadline for abstract submission is **NOVEMBER 19** (less than 6 days away!). Please submit an abstract yourself; please get your students to submit an abstract too! Please get your associates to submit an abstract as well!! The place to go to submit and register for the meeting is here:

`http://www.aps.org/meetings/march/`

The GQI executive committee and I hope to see you in Dallas. It'll be a whoppin' good time!

Chris Fuchs
Chair-elect of APS Topical Group on Quantum Information
GQI Program Chair for 2011 APS March Meeting

15-11-10 *Quantum Foundations at the APS March Meeting* (to S. L. Braunstein)

I hope you have a good student or postdoc who needs some speaking practice or exposure that you can send. Better yet, come yourself. Your work on Heisenberg groups would fit right in (perfect for the foundations session, and would complement the discrete structures symposium). Beside everyone in the lists below and above, I know that Gerard Milburn, Danny Greenberger, several Zeilinger associates, . . . , will be there.

It really promises to be a very good meeting this year.

18-11-10 *Quantum Foundations in Dallas!* (to I. T. Durham)

OK, I give up. I'm off to have some dinner. I tried to get this thing posted on FQXi myself, and I just couldn't get it to stick. I don't know what I'm doing wrong. But this is the last you'll hear from me tonight. Please if you don't mind, use the exact wording I've given below (modulo adding your own title and adjusting to 36 if you wish). I was given hell from a visiting professor earlier today because of my previous wording (he was offended)—I hope this time I have made it clear that these titles "can be considered" foundations and that they are not all in one session, but "culled from all sessions".

===

Dear quantum foundations folk,

As I write to you, 3400 abstracts have already been submitted for the APS March Meeting, with 140 of those earmarked for the Topical Group on Quantum Information. Very importantly for quantum foundations, **35 of those abstracts** (culled from all sessions) can be considered with good justification to be **quantum foundations submissions**!! In other words, at the moment, we've got 1% of the whole meeting thinking about the foundations of physics!

Have a look at some of the titles and speakers below; there are going to be some very good talks at this meeting. It will be a grand opportunity for everyone in our community to mix and mingle and learn from each other.

Please don't forget that the abstract submission deadline is tomorrow, November 19, at 5:00 PM EST.

I really encourage everyone who wants to see quantum foundations thrive and be memorable to please submit a talk to this meeting. Encourage your colleagues and students too. Let's build a critical mass. Your voice will count.

The place to go is: `http://www.aps.org/meetings/abstract/instructions.cfm`. You must have an APS membership before submitting ($128 regular, $64 for recently completed PhDs, and $0 for students first joining), but you can still submit an abstract even if you don't have your membership number yet–the instructions at the link explain how to do it. (It is not necessary, but please do spend the extra $8 to join the Topical Group on Quantum Information, the official home within the APS for quantum foundations research.)

Sincerely,

Chris Fuchs

20-11-10 *How Foundations Did* (to D. M. Greenberger & A. Zeilinger)

I thought I'd give you a summary of how foundations ended up doing. There were 7,700 submissions for the March Meeting as a whole. The topical group for quantum information got 352 submissions. That is up from 256 last year (and 227 the year previous to that). The impressive thing for us is that we got 66 talks that should be of foundational interest. This means we will commandeer 4 sessions for the submitted foundational talks alone! I'll put all the titles below; and you can notice that there's not even any crazy ones in the list! The best we'd ever done on foundations before was two sessions (one mostly solid stuff, and one mostly crazy).

I've got to say, I'm very proud of what we accomplished this year. Thanks Anton for getting so many of your guys there. Our community can stand and rise!

Long Talks

1. A Brief Prehistory of Qubits
   Benjamin Schumacher

2. Quantum Information and the Foundations of Quantum Mechanics: A Story of Mutual Benefit
   Anton Zeilinger

3. Toward a Conceptual Foundation of Quantum Information Processing
   Giulio Chribella

4. Pairwise complementary observables and their mutually unbiased bases (MUBs)
   Berthold-Georg Englert

5. Quantum States as Probabilities from Symmetric Informationally Complete Measurements (SICs)
   Åsa Ericsson

6. The Lie Algebraic Significance of Symmetric Informationally Complete Measurements
   Steven T. Flammia

7. Experimental access to higher-dimensional discrete quantum systems, towards realizing SIC-POVM and MUB measurements, using integrated optics
   Christophe Schaef

8. Isotropic States in Discrete Phase Space
   William K. Wootters

Short Talks:

1. Physics as Information
   Giacomo Mauro D'Ariano

2. Quantum theory cannot be extended
   Roger Colbeck, Renato Renner

3. The quantal algebra and abstract equations of motion
   Samir Lipovaca

4. Scaling of quantum Zeno dynamics in thermodynamic systems
   Wing Chi Yu, Li-Gang Wang, Shi-Jian Gu

5. Mathematical Constraint on Realistic Theories
   James Franson

6. Uncertainty Relation for Smooth Entropies
   Marco Tomamichel, Renato Renner

7. Quaternions and the Quantum
   Matthew Graydon

8. A Linear Dependency Structure Arising from Weyl-Heisenberg Symmetry
   Hoan Bui Dang, Marcus Appleby, Ingemar Bengtsson, Kate Blanchfield, Åsa Ericsson, Christopher Fuchs, Matthew Graydon, Gelo Tabia

9. Proofs of the Kochen-Specker theorem based on the 600-cell
   P. K. Aravind, Mordecai Waegell, Norman Megill, Mladen Pavicic

10. Proofs of the Kochen-Specker theorem based on two qubits
    Mordecai Waegell, P. K. Aravind

11. Quantum Theory for a Total System with One Internal Measuring Apparatus
    Wen-ge Wang

12. The thermodynamic meaning of negative entropy
    Lidia del Rio, Renato Renner, Johan Aaberg, Oscar Dahlsten, Vlatko Vedral

13. Pseudo-unitary freedom in the operator-sum representation
    Yong Cheng Ou, Mark S. Byrd

14. Quantum Computational Geodesic Derivative
    Howard Brandt

15. Hardy's paradox and a violation of a state-independent Bell inequality in time
    Alessandro Fedrizzi, Marcelo P. Almeida, Matthew A. Broome, Andrew G. White, Marco Barbieri

16. Topos formulation of History Quantum Theory
    Cecilia Flori

17. Quantum Darwinism in an Everyday Environment: Huge Redundancy in Scattered Photons
    Charles Riedel, Wojciech Zurek

18. Redundant imprinting of information in non-ideal environments: Quantum Darwinism via a noisy channel
Michael Zwolak, Haitao Quan, Wojciech Zurek

19. Foundational aspects of energy-time entanglement
Jan-Åke Larsson

20. A Bigger Quantum Region in Multi-Party Bell Experiments
Matty Hoban, Dan Browne

21. Qutrits under a microscope
Gelo Noel Tabia

22. Quantum systems as embarrassed colleagues: what do tax evasion and state tomography have in common?
Chris Ferrie, Robin Blume-Kohout

23. Modal Quantum Theory
Michael Westmoreland, Benjamin Schumacher

24. On the Experimental Violation of Mermin's High-Spin Bell Inequalities in the Schwinger Representation
Ruffin Evans, Olivier Pfister

25. Measurement backaction and the quantum Zeno effect in a superconducting qubit
Daniel H. Slichter, R. Vijay, Irfan Siddiqi

26. A derivation of quantum theory from physical requirements
Markus Mueller, Lluis Masanes

27. Quantum simulation of time-dependent Hamiltonians and the convenient illusion of Hilbert space
Rolando Somma, David Poulin, Angie Qarry, Frank Verstraete

28. Time-asymmetry and causal structure
Bob Coecke, Raymond Lal

29. Large violation of Bell's inequalities using both counting and homodyne measurements
Valerio Scarani, Daniel Cavalcanti, Nicolas Brunner, Paul Skrzypczyk, Alejo Salles

30. Simulating Concordant Computations
Bryan Eastin

31. A generalization of Noether's theorem and the information-theoretic approach to the study of symmetric dynamics
Iman Marvian, Robert Spekkens

32. MUB Entanglement Patterns by Transformations in Phase Space
Jay Lawrence

33. Regrouping phenomena of SIC POVMs covariant with respect to the Heisenberg–Weyl group
Huangjun Zhu

34. Quantum networks reveal quantum nonlocality
Daniel Cavalcanti, Mafalda Almeida, Valerio Scarani, Antonio Acin

35. Interpreting quantum discord through quantum state merging
Vaibhav Madhok, Animesh Datta

36. Long-range spin-coupled interactions: a Gedankenexperiment on the nature of spin
Ian Durham

37. Affine Maps of the Polarization Vector for Quantum Systems of Arbitrary Dimension
Mark Byrd, C. Allen Bishop, Yong-Cheng Ou

38. Inadequacy of von Neumann entropy for characterising extractable work
Oscar Dahlsten, Renato Renner, Elisabeth Rieper, Vlatko Vedral

39. Causality, Bell's theorem, and Ontic Definiteness
Joe Henson

40. Entanglement in Mutually Unbiased Bases
Marcin Wiesniak, Tomasz Paterek, Anton Zeilinger

41. Experimental Violation of Two-Party Leggett-Garg Inequalities with Semi-weak Measurements
Justin Dressel, Curtis Broadbent, John Howell, Andrew Jordan

42. Testing spontaneous localization with ultra-massive cluster interferometry
Stefan Nimmrichter, Klaus Hornberger, Markus Arndt

43. Experimental non-classicality of an indivisible system
Radek Lapkiewicz, Peizhe Li, Christoph Schaeff, Nathan Langford, Sven Ramelow, Marcin Wiesniak, Anton Zeilinger

44. Violation of local realism with freedom of choice
Johannes Kofler, Thomas Scheidl, Rupert Ursin, Sven Ramelow, Xiao-Song Ma, Thomas Herbst, Lothar Ratschbacher, Alessandro Fedrizzi, Nathan Langford, Thomas Jennewein, Anton Zeilinger

45. Matter wave interferometry with large and complex molecules
Stefan Gerlich, Sandra Eibenberger, Mathias Tomandl, Jens Tüxen, Marcel Mayor, Markus Arndt

46. Surface based detection schemes for molecular interferometry experiments – implications and possible applications
Thomas Juffmann, Adriana Milic, Michael Muellneritsch, Markus Arndt

47. Integrable matrices with a given number of commuting partners and their exact solution
Haile Owusu, Emil Yuzbashyan

48. Closed Systems that Measure Particles
Michael Steiner, Ronald Rendell

49. Causal Tapestries
William Sulis

50. Measures of non classical correlations
Matthias Lang, Anil Shaji, Carlton Caves

51. Information geometric approach to foundations of quantum theory
Ryszard Kostecki

52. A non-local quantum eraser
X. Ma, J. Kofler, A. Qarry, N. Tetik, T. Scheidl, R. Ursin, S. Ramelow, L. Ratschbacher, T. Herbst, A. Fedrizzi, T. Jennewein, A. Zeilinger

53. Homogeneous Self-Dual Cones and the Structure of Quantum Theory
Alexander Wilce

54. Quantum Measurement, Correlation, and Contextuality
Masanao Ozawa

55. Operational interpretations of quantum discord
Marco Piani, Daniel Cavalcanti, Leandro Aolita, Sergio Boixo, Kavan Modi, Andreas Winter

56. Multipartite Entanglement: Classification, Quantification, Manipulation, Evolution and Applications
Gilad Gour

57. Decoherence Free Neutron Interferometry
Dmitry A. Pushin, David G. Cory, Michael G. Huber, Mohamed Abutaleb, Muhammad Arif, Charles W. Clark

58. Time-Reversal Symmetry and Temporal Coherent Back-Scattering in a Driven Two-Level System
Simon Gustavsson, Mark Rudner, Jonas Bylander, Leonid Levitov, Will Oliver

25-11-10 *Pauli's Dreams + Dinner + Additionism* (to F. De Martini)

And let us join forces. From our brief conversation after my return from South Africa, I got the sense that there is a good bit in common between our views of the "nature of classicality." It is a view that Appleby and I call "additionism"—that quantum behavior is something that comes "in addition to" to classical. As you write on the subject and have your lab perform relevant experiments, please keep me informed.

26-11-10 *Qbism* (to W. C. Myrvold)

Myrvoldism 7: *Did you know that "Qbism" is an iPhone game? See*

`http://www.blowfishstudios.com/`

Very cool! But too bad they misspelled QBism.

29-11-10 *Mermin's Cautionary Tale* (to D. M. Appleby)

Below is David's cautionary tale.

Merminition 221: *You've forgotten that my interest* [in SICs] *goes back at least to our independent, but strongly correlated interactions with Gabe Plunk. Why is it so damned hard to show that such sets exist, or to find a counterexample? (A cautionary tale is unique factorization in the cyclotomic integers—remember the videotape of my lecture at Bell?—which holds for every degree up to 22, before breaking down at 23. But that's a much more subtle issue. Why is this apparently trivial one so stubborn?)*

(Independent, poetic) question of the day: What is the shape of a philosopher's stone? Prompted by this passage that I just wrote:

> There is an anecdote I sometimes use for starting my talks on quantum foundations that is particularly relevant to the proposal at hand. It is about a conversation I had with my (then) seven-year-old daughter. For some time over the last year or two she had been asking me what is my favorite color. But one day she took me quite by surprise by asking, "Dad, what is your favorite shape?" At first, I started to answer glibly, "A ball." But I caught myself and became quite delighted with the possibilities. "It's Hilbert space," I said, "My favorite shape is Hilbert space." "What does it look like?" she asked. The only honest reply I could give was *I don't know!* "Then how do you know it's your favorite shape?" "Because we know enough about it to know that it is the most beautiful shape ever imagined. We can already see that much even if we don't know all its details. When I go to work at Perimeter Institute every day that's what I work on—trying to understand this beautiful shape." Two days later, my daughter announced that when she grew up she would work where I work!
>
> What the anecdote really refers to is the convex body that makes up the set of quantum states (pure and mixed) for a finite-dimensional quantum system. It is easy enough to say what this body is in conventional, algebraic terms: It is the set of trace-one positive semi-definite operators over a complex inner-product space of finite dimension d. But what is the object geometrically? There a great mystery lies and coming to grips with its answer is of the utmost importance for the foundations of quantum theory.
>
> In the broadest terms, this is what Dr. X's proposal to you is all about: Understanding this wonderful shape that empowers quantum information processing and quantum computing like a philosopher's stone.

02-12-10 *Your Notes* (to D. M. Appleby)

I have read your notes now, and they were quite interesting to me. I like this stress of yours between a probability assignment on the one hand, and a "decision" on the other.

Also, I liked these lines very much:

> And what is that objective something? It would be fair to say that finding out what that objective something truly is was one of the central projects of classical physics. Trying to answer that question eventually led to the destruction of classical physics. And we still have the problem now, in the shape of interpreting quantum mechanics.

I am glad you have decided to write a paper on all this. Now that I've read your notes, I am even more convinced that you'll make a real contribution with this. Your emphasis that "when one judges two samples to have two distinct half lives, one is ipso facto committed to the belief that there is an objective difference between them" is more and more pressing on me. It is right, and it needs fleshing out. At the moment, it remains beyond my ability, but somebody has to start the process of unwinding this issue somewhere.

If the topic comes up, as you wish, I will reveal your identity.

Happy birthday, yesterday. I wish that I had known. I will try to make it up to you when I am back in town.

02-12-10 *QI Meets GR in a Real Way* (to N. Waxman)

I'm on my way to Washington for a planning meeting for the APS March meeting (I'm program chair for the 400 talks on quantum information), and I was thinking about one of my invited speakers, Till Rosenband from NIST. It dawns on me that doing a story on his experiment for *Inside the Perimeter* would be a good way to highlight the potential for fruitful interchange between quantum information and general relativity (and gravitational experiments)—i.e., PI so well representing both fields.

Till has built the world's most accurate clock, one so accurate that he can see two such clocks come out of synchronization because of GR effects over only 33 centimeters of height difference! And the cool thing is that the clock mechanism is based on quantum computing techniques. NIST calls them "quantum logic clocks". You can read a bit about them here:

- `http://www.nist.gov/pml/div688/clocks_092810.cfm`
- `http://www.nist.gov/pml/div688/logicclock_020410.cfm`
- `http://www.nist.gov/pml/div688/logic_clock.cfm`

Just an idea that I thought I'd record.

02-12-10 *The Size of Quantum Information* (to N. Waxman)

How do you like that title? Thinking further. Once everything gets settled on planning this meeting, I might write something for you on the whole breadth of quantum information at this meeting. The number of talks in quantum information might actually far exceed the 400 I've already told you about. (The GQI that I chair had 360 submissions, and then there were at least 22 invited talks from other divisions that are on the subject of quantum information as well. I have no idea how many submitted talks from other divisions will be on quantum information until I see the titles, but I was quite confident there would be far in excess of 20 if there were already 22 invited speakers.)

Then if you wanted to write a little accompanying piece on the Rosenband/Wineland experiment (the one I mentioned earlier)—the two pieces might go together well.

02-12-10 *Probability Distributions* (to S. Gharibian)

Good question. And your intuition is right: For a general POVM with $|M|$ outcomes and an arbitrary probability distribution P over $|M|$ outcomes, one cannot find a quantum state that will give rise to P.

Take for example the SIC POVMs that I always talk about. This is a POVM on a d-dimensional Hilbert space with d^2 outcomes. It turns out that no quantum state can ever give too sharply peaked a probability distribution for its outcomes. For instance, no probability can ever be larger than $1/d$. More generally, the probability distributions arising from quantum states are always confined within a very interesting convex subset of the full simplex of probability distributions. See the story I wrote below about this shape (from a review that I was writing on someone's proposal). [See 29-11-10 note "Mermin's Cautionary Tale" to D. M. Appleby.]

So, I think this answers at least your question 2. For instance take the valid probability distribution $P = [1, 0, 0, 0, ..., 0]$ over d^2 outcomes. The closest distribution one can get to that with a SIC POVM is $Q = [1/d, 1/d(d+1), 1/d(d+1), 1/d(d+1), ..., 1/d(d+1)]$. You could for instance measure the distance between these two vectors with the standard Euclidean distance.

You can read a bit more about the geometry of this convex set in this paper of mine: `http://arxiv.org/abs/0910.2750`. Of course, it is particular to the SIC POVM but up to an affine transformation it is generic behavior.

Toy theories where your question can be answered in the positive are called "classical". You can read plenty about that in some of Howard Barnum's papers.

If you want to talk more about this, drop by my office some time. I think it's one of the most important questions in all of quantum foundations.

04-12-10 *Wave Function Volume* (to A. Ney)

The paper you mention is dated, and I have evolved much since then. Would you consider this one instead: `http://arxiv.org/abs/1003.5209`. How does its length look for your needs? How much would it have to be trimmed?

So, that is a potential "yes", depending upon what you say. Thanks for thinking of me.

PS. It is very funny: When I first looked at your email title, I thought that you had some question about the "volume of Hilbert space". See story below that I had just written up for a referee report. [See 29-11-10 "Mermin's Cautionary Tale" to D. M. Appleby.]

05-12-10 *Quantum Information at the March Meeting* (to the American Physical Society)

You asked for a heads-up of some newsworthy items at the March meeting. I've worked hard to put together a good program on the 20th anniversary of quantum information and quantum computing in APS journals. Attached is my list of speakers. Particularly, the 20th anniversary session is filled with several founders of the field. For instance, Bennett is one of the authors of the original quantum teleportation paper; Ekert is one of the discoverers of quantum cryptography; and Schumacher is the very inventor of the qubit (word and idea). Wootters, another session, was a discoverer of the no-cloning theorem, and also one of the authors of the quantum teleportation paper. Two of the guys in the experimental session, Jeff Kimble and Anton Zeilinger, performed the first two quantum teleportation experiments back in 1997/98.

Let me also flag this guy in the experimental session: Till Rosenband from NIST. Till, most recently, has built the world's most accurate clock, one so accurate that he can see two such clocks come out of synchronization because of general relativistic effects over only 33 centimeters of height difference! And the cool thing is that the clock mechanism is based on quantum computing techniques. NIST calls them "quantum logic clocks". You can read a bit about them here:

- http://www.nist.gov/pml/div688/clocks_092810.cfm
- http://www.nist.gov/pml/div688/logicclock_020410.cfm
- http://www.nist.gov/pml/div688/logic_clock.cfm

Anyway, needless to say, I would love to see you work up a bit of a feature on quantum information and computing with the press. I do think it would be of general interest.

08-12-10 *Receipt and Bill* (to O. J. E. Maroney)

OK, I was a bit late, but both letters are off now. In the case of Pitt, I sent the signed version by snail mail, but I also sent an electronic copy to John Norton and asked him to put it into your file.

I wrote the letters in a way to be intellectually honest ... but you shouldn't worry in any way. They both came off very strong I believe. I wish you all the luck.

If you haven't already surmised however, you should know that nothing from me ever comes for free. Thus, for my labors, let me bill you this: A reading of two of Marcus Appleby's papers: `http://arxiv.org/abs/quant-ph/0402015` and `http://arxiv.org/abs/quant-ph/0408058`. As an un- or non-initiate in personalistic probability, I'd like to know what you find convincing in them (if anything) and what you don't (if anything).

Thanks for the comments last week on Bennett's TIDY classical computers and their potential quantum analogs. I think it would be good to make that explicit in your research proposal—i.e., that you are talking about those computers particularly. I am cautious, however, in my belief of you on this one. To my nose, it smells a bit too much of the stories one used to hear of quantum error correction before Shor, i.e., that the no-cloning theorem would forbid it. But the key point was the clean subspaces, not the redundancy of $|\psi\rangle \to |\psi\rangle|\psi\rangle|\psi\rangle$ (which can't be made generally). Anyway, you might be right; I'm just saying I'm cautious of believing you. Also, when thinking of the circuit models of quantum computation that everyone uses, my mind goes back to the computer geeks I used to know in college who would laud the beauties of the C programming language. "Dude, it's so structured, it won't let you be inefficient!" It strikes me that the circuit models might already be like that—they won't let you be inefficient (in comparison to Bennett's original FORTRAN). If the quantum circuit models are inefficient in bit usage, then in what way?

Anyway, this note counts as your receipt—your letters are off; I hope you do well. And my bill is that you give Appleby some serious thought.

08-12-10 *Diracula!* (to D. Lynch)

I hope you understood: Diracula was sheer genius! I never heard that one before.

Here's the quote from David Deutsch at the bulletin board associated with his book *Fabric of Reality*, dated 16 July 2000. It refers to Asher Peres and me:

> A. Carvalho wrote, *"'Contrary to those desires, quantum theory does not describe reality ... ' I wonder what it can possibly describe. Is there anything else beyond reality?"*
>
> No, but that's not what they think. They think it describes our observations, but that we are not entitled to regard this as telling us anything about a reality beyond our observations. Why? Just for the Bohring old reason that they don't like the look

> of the reality that it would describe, if it did describe reality. Why? — I have many speculations, but basically I don't know. I don't understand why.
>
> It's sad enough when cranks churn out this tawdry old excuse for refusing to contemplate the implications of science, but when highly competent physicists — quantum physicists — dust it off and proudly repeat it, it's a crying shame.
>
> They really need to read FoR, don't they?

By the way, David Deutsch is sometimes described as being vampirish in his habits (being reclusive, only receiving visitors at his home at night, after midnight, etc). And he was a winner of the Dirac prize in 1998! So maybe you're on to something.

Mischievous wishes,

09-12-10 *The Shape of Quantum Theory* (to N. Waxman)

Attached are a few paragraphs from a referee report I wrote for the Guggenheim Foundation last week. Definitely, consider it *only* a first pass on the question you asked me. I'm sure for the annual report we'll need to sober it all up significantly. But it is a true story (about Katie) as it presently stands, and conveys in an essential way what's really driving me on the day-to-day basis at PI.

We can fill out, subtract, rearrange, etc., later. I just wanted to record this now since you asked tonight.

> There is an anecdote I sometimes use for starting my talks on quantum foundations that is particularly relevant to the proposal at hand. It is about a conversation I had with my (then) seven-year-old daughter. For some time over the last year or two she had been asking me what is my favorite color. But one day she took me quite by surprise by asking, "Dad, what is your favorite shape?" At first, I started to answer glibly, "A ball." But I caught myself and became quite delighted with the possibilities. "It's Hilbert space," I said, "My favorite shape is Hilbert space." "What does it look like?" she asked. The only honest reply I could give was, *"I don't know!"* "Then how do you know it's your favorite shape?" "Because we know enough about it to know that it is the most beautiful shape ever imagined. We can already see that much even if we don't know all its details. When I go to work at Perimeter Institute every day that's what I work on—trying to understand this beautiful shape." Two days later, my daughter announced that she when she grew up she wanted to work at Perimeter Institute too!
>
> What the anecdote really refers to is the convex body that makes up the set of quantum states (pure and mixed) for a finite-dimensional quantum system. It is easy enough to say what this body is in conventional, algebraic terms: It is the set of trace-one positive semi-definite operators over a complex inner-product space of finite dimension d. But what is the object geometrically? There a great mystery lies and coming to grips with its answer is of the utmost importance for the foundations of quantum theory.
>
> In the broadest terms, this is what Dr. [X]'s proposal to you is all about: Understanding this wonderful shape that empowers quantum information processing and quantum computing like a philosopher's stone.

09-12-10 *Time Stories* (to N. Waxman)

By the way, your son seems to be quite some young physicist! Below is a little story I wrote up nearly 13 years ago (it's drawn from one of my samizdats). You can pass it on to your son if you wish and tell him what I think the missing ingredient is: It's time. [See story "It's a Wonderful Life" in 05-12-01 note "Lucky Seven" to B. W. Schumacher.]

09-12-10 *My Clifford Lectures* (to R. Penrose)

When you were last visiting Perimeter Institute, you showed some interest in the problem of the "maximum number of equiangular lines in a complex vector space of dimension d". Also my postdoc Åsa Ericsson told me that you had expressed a potential interest in participating in a meeting on the subject she is organizing in Banff for 2012.

Anyway, the reason I write you now is that (by some miracle) I was chosen to be the Clifford Lecturer at Tulane University for 2011 (see `http://www.math.tulane.edu/activities/clifford/`) and a small workshop will be built up around my own lectures, March 14–17. There should be some quite interesting people there, and maybe some old friends of yours. Beside whoever else is at Tulane, Lane Hughston, Samson Abramsky, +6 more, for instance will be there. And particularly, my colleague Marcus Appleby, I think you would enjoy meeting:

`http://arxiv.org/find/quant-ph/1/au:+Appleby/0/1/0/all/0/1`.

Most recently we have found a lovely connection between this equiangular line problem and cyclotomic number fields, at least in dimensions 2, 3, 4, 5, and 7. So we certainly get the sense that some real progress can be made on the problem in the near future, and that this once very specialized problem has tendrils into all sorts of mathematics.

Anyway, in all, would you have some interest in participating? You could speak on any subject you wish. But mostly, personally, I would like to get any input and feedback on this interesting problem in algebraic geometry you could give in our personal discussions outside the talks.

If you have an interest, I'll get an official invitation sent to you. All expenses paid, of course.

10-12-10 *Texan Roots* (to M. E. L. Oakes)

You probably don't remember me. I was in two of your courses in 1984/1985, I believe.

Last night I was up with a bout of insomnia, and somehow in all the web surfing, I ended up wandering (first) to the *Daily Texan* and (then) to the UT Physics Dept. It was quite a stroll down memory lane.

I suppose it was a natural consequence of my working on an interview article the last few days for a book someone is compiling. One of the questions caused me to be semi-autobiographical again, and I suppose Texas has been on my mind. In fact, this is the third round of autobiography I've had to do this year: The first was for the introduction to my book *Coming of Age with Quantum Information* (Cambridge U. Press, to be released in about a week), and the second was for my tenure application here at Perimeter Institute.

I'll attach both of these in case you have some interest. They tell the story of how one Texas boy ended up doing physics, and even making a mark in the crazy (usually markless) world of quantum foundations.

I guess I'm saying I haven't done too badly, and seeing your picture last night reminded me of what a great teacher you were. Without exaggeration, your lectures were the best I encountered in my four years of physics at UT. They kept me going at a time when I had doubts of why I was even there (the opening pages of the *Coming of Age* intro explain why I say this).

There's a line on the second page of the Perimeter research statement that says, "To the best students who came asking for a research project, graduate and undergraduate alike, John [Wheeler] would say, 'Derive quantum theory from an information theoretic principle.' In my case, I was given a more workaday project in the Regge calculus . . . " The student I had particularly in mind when I was writing that was Drew Debelack; he was also in your classes at the same time. I looked for him on the web but didn't find much—it looks like maybe he dropped out of physics.

Anyway, thanks again for all the time you put into the students (like me) way back when and the ones more recently. Seeing your title of "Distinguished Teaching Professor Emeritus" last night, it was clear that it is the perfect title for you.

12-12-10 *Dallas* (to A. Wilce)

Wilce-ism 9: *I'm trying to sort out my spring travel plans. It would be helpful to know when, approximately, we'll be hearing about the acceptance of talks submitted to the APS foundations meeting in March. Do you have a sense of when we might hear about this?*

You, of course, are accepted! And your talk will be in the featured foundations session, along with the invited speaker Chiribella, and submitted talks by D'Ariano, Masanes, Greenberger, and 9 others. I think the session was called "Axiomatics and Toy Models". In total, we have four foundations sessions this year! A total of 58 talks in those sessions. Then there's the discrete structures invited session with Wootters, Englert, Flammia, Ericsson, and Schaeff (an experimentalist) that might interest you. And the seven Nobel prizers' talks.

Attached is the latest list of all QI relevant invited talks. In total, there were over 360 GQI submissions. And I would guess at least 20 to 40 more quantum-information talks that were not classified so.

I can't tell you exactly when yet, but the session you'd speak in will most likely be on the Monday or Tuesday. And for your reference, I'll be staying in the Adolphus Hotel (with its ghost).

14-12-10 *The Archeology of SICs* (to A. Karlsson & L. Piispanen)

Two things to read on the archaeology of SICs:

- W. A. Fedak and J. J. Prentis, "The 1925 Born and Jordan paper 'On quantum mechanics'," Am. J. Phys. **77**, 128–139 (2009).
- Erhard Scholz, "Weyl Entering the 'New' Quantum Mechanics Discourse," conference contribution to *History of Quantum Physics 1*, Berlin, July 2–6, 2007. `http://quantum-history.mpiwg-berlin.mpg.de/eLibrary/hq1_talks/mathematics/35_scholz`

18-12-10 *Greetings and Thanks!* (to F. De Martini)

Thank you for the kind words. We much enjoyed having you over.

I'm writing to you from a café in a small ski-resort town. We came here to celebrate Katie's 9th birthday, and the girls are out on the slopes. They have all the fun. For myself, I am using the time to write an "interview" paper for a volume that Max Schlosshauer is putting together. I'll surely send you a copy when it is complete. One of the questions in it is, "If you could choose one experiment, regardless of its current technical feasibility, to help answer a foundational question, which one would it be?" I wonder what your answer would be. At the moment, I have no idea how I'm going to answer it.

Please give my best regards to Fiorenza, and a very merry Christmas to both of you.

19-12-10 *The Qubit Story* (to A. Stairs)

Stairsism 3: *The usual lore seems to be that Ben Schumacher coined the term 'qubit' in 1995. But the wonderfully nifty NGram tool from google suggests otherwise. The vertical axis is percent of all words in books in English that Google indexed between 1975 and 2008. (You can also look for several words; separate by commas.)*

So if not Ben S., who coined it?

It was definitely Ben. Story of its origin below. [See 28-04-04 note titled "Quantum History" to B. W. Schumacher and W. K. Wootters.] But I believe it is also an allowed spelling for cubit. That might explain why Google shows the word in use before 1992/93.

I believe Daniel Gottesman coined the word qudit. And it would be fun to learn who was the first to write qunit. I believe I coined the term rebit, for real-Hilbert-space qubits. I wonder what statistics Google gives on that one!

22-12-10 *Did I Do You Good?* (to R. W. Spekkens)

Spekkensism 52: *Incidentally, the example of nonlocality without entanglement that has the closest analogue in the toy theory is the one using three qubits due to Tal Mor.*

Yes, I knew that it had to be: Your toy model has no qutrits. I troubled over this a bit, and your remark causes me to feel (again) that maybe I'm being a bit too disingenuous in my presentation. The reasons I opted for the qutrit example are 1) that it's closer to my heart—it was the example for which we made the name, 2) it was the only example we had a genuine proof for (but maybe that has changed in the intervening years, I didn't look), and 3) the qutrit example was genuinely more ugly, and I wanted to make a point of that.

But then I also wanted particularly to make the point, "he can pull a little conceptual model from his pocket and gain quick insight into any number of technical questions in quantum theory, just by having started with the right conception of quantum states! That is physical insight ..."

Part of me says, "Ah, let them eat cake." The other part of me says I should add a sentence to soften the transition.

Spekkensism 53: *My only minor quibble is when you say: "The toy theory is not quantum theory itself (nor does it pretend to be a start for deriving the real theory)." I guess I did think about it as a kind of start to deriving the real thing in the sense that a proper axiomatization is likely to include an epistemic constraint (and maybe the knowledge is even about a pre-existing reality!).*

The thing that always struck me was how much power you got from a *simple* epistemic constraint. That really did hit me over the head and is probably a significant part of the source of my own faith that, in the right language (SIC language for instance), the ultimate epistemic constraint (which in turn, for me, must arise from some new Bayesian rule for consistency between probability assignments) will itself be simply stated. Of course, you know that I have my problems with the parenthetical part of your sentence. Anyway I will think about how I might modify my sentence so that a little bit of "the toy model being that much of a start" is on display.

I'm listening to a great album of Ozzy Osbourne doing covers of all kinds of songs. At the moment, the Beatles' "In My Life". Kind of bizarre.

22-12-10 *More Honesty* (to R. W. Spekkens)

The attached draft should do your quibble some justice (I hope). Also, it slips in a clause about the triple-qubit example so that my soul might rest more peacefully tonight.

26-12-10 *Egg Nog* (to L. Hardy)

Thanks for the sympathetic note. In the end, I'll get over it — chalking it up to a learning experience. When I get my head around what happened, I'll probably end up thinking the new understanding is something we ought to incorporate into our next physical theories!

. . . semi-seriously. Already I've become more keenly sensitive to something I've been repeating for quite a while, that "the world is not sentence shaped." Take van Fraassen's example, "Why did Adam eat the apple?" What does it ask? Depending upon how you read it and where you put the emphasis, it can be asking any number of things. Two days ago, I said some nasty things about [Professor X], but if I were to present a transcript of the conversation we had to a court of law, they would be completely puzzled over why I felt slighted. I've come to realize that most of the "conversation" wasn't conveyed through the "transcript words" but through the intonation, emphasis, and tone of speech. Even [Professor X]'s eye movements and chuckle were part of it. This is really interesting and makes the point very concrete for me, where it was mostly academic before.

06-01-11 *Quadits Inside SIC Simplexes* (to M. A. Graydon)

Graydonism 4 : *I have been wondering about the shape of quaternionic quantum state spaces inside complex SIC probability simplexes. In case you are interested, I have attached some notes from the past few days on that subject. The calculations are routine, but the results could serve as food for thought. I must admit that I am finding the idea of dimensionality as an ontic property harder to swallow these days, and I have included some brief thoughts on that in the notes (I also quote one sentence of yours that I am at odds with at the moment.) Today, at least, I feel like there is a lot more to do before I would be happy saying that dimension is agent-independent.*

Take a coin, and imagine flipping it. We generally write down a (subjective) probability distribution over two outcomes to capture our degrees of belief of which way the flip will go. But of course it is a subjective judgement that it can only go two ways. Steven van Enk would say it could always land on its side; so he would always write down a probability distribution over three outcomes.

If one takes (p_0, p_1) as a subjective assignment, the number 2 is objective with respect to it. Something we imagine or hypothesize about the coin. If one takes the (p_0, p_1, p_2) as a subjective assignment, then the number 3 is objective with respect to it—something we imagine or hypothesize about the coin, that it can fall three ways. I.e., it will fall one of three ways regardless of what we believe of which of the three ways it will fall.

So objectivity/subjectivity comes in layers. We call something objective, and then make probability assignments in the subjective layer above it. But of course, the first "calling something objective" was a subjective judgment in itself.

What if I had said it like this:

> Dimension is something [I hypothesize] a body [to hold] all by itself, regardless of what an agent thinks of it.

Much like I hypothesize that a coin can fall out two ways, while van Enk hypothesizes that it can fall out three ways.

06-01-11 *Invitation to xQIT Conference May 3–4* (to S. Lloyd)

Yes, I can come. I haven't been to Cambridge in a few years, and it would be nice to see it again. You can give my talk the title: "Still Seeking Those Damned SICs".

Please keep me up to date on where I should book a room, etc.

07-01-11 *Paper for Itamar's Volume* (to W. G. Demopoulos)

Demopoulosism 41: *A quantum question: Would it be fair to say that instead of effects in my sense (whatever that may be) you prefer "effects" in the sense of changes in subjective probability assignments by your "agents" in response to their "probing" the world? Thus an effect is not any kind of property of anything, but a probability assignment or judgement.*

Congratulations on the reprieve! I'm glad to hear it. Very best of luck on all that's to follow. Your friends' thoughts are with you, and my heart is definitely with you.

On your quantum question: Yep, that's it. I have a very old discussion of it somewhere in `http://arxiv.org/abs/quant-ph/0205039`. But the key point is this: Take a POVM consisting of operators E_k. I.e., these are positive semi-definite operators that sum to the identity operator. Thus they might seem like mysterious abstract entities (perhaps properties of the system, or properties of the 'measuring device', or maybe something still weirder, though surely agent-independent). But, via a fiducial SIC POVM in the sky (as I talk about in my papers), one can map these operators to a set of conditional probabilities $p(i|k)$ in a one-to-one fashion. That is, these operators contain nothing over and above the prescription of a probability assignment. There is nothing to them mathematically but that—nothing is lost by thinking of them in these terms, as probability assignments. Similarly, the philosophical point should be this: That there is nothing conceptually more than this either.

So, what should one call the "outcome" of a quantum measurement? Well, for the agent it is an experience "k" ... but what meaning does that have for him? How could he articulate it? What does it mean to him? How will he change his behavior with regard to it? The answer is: It is $p(i|k)$. It is a probability distribution conditioned on k. The only operational handle the agent has on k is through the assignment he makes, $p(i|k)$.

But all probabilities (for the personalist Bayesian) are subjectively given (i.e., functions of the agent only, his history and experiences, not the object). And thus, I guess, my resistance to part of your way of thinking about effects. (Of course, as you should know by now, I am in serious agreement with you in other ways ... in fact, probably with you more than with any other living philosopher.)

Attached is a little thing I've just finished for Schlosshauer's interview book. I hope I'm not too harsh on your friends in it. You'll see that I'm my usual belligerent self. Still I hope it will give you a smile from time to time (I can always hope).

08-01-11 *Strange Einstein Remark* (to R. W. Spekkens)

Having finally watched the video of Ernst Specker that Adán gave me, I wanted to learn a little bit more about this guy Gonseth that Specker mentions (and whose name I had known through a couple of remarks by Wolfgang Pauli). Anyway, a Google search landed me on one of Mehra and Rechenberg's volumes of *The Historical Development of Quantum Mechanics* (I can't quite figure out which one because of an inconsistency in Google Books, and I'm too lazy to figure it out).

Anyway, it's talking about the 1948 issue of Dialectica that Pauli edited and says:

> Einstein, on the other hand, used the opportunity to repeat again his objections that had been familiar since the Einstein-Podolsky-Rosen paper (1935), recalling that 'if in quantum mechanics we consider the ψ-function as (in principle) a complete description of a real physical situation we thereby imply the hypothesis of action-at-a-distance, a hypothesis which is actually hardly acceptable,' and 'if, on the other hand, we consider the ψ-function as an incomplete description of a real situation, then it is hard to believe that, for this incomplete description, strict laws of temporal dependence hold' (Einstein, 1948, p. 323).

Of course, their commentary about "familiar since EPR" is not exactly right, but I'm struck by the second Einstein quote. Surely Einstein was familiar with Liouvillean mechanics. I wonder whether he was really trying to get at something else, or just made a mistake? Have you ever run across Einstein saying something like this before? Do you know the wider context?

Here's the link in case you have an interest in looking yourself:

```
http://books.google.ca/books?id=kn6mb0ltm0UC&pg=PA1198&lpg=PA1198&dq=
pauli+gonseth+quantum&source=bl&ots=v07etN9maM&sig=q92eq_GyRanHzwEv8D
f4hSQ2KBk&hl=en&ei=VHYoTaHBG6TenQfo4dC9AQ&sa=X&oi=book_result&ct=resu
lt&resnum=7&ved=0CEQQ6AEwBg#v=onepage&q=pauli%20gonseth%20quantum&f=f
alse
```

Another thing that was kind of interesting was a little discussion on Max Born a few pages later, talking about a 1955 paper of his where (apparently) he first emphasized the similarity of quantum mechanics to Liouvillean mechanics (and sounded very Bayesian as well, I might add):

> It is misleading to compare quantum mechanics with the deterministically formulated classical mechanics; instead, one should first reformulate the classical theory, even for a single particle, in an indeterministic, statistical manner. After that some of the distinctions between the two theories disappear, [while] others emerge with great clarity. Amongst the first is the feature of quantum mechanics, that each measurement interrupts the automatic flow of events and introduces new initial conditions (so called "reduction of probability"); this is true just as well for a statistically formulated classical theory.

08-01-11 *Rampant Anti-Realism* (to R. W. Spekkens)

I wonder what this guy would think of me?

`http://www.sfu.ca/content/dam/sfu/philosophy/docs/bradley/anti_realism.pdf`.

Anyway some quotes from Max Born's correspondence with him in there.

08-01-11 *Strange Einstein Remark, 2* (to R. W. Spekkens)

Spekkensism 54: *I love the Born quote. I hadn't realized he had ever made statements that so clearly espoused an epistemic view of the quantum state. The view attributed to Einstein in the statement: "it is hard to believe that, for this incomplete description, strict laws of temporal dependence hold" is a bit puzzling. Of course, it's hard to take something that isn't a direct quote too seriously. Many of his contemporaries couldn't even understand what Einstein was getting at, so I wouldn't be surprised if they failed to summarize it adequately. If Einstein did say something like this, it doesn't follow that he was endorsing indeterminism at the level of epistemic states for isolated systems. Perhaps he just meant that discontinuous changes in the epistemic state as a result of measurement on a correlated system are natural.*

No, I think that was a direct quote of Einstein. (Well, a translation from the German.)

08-01-11 *Strange Einstein Remark, 3* (to R. W. Spekkens)

Spekkensism 55: *Okay, then it is somewhat puzzling. I take it you think that he may here be endorsing indeterminism of some variety?*

No, not endorsing indeterminism.

The more I think about it, it is maybe this: That he found a puzzling incongruity in being stuck with epistemic states for the systems themselves, but presumably "complete" information about their evolutions. I.e., that we could still interpret unitary time evolution (Hamiltonians) in ontic-style terms.

I sure would like to read his real article. How's your German?

08-01-11 *Strange Einstein Remark, 4* (to R. W. Spekkens)

Spekkensism 56: *Ah, the question of the status of unitaries . . . I see.*

Here is essentially the extent of my German: Ein grosse bier, bitte. You can get by pretty well in Germany knowing only that . . .

Actually, it hadn't dawned on me until now that that might be the issue. I was just genuinely perplexed that Einstein would say something like that. At least if he knew about Liouvillean mechanics, that is. But maybe he didn't. I don't know. I guess it also seems strange to me that Max Born didn't seem to understand the similarities between QM and LM until the mid-fifties.

08-01-11 *Strange Einstein Remark, 5* (to R. W. Spekkens)

Spekkensism 57: *Ah, the question of the status of unitaries … I see.*

That does seem to be an important paper of Einstein's that I'd like to get hold of (and get translated). It also apparently contains this quote:

> The following idea characterises the relative independence of objects far apart in space A and B: external influence on A has no direct influence on B; this is known as the Principle of Local Action, which is used consistently only in field theory. If this axiom were to be completely abolished, the idea of the existence of quasienclosed systems, and thereby the postulation of laws which can be checked empirically in the accepted sense, would become impossible.

08-01-11 *Strange Einstein Remark, 6* (to R. W. Spekkens)

And you even cite the paper in your paper with Harrigan.

08-01-11 *Mehra and Rechenberg* (to R. W. Spekkens)

I had heard before that one should be careful with the Mehra and Rechenberg books—that they are not always that accurate. Well, I have just had my first case in point.

In the piece I pointed out to you this morning, they first report Pauli's commentary on the Einstein paper, in which Pauli says the following:

> According to my opinion one cannot draw from the particular cases of correlated systems any new conclusions which are not already contained in the previously mentioned requirement in quantum mechanics of giving up the general predictability, of the results of individual observations on a single atomic system in a given state. In view of both the empirical facts and the existence of the logically consistent quantum mechanical formalism it seems to me that only this renouncement enables us still to use in physics the concept "closed system" and the usual perception of space and time, which are so closely connected with each other. It is in this sense that I consider the quantum mechanical description to be complete.

I've now read the original Pauli article and he was clearly talking about the issue of locality here.

On the other hand, Mehra and Rechenberg then go on to say:

> A more explicit description of 'closed systems' was provided by Heisenberg (1948) in the same issue of the *Dialectica*.

And I've now read the Heisenberg article too. (It was reprinted and translated in his book *Across the Frontiers*, on my shelf.) That article is titled "The Notion of a 'Closed Theory' in Modern Science" and had nothing whatsoever to say about "closed [atomic] systems" in the Pauli and Einstein articles. It was instead about how theories don't actually reduce to one another—how for instance classical mechanics and quantum mechanics live side-by-side, both distinct, both valid. (Which is a position somewhat like QBism's present one. Makes me wonder whether I ever actually say anything new. I must have read this article 25 years ago.)

So! Be careful with those guys.

09-01-11 *Sunday Letter* (to W. G. Demopoulos)

Thanks for the new draft I like the increased discussion on the timeless properties; I have much agreement with that, you know. You have a little typo at the end of your footnote 6; it ends with a ",".

I didn't see that you strengthened your defense against my charge of a kind of dualism. Maybe I'm still missing something. When you write, "Such systems are epistemically accessible to an extent that systems which are characterized only in terms of their eternal properties and their effects are not," I would think that you're admitting that there are (at least) two distinct kinds of systems in the world: Those that have a certain type of epistemic accessibility and those that do not, and that that epistemic accessibility is not characterized by things to do with the observer's situation, but rather the with system's itself.

Another typo on page 17, by the way, "does not precludes".

And you don't weaken my accusation any either by writing on page 18: "This kind of conceptual dependence, does not preclude the application of quantum mechanics to systems that record effects. Although it is largely a matter of convenience which systems are, and which are not, taken to record effects, it is not wholly a matter of convenience." The phrase 'not wholly a matter of convenience' again points me to an ontic distinction between two types of system. Again, a reason for my saying, "dualism". Similarly with respect to your sentence, "This leaves entirely open the empirical question of why it is that some systems appear to be amenable to descriptions that are expressible in the framework of classical mechanics." I.e., you don't explain why, but there is an empirical distinction between two kinds of system.

I'm not saying there's anything necessarily philosophically wrong with a dualism; mostly it is that it just doesn't match my taste, and doesn't feel like the right direction for moving physics forward. It adds a bigger burden on the physicist than I'd rather him have: For now, for each lump of matter, he'll have to—in some mysterious way—come to a conclusion of whether it supports dynamical properties or not. How does he do that? Where you leave us is where Bohr left us—as far as I can tell, in just telling us "it must be so, but I'm not going to tell you where/how to make that distinction" ... i.e., that there must be two kinds of system for us to build our evidentiary base for the quantumly treatable ones at all.

Imagine my going up to Rainer Blatt and saying, "Rainer, I just found this nice rock on the beach. You think you might be able to use it as a component in that quantum computer you want to build?" Asher Peres would say, "Of course he can use it as a component; it is just a matter of money. With enough money, any old rock can be polished into a quantum computer." But if it ain't so, then it must be a burden on physics to say when it can and when it cannot be done. My guess is that Rainer will never be able codify and make explicit such a criterion of distinction; he'll never be able to tell me which tests he must perform to certify my rock ineligible for quantum computation.

On the question of Rovelli, I don't know what to say. I leave it to you to come to your own conclusions of whether there's any (strained) similarity between your "functionalism" and his "relationalism". I just like to flounder with all kinds of ideas; every now and then one emerges as providing some insight.

On Israel, I go between Feb 13 and 19.

Oh, how's your French? I was reading through the 1948 issue of Dialectica edited by Pauli yesterday, and came across this description of his of the Gonseth paper in it:

> Many of the articles mention possible applications of the idea of complementarity outside physics, as for instance to questions connected with biology or psychology. I shall

> not discuss these questions in this introductory survey but wish to draw the reader's attention to the interesting attempts of Gonseth to formulate the idea of complementarity so generally that no explicit reference is made anymore to physics in proper sense. This is, of course, only possible by use of a language to which the physicists are not accustomed, which uses expressions like "horizons of reality", "profound horizon" and "apparent horizon", "events of a certain horizon". The word "phenomenon", however, is used in this article strictly in the above mentioned sense given to it by Bohr. To the "profound horizon" of Gonseth belong the symbolic objects to which conventional attributes can not be assigned in an unambiguous way, while the "traces" of Gonseth are identical with the "phenomena" in our sense. I wish again to stress here the circumstance that the free choice of the observer can produce either the one or the other of two "traces" and that every phenomenon or "trace" is accompanied by an unpredictable and irreversible change in the "profound horizon".

I was struck by the use of the word "trace" since I know that you also use it. Maybe that's where the similarity stops. Still, I attach the Gonseth paper in case you care to find out.

One last thing with regard to my nasty accusations of dualism, as you get a chance, I'd like to know what you think of Heisenberg's article in that same issue of Dialectica. It was reprinted and translated as "The Notion of a 'Closed Theory' in Modern Science" in his book *Across the Frontiers*.

09-01-11 *The Gonseth Connection* (to W. G. Demopoulos)

Specker credits a seminar of Gonseth's (attended by Pauli) for his interest in quantum mechanics. I have a little video of him telling a bit of the story to someone last year or so that I was listening to yesterday morning. Below is the conversation it spurred on other matters. If your German is better than your French you might be interested in the attached Einstein paper. You might be interested in the part about Einstein's general methodological considerations for requiring locality (a bit reported below).

09-01-11 *The Gonseth Connection, 2* (to W. G. Demopoulos)

Demopoulosism 42: *Isn't this paper translated and re-printed in the Born-Einstein Letters?*

Is it???? Certainly he's given variations of the locality argument all over the place—in papers and correspondence. What intrigued me most was the sentence I was curious about on time evolutions—I had never noticed him saying something like this before.

09-01-11 *Mine! Yours?* (to N. D. Mermin)

"I'll show you mine, if you'll show me yours!" Attached is the interview I finally sent off to Max last Wednesday. I think I wrote you in November, "It's just 17 questions for god's sake." Ha! That'll teach me. At least it sounds like Zeilinger was every bit as late as I was. So, if you throw darts in your mind, don't just throw them at me. [...]

But enough of these bad things. Now that I've got the nerve to read it, I hope you'll send me your own interview for Max's book. It'd be a pleasure to read it, and it'd make my Sunday a brighter, happier one. My three girls are out skiing now, and as you can see, I'm catching up on long waiting correspondence etc. Actually, I should be writing the cover story for the GQI newsletter, The Quantum Times, bragging about the March Meeting … but that's only three days overdue! So my cycles repeat …

09-01-11 *Mine! Yours?, 2* (to N. D. Mermin)

Reading through your answers slowly, as Kiki and the kids tell me of this week's ski adventure. (There is a new one every week.) What is this, "Adán Cabello's demonstration that, whatever the sense in which correlations have physical reality, it cannot be that their values are EPR 'elements of reality'." What paper does that refer to?

Merminition 222: *I look forward to the day when some clear-headed gifted writer has spelled it out so lucidly that everybody is completely convinced that there is no such problem.*

There go my credentials …

Merminition 223: *This adds a word to Asher's famous title: "Unperformed experiments have no conceivable results." That addition makes his point just a little harder to swallow.*

But swallowing becomes easier again if I expand Asher's title further to "Many different sets of unperformed experiments have no conceivable sets of results with the result for each local test being the same for every member of the set of results in which that particular local test appears." (The expanded title, however, is itself harder to swallow.)

I loved that!!!

Merminition 224: *My intuitions about the nature of quantum mechanics are not coherent enough to add up to anything I would dignify with the term "interpretation". Admittedly, shortly after turning 60 I did write a few papers setting out what I called the "Ithaca Interpretation" (see also my answer to Q6). But I was young then, innocent, and overly willing to sacrifice an accurate phrase for an entertaining one.*

Loved this one too!!! Compare to my, "Switch sides to what?"

Merminition 225: *It remains entirely possible that some wise, imaginative, and readable person may in the future lure me away from the position I am trying to sketch in my answers to these questions.*

There go my credentials again …

Merminition 226: *What I don't like about consistent histories is the reluctance—verging on refusal—of many of its practitioners to acknowledge the utterly radical nature of what they are proposing. The relativity of time was a pretty big pill to swallow, but the relativity of reality itself is to the relativity of time as an elephant is to a gnat.*

Three cheers!

Merminition 227: *I would nominate for the most important recent development the application of quantum mechanics to the processing of information, starting with the invention of quantum cryptography by Bennett and Brassard in 1984, and continuing with the development of quantum* *computation. As runner-up, I would cite the study of pre- and post-selected ensembles by Aharanov and his collaborators, and (perhaps—I still lack a good feeling for it) the ensuing notion of weak measurement. In third place I would put the consistent histories point of view, as put forth by Bob Griffiths.*

... There go my credentials for the final time of the evening!!!
Good night!!!

09-01-11 *One Endorsement* (to M. Schlosshauer)

The usual: I should thank you for everything you've done for me. In the present case, forcing me to finish the interview for you. There was a time when I genuinely wanted you to let me off the hook, but you wouldn't do it. If Appleby is genuine below, at least he got something from my answers—and maybe that ought to be enough for me and my spirits. But if Appleby is right to the point of there being one really clever, really technically-capable student inspired to develop QBism far beyond what we old guys have been capable of, then I should thank your persistence ever that much more.

Marcus's Preply

I think your interview is great. Really, really good. You sound depressed about it. But I think this is an example of an author not necessarily being the best judge of his own work. I think it could have a big impact. I don't even know who the other contributors are, let alone what (exactly) they will say. But I would be willing to bet a lot of money that someone uncommitted—a student say—reading this volume will be deeply impressed by your contribution, and will promptly forget all the others. And it is the uncommitted, above all the students, whom we most want to catch. I think this must be the first time that qbism has been set out in this way, side by side with all the other presently (but not for much longer) more fashionable approaches. At any rate, if it has been done before, it can't have been done often. There is only one possible winner from such a comparison. It is going to be just as it was with the course at the University of Waterloo, where the students were asked to vote on their favorite interpretation. It is not simply the force of the argument (important though that is). It is a deep down intuitive thing. You are just so much more alive than everyone else. People (people with a bit of youth in their soul, that is) feel that: can sense at a level below words the difference between the fresh, new-baked bread that you are giving them, and the stale old crusts which is all that anyone else has got to offer.

Actually, I found it thought-provoking myself. This may sound surprising, as I am obviously familiar with the general argument. Even so, it didn't read like yet another reiteration of the same old thing. The trouble with familiarity is that one develops intellectual habits. One's mind starts to run along rails. But reading your interview I found my mind kept jumping the tracks—following a train of ideas different from the one always suggested before. I am not sure why this was exactly. I think it was partly because the writing really is fresh—it isn't simply a cut and paste job. It is also because I happen to have been reading Schweber's book on the history of QED. Not that Schweber's book is all that good. But there are a few things in it which somehow hooked up with your interview and caused me to look at things from a different angle.

It is what Schweber says about Feynman which is relevant. It started with what you say about telling a story. Reading that I thought that telling a story is exactly what Feynman wanted to do. Nowadays the robots all think of Feynman diagrams as a mere calculational device. And perhaps that is how Feynman himself came to think of them in the end. But it is not how he thought of them in the beginning. In the beginning he was trying to tell a story. I think that is the main reason everyone loves him—why he stands out from all his contemporaries. He was the only one trying to do that (or nearly the only one—I guess Wheeler should also be included as it was he, not Feynman, who originally came up with the picture of electrons zig-zagging backwards and forwards in time). And this got me to wondering about the differences between the story Feynman told, and the one we want to tell. Which in turn led to me to thoughts about space-time. On the face of it Feynman was thinking in very blockist terms. Positrons moving back in time, advanced and retarded potentials—it is hard to see how such ideas could be meaningful if one was not thinking of the future being somehow given, along with the past, all in one go, as one great block. On the other hand, it is obvious that Feynman didn't take the idea entirely seriously. He didn't think it was the literal truth about things. Only that it was, for certain limited purposes, a useful way to think. So I don't think that Feynman was really a blockist. I digress, however. Although Feynman didn't think of his pictures as the literal truth about things, they clearly do, so far as they go, take the space-time manifold for granted. And that got me to thinking: what does a qbist say about space-time? Well, we have asked ourselves that question before of course. But on this occasion I suddenly had the sense of new vistas opening up.

I am still feeling very confused, and I am certainly not up to writing out a coherent argument. Really I want to talk about this, not write about it. Perhaps we can do that when I get back to Waterloo? But I think I would like to jot down a few thoughts while they are fresh. Not a connected piece of Jamesian prose. Just a few markers, which may serve as the jumping off point for future discussion.

The basic principle of qbism (so far): QUANTUM STATES DO NOT EXIST. I think we should supplement that with the principle: SPACE-TIME DOES NOT EXIST. In particular THE PAST DOES NOT EXIST. THE PRESENT DOES NOT EXIST. THE FUTURE DOES NOT EXIST.

Perhaps this sounds rather wild to you? But I think we are strongly pushed to it. Obviously, if one believes in free will one can't believe the future exists. If one believes in relativity one can't believe the present exists (there is no preferred space-like slice). And once one has gone that far isn't it strongly suggested that one should go the rest of the way, and also deny that the past exists?

I think we have discussed this idea before. But for me, this time, it is different. Before I somehow felt blocked from pursuing this train of thought. But now I have a sense of inner conviction.

What was blocking me? Two things, I think.

The first was Minkowski's suggestion that relativity forces us to think of space-time as a single entity. I have somehow been brain-washed by that into thinking that relativity naturally suggests a blockist conception. But I don't think it does. For sure relativity obliges us to abandon the Newtonian conception, of space as a physically existent thing. But once you have taken that step there are two possible directions in which to go. One possibility is to take the Minkowski route, and to think of space-time as a physically existent thing. The other is to reject the idea that either space or time are physically existent things.

The second was the phrase "frame of reference". The word "frame" suggests something physical. Indeed Einstein himself strongly encouraged that, with his talk of measuring rods and clocks. But now a different characterization occurs to me. Hartle (it was Hartle wasn't it?) characterized the quantum state as a "catalogue of probabilities". I think space-time is similar to that. Except it is something still more tenuous—something even less like a real existent thing. Space-time isn't the catalogue itself, only the cataloguing system. Something like the Dewey system used in libraries. Not the actual cards. Only the abstract principle used to organize the cards.

For instance, we have the actual book *Galois Theory* by Harold M. Edwards. Then we have the card which has printed on it "Harold M. Edwards, *Galois Theory* [various additional bibliographical information] MATHS E30 EDW". (I am looking at the copy I took out from University College London, who it seems don't use the Dewey system—but never mind that). Now consider the actual event, of Obama being elected president. This actual event is analogous to the actual book. Corresponding to the catalogue card we have the proposition "Obama was elected president in 2008". The proposition describing the event is as different from the event itself as the catalogue card is from the book itself. And finally, corresponding to the catalogue mark MATHS E30 EDW we have the temporal marker 2008.

Temporal markers are really useful. The temporal marker 2020 will cause me to think: well, this hasn't happened yet and it is incumbent on me, either to try to ensure that it really does happen (if I think it desirable), or to ensure that it doesn't really happen (if I think it undesirable). By contrast the temporal marker 2008 will cause me to think "well, like it or loathe it, there is nothing I can do about it". Like probabilities, temporal markers play a crucial role in organizing our thoughts, and deciding on our actions. But, also like probabilities, that doesn't mean they are actually existent parts of the world. Similarly with the concepts of past and future. Being in the past isn't a property of the event. Just a feature of the way I think about the event.

The single most important message of quantum mechanics (as I see it) is that we need to introduce some distance between our concepts and the things they are concepts of. We are used to the idea that our usual idea that everything has a position doesn't apply to electrons. I think maybe we need to go much farther than that. It isn't only microscopic things like electrons which slip through our conceptual net. It is also macroscopic things, such as Obama (or me, or you). Obama in his own nature is neither past nor future.

In a way this is not so different from the standard Minkowskian view, according to which the concepts of past and future have no absolute significance. On that view one can talk of event A being past relative to event B, but it makes no sense to talk of an event being past absolutely and intrinsically, in its own nature. However, Minkowski then introduces the concept of space-time as an absolutely existent entity. And the associated, truly horrible idea that everything has already happened.

I was intending to go on. There is certainly quite a lot more in my mind. But I think I won't because, although it is in my mind, it is very confused. All I set out to do here is to put down enough on paper to start a conversation when we next meet (I will be back in Waterloo a week today). And I think I have achieved that already.

But there is one other thing I would like to get down before I forget. It concerns the Pauli-Jung idea of synchronicity. I was never very impressed by this. But now I am suddenly wondering if there might not be something in it. Consider Feynman's definition of science as "a method for, and a body of information obtained by, trying to answer only questions which can be put in the form: If I do this, what will happen?" (Schweber, pp. 462–3). I rather like that definition (I like it because it is so strongly agent-relative: what will happen if I do this?). I also think it captures the essence of the concept of causation. Causation is all to do with control. For instance, turning the ignition key causes the car to start (causal thinking is mechanical thinking, as is acknowledged by such phrases as "mechanical materialism", or "the clockwork universe"). I think this relates to non-locality. In your discussion of non-locality you focus on "unperformed experiments have no results". Suppose, however, that one has performed the experiments. One has this great long sequence of measurement outcomes which display certain striking correlations. This often leads people to ask "what is the explanation? How could those correlations have come about?" And they feel compelled to postulate the existence of some superluminal causal influence. It seems to me, however, that it isn't a causal influence by definition, because there is no possibility of control. Nevertheless one is still left with the existence of those undoubted correlations. What would be a good name for them? Well, how about "synchronicity"? And is it possible that it was something like this that Pauli actually had in mind?

10-01-11 *Freedom = "Each with a Fire of Its Own"* (to W. K. Wootters)

I never came back to answering your wonderful note below. I know I still owe you and need to work my way through the exercise of answering your query 3—it would be very good for me to do that; I know I'll learn from it. But in the meantime, I wonder if the attached thing I just wrote up for Max Schlosshauer's interview book might lay some groundwork and context for how I should eventually answer. I think I get close to your question in my answer to Max's question 5. Unfortunately, that too relies on some of the groundwork in the pages previous to it. But if you can stomach reading the first 10 pages or so, as you get a chance, please let me if you think this might be working us toward an answer to your question.

It must be the beginning of the semester for you, and I know you're awfully busy. Best of luck for the new year.

Bill's Preply, "Nate Stories"

Greetings from Kigali! Things here are going well, though I confess we haven't yet tried banana beer.

Thanks for sending me your paper. I read it immediately but it has taken a while for it to sink in, and I know for a fact that it still hasn't fully sunken in! You have some really good arguments here, and you do a particularly good job of fending off likely misconceptions.

I have a few comments for now, maybe more later.

1. It's cool that you were able to use the story about me and Nate and the flower.

2. A trivial comment regarding the end of Section VI: I'm not sure I can think of a freshman physics problem that treats the earth's gravitational mass as infinite. Sometimes we treat the earth's *inertial mass* as infinite. That is, we say that the earth doesn't move when a force acts on it. We do this even though we also say, in the same problem, that the earth exerts a finite gravitational force on, say, an orbiting satellite.

3. I'm struggling with this important sentence: "Sometimes one will have no strong beliefs for what will result from the creation (as with the measurement of H), and sometimes one will have very strong beliefs (as with the subsequent measurement of H^{T}), but a free creation of nature it remains." I completely agree with the claim that every quantum measurement creates a new fact that was not there before. It's the word "free" that I'm struggling with. Let me begin with this question: Is there any possibility of quantifying nature's freedom? Of course an agent can associate an entropy with the outcome of a measurement he is about to perform, and thereby get a personal estimate of nature's freedom for that measurement. For example, the agent might assign entropy zero to a certain measurement, as in the scenario you imagine. In that case the agent will say he believes that nature is not free to choose the outcome of that particular measurement. But you, who are acting not as an agent but rather as a theorizer of agents, say that nature is free even in that circumstance. Is there any way for you, acting in this capacity, to quantify the freedom of nature? Or is nature always simply free—there is no "more free" or "less free"? I think the QBist answer must be that there is no way to objectively quantify nature's freedom in choosing a particular outcome of a measurement. To do so would suggest a propensity interpretation of probability. So nature is simply free to choose whatever measurement outcome it wants.

But even in QBism, surely nature is not totally free. There is order in the world; it is not total chaos. How does one express the constraints on nature's freedom? It can't be directly through probabilities, since probabilities belong to the agent, not to nature. So what does one say?

10-01-11 *Q3, Part 1* (to N. D. Mermin)

I quite enjoyed reading your interview last night, despite all the noise around me. But I would guess you woke up to already find that this morning!

Here's the first of my promised answers:

Merminition 228: *In Q3, Bob Griffiths and Niu* did *discover their spectacular simplification of the Shor algorithm (replacement of the 2-Qbit gates with 1-Qbit gates in the quantum Fourier transform) by viewing it from the Consistent Histories point of view, but that's the only example I know of. I note that it did not convert you.*

This is true, and you have brought this up with me before. For instance at the PIAF meeting panel discussion a couple of years ago.

But let me tell you another Griffiths story. I am quite sure I have written this one up before, but I have not been able to find it in my email system, so I guess there is nothing to do but write it again.

In 1996, Bob and I were office mates at the ITP in Santa Barbara, and we ended up collaborating on a problem that Asher and I had started up. Something on optimal eavesdropping in BB84. You can read about it in these two papers: `http://arxiv.org/abs/quant-ph/9701039` and `http://arxiv.org/abs/quant-ph/9702015`. You'll note that "part 1" of the paper has Fuchs, Gisin, Griffiths, Niu (a student of Bob's), and Peres as authors, while "part 2" has just Griffiths and Niu. The reason the paper bifurcated into two parts was because after all the first calculations, Niu had found a quantum circuit for enacting the eavesdropping strategy, and Bob said that the only way to *understand* its operation and *motivate* it was through the consistent history picture. Well you can imagine that Peres and Gisin would have none of that and didn't want any such thing mentioned in the paper. Bob was adamant that it needed to be in the explanation. So we decided on an amicable split.

Anyway, a couple years later Niu came by Caltech and gave me a visit. As it so happens, I was in correspondence with Bob at the time about CH, and I remembered back to our old collaboration. So I asked Chi-Sheng about how exactly consistent histories made an impact on his thinking when he discovered the circuit. He revealed to me that he hadn't used consistent histories at all when finding it. He "just played around" until he got the right unitary. I got a great laugh out of that one!

Let me tell you another story. I once did something rather sneaky for a talk I had to give at a "50 years of Everett" meeting. I sent out a questionnaire to various people asking if Everett imagery helped them make their discovery (whatever it was) in quantum computing. For instance, I asked Shor about his algorithm, Simon about his own, and the pièce de résistance was asking Deutsch and Jozsa individually about the Deutsch-Jozsa algorithm (I had a suspicion about the answers I would get). Their replies are attached. Be sure to read them in the order: Deutsch, Jozsa, Shor, Simon. It's fun.

10-01-11 *Q3, Part 2* (to N. D. Mermin)

Continuing,

Merminition 229: *Also in Q3, it wasn't clear to me (as it is clear in the case of Griffiths) how the epistemic leads directly to the answer. Is it just that Spekkens has analogous simple examples?*

Yes, you're on to me. What really happened was that Spekkens noticed the three-qubit example we had in the paper and thought, "I bet I can find the same phenomenon in the toy model." Sure enough, it was so. I thought for a while about being less ingenuous in my presentation, but our three-qubit states didn't have the same spark of *ugliness* about them that the original 9 two-qutrit states did. I wanted the ugly factor to be there.

A better story might have been the time I thought the SIC states were the only sets of states in Hilbert space to have a certain property. Rob said, "Really?" Then he showed me a set of states in his toy model that had the same property. A much closer to the process I advertised in the interview: He just thought for a moment, and then exhibited the set. Sure enough, once I checked on my own in regular quantum mechanics, I found that I had been wrong.

I should ask Rob if he has an analogous example to our 9 two-qutrit states in one of his later toy models.

10-01-11 *Born-Einstein* (to R. W. Spekkens)

Bill Demopoulos thinks that the Einstein paper we were talking about a couple of days ago was translated and reprinted in the Born-Einstein letters. You don't have that book, do you? I was kind of shocked that I don't have it on my shelf. I believe I've read it twice in the past.

11-01-11 *Mr. Physics, professional sidekick* (to R. W. Spekkens)

I realized I didn't explain my story so well yesterday. As Katie was announcing SuperMom, SuperOma, and SuperOpa, I was in the process of pouring their wine. I suppose that's how I became Wine Guy. But as I say, the next morning she relayed to me that she had thought it over a bit, and that I should be called Mr. Physics.

This morning at breakfast, she announced that there was nothing wrong in being Mr. Physics — it really is a important role. "Mr. Physics is SuperMom's sidekick!"

Maybe it's the best I could have hoped for anyway.

11-01-11 *Jaynes* (to R. W. Spekkens)

> But our present quantum mechanical formalism is not purely epistemological; it is a peculiar mixture describing in part realities of Nature, in part incomplete human information about Nature — all scrambled up by Heisenberg and Bohr into an omelette that nobody has seen how to unscramble. Yet we think that the unscrambling is a prerequisite for any further advance in basic physical theory. For, if we cannot separate the subjective and objective aspects of the formalism, we cannot know what we are talking about; it is just that simple.
>
> — E. T. Jaynes

Spekkensism 58: *Incidentally, I presented this slide to the PSI students yesterday. It reminded me of a comment that Graeme Mitchison once made about the same picture of E. T. Jaynes (which was hanging in my office in Cambridge). "That's a haircut that you can set your watch to!"*

And Carl Caves tells me that his politics was just like his hair.

11-01-11 *For January Issue, Part 1* (to I. T. Durham)

Here's the first piece, along with the relevant attachment. How does it look to you?

March Meeting, Take Note of Quantum Information!

Put on your cowboy hats, it's time to go to Dallas! This year we will have an impressive line-up of quantum information talks for the APS March Meeting in Dallas, Texas, and you won't want to miss it . . . or at least you shouldn't!

This will be the biggest year yet for quantum information and computing at an APS March Meeting. There will be over 400 talks on the subject, covering nearly every aspect of the field you can imagine—superconducting qubits, semiconducting qubits, optical qubits, ion traps, entanglement, coherent control, decoherence, quantum error correction, and much, much more. (For gosh sakes, there's even 60 talks on the foundations of quantum mechanics!) On the back of this page, you can find a full list of GQI invited speakers and topics, as well as a list of speakers and topics from other divisions that are relevant to GQI concerns. The full schedule of GQI-sponsored talks can be found here: `http://meetings.aps.org/Meeting/MAR11/sessionindex2?SponsorID=GQI`.

Two of the invited sessions particularly stand out. "20 Years of Quantum Information in Physical Review Letters" on the Wednesday will feature five retrospective talks from five of the field's founding fathers. Want to see the man who invented the word qubit (and lived to watch it become an entry in the Scrabble Players' Dictionary)? He'll be there! We're hoping this session will be a big draw for the whole APS and serve to entertain and educate them about our growing field. Before that though, on the Tuesday, there'll be a session titled "Quantum Information: Featured Experiments". Who in the general (non-GQI) APS would have thought that the world's presently most accurate clocks are directly reliant on quantum-computing techniques? We hope it'll be a lesson. Quantum information is not only crucial for the future of computing; it is forcefully relevant for weights and measures today!

Beyond the talks, GQI will also sponsor a tutorial "Quantum Simulation and Computing with Atoms" (given by Ivan Deutsch), two "Graduate Student Lunches with the Experts" (hosted by Benjamin Schumacher and Anton Zeilinger), and a "pizza and beverage-of-your-choice reception" before the business meeting. (Yes, we'll have beer; it's Texas.)

At the risk of sounding like a Slap Chop infomercial, "But wait, there's more!" The March Meeting in general this year is just going to be an exceptionally good one. For instance, there'll also be a celebration of the 100th year anniversary of superconductivity, with a Nobel laureate session associated with it. Speakers include Ivar Giaever, Wolfgang Ketterle, Sir Anthony Leggett, K. Alexander Mueller, and Frank Wilczek. Furthermore, one of this year's Nobel prize winners for the discovery of graphene, Konstantin Novoselov, will give a special talk.

There are all kinds of reasons to come. We hope that nearly every member of the GQI will be there. We have a real chance to show our relevance and importance to the APS this year. Going to the March Meeting is, of course, about learning and communicating physics, but it is also about building community and friendships and establishing a base for career paths in our field. Young people need jobs, and one way to see to it that there will be some jobs out there is to get the world physics community to take note of quantum information.

So, please tell your students, tell your teachers and friends, that important things will happen in Dallas this year. Here's the website to go to for all the details on the meeting: `http://www.aps.org/meetings/march/`. Don't forget, January 21 is the deadline for early registration—thereafter registration fees go up. Get everyone you can to come. Texas (like Hilbert space) is a big place and always accommodating!

11-01-11 *For January Issue, Part 2* (to I. T. Durham)

And how does this sound?

And probably no need to use it, but I've asked Charlie Bennett permission to use this photo in case we might want to. (But no reply from him yet; so maybe best not to plan around it.) The photo could be called, "The World of Quantum Information, When it Could Fit in One Photo Frame". This was taken just after Shor's factoring algorithm came out.

I really apologize again for delaying you so long. It'll surely be great to get this issue out so that some might act before the early registration deadline is up (Jan 21).

Letter from the Incoming Chair

It's hard to compete with last year's letter from last year's chair, Dave "Pledge Drive" Bacon—I won't even try. But pledge drive is what it's all about! So, I am glad he set the tone.

My guess is that this is going to be a key year for the GQI. Presently our membership is just a bit below 1,100. If we can get it up to 1,450 members and sustain that for two years, we can petition to become an APS division. That might look like a lot, but I don't think it is really—that is why I say this could be a key year. With our upcoming much-larger-than-previous turn-out at the APS March Meeting (our submissions grew by 40% from last year!), I think we will be in a very good position to make it happen. The March Meeting is our crystal. We just need to give the APS the best showing of quantum information it's ever seen, and that is bound to build excitement and a desire in many to be part of the topical group. I'll tell two friends, and they'll each tell two friends, and the same for each of you, and we can make this thing happen.

"APS Division of Quantum Information," doesn't that sound so sweet to the ear? And doesn't it sound so respectable? We would obtain for the first time actual representation within the APS—we'd be respected brothers and sisters to the Division of Condensed Matter Physics, the Division of AMO Physics, and all the others. American physics would respond in part to our membership's desires and needs.

I will tell two (embarrassing) stories from my history in this field, from earlier times when I was trying to get a faculty position. At the conclusion of one job colloquium, one of the professors asked me, "This is nice for weekend physics, but what do you during the week?" Of another interview, it was leaked to me that in the faculty discussion after my departure, one of the professors implored, "Well, if he likes quantum mechanics so much, why doesn't he do anything with it!?" But I was doing quantum information then, as I am doing quantum information now—the subject matter has not changed particularly.

So many of you must have experienced (or will soon experience) something similar in your own careers. But we want that number to be less and less. To the extent that such behavior in hiring committees has abated over the years, it has done so only because of the increased awareness and respect the rest of the physics community has come to for this subject we hold so dear to our hearts. We have made great progress in the 20 years since Physical Review Letters started publishing papers in quantum information—2011 is an anniversary for us—but there is so much further to go.

I look to 2011 to be a bend in our curve of growth within the APS. So, my job for the coming year will be to "tell two friends" every chance I get about the beauty and promise of quantum information. I hope all the GQI will do their best to do the same.

We have a world to change. Let's do it!

12-01-11 *Quick and Dirty (a conversation)* (to M. Schlosshauer)

Schlosshauerism 33: *What are you doing up so late?*

Reading Hardy's interview at the very moment.

Schlosshauerism 34: *It's a good one, isn't it?*

Haven't gotten far enough yet to know. I did jump to the little bit on QBism 'cause he had flagged it—the guy still gets it wrong. Chairs are no more accountable by quantum theory—on QBism's account—than the particular outcome of a Stern-Gerlach measurement. QBism's framework is empiricism; Hardy is still looking at it through reductionist glasses.

Schlosshauerism 35: *Yeah, I know what you mean. I too was surprised by Hardy's insistence on ontology as a necessary part of quantum theory.*

Not quite right. "Ontology is a necessary part of physics," he would say. He's not sure that quantum theory itself has the tools to give a correct ontology. This is because he thinks QT is an effective theory. (Or should that be affective theory? Told you I always get confused.)

14-01-11 *Great Incendiary Fun* (to I. T. Durham)

I'm sorry! First, things didn't go nearly as smoothly as I had expected for our transition from Waterloo to here. (Blue Mountain is in Ontario, on the coast of Lake Huron.) Then, for some reason, I repeatedly would remember that I needed to take care of this for you, but then would forget again. Here's the new by-line:

> Christopher A. Fuchs is a Senior Researcher at the Perimeter Institute for Theoretical Physics in Waterloo, Canada and an Adjunct Professor at the University of Waterloo. He is a winner of the 2010 International Quantum Communication Award and Chair of the American Physical Society Topical Group on Quantum Information. His Erdos number is 3, but so is his Einstein number. Mostly, he is very proud that his academic great-great-great-great grandfather Franz Exner (through the lineage Carlton Caves, Kip Thorne, John Wheeler, and up) believed, long before quantum mechanics was around, that our ultimate physics would be indeterministic. Chris's Cambridge University Press book *Coming of Age with Quantum Information* has just appeared at the bookstores, and he's been told, makes for some "great incendiary fun."

On the picture, I still haven't heard back from Charlie. So, let's just drop it. I'm quite sorry I've already delayed you this much. If the notes are going to be effective at all for getting the populace to the polls before the Jan 21 early-reg deadline, the sooner we can get the issue appearing the better.

You're a saint for putting up with contributors like me!

Hope all the snow shoveling you had to do didn't break your back.

18-01-11 *What Is the Scale at which Quantum Theory Applies?* (to R. W. Spekkens)

Spekkensism 59: *So I spoke to a public audience about quantum theory on the weekend. It was a "café scientifique" in a bar. Each of the four panelists tried to answer, in 10 minutes, the question of what quantum theory was and why the audience should care. After the break, the moderator asked us if we could remind the audience that quantum theory is a theory of stuff at small scales. That idea always sat badly with me because quantum theory applies to all systems, even macroscopic ones. So I got to thinking about how to better describe the regime in which quantum effects are important. Here's what I came up with (and told the audience): If quantum theory were about particles and forces and motion then one might have expected a length scale to be significant, but given that it is actually about information and knowledge, the scale that is important is a scale of certainty. If one is talking about a system about which one has very imprecise information, for instance the position and momentum of a car, then one is nowhere near the regime in which the Heisenberg uncertainty principle is important and classical mechanics suffices. If one is talking about an atom that is being measured extremely precisely, then one can begin to see the effect of* *the Heisenberg limit and quantum theory is important. The reason that quantum effects were first seen in microscopic systems is because these are the systems wherein it is easiest to achieve a great deal of certainty. It is difficult to do so for macroscopic systems because these generally interact more readily with their environment, and this generally leads to a decrease in our degree of certainty about the system because we typically have a great deal of uncertainty about the environment.*

So I have a new slogan: The scale at which quantum theory applies is the scale of small uncertainty. What do you think?

Here, here! I like honesty to the layman, and I can see why the moderator's suggestion wouldn't sit well with you. I wish I had been there to hear the whole story. Who and what were the other points of view? (I had to decline their invitation when they asked me.)

I liked your answer all the way to the bit about "decoherence" (though I resumed liking it again at your slogan). Of macroscopic systems, I would say we never had any certainties to begin with to lose. For instance, for a cat, no one has ever come close to making a pure-state assignment for it for which decoherence would then be relevant. In my mind, decoherence as an "explanation" of classicality is defunct. I lay my money on something closer to what Kofler and Brukner propose: `http://arxiv.org/abs/quant-ph/0609079` and then in more detail in Kofler's thesis.

Of regular "decoherence," (as used for quantum foundational discussion à la Zeh, Zurek, etc.) my new view is that it has essentially nothing to do with interactions with an environment. Instead it has everything to do with how an agent should gamble under the supposition of future certainties. Attached is a presently poorly written draft of a paper where Rüdiger and I finally try to write down this point. Or at least this is our first stab at it. The quantum section will be strengthened as I rewrite it (much comes from an earlier conference abstract of mine), but the essential point is there: Quantum decoherence (in the context of measurement theory) is none other than van Fraassen-ian reflection.

Maybe as a modification to your slogan that fits a bit better my own proclivities: Quantum theory applies to the scale of precision where contextuality and counterfactuals start to matter.

19-01-11 *Born's Rule* (to J.-Å Larsson)

Larssony 4: `http://xkcd.com/849/`.

Thanks, that was funny. Attached is my own latest cartoon. [See `http://arxiv.org/abs/1207.2141`.] I can't post it for a few months, but that doesn't stop me from sending it to friends like you.

At the moment, I'm working on a more Rüdiger-style paper on "decoherence" from the point of view of QBism. I.e., what I disappointed everyone with at Khrennikov's meeting last year. I hope we do a better job this time. Here's the abstract for it:

> The probabilities a Bayesian agent assigns to a set of events typically change with time, for instance when the agent updates them in the light of new data. In this paper we address the question of how an agent's probabilities at different times are constrained by Dutch book coherence. We review and attempt to clarify the argument that, although an agent is not forced by coherence to use the usual Bayesian conditioning rule to update his probabilities, coherence does require the agent's probabilities to satisfy van Fraassen's [1984] *reflection principle* (or the similar constraints due to Goldstein [1983] and Shafer [1983]). Bringing the argument to the context of quantum measurement theory, we show that "quantum decoherence" can be understood in purely personalist

terms—quantum decoherence (as supposed in a von Neumann chain) is not a physical process at all, but an application of the reflection principle. From this point of view, the decoherence theory of Zeh, Zurek, and others as a story of quantum measurement has the plot turned exactly backward.

20-01-11 *Combining Probabilities* (to R. W. Spekkens & M. S. Leifer)

This may be a useful paper for you [C. Genest and J. D. Zidek, "Combining Probability Distributions: A Critique and an Annotated Bibliography," *Statistical Science* **1**, 114–148 (1986)], in case you don't know about it:

> `http://www.jstor.org/pss/2245510`.

21-01-11 *Section 5* (to R. Schack)

And I am confused on the priority of Section 5. Is that an argument purely due to you? Or had someone else given it before, perhaps in different form?

Here's the present version of the abstract. Have I made it too weak with respect to what's actually been done?

> The probabilities a Bayesian agent assigns to a set of events typically change with time, for instance when the agent updates them in the light of new data. In this paper we address the question of how an agent's probabilities at different times are constrained by Dutch book coherence. We review and attempt to clarify the argument that, although an agent is not forced by coherence to use the usual Bayesian conditioning rule to update his probabilities, coherence does require the agent's probabilities to satisfy van Fraassen's [1984] *reflection principle* (or a related constraint due to Goldstein [1983]). Bringing the argument to the context of quantum measurement theory, we show that "quantum decoherence" can be understood in purely personalist terms—quantum decoherence (as supposed in a von Neumann chain) is not a physical process at all, but an application of the reflection principle. From this point of view, the decoherence theory of Zeh, Zurek, and others as a story of quantum measurement has the plot turned exactly backward.

22-01-11 *Woefully Inadequate* (to the QBies)

I felt woefully inadequate yesterday in our discussion of "facts" and "experience". I feel the same this morning. I feel so far from verbalizing whatever it is that's trying to form in my mind. Attached are my two best shots at it so far (from two recent papers). Maybe putting it in the middle of poetry, like in my pseudo-Shakespearean quote, is the most I can hope for at the moment:

> Our revels are now ended. These our actors,
> As I foretold you, were all spirits and
> Are melted into air, into thin air . . .
>
> We are such stuff as
>   quantum measurement is made on.

The young Wittgenstein started off the *Tractatus* with, "The world is everything that is the case. What is the case, the fact, is the existence of atomic facts." Somehow, someway, I want to replace his "facts" with something closer to "birth" in its imagery. Facts, as usually thought, are kind of dead things. (I said something like that yesterday.) In any case, I do very much believe that whatever it is that I'm looking for should be modeled on "quantum measurement" (whatever that is) in its first pass.

Marcus's Reply

> I agree totally with this
>
> > Facts, as usually thought, are kind of dead things.
>
> and I agree also that there is something wrong with that. Except "wrong" is too weak. So let me try again. Black as night. Dark as the grave. Life denying. Soul destroying. A figment of Satan.
>
> But, like you, I am not sure where to go from here.

22-01-11 *Creatia!* (to the QBies)

Figment of Satan! Beautiful. Attached is just a bit more to read. It comes from somewhere in the middle of the proposal I wrote for the Templeton Foundation. In it, I called this new stuff of the world "creatia."

> As important as getting straight the "quantum-theory-as-a-user's-manual conception" has been for Quantum Bayesianism, it is striking that taking that step leads right away to the very next one. The journey is not concluded by settling the foundational conundrums; instead, it is just the start of a greater, more important trek.
>
> What we have learned from the user's-manual conception of quantum theory is that every quantum measurement (by definition, a transaction between an agent and a system) represents a moment of creation. Something new comes into the world that was not there before. A knee-jerk reaction that one often hears as a response to these ideas is that they're a veiled form of solipsism—the idea that the world consists only of *the self* (presumably the Project Leader?). We have argued strenuously, however, in `\cite[Section VI]{Fuchs10b}` that the source of the knee-jerk reaction is mostly a lack of appreciation that physical theories can have any reading other than reductionistic ones.
>
> The key is not to view quantum theory in reductive terms and try to derive the world we commonly see around us out of the theory's mathematical structure, but rather to view the advice of quantum theory as *additive* to the world of (pre-quantum) experience. Here is the way it was put in `\cite{Fuchs10b}`,
>
> > The expectation of the quantum-to-classical transitionists is that quantum theory is at the bottom of things `\cite{Schlosshauer07}`, and "the classical world of our experience" is something to be derived out of it. QBism says "No. Experience is neither classical nor quantum. Experience is experience with a richness that classical physics of any variety could not remotely grasp." Quantum mechanics is something put on top of raw, unreflected experience. It is additive to it, suggesting wholly new types of experience, while never invalidating the old. To the question, "Why has no one ever *seen* entanglement

in diamond before?," the QBist replies: It is simply because before recent technologies and controlled conditions, as well as lots of refined analysis, no one had ever mustered a mesh of beliefs relevant to such a range of interactions with diamonds. No one had ever been in a position to adopt the extra normative constraints required by the Born Rule. For QBism, it is not the emergence of classicality that needs to be explained, but the emergence of our new ways of manipulating, controlling, and interacting with matter that do.

The backdrop for this program of thought is in recognizing that the happiest philosophical home for QBism is a kind of empiricism—the idea that everything experienced, everything experienceable has no less an ontological status than anything else. From this view, an experienced dream and a Higgs-boson detection event at the LHC are equal elements in the filling out and making of reality. Instead of a starkly empty world, as a quantum reductionist might have it ("the world is *nothing but* the universal wavefunction undergoing unitary evolution"), the world of QBism is overflowingly full—it is a world whose details are beyond anything grammatical or rule-bound expression can articulate. In other words, it avoids the great "original sin" of "vicious abstractionism" (as William James called it),

> We conceive a concrete situation by singling out some salient or important feature in it, and classing it under that; then, instead of adding to its previous characters all the positive consequences which the new way of conceiving it may bring, we proceed to use our concept privatively; reducing the originally rich phenomenon to the naked suggestions of that name abstractly taken, treating it as a case of 'nothing but' that, concept, and acting as if all the other characters from out of which the concept is abstracted were expunged.

Previous to QBism's thinking, the seed of that sin was spread over nearly every flavor of quantum interpretation known.

So what are the "salient and important features" QBism singles out to be *added* to the "previous character" of common experience? We have at least one answer to this so far, and it is identified right at the front of

$$Q(D_j) = (d+1)\sum_{i=1}^{d^2} P(H_i)P(D_j|H_i) - 1\ .$$

It is the single number d, called dimension, associated with each quantum system. What is so nice about this equation, as opposed to the usual way of expressing the Born Rule, is that dimension is pulled out and displayed prominently: It represents the *deviation* from the classical Law of Total Probability one should use in one's considerations for a given system. In `\cite[Section VI,VII]{Fuchs10b}`, we have argued that dimension should be thought of as a new *capacity* inherent in all matter, much like "gravitational mass" can be thought of as a capacity inherent in all matter `\cite{Cartwright99}`. It is this new capacity that allows one to do unexpected and wonderful things with quantum systems.

But our thoughts really are nascent in this, and so much work needs to be done to distill it into productive physics. With JTF's support, having Dr. Schlosshauer stationed at Perimeter Institute and Dr. Appleby available for more conceptual work, we will be able to have a devoted conceptual-research group set to get straight to the heart of this matter. (For instance, by taking advantage of the 1,000-book "pragmatism library" already built up by the Project Leader for the purpose of exploring this line of thought; see supplementary material.) Extended visits by Co-Project Leader Schack will also be decisive in this matter.

Chief among our considerations is making a push to pin down exactly which flavor of empiricism surrounds the technical apparatus of QBism. At the moment, we think it is a combination of Wolfgang Pauli's thoughts (where the individual stuff of the world is "neutral," neither matter nor psyche) and William James's "radical empiricism" of "pure experience." QBism says that every quantum measurement is a moment of creation, and the formal apparatus of quantum theory is an aid for each agent's thinking about those "creatia" she is involved with. But surely a Copernican principle applies just as much to QBism as to any other science. QBism's solution starts by saying the last point just that much more clearly: "Quantum measurement represents those moments of creation an agent happens to seek out or notice." It does not at all mean that there aren't moments of creation going all around, unnoticed, unparticipated in by the particular agent, all the time. The larger world of QBism is something aligned with James's vision of a pluriverse where "being comes in local spots and patches which add themselves or stay away at random, independently of the rest."

The biggest goal of the research group, of course, would be to say something decisive on John Wheeler's Big Question, "Is the Big Bang here?":

> Each elementary quantum phenomenon is an elementary act of "fact creation." That is incontestable. But is that the only mechanism needed to create all that is? Is what took place at the big bang the consequence of billions upon billions of these elementary processes, these elementary "acts of observer-participancy," these quantum phenomena? Have we had the mechanism of creation before our eyes all this time without recognizing the truth?

Concretely, in the period of the funding, what will happen is that the total force of our collective thought will make its way into the chapters of Schlosshauer's book—particularly, the parts devoted to the larger worldview of QBism—as well as some papers that Appleby has long been gearing up to write. Finally, Fuchs and Schack will write a detailed, more specialized monograph on the sum total "Worldview of QBism"—the monograph be as thorough as possible, expressing all pros, cons, and obstacles identified by the research group.

23-01-11 *Creatia!, 2* (to the QBies)

A quick example of the trouble that might be caused by a quick choice of phrase. Marcus writes, "the radical empiricism of Mach" in this note. Whereas in lots of recent papers, I cite James's book *Essays in Radical Empiricism*. In the case of James, "radical empiricism" was his own name for his particular doctrine. In the case of Marcus, though, I think "radical" was chosen (I would guess) as a way to express that Mach went further in a certain way than Locke and Hume.

You can get a quick sense that these might be different ideas by looking at the wiki page: `http://en.wikipedia.org/wiki/Radical_empiricism`. I don't believe Mach's own philosophy depended upon "relations themselves" being directly experienceable.

Anyway, here's how James defines his "radical empiricism":

> I give the name of radical empiricism to my Weltanschauung. Empiricism is known as the opposite of rationalism. Rationalism tends to emphasize universals and to make

> wholes prior to parts in the order of logic as well as in that of being. Empiricism, on the contrary, lays the explanatory stress upon the part, the element, the individual, and treats the whole as a collection and the universal as an abstraction. My description of things, accordingly, starts with the parts and makes of the whole a being of the second order. It is essentially a mosaic philosophy, a philosophy of plural facts, like that of Hume and his descendants, who refer these facts neither to Substances in which they inhere nor to an Absolute Mind that creates them as its objects. But it differs from the Humian type of empiricism in one particular which makes me add the epithet radical.
>
> To be radical, an empiricism must neither admit into its constructions any element that is not directly experienced, nor exclude from them any element that is directly experienced. For such a philosophy, the relations that connect experiences must themselves be experienced relations, and any kind of relation experienced must be accounted as real as anything else in the system. Elements may indeed be redistributed, the original placing of things getting corrected, but a real place must be found for every kind of thing experienced, whether term or relation, in the final philosophic arrangement.

Anyway, I'm not wedded to the terms "empiricism" or "experience" myself—I might change to something else radically different in the near future. They just seemed expedient at the time of my writing. I didn't know better words and I had been influenced by James, Schiller, and Dewey.

23-01-11 *I Am Available to Talk* (to D. M. Appleby)

Timing was bad. Your note came a bit after we took off for the movies; we saw the new Narnia movie. (I much liked it.) We just got back now. Maybe we can wait on philosophy till tomorrow.

I read the wiki page on empiricism this morning, and learned that there is a bit of an echo of J. S. Mill in the footnote 37 I sent you yesterday. Mill called matter "the permanent possibility of sensation."

24-01-11 *Putnam* (to W. G. Demopoulos)

Demopoulosism 43: *Apropos Hilary's citation of the quote attributed to Bohr by Aage Petersen (text to Hilary's Fn. 19), I would put things differently:*

> There is no classical world. There is only an abstract classical mechanical description.

Hence, I don't see myself as just recycling Bohr, although I do "echo" him.

I liked your play on the Petersen quote! Nice.

On your lines,

Demopoulosism 44: *We agreed earlier that on your view, it is the effects the would has on Bayesian agents that forms the subject matter of quantum mechanics. I regard the dualism implicit in this view as entirely tenable—it's the dualism between our intentions and expectations about the future on the one hand, and reality on the other. But I can't follow you in your incorporation of this dualism into the thesis that QM is about the consequences of our actions.*

There must be a typo in the first sentence; I would like to know what your exact words would have been. But I think I get the gist. I found myself thinking, "What a strangely asymmetric world. I feel it, but it never feels me."

I have to admit that I've been frightened ever since you told me that Putnam may be in my audience in Jerusalem. I guess I'm still trying to get over the "postmodern sauce" he flung at Jeff Bub and me at your meeting a couple years ago. You think there's any chance I could get him to read my `http://arxiv.org/abs/1003.5209` before my talk, before he comes out with his ladle full?

I will think harder and deeper on your remarks. I know you probably don't think much of my "experience mumbo jumbo" but your play on Petersen rings a bit with something I wrote in that paper:

> The expectation of the quantum-to-classical transitionists is that quantum theory is at the bottom of things, and "the classical world of our experience" is something to be derived out of it. QBism says "No. Experience is neither classical nor quantum. Experience is experience with a richness that classical physics of any variety could not remotely grasp." Quantum mechanics is something put on top of raw, unreflected experience. It is additive to it, suggesting wholly new types of experience, while never invalidating the old. To the question, "Why has no one ever *seen* superposition or entanglement in diamond before?," the QBist replies: It is simply because before recent technologies and very controlled conditions, as well as lots of refined analysis and thinking, no one had ever mustered a mesh of beliefs relevant to such a range of interactions (factual and counterfactual) with diamonds. No one had ever been in a position to adopt the extra normative constraints required by the Born Rule. For QBism, it is not the emergence of classicality that needs to be explained, but the emergence of our new ways of manipulating, controlling, and interacting with matter that do.
>
> In this sense, QBism declares the quantum-to-classical research program unnecessary (and actually obstructive) in a way not so dissimilar to the way Bohr's 1913 model of the hydrogen atom declared another research program unnecessary (and actually obstructive). Bohr's great achievement above all the other physicists of his day was in being the first to say, "Enough! I shall not give a mechanistic explanation for these spectra we see. Here is a way to think of them with no mechanism."

BTW, the rocks on the beach were diamond. Diamond has recently been learned to be a very promising material for quantum computation.

24-01-11 *Putnam, 2* (to W. G. Demopoulos)

Demopoulosism 45: *My talk of there being admissible classical descriptions is just another way of saying that our experience is classical.*

Yes, you're right: There's probably not as much resemblance as I was hoping for. All I was really meaning to say is that I would be willing to mimic part of what you were saying. Maybe my own (not so pithy) modification to Peterson would be:

> There is no quantum world. There is only an abstract quantum mechanical description for some of the things in it (at certain times and places in our relations with it). But there is no classical world either. There is only an abstract classical mechanical description of some of the things in it (at certain times and places in our relations). The former is additive to the latter—in the sense of our operational uses of the world's objects. The world in itself is richer than either schema—classical or quantum—can accommodate.

On Putnam, you are probably right. I will hold my tongue until (and unless) I am forced to.

27-01-11 *Schlosshauer and Mach* (to A. Zeilinger)

Thank you for the kind letter—your continued patience moves me. I apologize for not having written you sooner: I had wanted the latest update from Max Schlosshauer before writing you again, and he had fallen silent. It turns out he was on a small island somewhere editing his book, and he had had no internet connection for several days. [...]

I enjoyed reading your short interview. It was helpful for my orientation to see a new portrait of you. (It was similarly useful with respect to understanding Mermin and Hardy, whose contributions I have read as well.) I particularly liked the way you put a point near the end:

> This is not to say that everything is just information or knowledge. What I mean is that we need a new fundamental concept unifying the notions of information and reality.

There is some amount of similarity between that and the far end of my own QBism program. Or at least I think there is. I say so because of (for instance) this passage from a recent paper of mine:

> [W]e have learned enough from Copernicus to know that egocentrism, whenever it can be shaken away from a weltanschauung, it ought to be. Whenever "I" encounter a quantum system, and take an action upon it, it catalyzes a consequence in my experience that my experience could not have foreseen. Similarly, by a Copernican principle, I should assume the same for "you": Whenever you encounter a quantum system, taking an action upon it, it catalyzes a consequence in your experience. By one category of thought, we are agents, but by another category of thought we are physical systems. And when we take actions upon each other, the category distinctions are symmetrical. Like with the Rubin vase, the best the eye can do is flit back and forth between the two formulations. In the common circles of the philosophy of science there is a strong popularity in the idea that agentialism can always be reduced to some complicated property arrived at from physicalism. But perhaps this republican-banquet vision of the world that so seems to fit a QBist understanding of quantum mechanics is telling us that the appropriate ontology we should seek would treat these dual categories as just that, dual aspects of a higher, more neutral concept. That is, these concepts "action" and "unforseen consequence in experience," both so crucial for clarifying the very meaning of quantum measurement, might just be applicable after a fashion to arbitrary components of the world—i.e., venues in which probability talk has no place. Understanding or rejecting this idea is the long road ahead of us. The development of formalism in this paper we see as at least one promising entrance into that road.

It is probably a bit hard to understand out of the context for which it was originally written.

Anyway: What it is trying to get at is, that on the one hand, the quantum mechanical measurer is an agent (in the sense of probability and decision theory) and, on the other hand, it is a physical system like any other. You use the words "information" and "reality" ... and I use the words "agent" (bearer of probabilities) and "system". I think we are both thinking "complementary aspects of ... something."

In both cases, I think a philosopher of science would say that he thinks we are seeking a "neutral monism." I don't know that that is the best name for it, but we both are certainly seeking something that breaks the cut between Descartes' *res cogitans* and *res extensa*.

We are not the first to want to want something like this, and it explains in part why I find such inspiration in the writings of William James (who aimed for this explicitly with his concept of "pure experience") and the private letters of Wolfgang Pauli (who tended to just call it "psychophysically neutral" stuff).

More recently I've taken a great interest in Ernst Mach's own version of it, with his "sensations" or "world elements". I have to admit that until recently, I had never understood the depths of his thoughts in this regard. I had only known of the logical-positivist leaning extensions of his earlier thoughts by others. So much is hidden to us who cannot read the German language!! The actual man's thinking is so much more interesting to me than the other schools that arose (in Vienna) immediately after him.

At the moment, I am in Texas to spend a bit of time with my mother for her 82nd birthday, and I brought a book with me that I've been reading voraciously: Erik C. Banks' *Ernst Mach's World Elements: A Study in Natural Philosophy*. It is a very useful resource because the whole thing is devoted to giving a "conclusive demonstration" that the answer to this question:

> What one really wants from Mach is some clear statement that he believed in objects or elements that were not human sensations . . . : elements that made up a mind-independent world of nature even when no human being is sensing it, similar to what Russell later called sensibilia . . .

is "Yes." Mach's elements were psychophysically neutral elements (in the way that Pauli and James wanted such a thing), but not explicitly tied to human existence.

It is a very good book, and I would recommend it wholeheartedly. It is a certainly a good source of ideas for me, and I suspect it will be for your own variations on the theme as well.

01-02-11 *How To Remove Yourself from Someone's Xmas Card List* (to M. S. Leifer)

Leiferism 6 : *I have written up some notes on my objection to your treatment of Wigner's friend in the QBism papers. It came out somewhat longer than I had intended, because I was trying to get all my thoughts on the subject straight. Somewhere along the way, it seems to have morphed into a paper. It sort of depends on the papers I am writing with Rob, so I definitely want to get those finished before I do anything further with it. That gives you plenty of time to make comments and maybe convince me that I have got it wrong and should junk the whole thing before I decide whether to post this anywhere.*

On the contrary: That you take me seriously enough to write a paper on my ideas (pro *or* contra, it doesn't matter) is a powerful reason to keep you in my correspondence that much more! (We should all beware of the unintended consequences of our actions.)

Thanks for this. I am sorry it took my so long to get back to you. I was in the backwoods of Texas last week, visiting my 82-year-old mother, and that took most of my energies.

This paper will be very valuable to me, as I work out how to respond to you. The Wigner's Friend issue is the central point for me now as I try to move a step beyond quantum mechanics to the kind of neutral-monism ontology (neutral pluralism really) that I promised at the end of my last few papers ("QB Coherence" and "QBism, the Perimeter of . . . "). Similarly in my defunct Templeton Foundation proposal:

> Chief among our considerations is making a push to pin down exactly which flavor of empiricism surrounds the technical apparatus of QBism. At the moment, we think it is a combination of Wolfgang Pauli's thoughts (where the individual stuff of the world is "neutral," neither matter nor psyche) and William James's "radical empiricism" of "pure experience." QBism says that every quantum measurement is a moment of

> creation, and the formal apparatus of quantum theory is an aid for each agent's thinking about those "creatia" she is involved with. But surely a Copernican principle applies just as much to QBism as to any other science. QBism's solution starts by saying the last point just that much more clearly: "Quantum measurement represents those moments of creation an agent happens to seek out or notice." It does not at all mean that there aren't moments of creation going on all around, unnoticed, unparticipated in by the particular agent, all the time. The larger world of QBism is something aligned with James's vision of a pluriverse where "being comes in local spots and patches which add themselves or stay away at random, independently of the rest."

The key issue in any response to you, my guess is, is going to be in the meaning of Claim 1—the explicit "two levels of personalism" QBism now adopts probably does not mesh well with the current philosophy-of-science usage of the term "objectively real" (with strong connotations toward "publicly accessible"). Maybe just as importantly will be this thing you call an "ignorance interpretation". I don't know yet, but from the sounds of it (i.e., your choice of wording), it would indicate that you're missing a key point in my thinking ... or ... that I'm being grossly inconsistent. You'll forgive me for thinking it'll be the former rather than the latter—but I could be wrong, and time will tell.

I hope to get back to you from Israel the week after next, where I will be giving the Pitowsky memorial lecture. They particularly want an explication of the similarity and distinctions of my Bayesianism and his, and all this should be deeply on my mind.

Best wishes, and honestly, thanks for this!

01-02-11 *Mechanism, Sensation, Texarkana* (to C. Smeenk)

On other matters, I've been studying Erik Banks' book *Ernst Mach's World Elements* (UWO Series) for the last week and have been greatly enjoying it. I honestly hadn't appreciated the depths of Mach's thought (even in the 1860s and 1870s already). It's anything but the logical positivism I had always mislabeled him with. You read some of his passages, and if you didn't know better, you might think he was in the quantum gravity group at PI. Anyway, it's been enlightening, and it teaches me once again that some of the best sources of ideas in physics *for me* are in long forgotten 120-year-old books. I've got to learn much more about Mach now.

Attached is something I just wrote that's bound to get any philosopher of science's dander up. I hope you get a laugh from it every now and then, even as you grimace.

04-02-11 *Mach on James on Wine, Coffee, and God* (to D. M. Appleby)

This comes from a 1911 letter of Ernst Mach to Anton Thomsen. James had just died in 1910.

> My personal memories of William James are very pleasant; he visited me while still in Prague in 80 or 81. [In fact it was 1882. CAF] I remember no one with whom, despite the divergence of viewpoints, I could discuss so well and fruitfully. He opposed me almost everywhere and yet I benefited almost everywhere by his objections. Already at that time he avoided any drop of wine or coffee so that I believed him more of a nervous hypochondriac than a really sick man. The center of his work certainly lies in his excellent *Psychology*. I cannot quite come to terms with his Pragmatism. "We

> cannot give up the concept of God because it promises too much." That is a rather dangerous argument.

Reading this again, it reminds me that here is another noteworthy distinction between Mach and James. Mach was an atheist and wanted to weed out as many "transcendent" terms from science as possible (presumably God was one of them). On the other hand, James's "radical empiricism" strives to be as inclusive as possible with all experiences: "To be radical, an empiricism must neither admit into its constructions any element that is not directly experienced, nor exclude from them any element that is directly experienced." So, now think of what he sought to establish in *The Varieties of Religious Experience*—that the experience of God is a widespread and very real thing for so many people. A radical empiricism, therefore, cannot exclude it.

07-02-11 *The 2011 QBist Challenge* (to the QBies)

I attach the QBist Glossary to remind you of the running theme of our work.

The other day at group meeting, I read you all a passage that I had written for a 2004 lecture at Caltech:

> A lecturer faces a dilemma when teaching a course at a farsighted summer school like this one. This is because, when it comes to research, there is often a fine line between what one thinks and what is demonstrable fact. More than that, conveying to the students what one thinks—in other words, one's hopes, one's desires, the potentest of one's premises—can be just as empowering to the students' research lives (even if the ideas are not quite right) as the bare tabulation of any amount of demonstrable fact. So I want to use one percent of this lecture to tell you what I think—the potentest of all my premises—and use the remaining ninety-nine to tell you about the mathematical structure from which that premise arises.
>
> I think the greatest lesson quantum theory holds for us is that when two pieces of the world come together, they give birth. [Bring two fists together and then open them to imply an explosion.] They give birth to FACTS in a way not so unlike the romantic notion of parenthood: that a child is more than the sum total of her parents, an entity unto herself with untold potential for reshaping the world. Add a new piece to a puzzle—not to its beginning or end or edges, but somewhere deep in its middle—and all the extant pieces must be rejiggled or recut to make a new, but different, whole. That is the great lesson.
>
> But quantum mechanics is only a glimpse into this profound feature of nature; it is only a part of the story. For its focus is exclusively upon a very special case of this phenomenon: The case where one piece of the world is a highly-developed decision-making agent—an experimentalist—and the other piece is some fraction of the world that captures his attention or interest.
>
> When an experimentalist reaches out and touches a quantum system—the process usually called quantum 'measurement'—that process gives rise to a birth. It gives rise to a little act of creation. And it is how those births or acts of creation impact the agent's *expectations* for other such births that is the subject matter of quantum theory. That is to say, quantum theory is a calculus for aiding us in our decisions and adjusting our expectations in a QUANTUM WORLD. Ultimately, as physicists, it is the quantum world for which we would like to say as much as we can, but that is not our starting point. Quantum theory rests at a level higher than that.

To put it starkly, quantum theory is just the start of our adventure. The quantum world is still ahead of us. So let us learn about quantum theory.

As Marcus pointed out, I'm certainly using the word "facts" (in all caps) in an awfully non-standard way there. For instance, one does not usually think of facts as having "untold potential for reshaping the world."

So, I've spent the last few minutes trying to find a better word that fits our group theme. The one that strikes me most at the moment is

- **QBoom** – cf. *kaboom*; a fundamental event in analogy to the outcome of a quantum measurement. "In the QBist weltanschauung, the universe does not come into being with a Big Bang, but instead arises 'in spots and patches' through millions upon millions of little QBooms."

If any of you think of a more elegant exercise in QBistry, I'm open to suggestions.

07-02-11 *More QB Silliness* (to the QBies)

- **QBoom** – cf. *kaboom*; the sought-for deanthropocentrized distillate of a quantum measurement that QBism imagines as powering the world. William James called an early version of something along these lines "pure experience". John Wheeler asked, "Is the entirety of existence, rather than being built on particles or fields of force or multidimensional geometry, built upon billions upon billions of elementary quantum phenomena, those elementary acts of 'observer-participancy,' those most ethereal of all the entities that have been forced upon us by the progress of science?" and, "Is what took place at the big bang the consequence of billions upon billions of these elementary processes, these elementary 'acts of observer-participancy,'?" In other words, in place of the Big Bang, the QBist wonders whether it might not be billions upon billions of little QBooms instead?
- **QBlooey** – cf. *kablooey*; a QBist slur on the usual conception of the Big Bang—i.e., a conception of the universe in which nature already blew its wad at the very beginning.

07-02-11 *Renouvier* (to S. Weinstein)

Thanks for the music; I'll have a listen of it when I get home. And, no, I haven't read Hume. I should be ashamed of myself—with my abiding interest in free will, it would serve me to.

Attached are some of my notes from a book on Renouvier. [See 13-08-03 note "Renouvier" to R. Schack.] For Renouvier, free will was something that had to be fought for. It didn't come for free; unless you really wanted it, you would not have it. I also like (the flavor of) his argument that—surprisingly—the concepts of true and false are crucially dependent on freedom.

08-02-11 *From Screed to Screech* (to A. Wilce)

Thanks for the new paper! I've sent it on to my Jordan-algebra-savvy student Matthew Graydon, to get him to explain it to me. Also dug up your reference 8 since it looked like it might intrigue him. Noticed that you had Brukner's name misspelled as Bruckner, and you're missing some diacritical marks as well (on him and his co-author).

Attached is my own latest. [See "Interview with a Quantum Bayesian," `arXiv:1207.2141v1`.] It won't be posted for two or three months until after the book comes out. And if you read some of the nasty things I say about our philosophical friends, maybe that's a good thing!

I've got a more technical paper coming down the pipe soon, on diachronic Dutch book arguments and their relation to (what is misconstrued as a physical, rather than epistemic) quantum decoherence. I'll let you know when it's finally posted.

I'm off to Jerusalem Friday to give the first Itamar Pitowsky memorial lecture next week. A very flattering thing to do. But I'm also scared stiff: I've been told Hilary Putnam will be in the audience.

It'll be good to see you again in March. I'll make sure I reserve some time for you.

09-02-11 *Questions and Answers* (to R. Colbeck & G. Chiribella)

I enjoyed both your questions yesterday. They were completely on the mark, and I appreciated them.

For Roger's question on "what if they don't exist," I attach the write-up of a little epiphany I had while Howard Barnum and I were at some philosophy of science talk at the university. [See 13-03-10 note "Conceptual Barrier!" to the QBies.] I do well believe that someone will eventually show that SICs always exist, but if they don't I'm prepared for it, and the attached write-up makes the point with some passion. You might find it entertaining reading. I also include for your amusement the write-up of a dream I sent to Anton Zeilinger and its interpretation in terms of the epiphany. [See 01-04-10 note "Strange Anton Dream" to A. Zeilinger and H. C. von Baeyer.]

The "allusion to William James's faith ladder" that I mention in the note refers to this little ditty I had sent to my group and Howard in an earlier email:

> SICs are *fit* to be true. It would be well if they *were* true. They *might* be true; they *may* be true; they *ought* to be true. They *must* be true! They *shall* be true! For me at least!!

Anyway, what is powering my faith ladder is the simplicity of the displayed equation in the note. It's consistency + Bayes' rule + an assumption of maximality . . . these three things alone . . . imply an already very rich convex set structure that gets quite some distance toward quantum theory. If you have some interest, you can read about some of the properties of such sets here: `http://arxiv.org/abs/0910.2750`.

Now on to Giulio's question. I think it would be quite healthy for me to try to tackle some of the things he suggested — to try to understand what quantum-like protocols we can perform with this class of theories. It's a crucial question really. If you have any suggestions or any ideas or any methods for getting at some answers, I certainly invite you to get involved.

In that regard, attached are some notes that Howard Barnum wrote up after one of our conversations where he goes some way toward translating the QBist program into the more commonly-used convex-operational language. The equations don't look so pretty in that framework (to me), but it can be done. One of these days, these notes ought to be extended and written into a proper paper. If either of you have an contributions to make, I would surely welcome that as well.

Finally, let me attach an interview I just wrote up that won't be posted on the web for a while (until the book it appears in has been published). [See "Interview with a Quantum Bayesian," `arXiv:1207.2141v1`.] In question Q10, starting on page 16, I give my opinion on axiomatic reconstruction efforts. All my thinking is really in that kind of "literary" context.

Thanks again guys.

11-02-11 *On My Way* (to W. G. Demopoulos)

I just wanted to say hi before crossing the ocean. I'm writing from JFK airport, on my way to Jerusalem for Itamar's memorial. I accompanied myself with several things on neutral monism to read along the way and there, and I just ran across a reference to a paper by you and Friedman, apparently relevant to a discussion of Russell's particular version of it all.

It would be fun to talk to you again sometime soon. I hope you're doing as well as possible at this point.

12-02-11 *Incompatibility's Allure* (to R. Schack)

Ishtiyaque Haji, *Incompatibilism's Allure: Principle Arguments for Incompatibilism*, PB, 26.95 USD.

13-02-11 *Incompatibility's Allure, 2* (to R. Schack)

Here's a nice review of the book, in case you haven't read it yet. This hotel is fantastic!

`http://metapsychology.mentalhelp.net/poc/view_doc.php?type=book&id=4752`

13-02-11 *Primary Stuff* (to A. Zeilinger)

Greetings from a jet-lagged night in Jerusalem. I am here to deliver a memorial lecture in the honor of Itamar Pitowsky.

I am happy to hear that you have offered a position to Schlosshauer. Thank you so much; I was very worried about him. Let's hope this works out to everyone's advantage.

Some small remarks on the deeper stuff in your note.

Zeilingerism 2 : *I think of Schrödinger, who in his "Meine Weltanschauung" regards himself clearly as a monist. He is an even more radical monist than any of us, because he believes that we are all part of one single all-encompassing consciousness!*

I have read this side of Schrödinger in the past and am very aware of it. (There is a discussion about it between Mermin and me in my book Coming of Age ... which, by the way, you should advertise around your group!) Just to make sure we have a common language for future discussions, though, I want to emphasize the difference between a "monist" — someone who only thinks there is only *one thing* to the world — and those people called "neutral monists". The latter should not necessarily be thought of as a species of the former. "Neutral monism" is usually meant as a doctrine that the world consists of *one kind of stuff* (to put it into contrast, for instance, with the Cartesian mind/matter distinction). For instance, Mach is sometimes called a neutral monist, but he did not take the world to consist of just one thing (as, for instance, the modern-day Everettians do with their universal wavefunction), but the whole mass of "sensations."

My hero William James, went particularly far in the direction opposite to monism (that the world consists of only one thing), and because of that, I almost think the label of "neutral monism" is particularly bad in his case. Thus I tend to call his position "neutral pluralism" (along with Ruth Anna Putnam). This comes about because of these two remarks of his.

First:

> My thesis is that if we start with the supposition that there is only one primal stuff or material in the world, a stuff of which everything is composed, and if we call that stuff 'pure experience,' then knowing can easily be explained as a particular sort of relation towards one another into which portions of pure experience may enter.

But then a bit later:

> Although for fluency's sake I myself spoke early in this article of a stuff of pure experience, I have now to say that there is no general stuff of which experience at large is made. There are as many stuffs as there are 'natures' in the things experienced. If you ask what any one bit of pure experience is made of, the answer is always the same: "It is made of that, of just what appears, of space, of intensity, of flatness, brownness, heaviness, or what not." ... Experience is only a collective name for all these sensible natures, and save for time and space (and, if you like, for 'being') there appears no universal element of which all things are made.

A very readable article on neutral monism can be found in the *Stanford Encyclopedia of Philosophy*: `http://plato.stanford.edu/entries/neutral-monism/`. I think there is one person mentioned in there that might particularly intrigue you because he builds his neutral monism on the concept of information. It is a philosopher named Kenneth Sayre (still alive possibly, but 82 years old). They have a quote of him, for instance, where he says:

> If the project ... is successful, it will have been shown not only that the concept of information provides a primitive for the analysis of both the physical and the mental, but also that states of information ... existed previously to states of mind. Since information in this sense is prior to mentality, but also implicated in all mental states, it follows that information is prior also in the ontological sense ... Success of the present project thus will show that an ontology of informational states is adequate for an explanation of the phenomena of mind, as distinct from an ontology of physical events. [And Sayre adds:] It is a reasonable conjecture that an ontology of information is similarly basic to the physical sciences ...

Zeilingerism 3: *maybe there is a point where we might have some slightly different view. I personally would see (a) our roles of being agents, and, if I understand you correctly, (b) physical systems not as something complementary or mutually exclusive. Rather, I think that we have to find a new vantage point from which we can unify both into one concept. ... So to me, in other words, when I want to unify the notions of information and reality, I do not view them as complementary aspects, but as two aspects or features or manifestations of the same entity. An association which comes to mind is the fact that we have learned that space and time are the same in a deep sense rather than complementary.*

Seeing your remark makes me think that I was probably too sloppy with my choice of the word "complementary," for it certainly does usually carry the connotation of "mutual exclusivity" for anyone who has read Bohr. But I don't think I meant to imply that aspect of Bohr's use of the word. (Of course, I don't really know what I mean yet—I am most definitely groping in the dark for the right concepts.) Thus, I think what I do want to say is something closer to an analogue (but with agent and object) of your "I want to unify the notions of information and reality, I do not view them as complementary aspects, but as two aspects or features or manifestations of the same entity."

The way James pulls it off, for instance, is to make thought and matter relational aspects of his neutral "pure experience". A given "pure experience" when considered in relation to one set of other "pure experiences" is called a thought; and when considered in relation to another set of other "pure experiences" is called matter. Moreover, he imagines every gradation in between (I think), and still other aspects in all kinds of dimensions that are neither thought nor matter.

But of course all of this is just the beginning of my thinking on these things (as expressed in my last three or four papers). I've got a long way to go before I'm going to be able to put some substance to the way I ended my paper `http://arxiv.org/abs/1003.5209` where I wrote:

> Quantum states, QBism declares, are not the stuff of the world, but quantum measurement might be. Might a one-day future Shakespeare write with honesty,
>
> > Our revels are now ended. These our actors,
> > As I foretold you, were all spirits and
> > Are melted into air, into thin air . . .
> >
> > We are such stuff as
> > quantum measurement is made on.

13-02-11 *In Town* (to M. Hemmo)

No need to call. Thank you for the suggestions.

I've had some sleep, and a bit of a walk outside. And I think I'm so taken with the tranquility here, that I'd just like to get some work done for the rest of today and tomorrow (in the compound, with only small breaks out into the neighborhood). If that's OK with you? I'm rereading Itamar's papers, preparing my talk, and finishing up my paper for you. What a place to do these things!

Yemima says that I will go to the Dead Sea Thursday. I will see you Tuesday; is that correct? Maybe by then my head will be clear enough that I'll starting more broadly about other things to do.

13-02-11 *In Israel?* (to N. Argaman)

It is true that Norsen's writings get under my skin, so the idea of having to talk about one of his papers for an hour comes with some trepidation. (See, for instance, our exchange in this panel discussion: `http://pirsa.org/09090098/`, as well as my talk here `http://pirsa.org/09090087/` whose title aims squarely at him.)

I'll make a deal with you. If you'll read Section 5, "The Essence of Bell's Theorem, QBism Style," of `http://arxiv.org/abs/1003.5209` before coming here, we can talk. (Section 5 alone is adequate; I'm not asking that you read the whole thing.) There, I try to say as clearly as I can why taking a view of quantum theory that implies the existence of undiminishing, instantaneous causal connections between distant objects carries a far greater danger epistemically than the opposing point of view ever could (i.e., the one of QBism, that quantum measurement acts create their outcomes, rather than reveal pre-existing properties). Without the idea of an autonomy at some level for all physical systems, how could physics as an analytic science ever get off the ground? That was Einstein's worry; that is mine. Giving up the idea of autonomy for physical systems is an immense can of worms, and Norsen closes his eyes to it. If one gives up on the idea of the autonomy of physical systems, how can one be so self-assured that even experimenters can be autonomous from the systems they are testing? Anyway, that's what I argue in the paper (and in the talk mentioned above).

If we have a deal, I'll ask Yemima how she has me scheduled for Tuesday, and I'll tell you what time is available for us.

14-02-11 *Corrections?* (to S. T. Flammia)

I'm up with jetlag, preparing my talk for Wednesday. Giving one in honor of Itamar Pitowsky, who died a year or two ago. Funny how little things affect you. I remembered well the closing lines of the first paper I had read of his. Seemed like an appropriate way to start the talk.

> More broadly, Theorem 6 is part of the attempt to understand the mathematical foundations of quantum mechanics. In particular, it helps to make the distinction between its physical content and mathematical artifact clear.
>
> — Itamar Pitowsky
> Closing words of J. Math. Phys. **39**, 218–228 (1998)

16-02-11 *Thursday?* (to I. Belfer)

Do you know how we're supposed to meet up tomorrow and at what time?

The Dead Sea would be nice, but it's not essential if things get in our way. I'll follow your advice. Mostly it'd be nice to talk about the history of quantum information.

Roly's Preply

> My name is Israel (Roly) Belfer. I am a PhD candidate (BIU) working under Prof. Silvan Schweber. The subject of my research is the impact of Information Theory and informational terminology on physics.
>
> I was excited to hear that you are coming to speak at the Pitowsky memorial event on the 16th (a friend of mine is the recipient of the prize). If you have the time, I would very much like to speak with you about issues of information in physics, such as the evolution of QIT (your new book — which I cannot get here yet); the different approaches to information in science; philosophy-of-physics concerns about information.
>
> If so, I would love the opportunity to buy you a cup of coffee and discuss these topics.

16-02-11 *Since October* (to D. B. L. Baker)

I looked in my files and see that I haven't written you since last October. Pretty pathetic. Where have I been since then? South Africa, DC twice, and even Texas once. And where am I now? I'm writing from a little café in the Old City part of Jerusalem, behind the wall, I think (hope) near the Jaffa gate. Tonight I put on a jacket and tie and give a memorial lecture for a physicist/philosopher/friend who died last year. But that's five hours from now; at the moment, I'm having a "premium quality" Israeli beer . . . if you can believe such a thing (at least that's what it says on its label). Between typing words I take a bite of chicken schnitzel. Basic stuff.

Yesterday, after some business, I spent three hours in the in the Israel Museum. The highlight was a little building called the "shrine of the book" where I got to see the Dead Sea scrolls. I read every word of every display and tried to let my mind float across the centuries. Funny thing, I thought, "When I get home, I've got to get the kids to watch *The Ten Commandments* again."

It's really an interesting city; I regret not coming here before. (I've passed up two opportunities before.) Tomorrow, I'm taking a drive to the Dead Sea. More than the salt in the water, I'm intrigued by it being the lowest land point on earth. (I think 400 meters below sea level.) I came to Israel 11 years ago, and at that time stayed in Haifa, with visits to Bethlehem, the Sea of Galilee, and the Golan Heights. Jerusalem is a very different area—much prettier and more meaningful to me. So far, the only thing a little spooky is watching a soldier or two walk by from time to time carrying a sub-machine gun. It was well spookier the day I sat outside a café in Stellenbosch watching a black guy getting beaten with dowels or bamboo or something. Old write-up of the incident to Kiki below.

17-02-11 *Symmetries of the Magic Measuement* (to J. D. Bekenstein)

Was it perhaps you who asked the question about symmetries at my memorial lecture for Itamar Pitowsky last night? It's just a hunch that it might have been you; if I mentally erase the mustache I see in your web pictures, it coincides a bit with what I remember of the questioner.

If none of the paragraph above makes sense to you, then I've got the wrong person! On the other hand, if it was you, and you have some interest, perhaps we could chat for a small time about these mathematical questions while I'm still in Israel Friday. It was not emphasized last night, but all of this work is a legacy of John Wheeler's imploring for an information-theoretic understanding of quantum theory. (See attached recent interview.) [See "Interview with a Quantum Bayesian," `arXiv:1207.2141v1`.]

17-02-11 *Symmetries of the Magic Measuement, 2* (to J. D. Bekenstein)

Thanks for your kind offer of time. I'm very tempted to take you up on it, even if you aren't the guy who asked the question last night — it'd be nice to tell you about this math problem I find so consternating, but at the same time holds so much promise as a new formalism for quantum theory. Besides, I've always wanted to meet you.

However, the more I think about it, the more I think I probably ought to take one last advantage of the historical sites here, to see what kind of insights they might plant in my head.

Would you like to come to the Perimeter Institute sometime to discuss information in physics? I could bring you as my guest and take care of all expenses, etc.

Attached is an article for a Canadian Physics-Today kind of magazine that explains a bit of the open math problem in its last section. [See "Quantum Bayesianism at the Perimeter," `arXiv:1003.5182`.]

I hope you'll say "yes" to the invitation. As far as I know, you've never visited us at PI.

18-02-11 *On the Difficulties of Communicating across Professional and Philosophical Lines* (to I. Belfer)

I enjoyed yesterday very much and it was a pleasure to get to know you. You strike me as having a very sound head on your shoulders, and you gave me some good food for thought.

Here are the things on communicating with Leggett and the like that I mentioned yesterday. See [this samizdat] at the letters titled "Slammed by the Closet Door" and "November 8th" starting at pages 1177 and 1181, respectively. Tony Leggett is a very kind and gentle and great man. A great scholar and a penetrating thinker all around. And I would never want to hurt his feelings. But that is not to say he will ever understand the message of the quantum — there my gamble would be against him.

The Rotman Institute that I was telling you about yesterday can be found here:

`http://www.rotman.uwo.ca/index.shtml`.

I think it would be fantastic to have you in the neighborhood for a couple of years. Write a good PhD and get yourself noticed!

18-02-11 *The Chances of a Neutral Monism* (to H. Price)

I saw your cryptic job offer a while ago (why was it announced before it was announced?). Anyway, many, many congratulations! Here's an issue: If you become the Bertrand Russell Professor of Philosophy, will you take neutral monism (even neutral pluralism) as seriously as he did?

18-02-11 *First QBist Church of the Holy Sepulchre* (to H. C. von Baeyer)

As I recall, you were never completely happy with either putting the reference SIC up in the sky or putting it in a vault at the Bureau of Standards. What would you think about putting it in a Holy Sepulchre? It's a counterfactual measurement in any case and was never truly meant to be approached? The only thing I don't like about the image of the sepulchre is that it conveys the idea of something dead, whereas the SIC is really something more like the Holy Spirit.

Greetings from *somewhere* in the Old City of Jerusalem — I have no idea where. I have the hope that it is close enough to the original Church that I'll eventually stumble across it. I've been in town since Sunday to give a memorial lecture for Itamar Pitowsky, who died a bit over a year ago. The talk turned out pretty nice, I think, or at least I got a lot of praise for it. I included many anecdotes of Itamar for his family and his nontechnical colleagues, and I tried to give enough technical details to please his spirit up in the sky (and the 15 people in the audience who might understand it).

This has been a place of thought for me, letting my mind rove back to the writing of the Dead Sea scrolls, trying to feel the fear of Masada, watching as Jesus carried the cross down these small streets ... *Actually, at the very moment I write this, a fight has erupted at the fountain near me.* ... I will return eventually from another café.

... OK, it's a few hours later now. I did find the Church of the Holy Sepulchre, and many other things beside. At the Western Wall, I told an African couple a story about the time I ran into Arnold Schwarzenegger at the Pasadena flea market. When a vendor ran after him with a pencil and pad to get an autograph, he said, "Not now, later, I'll be back."

And so, I too — I am back. I've been wanting to write you for a couple of weeks, but of course things got delayed. At least this is the best place to write you from anyway. I told you that I've been following Marcus's therapy. That's been somewhat successful. We had good philosophical discussions every day at lunch, and I've launched into a new study of "neutral monism" (I hate that term though). I spent some time reading and contemplating what I was learning from Erik Banks's book *Ernst Mach's World Elements*. Before this, I really knew very little about Mach — I was always under the impression that he was a proto- logical positivist, but he really wasn't much like that at all. A much more interesting man.

Of course, it leaves me with a million questions on Mach's ultimate influence on Pauli. For instance, I have long known about Pauli's longing for a psycho-physically neutral language for describing physics. But how much of this is due to his interactions with Jung, and how much more is due to the influence of Mach and Mach's writings upon him? I had not sufficiently appreciated before that such "neutral stuff" was what Mach was seeking/positing with his "sensations" or "world elements". Nor had I appreciated how he ultimately wanted to de-anthropocentrize the idea (or at least Banks holds forth enough quotes along these lines to make one think it's true).

Lately I have not been able to get the fake Shakespearean lines I put in the last paper off my mind:

> Quantum states, QBism declares, are not the stuff of the world, but quantum measurement might be. Might a one-day future Shakespeare write with honesty,
>
> > Our revels are now ended. These our actors,
> > As I foretold you, were all spirits and
> > Are melted into air, into thin air . . .
> >
> > We are such stuff as
> > quantum measurement is made on.

The next step in my education in this regard is to study the work of the "American New Realists," particularly Ralph Barton Perry. Perry was a student, follower, and biographer of William James (the very best one in fact), who tried to move past his master, particularly, by working to carefully de-anthropocentrize James's "pure experience". I've started the bible of the movement this week, *The New Realism: Cooperative Studies in Philosophy*, a collective work by the leading six new realists. And it'll be my main reading on the flights tomorrow . . . all three of them! (From a Clash song circa 1982. "These are your rights . . . Know your rights . . . All three of them!")

Where do we go from here? I don't know at all, really. I wrote confidently in Schlosshauer's interview:

> The first [thing to do] is to find a crisp, convincing way to pose quantum theory in such a way that it gets rid of these trouble-making quantum states in the first place. What I mean by this is, if quantum theory is actually about how to structure one's degrees of belief, it should become conceptually the clearest when written in its own native terms.

What I mean by that, you know, is to re-write the Born Rule as a statement about probabilities based on a SIC representation — i.e., the urgleichung. But does that in any way move us closer to Pauli's psycho-physically neutral language? This has been on my mind all week.

Suppose I were to get all I wanted out of the urgleichung: I.e., that its consistency (in the sense of never generating negative probabilities), the identification of priors with posteriors and vice-versa (as we have been doing in the last papers), and a maximality condition, taken with one further mild assumption (yet to be identified), completely specifies quantum-state space. Suppose I get that holy grail of quantum-state space from the urgleichung predominantly. Of course I'll be immensely pleased by the simplicity of the product. It will mean that I have isolated the essence of the formal structure of quantum theory to a single counterfactual situation. I will have pulled the system's dimensionality to a place of prominence in our understanding — it is the extent of the deviation from the law of total probability in our counterfactual scheme.

All of this is fine. But how does it help us get closer to identifying the next step? That's what I'm not seeing at the moment. Maybe it's just too distant into the future, and we've got so much to do before then that it's not worth thinking about this *yet*. But what better place to try to see farther than one normally can than in a short visit to the Holy Land? (How much damage can be done in a short visit?)

Behind quantum mechanics is the idea that "we could do otherwise" in any experimental situation. *If* all the above is true, through Kochen-Specker type arguments on the final product, we know that in any experimental situation the world can, in return, do otherwise. I.e., there is no hidden-variable model for our urgleichung considerations. "We can do otherwise." "The world can do otherwise." Is that the extent of the psychophysical neutral ground Pauli dreamed for? There's got to be something much bigger, much deeper than this!

And it must play off the particular form of the urgleichung, if it's going to play off anything. But how so?

How so? How so?? How so?!?! I don't want to wait another 10 years for it to come to me. But I am as blank at the end of this note as I was at the beginning.

Yesterday, I went to Masada with a nice grad student, Roly Belfer, who's doing his PhD with Sam Schweber. His thesis will be on (roughly) "information as a style of thinking within physics." I very much enjoyed his company. A cute thing was when he was praising your book on information, I revealed, "Yes I know the book; we are close friends." You should have seen his eyes bug out in only the way the young ones do when they find out something interesting. It was as if he had met someone who had met a demi-god.

We brought up the possibility of your visiting PI in our last conversation. What do you think? It could be really good for giving us re-orientation. (Marcus needs it as much as I do!) Marcus will be in Waterloo March 17 to April 9. And I will be back from the APS March meeting starting on the 27th. I shouldn't be traveling again until April 28th. It'd be nice to get the triumvirate together again; we haven't held congress in a while and, no doubt, our philosophies are lacking for it.

Three prayers from the Holy Land!

19-02-11 *Alas!* (to A. Wilce)

Wilce-ism 10: *I hope your talk in Jerusalem went well – I'll be interested to know what sort of reactions you provoked.*

On a less happy note, in trying to fix what seemed a minor error in the manuscript I recently sent you, I found the entire thing unraveling. In fact, it's a tissue of errors, all stemming from one horrifyingly elementary mistake (the parameter "s" in Lemma 3 is generally negative).

I may yet be able to salvage something from this wreck, but for now, please accept my sincere apologies for troubling you with such a mess! And please pass along both this message, and my apologies, to Matthew.

I'm sorry to hear about this. I'll keep my fingers crossed that you can salvage a proof, and I'll make sure to buy you an extra beer in Dallas.

The talk went quite well. The way I wrote H. C. von Baeyer about it:

> I included many anecdotes of Itamar for his family and his nontechnical colleagues, and I tried to give enough technical details to please his spirit up in the sky (and the 15 people in the audience who might understand it).

It turned out that Hilary Putnam was not in the audience. I looked out across the room not knowing that, as I started to tell of the party where I last saw Itamar. I asked, "Is Hilary here?," mentioning that he too had been at the party. When I found out that he wasn't, I decided to report the conversation I had had with him that night. Hilary said, "Could you hold this for a second," handing me his cell phone. He dug quickly into his wallet for some piece of paper, and then said "thank you" as he took the cell phone back. I nodded.

In depth conversation with the man who sweepingly called *all* information-oriented reconstructions of quantum theory "instrumentalism with a post-modern sauce." I'll probably never recover from the trauma of that weekend: I really lost most of the intellectual respect I had for him. In any case, you can now tell your kids and grandkids, "Chris, bless his soul, respected me more than Hilary Putnam … even after my 4.5 axioms unraveled!"

20-02-11 *Monism Is the Devil* (to H. C. von Baeyer)

Good morning, this time from somewhere in my kitchen. The world is a kind of blooming, buzzing confusion this morning; everything is kind of shiny out of the sides of my eyes. I didn't get back to Waterloo until 2:30 this morning — 31 hours of travel total! It was a tortured route to begin with (just to get American Airlines miles), but then all the delays …

I'm sorry to have caused you confusion. That damned term—"neutral monism"—is trouble, and your letter, along with an earlier one from Anton, convinces me to banish it forever and never use it again! Hereafter "neutral monism" shall be a dead term for me. I should have explained to you like I explained to Anton after I saw his own confusion.

Here follows an excerpt from the note to Anton. … Actually, let me just copy in the whole note below. [See 13-02-11 note "Primary Stuff" to A. Zeilinger.] The hatched parts, of course, correspond to quotes from his earlier note to me. In a nutshell the trouble is that "monism" is the doctrine that the world is "one thing," whereas "neutral monism" is associated the idea that the world is composed of "a stuff of one kind of character" (even though it may be plural to the bones). See the quotes from James below to see how that fits in with his pluralism. Ruth Anna Putnam calls it "neutral pluralism," but I don't like that term so much either. It remains a bit lifeless in comparison to the heavy duty it is meant to be called to. But if "neutral pluralism" is lifeless already, "neutral monism" is surely dead, dead as doornail.

Trying to find the appropriate term has word for whatever is going on here has been a real thorn in my side, even before this nail in the grave of yours. That was the cause of my joking note with the word QBoom. On a more serious note, Marcus has toyed with urspracht … but I don't think I like that one either (or at least he hasn't convinced me yet).

Let me know if all this relieves the confusion I induced. If my family will let me go, I'd like to write you a bit more on the subject. But now they've kicked me off the table so they could set it for breakfast.

What's your physical location now?

20-02-11 *Urspracht* (to H. C. von Baeyer and D. M. Appleby)

From our emails this morning.

Chris said: "Trying to find the appropriate term for whatever is going on here has been a real thorn in my side, even before this nail in the grave of yours. That was the cause of my joking note with the word QBoom. On a more serious note, Marcus has toyed with urspracht … but I don't think I like that one either (or at least he hasn't convinced me yet)."

Hans said: "The word urspracht is gibberish. What do you and Marcus mean?"

Well, if it is gibberish, that might be a partial selling point for it (as you'll see in Marcus's last paragraph, which is a point I definitely agree with, about "keeping the bastards guessing"):

> But I think on reflection that the best option might be to avoid presenting any kind of fixed target for the philosophical labeling guns. The trouble with the two above suggestions is that they might lead to us being labeled as "mystics". And I no more want Hilary Putnam saying that we are just a pair of mystics, than I want him saying we are just a pair of empiricists. I want to keep the b***** guessing. Whilst at the same time being totally clear, and totally explicit.

But anyway, below is Marcus's original note on the sort of thing he was after, at least at that time. (Which, there is probably no need to say, may not be exactly the same thing that I'm trying to get after. But what I am looking for may have a lot of elements of what he is after too—I'm not sure—it's all so much confusion at the moment.)

21-02-11 *Einstein on Religion; Pragmatism on Spinoza* (to Å. Ericsson)

I greatly enjoyed reading through these quotes. My guess is you won't as I did; but still I thought I'd make you aware of them: `http://www.stephenjaygould.org/ctrl/quotes_einstein.html`.

A lot of Einstein's arguments would be my own. On the other hand, Spinoza's worldview in its details is certainly foreign to me. I like the way Ralph Barton Perry put it as the antithesis of pragmatism:

> The perfect antithesis to pragmatism is Spinoza, and it is the perpetuation of Spinozism in objective and absolute idealism that is the real object of the pragmatist attack. Absolutism is other-worldly, contrary to appearances; pragmatism [is] mundane, empirical. Absolutism is mathematical and dialectical in method, establishing ultimate truths with demonstrable certainty; pragmatism is suspicious of all short-cut arguments, and holds philosophy to be no exception to the rule that all hypotheses are answerable to experience. Absolutism is monistic, deterministic, quietistic; pragmatism is pluralistic, indeterministic, melioristic. That which absolutism holds to be most significant, namely, the logical unity of the world, is for pragmatism a negligible abstraction. That which for absolutism is mere appearance — the world of space and time, the interaction of man and nature, and of man and man, is for pragmatism the quintessence of reality. The one is the philosophy of eternity, the other the philosophy of time.

22-02-11 *Flesh and Blood* (to R. W. Spekkens)

Here is that line I was proud of:

> What is the source [of truth-value assignments]? When it comes to formal logic, one is tempted to think of it as the facts of the world. The facts of the world set truth values. But it is not the world that is using the calculus of formal logic for any real-world problem (like the ones encountered by practicing physicists). The "source" is rather a finite subscriber to the service, one with limited abilities and resources; the source is always one of us—flesh and blood and fallible through and through—the kind of thing IBM Corporation is taking its first baby steps toward with its *Jeopardy!*-playing

supercomputer Watson. The source of truth values in any application of logic are our *guesses*. Thus, it would be better to be completely honest with ourselves: Applications of formal logic get their truth values from an *agent*, pencil and paper in hand, playing with logic tables not so differently than crossword puzzles. The facts of the world only later let the agent know whether his guesses were acceptable or unacceptable judgments.

I agree that I should read more Dennett (I have read some) ... I know there's insight to be gained there. But I read a little piece in Perry yesterday about how Spinoza is the "perfect antithesis" to pragmatism (I'll copy it below), and I think it quite captures my pre-conceived notion of Dennett, i.e., that he is my antithesis. [See 21-02-11 note titled "Einstein on Religion; Pragmatism on Spinoza" to Å. Ericsson.] I'm aware that this is what is providing the friction to my reading.

22-02-11 *Solvay Conferences* (to I. Belfer)

Thanks for the Galison paper; it looks like it is going to be a lot of fun.

The Jammer paper I was referring to was: Max Jammer, "The EPR Problem In Its Historical Development," in *Symposium on the Foundations of Modern Physics: 50 Years of the Einstein-Podolsky-Rosen Gedankenexperiment*, edited by P. Lahti and P. Mittelstaedt (World Scientific, Singapore, 1985), pp. 129–149.

Jammer writes,

> ... what Einstein had in mind is confirmed by a letter which Ehrenfest wrote to Bohr on July 9, 1931. As Ehrenfest reports, Einstein uses the photon-box no longer to disprove the uncertainty relation but "for a totally different purpose." For the machine, which Einstein constructs, emits a projectile; well after this projectile has left, a questioner can ask the machinist, by free choice, to predict by examining the machine alone either what value a quantity A or what value an even conjugate quantity B would have if measured on the projectile. "The interesting point," continued Ehrenfest, "is that the projectile, while flying around isolated on its own, must be able of satisfying totally different non-commutative predictions without knowing as yet which of these predictions will be made ..."

The contrary story comes from Don Howard's translation of the Ehrenfest letter:

`http://www.nd.edu/~dhoward1/Early%20History%20of%20Entanglement/sld026.html`.

Don has a more extended discussion of this point in one of his papers but I can't find it in my files at the moment. I think you should be able to find it on his website.

23-02-11 *The Very Improbable Tamworth Iron Works* (to H. C. von Baeyer)

A most improbable thing happened to me yesterday, and I've been racing with adrenaline in my veins ever since. It's a long story, which I will tell below ...

... But first an introduction from Linda Simon's book *Genuine Reality*:

> In September [1886], James set out on a real estate search that ended at the base of Mount Chocorua, in a town called, infelicitously according to James, Tamworth Iron

> Works. The "small farm" that interested him consisted of seventy-five acres, most of it woods, the rest hayfields. The shingled, green-trimmed farmhouse, built in the year James was born, needed considerable work, but it was large enough—fourteen rooms, eleven with doors that opened to the outside—included a big barn, and looked out at Chocorua Lake and the mountain. "It is only 4 hours from Boston by rail and 1 hour's drive from the station," William told Henry. "Few neighbors, but good ones; hotel a mile off. If this is a dream, let me, at least indulge it a week or so longer!"

The very improbable thing that happened to me yesterday was that I set out to make arrangements for the MIT meeting May 3rd and 4th, and I got distracted by the hotel address. "Is that the street William James lived on?" So I did a Google search on "william james", "home", and "cambridge". "Nope, he lived on Irving Street; I should have known that!" But one of the other things that came up was a YouTube video of the house. Curiosity got me, and I watched it. Kind of creepy really; just someone standing outside with his video camera. But, you know, curiosity sometimes doesn't know what's best for it. I thought, "I wonder if the same guy took a video of the Chocorua house?" and so changed "cambridge" to "chocorua" in the Google search. He didn't, it turned out, but I did find a video by a real estate company instead!

What a place it turned out to be. 4,387 square feet, 44 acres, barn, swimming pool, and woods, woods, woods. Have a look yourself: [...] If you click on the little down arrow at the address, a box will open with details on the house. And if you go to this website, [...] you can get a satellite view of the property, right next to state forest and national conservation ares. Zoom out enough, and you'll find the nearby lake. And if you go to this wiki link `http://en.wikipedia.org/wiki/Chocorua,_New_Hampshire` you'll see it described as "among the most beautiful lakes in the White Mountains." Half hour drive from good skiing (lots of skiing in fact), and an hour and a half drive from the seashore, similarly to Portland, etc.

Their asking price had been $895,000, but it's off the market. Curiosity kicked in again, and I called the real estate company. Why off market? The agent I talked to said that she would talk to her colleague who had listed it and get back to me. She said one possibility was the owners simply changed their minds about selling. Another was that when Winter encroached and it had not sold yet, maybe they took it off the market till Spring when the weather would be better.

Anyway, all of that was enough to spur all kinds of crazy thoughts. My imagination has been running wild all night. Ever since Kiki and I uncorked a bottle of wine in 2001 and sat down dreaming over Peter Robertson's book of the early years of the Niels Bohr Institute (including floor plans of the place), we've had a fantasy of a little institute where big things might happen. And wouldn't you know it, the details of the fantasy were precisely this: An old farmhouse somewhere in New England, with some forested land to build a few bungalows and a small conference center on. Kiki would be the caretaker and social director; I would manage the science and philosophy and, somehow, someway, bring the money in.

I remember Dr. Ruth Westheimer in the 1980s saying, "Fantasy is OK, even encouraged, as long as it's not actualized." The trouble now is that this *fact* hits so close to the *fantasy*! I had never imagined that that much of the James land was still intact. 44 acres in an idyllic setting! And surely of all places on earth, this one is the very spiritual home of QBism.

I've just been overwhelmed emotionally. How, how, how could I make it happen? Or at least buy the damned thing for myself and the family, until somewhere down the road a real institute might materialize? Or even just keep the thing off the market for a few years ... so that some "investor" doesn't get the idea of making it a two million dollar home before I can get to it?

Easy enough, right? I just sell this house, and buy that one. Yeah, right! The trouble with a house is that it ought to be close to one's source of income! And what income would I have without the Perimeter Institute.

Unfortunately, even my craziest ideas aren't crazy enough. For instance, I had a little fantasy that I would pay my $200K of it for my in-laws (to sweeten the pot); they sell their house outside Munich and move back to New Hampshire, with the agreement that we eventually inherit it from them, instead of their German house. (My father-in-law had started as an assistant professor of history at UNH in Durham, before joining the business world; they still have lots of old friends in Durham.) But two things count against the idea: 1) I expect them to live a long, long time, and 2) even though my mother-in-law has talked of moving back to the States from time to time, they haven't precisely because my father-in-law loves Germany too much.

Of course, it could be that the house will never come back on market anyway. It is curious the date the house went on market: 27 August 2010. The very day after the 100th anniversary of William James's death. (He had died in the house, by the way.) Two weeks before that, there had been a symposium in Chocorua, with house tours, etc. Thus it has struck me that it could be that the owners put it on market because of the enthusiastic reactions they were getting from the participants, and they thought they might feel out how much money they could get. Maybe they learned that they couldn't get nearly so much in that area; maybe they learned that they could get a lot more if they play their cards right and market it appropriately.

Anyway, dreaming, dreaming. "If this is a dream, let me, at least indulge it a week or so longer!"

There, I had to get that off my chest! The question now is do you have any ideas? Do you know of any philanthropists who might be convinced to help finance an institute on pragmatism and the quantum? Do you know of any physics or philosophy departments near Chocorua that it would be fruitful to inquire into? (Perimeter tenure coming? Who would care about Perimeter who could live and think in William James's home?!) Do you have any wilder ideas still? A thought on how to make a QBist commune viable?

But dreaming, dreaming … Now with too much adrenaline and *too much coffee*!!

Oh, long note on "neutral stuff in the pluriverse" coming soonish; it's been percolating in my head since the weekend. (We need a better name than "neutral stuff"!)

23-02-11 *Whitehead on James, 2* (to A. Hamma)

It was nice to learn of your philosophical inclinations the other day. I don't have *Process and Reality* in front of me to find the lines where Whitehead said that his effort was to extend and make precise James and Bergson. But below are some quotes I sent to Appleby on Whitehead's regard for James. [See 21-09-10 note titled "Whitehead on James" to D. M. Appleby.]

Attached also is a little interview I wrote up recently. In the answers to Q2 and Q10, I made the point that you seemed to like.

Let's indeed talk sometime. I'd love to learn more about Whitehead's thought.

24-02-11 *Whitehead on James, 3* (to A. Hamma)

No, I didn't know that. Bryce had said it when I was an undergraduate taking a class on Lagrangean mechanics from him. It was just something that caught my ear then. If you find the precise Whitehead quote, please send it my way. I enjoy collecting such things.

Alioscia's Preply

Thank you for sharing the interview. I am reading it with great interest.

By the way, do you know that what Bryce DeWitt said about mathematics is itself a quote (maybe involuntary) from Whitehead? Whitehead said the same thing in the introduction to algebra, if I recall. It is interesting that also Hannah Arendt shares a similar opinion. It would be great to find some time to talk about this and other philosophical topics!

Alioscia's Reply

This is the quote I promised. It is in *Introduction to Mathematics*, around page 60 (depending on the editions). Whitehead is talking about the importance of symbolism in mathematics. He is showing an example in algebra where identities are very easy to state symbolically while they are difficult to explain in words. Then he says:

> This example shows that, by the aid of symbolism, we can make transitions in reasoning almost mechanically by the eye, which otherwise would call into play the higher faculties of the brain.
>
> It is a profoundly erroneous truism, repeated by all copy-books and by eminent people when they are making speeches, that we should cultivate the habit of thinking of what we are doing. The precise opposite is the case. Civilization advances by extending the number of important operations which we can perform without thinking about them. Operations of thought are like cavalry charges in a battle — they are strictly limited in number, they require fresh horses, and must only be made at decisive moments.

24-02-11 *Whitehead on James, 4* (to A. Hamma)

And here are the lines from the preface of *Process and Reality*. My false memory made it much more detailed than it really was.

> Among the contemporary schools of thought, my obligations to the English and American Realists are obvious. In this connection, I should like especially to mention professor T. P. Nunn, of the University of London. His anticipations, in the *Proceedings of the Aristotelian Society*, of some of the doctrines of recent Realism, do not appear to be sufficiently well known.
>
> I am also greatly indebted to Bergson, William James, and John Dewey. One of my preoccupations has been to rescue their type of thought from the charge of anti-intellectualism, which rightly or wrongly has been associated with it. . . .

It's good to know one's intellectual grandfathers. As a coincidence, I had only recently started studying the "American New Realists" (to which Whitehead is undoubtedly referring to), particularly (at the moment) the writings of Ralph Barton Perry.

24-02-11 *The Manic and the Depressive* (to H. C. von Baeyer)

If Gleick could get away with *The Information* for the title of his book, I figure I can get away with using inappropriate definite articles in my own titles. (This is not stroking: I don't like the title. It could be that when I read the book, I will find it to be very natural and suggestive for the work, but at the moment, to my eye, it sticks out like a sore toe.)

Anyway, to THE subject. Oh, a soberer mood started to set in last night while Kiki and I looked over the house plans and details, and I started—as I knew I would eventually—to admit defeat to myself. With honesty, I am no position to see this kind of thing through at the moment.

Any institute would have to be three, four, five, six years down the road. It would take so much effort to build the idea, the support, the funding, the logistical infrastructure. The real concern for me (the one that put me into the manic panic) is that the property be secured before some feckless investor or vacation-homer buy it and do more damage.

You are right that the essential idea is James's aura. That land and house and barn that he purchased for $750 is the geographical center of his aura. He died in the house; it was where he wanted to die. If ghosts live, as James had so hoped to gain evidence for with his dozens of interviews with mediums and his presidency of the American Society for Psychical Research, then his ghost lives in that house. The left horn of my own dilemma is that I feel I am possibly the only person alive who could channel that ghost to the good of physics. It may be lunatic, but it is a responsibility I feel. But the sharper right horn remains: I am in no position to buy that property on the fly like this.

Your question about the architecture is not lost on me, and certainly not Kiki. We have pored over the photos and the listing, looking for clues of this and that. There are certainly places where we can see that the ceiling has been dropped (kitchen being the most obvious example, but also the red-walled foyer). On the other hand, it looks that quite some of the original does remain. Only direct eyesight, and Kiki's expertise, with a physical visit will give me a truly accurate picture though.

You might have a look yourself. The realtor posted the old listing for me: [...] The little camera at the top of the webpage (for viewing photos) appears to be redundant—there are no more photos than are on the first page—but if you click on the paper clip, you'll find house plans and a survey of the farm. Here's a sketch of the outside from 1902 for some comparison: `http://www.uky.edu/~eushe2/Pajares/JamesChocorua.html`. And this photo gives some sense of how the stone walls and hay field have stayed the same since James and Royce gave a similar pose in 1903:

`http://www.flickr.com/photos/wjsymposium/5269017904/in/set-72157625617564916/`.

On the other hand, the James house is clearly not preserved as accurately as this other (though much younger) house in the area: [...] The wood trim really speaks for itself. (And—though it pierces my heart—Kiki has made it clear to me that she finds this house much more interesting than James's own.)

One thing that becomes clear by comparing the two listings (and some others), is that the owners of the James home know that they are selling his ghost more than the house. The +$270,000 / -1274 sq ft differences say a lot. (But there is a -33 acre difference too, and maybe I should give that more credit.)

I also know by direct experience that your remark, "starting with a building often ends in disappointment," is accurate. But then I remind myself of your other remark that the issue is an aura, not a building. Maybe I am particularly sensitive to this (or particularly illusioned by this) because it all comes just after my visit to Jerusalem's Old City. In the end, it is not as much the building as the ghost. Think of how holy the Western Wall is, the mere remnant of a temple though it be.

Woe is me. Kiki and I will certainly go see the thing if it is still up for grabs by the time the March Meeting comes and goes. But it'll almost surely be a painful act of self-flagellation.

The only Rutherfordity I know is, "To any young man who utters the word 'universe' in my laboratory, I ask him to pack his bags and leave." (Or something along those lines.)

On your suggestion about the James Society, one would think that they would have already been in action, given their symposium in Chocorua last year. Delving further into the documentation the realtor made available, I note that the owners actually put the house on the market three days before they gave the guided tour of it. Surely the appropriate people were all abuzz with the news, and the sellers wanted it that way.

von Baeyerism 66 : *The place seems to be halfway on a straight line between my brother-in-law in Kennebunk, ME, and my cousin in Weybridge VT. A lovely place.*

You never thought about moving closer to your family, did you?

25-02-11 *Home and Home* (to W. G. Demopoulos)

I'm glad to hear that you're back home!! It's much earlier than I expected actually. I wish you the best possible recovery.

Let me give you some light reading for your iPad; maybe some of it will make you chuckle. (My guess is you're spending time in bed mostly?) The first attachment below answers your question about my talk in Jerusalem. The next two (of many more than that that I won't bore you with) detail a bit of my crazy quest to find some way to buy William James's Chocorua, New Hampshire home. If you have any ideas, feel free to suggest! [See 23-02-11 and 24-02-11 notes "The Very Improbable Tamworth Iron Works" and "The Manic and the Depressive" to H. C. von Baeyer.]

Somewhere in my reading in Israel I made a note on "effects" (either from Schiller or Perry or, perhaps, the new realist consortium) that I wanted to send to you. I will try to dig it up tomorrow. (Unfortunately my wife is forcing me to ski this morning . . .)

25-02-11 *The Biggest and Best* (to I. Belfer)

Belferism 1 : *Can you think of indispensable highlights of the quantum-information era (like your statement about the inauguration of QIT as a real field after 1993)?*

Off the top of my head:

1973: Alexander Holevo proves his famous bound that limits the information that can be retrieved from a quantum system

1979: Holevo points out that the classical capacity of a quantum channel is nonadditive; Holevo's discovery was essentially unrecognized, until it was rediscovered by Asher Peres and Bill Wootters in 1991, when it became the problem that motivated quantum teleportation later in 1993

1982: Richard Feynman's paper "Simulating Physics with Computers" (in my opinion still one of the speculations closest to being correct on what powers quantum computation)

1982: Wootters and Zurek, and independently Dieks, point out the quantum no cloning theorem

1984: Bennett and Brassard's first quantum key distribution protocol

1985: David Deutsch's paper "Quantum theory, the Church-Turing principle and the universal quantum computer" (first example of a non-quantum-simulation problem that gets a speed up from quantum equipment)

1992: Ben Schumacher invents the idea of a qubit on a drive to the Columbus, OH airport, in conversation with Bill Wootters; finally appears first in a 1995 paper (with a 1993 submission date), but had long been a common term in the community by then

1993: Quantum Teleportation

1994: Peter Shor's factoring algorithm (many would mark the beginning of the field here; but I stick with 1993 as being deeper conceptually)

1995: Peter Shor and independently Andrew Steane discover the ideas of quantum error correction and fault tolerance (enabling the idea that quantum computers can actually be built)

1995: Cirac and Zoller's paper "Quantum Computations with Cold Trapped Ions" (the first serious implementation for quantum computation ever proposed)

2000: Robert Raussendorf and Hans Briegel's paper "Quantum Computing via Measurements Only"

2001: Fuchs's paper "Quantum Foundations in the Light of Quantum Information" points out the true path to progress in the quantum foundations debate! ☺

At least that's what comes to mind as I have my first cups of coffee this morning.

26-02-11 *Feelings of Guilt* (to the QBies)

PPS. I refined the definitions of QBoom and QBlooey (with no off color jokes this time either):

- **QBoom** – cf. *kaboom*; the sought-for deanthropocentrized distillate of quantum measurement that QBism imagines powering the world. William James called it "pure experience," where "new being comes in local spots and patches which add themselves or stay away at random, independently of the rest." John Wheeler asked, "Is the entirety of existence, rather than built on particles or fields or multidimensional geometry, built on billions upon billions of elementary quantum phenomena, those elementary acts of 'observer-participancy'? ... Is what took place at the big bang the consequence of billions upon billions of these elementary 'acts of observer-participancy'?" In place of a Big Bang, the QBist wonders whether it might not be myriads and myriads of little QBooms!

- **QBlooey** – cf. *kablooey*; a QBist slur on the usual conception of the Big Bang, where the universe had its one and only creative moment at the very beginning.

27-02-11 *Home and Home, 2* (to W. G. Demopoulos)

By the way, not to worry, the version of the story I told at my talk, was a lighthearted, gentle version targeted to make people laugh. Everything said with a smile. I didn't say all the business about the postmodern sauce and his newfound Bohmianism, etc.

You are correct that the instrumentalism remark was confined to the conference. Sorry to conflate two stories into one in the email I forwarded to you. I wasn't bothered by the charge of instrumentalism; it was the "postmodern sauce" that got under my skin. It's a general symptom of philosophers that they ignore that there are NEW equations and theorems behind this interpretative effort. And to hear the charge of it being a "postmodern sauce" just went too far.

But now you catch me off guard yourself:

Demopoulosism 46: *I'd be very surprised if you can get anything out of neutral monism but would love to talk with you about it; in my view it's not that different from what underlies "flash ontologies." What is distinctive about the BDP point of view is its eschewal of ontology, its embrace of a moderate instrumentalism which, however, is* not *anti-realist.*

Flash ontologies?!?!?!? Not at all!!!! You should expect something much more subtle from me than that by this point in our relationship! I can see I've got my work cut out for me to try to explain myself (more precisely explain my desires). Alright, I take the challenge. But you'll have to wait some time for me to compose myself.

Stay away from germs for the next 83 days!

Bill's Reply

> Looking forward to hearing more from you on neutral monism.
>
> I don't think NM's connection with Flash Ontologies is obvious, and I may be very mistaken about this. But the development of NM in *Analysis of Matter* by Russell is very suggestive of a connection. I appreciate that you don't care for Russell and that you're more interested in James's version. But R's development tries hard to spell out James's metaphors. Let me know what you come up with.
>
> As for Hilary's remark about "PoMo sauce," I'm not sure what he had in mind. Perhaps the notion that instrumentalism can be derived from a more general relativism? I think this is not entirely alien to your view of it and its connection with personalism, but I say this only to insert a further sense of urgency in you to write further on this stuff (pardon the pun)!

27-02-11 *Pragmatism in Sweden* (to Å. Ericsson)

... a gift for Sunday morning!

[See: Sami Pihlström, "Nordic Pragmatism," Euro. J. Pragma. and Amer. Phil. **2**(1); online at `http://lnx.journalofpragmatism.eu/`.]

27-02-11 *SAAP Membership* (to W. T. Myers)

How I wish I could attend your annual meeting, now that I've discovered the society. But March 13, I head to Tulane U to give their Clifford lectures this year, and then immediately after that it's to Dallas for the big American Physical Society meeting—I organized the part for the Topical Group on Quantum Information this year (being the chair), and we're having over 400 talks! The point is, though in principle I could get to the SAAP meeting, it hits at an awfully bad time for me. I'll try my best to be at next year's meeting.

Seeing the link to your webpage below, I got snoopy, and I'm glad I did. It's good to meet another University of Texas alumnus. UT Austin is without doubt my spiritual home. (I tell some of the story in my answer to Question 1 in the interview I sent you yesterday.)

I'm also quite intrigued by your research. Where I am headed with my own is to develop a kind of "process physics" behind quantum measurement theory, though I haven't been so much in the habit of calling it that. (I do so for you.) You can see some of the yet-very-vague thoughts I am having at the end of this recent paper of mine `http://arxiv.org/abs/1003.5209` and also at the end of the interview. They will certainly be beefed up one day or another.

I would be much appreciative if you could send me a copy of your PhD dissertation. From the abstract you post, it seems to be just what the doctor ordered. An electronic version of it would be just fine.

27-02-11 *Lenovo Machine* (to C. M. Caves)

Random things now.

1) I found these words in some old correspondence from you a couple days ago, and I really liked the way you put it:

> [QBism takes] a three-pronged approach to subjectivity and objectivity: (i) quantum states and probabilities are wholly subjective; (ii) system attributes are wholly objective; and (iii) measurement outcomes are where the rubber meets the road, i.e., where subjective and objective meet to produce something that is not under the control of the agent, but is also not out there in the world.

Very eloquent.

2) I really wish you were more a fan of William James and old-school pragmatism. I discovered last week that his farm in Chocorua, NH will be on the market in the Spring (it was on the market in the Fall, and taken off for the Winter). It's the house in which James died. The 4387 sq ft house is relatively historically intact (though a lot of updates) and barn still there, but with swimming pool now in addition. 44 acres of land, 39 of it thick forest, and beautiful hay fields and rock walls still there. Quiet secluded place. Perfect for a QBistic Institute!! (Imagine carving 5 little bungalows into the forest, a lecture room, etc.) 20 minutes from good skiing. 1.5 hours to Portland, ME and Portsmouth, NH. $895,000 asking … but probably overpriced by $100K. I've been wracking my brain trying to figure out a way I could secure the place till said institute could become a reality. Know any philanthropists with deep pockets for pragmatism or QBism or both? Seriously; I'm not joking.

Glad to hear you're back in Oz. You always seem happiest there.

28-02-11 *Home and Home, 3* (to W. G. Demopoulos)

Demopoulosism 47: *I think this is not entirely alien to your view of it and its connection with personalism, but I say this only to insert a further sense of urgency in you to write further on this stuff (pardon the pun)!*

Sadly, I didn't catch the pun! What is it?

Demopoulosism 48: *Russell, and I thought James as well, call the neutral constituents of the world which are neither mental nor physical, "stuff."*

28-02-11 *xQIT Meeting* (to MIT)

Title and abstract below.

> Title: Charting the Shape of Quantum State Space
>
> Abstract: Physicists have become accustomed to the idea that a theory's content is always most transparent when written in coordinate-free language. Sometimes though

the choice of a good coordinate system can be quite useful for settling deep conceptual issues. This is particularly so for an information-oriented or Bayesian approach to quantum foundations: One good coordinate system may be worth more than a hundred blue-in-the-face arguments. This talk will motivate and chronicle the search for one such class of coordinate systems for finite dimensional operator spaces, the so-called Symmetric Informationally Complete (SIC, pronounced "seek") measurements. The desired class will take little more than five minutes to define, but the quest to construct these objects will carry us down a 35 year journey, with the most frenzied activity only recently. Beyond this, we will turn the tables and discuss how one might hope to get the formal content of quantum mechanics out of the very existence of such a coordinate system. It has to do with seeing the Born Rule as a "tiny" modification to the Bayesian Law of Total Probability.

28-02-11 *Postmodern Smoke* (to C. M. Caves)

Cavesism 86: *As for pragmatism, here's my problem. Any approach that doesn't recognize that there is a hierarchy of concepts and truths—and not just a set of utilities—has problems, in my view. Clearly, the truths of the human experience are special to us; they don't even apply to other life on earth. The truths of life that has evolved on earth are special to earth; they wouldn't apply generally to life on other planets. The truths of physics might apply to the whole Universe. And I use truths here advisedly, willing to discuss the right word and concept for what I'm talking about.*

Last July at QCMC I got the clear impression that you don't have any ability to assert the fact or truth of climate change, and if that's where pragmatism takes you, well, I ain't going there. It could just be that you're too wrapped up in your professional and personal concerns to have much of a position on climate change, but I got the impression that even if you did have a position, you wouldn't be willing to assert it in the face of the deniers. And that just doesn't cut it, in my view.

I wish I had never given you that Rorty book. I actually tried to divert your thought away from it in advance, by writing "old-school pragmatism" (to take your mind back to the metaphysical club days) but that was far too small a fin in the water if it was meaningful to you at all. Sorry, I didn't mean to rile you.

Below is a little bit I wrote on what I think is the issue at hand here (it comes from Max's interview).

Of course, I believe global warming is a clear and present danger. Just ask Kiki about my own rants. And I am appalled that much of the rest of the world does not acknowledge it (certainly not America's politicians). The world is very likely at a turning point, and its fate will be decided by whether we do something about it.

The issue will be decided at the point "where the rubber meets the road" as you nicely put it. (I see no difference between the quantum and all the rest of life.) We act because of our beliefs, and nature grants passage of the belief *or not* by its power.

If I understand you correctly, the gulf between us might be this. I think you would like to say of some beliefs, they are correct, right here and right now, before any action has been made based upon them (and regardless of whether any action will ever be based on them at all). The truth of an idea is a timeless, tenseless thing on such a conception. Whereas I wish to reserve "right" and "wrong" to the sense of "only time will tell." That is, "right" and "wrong" are always bestowed (to a belief, proposition, sentence, policy, quantum state assignment) after the *fact*. Like that great scene in one of the *Lord of the Rings* movies, where Gandalf says commandingly to the balrog, "You shall not pass!" The universe made a decision at just that point, I would say, not before.

Question 6: Quantum probabilities: subjective or objective?

"Subjective" is such a frightening word. All our lives we are taught that science strives for objectivity. Science is not a game of opinions, we are told. That diamond is harder than calcite is no one's *opinion*! Mr. Mohs identified such a fact once, and it has been on the books ever since.

In much the same way, quantum theory has been on the books since 1925, and it doesn't appear that it will be leaving any time soon. That isn't lessened in any way by being honest of quantum theory's *subject matter*: That, on the QBist view, it is purely a calculus for checking the consistency of one's personal probabilities. If by subjective probabilities one means probabilities that find their only source in the agent who has assigned them, then, yes, quantum probabilities are subjective probabilities. They represent an agent's attempt to quantify his beliefs to the extent he can articulate them.

Why should this role for quantum theory—that it is a calculus in the service of improving subjective degrees of belief—be a frightening one? I don't know, but a revulsion or fear does seem to be the reaction of many if not most upon hearing it. It is as if it is a demotion or a slap in the face of this once grand and majestic theory. Of course QBism thinks just the opposite: For the QBist, the lesson that the structure of quantum theory calls out to be interpreted in *only* this way is that the world is an unimaginably rich one in comparison to the reductionist dream. It says that the world has excitement, risk, and adventure at its very core.

Perhaps the source of the fear is like I was taught of "that marijuana" in my little Texas town: Use it once, and it will be the first step in an unstoppable slide to harder drugs. If quantum probabilities are once accepted as subjective, somewhere down the line Mr. Mohs' scale will have to disappear in a great puff of postmodern smoke. There will be no way to enforce a distinction between fact and fiction, and the world will be anything our silly imaginations make up for it!

The first symptom is already there in a much more limited question: If quantum probabilities are subjective, why would an agent not make them up to be anything he wants? Why not pull them from thin air? The defense to this little question is the same as the defense against the "inevitable" postmodern horrors. My colleague Marcus Appleby put his finger on the issue sharply when he once said, "You know, it is *really hard* to believe something you don't actually believe!" Why would one assign arbitrary probabilities—ones that have nothing to do with one's previous thoughts and experiences—if the whole point of the calculus is to make the best decisions one can? The issue is as simple as that.

28-02-11 *On the Lighter Side* (to H. B. Geyer)

And now for something on the lighter side. I wasn't lying when I said that I was impressed with your fund-raising skills.

Just last week, I learned that my philosophical hero William James's farm is up for sale, and I have been going crazy thinking how I might secure it with the ultimate intent of turning it into a small New England version of something like STIAS (though with the focus being on the intersection between pragmatist philosophy and physics, QBism, and further such things).

For instance, I wrote this description to my old advisor Carlton Caves:

> I really wish you were more a fan of William James and old-school pragmatism. I discovered last week that his farm in Chocorua, NH will be on the market in the Spring (it was on the market in the Fall, and taken off for the Winter). It's the house in which James died. The 4387 sq ft house is relatively historically intact (though a lot of updates) and barn still there, but with swimming pool now in addition. 44 acres of land, 39 of it thick forest, and beautiful hay fields and rock walls still there. Quiet secluded place. Perfect for a QBistic Institute!! (Imagine carving 5 little bungalows into the forest, a lecture room, etc.) 20 minutes from good skiing. 1.5 hours to Portland, ME and Portsmouth, NH. $895,000 asking … but probably overpriced by $100K. I've been wracking my brain trying to figure out a way I could secure the place till said institute could become a reality. Know any philanthropists with deep pockets for pragmatism or QBism or both? Seriously; I'm not joking.

And here was part of a further explanation to another friend (H. C. von Baeyer):

> Any institute would have to be three, four, five, six years down the road. It would take so much effort to build the idea, the support, the funding, the logistical infrastructure. The real concern for me (the one that put me into the manic panic) is that the property be secured before some feckless investor or vacation-homer buy it and do more damage.

And I've sent out more than handful of significantly more detailed pleas as well. (None to any avail … of course.)

So maybe let me ask your advice. If you were confronted with a similar situation, how would you tackle it? What would be your first ideas for building up a funding effort (in a short timescale)? Any advice you could give would be most appreciated.

01-03-11 *Addiction Control* (to H. C. von Baeyer)

Just dropping in to give you an update. In case you're wondering about the title, I suppose it struck me because I've been watching and reading so much in the news on Charlie Sheen the last couple of days—I've never seen anyone go so over the top, and I've found it strangely fascinating. Of course, I also flinch in those moments when I think about the impending train wreck: I fear something really bad is going to happen in his private hours.

But on to my own addiction!! I haven't shaken it completely, but I feel I have regained control back to a relatively healthy level. It started by removing the house listing from the open tabs in my browser. That was a start. Then I stuffed the house plans and property map into my backpack, out of sight and off my desk. Now, every day, I think about Chocorua a little less. A feeling of health is starting to return.

On other matters, you never answered on whether you might come out to play the next time Marcus is in town. Having visitor money sometimes burns a hole in one's pocket. Mostly though, I'm trying to look ahead a little and get some inspiration … in a kind of "neutral stuff" study group. I want to know more about Pauli's thoughts there and his influences, etc. Not quite sure what questions I ought to ask, but if we get the ball rolling maybe it'll go somewhere. "Neutral stuff" is surely a better addiction.

01-03-11 *Entities and Effects* (to W. G. Demopoulos)

I was just looking at the wiki article on entity realism (because of some little debate on climate change that I'm having with Carlton Caves at the moment), and this line caught my eye: "[E]ntity realism claims that the theoretical entities that feature in scientific theories, e.g. 'electrons', should be regarded as real if and only if they refer to phenomena that can be routinely used to create effects in domains that can be investigated independently." It caused me to think of your "effects" of course, and I wondered whether you had ever thought about how your own position compares and contrasts to entity realism.

01-03-11 *Whitehead, Dewey, and a Potent Premise* (to W. T. Myers)

Thanks for the article. Reading it made for a very pleasant lunch in my office. I do wish you could send me the complete thesis; I would read it with just as much relish. It'd make a nice addition to my big Palazzo del QBismo library of pragmatism (nearly 700 volumes on the philosophical side of the room). If you find that you can still print it out, I would love it if you mailed me a copy. I've got a lot to learn about Whitehead's relation to the other things that feel right to me (*pieces* of James, Dewey, Schiller, and *parts* of the new realists), and I'd like to make the process as painless as possible.

Reading your quote of Whitehead on the "category of the ultimate" reminded me faintly of something I said at the start of a lecture once. Quote pasted in below. [See 07-02-11 note "The 2011 QBist Challenge" to the QBies.] My colleague, Appleby, and I have been debating a replacement for the word "FACT" used there; the common usage of the word is out of place with respect to the rest of the passage, which makes it clear that I am talking about some kind of "active entity" (i.e., not something "dead" as one usually thinks of facts).

Sure, you can share the interview; I don't mind. (The reason for writing is so that people might read.)

Bill's Preply

> I've attached an chapter I wrote for the *Hanbook of Whiteheadian Process Thought* on the intellectual relationship between Whitehead and Dewey. This piece distills my thinking on Dewey's metaphysics in a much neater fashion that my dissertation. Also, I have never distilled my dissertation into a single .doc file, so it's messy to send. I wrote the thing in Wordstar, and I'm still not sure it's all been converted properly. I need to tend to that at some point. But, the meat of the interpretation is in this article.
>
> I checked out the interview piece you sent me, and that is fascinating. Would you object to my sharing it will a few of my colleagues? I know a couple of folks who would find that of great interest, folks who know more about the physics than I do.
>
> I hope that some day you'll find your way to our meeting. It's a pluralistic, very congenial group of scholars. The meeting truly represents the highlight of my academic year.
>
> Off to teach Leibniz!

01-03-11 *Second Rant* (to M. A. Graydon & L. Hardy)

I've been watching the Charlie Sheen case very closely this week, and I think I've learned a pointer or two from him. Thus I launch into my second rant.

The quote below is from William James and refers to the German philosophers of his time. But in my mind, I often shift its relevance to be about much of modern-day "philosophy of science":

> In a subject like philosophy it is really fatal to lose connexion with the open air of human nature, and to think in terms of shop-tradition only. In Germany the forms are so professionalized that anybody who has gained a teaching chair and written a book, however distorted and eccentric, has the legal right to figure forever in the history of the subject like a fly in amber. All later comers have the duty of quoting him and measuring their opinions with his opinion. Such are the rules of the professorial game — they think and write from each other and for each other and at each other exclusively. With this exclusion of the open air all true perspective gets lost, extremes and oddities count as much as sanities, and command the same attention …

"Extremes and oddities count as much as sanities, and command the same attention …" Over and over I feel like I see that when I watch philosophers of science discuss physics.

02-03-11 *New Scientist? … New Sensationalist, Maybe!* (to H. C. von Baeyer)

First you wrote:

von Baeyerism 67: *After Valerie Jamieson, physics feature editor for* The New Scientist*, had made very positive noises about an article by me about QBism, I heard nothing from her for a while. Finally I phoned her, and found out that she is quite knowledgable (reads* `arXiv` *and has seen some of my work and yours), but basically of the opinion that quantum mechanics has done well all these years, and unless you have a fully worked out new formulation, there's not much interest.*

Then, because of our new emailing system, I noticed that New Scientist has been sending notices of the latest issues to my gmail account … I guess for some time. (Never noticed that before … I usually only use that account when I'm on the road and can't get into my PI account. But with the new system, there's not so much noise on my gmail account. Difficult to explain …) Anyway, the point is, I read this:

> **This week's top stories: The search for quantum loopholes**
>
> Can the universe really be as weird as quantum theory suggests? Einstein suggested that loopholes might let us escape its more baffling implications and now ingenious experiments are finding out if they actually exist …

Therein is the key! You've got to say that QBism makes the world look really, really weird! You've got to make all those other doofus interpretations look tame in comparison.

You mean man's free will has the potential to shape reality itself? How weird, how fantastic, how UNscientific is that! You mean our actions actually matter? Things can be moved to places that they might not have been otherwise? The world is made of a stuff that's neither matter nor mind?!? … Ahh, these people are worthless … Not much different than every news outlet in the land updating us on Charlie Sheen's sick mind with each of his latest "tweets."

03-03-11 *Normalizing Fiducial Stability Groups* (to M. A. Graydon)

I was very impressed by all that you did and all that you understood, of course. I never expected so much; I just wanted to alert you all to the thing before I ripped into the guy.

A much more subtle and interesting case will be Matt Leifer's paper, "Retrodiction In Quantum Bayesianism, Or Why Wigner's Friend Is Fuchs' Enemy," which I will handle gently and with great care. In case you're interested it's attached. I am amazed that Matt gets so much about the program (well, the subjective Bayesian part), but doesn't seem to absorb at all the American pragmatist side of it, i.e., the personal character of the measurement outcomes. Or the way Carl Caves got close to getting it right with:

> "[QBism takes] a three-pronged approach to subjectivity and objectivity: (i) quantum states and probabilities are wholly subjective; (ii) system attributes are wholly objective; and (iii) measurement outcomes are where the rubber meets the road, i.e., where subjective and objective meet to produce something that is not under the control of the agent, but is also not out there in the world."

Independently of that though, Matt's formalism is worth much thinking about.

03-03-11 *My Consternating Collaborator* (to R. Schack)

Section 5 starts out thus:

> The reflection principle is a constraint on an agent's beliefs about her future probability assignments.

Why, why, why do you write like that?!?!?! I would not be able to hold you to it in a court of law, but I am personally confident that the average reader will read it exactly in the way that caused all the confusion over van Fraassen to begin with. I.e., that the reflection principle demands that the agent set her present beliefs by her supposed future probabilities. Our task, as I recall, was to try to blunt that debate a little.

Something else would surely do better justice. Maybe for instance, "The reflection principle is a constraint on the relation between an agent's present beliefs of her future beliefs and those future beliefs themselves." I'll think some more; there's still much room for improvement.

Oh, I get frustrated so easily by iniquitous choices of words: Words that cause the very damage that we are trying mend. Your draft has been more riddled with these kinds of things than usual.

Oh, I'm frustrated, and I've got to finish this damned thing. Your Dutch book argument in Section 4 still has me totally confused. It looks to me like the paragraph starting "So let us first assume. . . " is a dangling appendage, not needed at all for the actual Dutch book argument that kicks in at the following paragraph. I am probably misunderstanding something very deeply, but *then I blame it on your exposition* in that section.

Can we talk or Skype tomorrow? I think I desperately need this.

Take my grumpiness with a grain of salt. Attached is the latest draft.

04-03-11 *Wherefrom Such Confidence* (to Å. Ericsson & M. A. Graydon)

I've got no good answer except to say, "From a long, hard fight." I have a collection of letters on my website titled *The Post-Växjö Phase Transition: Knowledge → Information → Belief → Pragmatic Commitment* that documents the gradual change of my view on quantum states. (But it only picks up from the days when I was already calling them knowledge; ten years before that I was thinking they were objective propensities of some sort.) Here's the file: `http://www.perimeterinstitute.ca/personal/cfuchs/PhaseTransition.pdf`.

But I don't really know what it shows but a soul in torment. Or an oyster trying to remove the grains of sand from its shell. No one argued more strongly that quantum states were personalist

Bayesian than me—more and more determinedly, in fact, as I checked my own consistency and found my failings therein. (In fact, as far as I know, no one had ever argued for such an extreme view at all.) No one led me; it was my own push and shove that got me there. You'll see it in every letter of exasperation I wrote to Caves, Schack, and Mermin as they fought back and I tried more and more to put together a convincing picture.

The conception was my baby, and maybe that's why I love it and have confidence in it like no one else.

04-03-11 *Among the World's Religions* (to Å. Ericsson)

Thanks for your thoughtful note. I've read it and reread it and two times beyond that (and I'll probably read it again), as I've been building and tending this fire for Kiki's return tonight. She's out at some kind of spousal dinner, and the children are away at a girl scout camp.

Particularly, I keep coming back to these lines:

Åsa-ism 2: *The thing is that I find my beliefs as based on something real outside myself, they are not crucially dependent on my philosophizing and it includes an explanation to how my beliefs can be strong. To me it is consistent in a way I can't see how anything I think about physics ever could be. So then I find it amazing you can believe, if not as much as I, still close to it. It's not a criticism, it is a conundrum to me.*

[OK, I fixed your spelling.]

I'm not sure you'll understand it, but my mind kept coming back to the image of Napoleon's coronation as Emperor. He somehow convinced the pope to travel from Rome to crown him in Notre Dame Cathedral rather than at the Vatican. (Something unheard of before.) At the very last moment, in front of hundreds of witnesses, as the pope reached for the crown to place it on Napoleon's head, Napoleon grabbed it and placed it on his head himself. "I crown myself Emperor!"

It's not unconnected to the last note I sent you. "I build my own religion." Contemplating the holy mystery of quantum theory is my personal sacrament. It seeps into every aspect of my life like a religion does. See for instance, the first two lines of an old proposal I wrote for Caltech once upon a time (attached). Better still, see the story "Some Things Should Not Pass" from 16 February 2002 on page 150 of the web document I noted to you earlier. All these things are tied together in my mind. Quantum theory is the closest I've yet come to an articulated expression of what I strive to say in the line, "For a small time we have the chance to move around and determine our courses as we please—to leave a trail behind us." See also Footnote 33 (page 20) in `http://arxiv.org/abs/1003.5209`.

I do hope I am not hurting your feelings with my jesting with you. In my mind it is playful, though I fear that I do not always convey it that way to you. I think long and hard, contemplating our disparate positions on religion. You are a catalyst to me, even if I don't reciprocate to you. I'm just saying I value these discussions.

06-03-11 *WTB, Reason and Emotion* (to H. Yadsan-Appleby)

I am sorry to take so long to reply to you. I wanted to get home to look at some quotes before responding, and then once I got home, I became ill (as you have probably heard).

I am glad that you are enjoying O'Connell's book [*William James on the Courage to Believe*] and finding some new thoughts in James's philosophy.

At the moment, I can't help you much with the meanings of "forced", "living", "momentous", etc., as it has been a long time since I've read the appropriate essays, but I think you will find the definitions clear enough if you read the actual essay "The Will to Believe".

In fact here is what I suggest as a study plan. I would say the next thing you should read is precisely "The Will to Believe". And then follow that with the magnificent, particularly deep (but harder to read) essay, "The Sentiment of Rationality."

On one of your points:

Hulya-ism 1: *I never accepted or even understood the split between reason and faith (or reasoning and feeling emotions).*

I wanted to bring your attention to a nice paragraph from Robert D. Richardson's biography of James:

> About a month after he sent off his "Remarks on Spencer's Definition of Mind as Correspondence," James sent off, in January 1878, an article called "The Sentiment of Rationality." He later described it as "the first chapter of a psychological work on the motives which lead men to philosophize," and he noted ruefully that it might better have been called "The Psychology of Philosophizing."
>
> We may, at this distance, prefer the original title, if only for its fresh and unorthodox, not to say brash, announcement that rationality is at bottom a feeling. Not a matter of logic or math, not reasoning or ratios, not induction, deduction, or syllogism, not something higher than and detached from the senses, not the opposite of a feeling or emotion—rationality is itself a feeling or emotion. He might even have called the essay "The Feeling of Rationality." He begins by asking how we recognize the rationality of a conception, and he answers, "By certain subjective marks, that is, a strong feeling of ease, peace, rest." He amplifies, saying, "This feeling of the sufficiency of the present moment, of its absoluteness—the absence of all need to explain it, account for it or justify it—is what I call the Sentiment of Rationality."

This sounds a lot to me like what you were saying above, and I suspect you would have quite an agreement with it. So I think when you are prepared for it, and your mind has gotten a bit accustomed to James's peculiar writing style, you would get much out of reading "The Sentiment of Rationality". It is a wide-ranging essay on much, more than this subject.

07-03-11 *Einstein, Indeed!* (to R. W. Spekkens)

> There can <u>*be*</u> no difference that <u>*makes*</u> no difference.
>
> — William James, "What Pragmatism Means" (1907)

[underlines mine for still extra emphasis, italics his own]

Rob's Reply

> Ah, but Einstein took that principle (in the form of the equivalence of acceleration and gravitational force) and derived general relativity! Surely no amount of prose can provide a better *justification* of the principle than that.

07-03-11 *The Battle of the Eyeballs* (to J. B. Hartle)

I was amused by the no-eyeball sign in your talk today. See attached for my dueling point of view. [See Figure 6 in "QBism, the Perimeter of Quantum Bayesianism," `arXiv:1003.5209v1`.]

I enjoyed your talk, and I'm glad I was able to get there: Seeing it teaches me that there's a bit of common groundwork between us for this little piece of formalism I want to show you tomorrow or Wednesday.

08-03-11 *Quantum Systems 101* (to the QBies)

"If the universe is a quantum mechanical system, then it has a quantum state." – J. B. Hartle

See the first two minutes of Jim Hartle's talk today, `http://pirsa.org/11030103/`.

Here's an essay question for you QBies: What does it mean to be a quantum mechanical system?

08-03-11 *Teaching the Teacher?* (to M. A. Graydon)

Graydonism 5: *I have attached the absolute latest version of the paper. A while back I tried to defend my opening sentence. Jim Hartle said something yesterday which might help my cause:*

A physical theory provides reliable probabilities for betting on the regularities of the universe.
— James Hartle (`PIRSA:11020124`)

Jim's statement is too "objectivist" about probabilities for my taste. Reliable? By whose measure? With respect to whose priors? (Don't fool yourself into thinking you can define such a notion without a prior.) Regularities? Is that a sneaky way of endowing nature with propensities?

My present thinking is that probability theory is a calculus for flagging "inconsistency"—nothing more. By my view, quantum theory does not *provide* probabilities any more than the raw axioms of probability theory do. Probabilities come out of a hat that no theory itself has yet entered (i.e., the subjective agent).

I expand on this view in Section III of `http://arxiv.org/abs/1003.5209` and my answer to Question 4 in the attached. [See "Interview with a Quantum Bayesian," `arXiv:1207.2141v1`.]

Thanks for the offer of a tutorial. I am going to try to get in early tomorrow morning to hopefully give Hartle a session on the urgleichung. Drop me a note when you're in the building, and I'll let you know if I'm free. Unfortunately, I have to chair the colloquium tomorrow; so that time will be taken up.

PS. Rüdiger tells me that Logue's book *Projective Probability* makes a good case for the idea (in opposition to E. T. Jaynes and the objective Bayesians) that nothing more than coherence is needed for making probability assignments useful tools. I can lend you the book if you wish.

10-03-11 *Late Great Johnny Ace* (to M. A. Graydon)

On a cold December evening
I was walking through the Christmas tide
When a stranger came up and asked me
If I'd heard John Lennon had died
And the two of us went to this bar
And we stayed to close the place

And every song we played
Was for the late great Johnny Ace, yeah, yeah, yeah

— Paul Simon, "The Late Great Johnny Ace"

Your choice of photos for your Beamer example took me down memory lane. I remember well the day John Lennon died. I heard it on the radio driving home from school. I had literally just gotten into the Beatles a few days previous, after reading the *Playboy* interview of John and Yoko (sifting through my brother-in-law's stash of the magazine). It was devastating; I recorded as much Beatles music as I could directly off the radio. No internet, no YouTube back then; no record store in my hometown.

I later named my first golden retriever Albert Winston Fuchs. Albert was for Albert Einstein; Winston was for John Lennon.

I remember being home from school sick the day Elvis Presley died. A ticker scrolled across the bottom of the TV screen saying "Elvis Aaron Presley, the king of rock and roll, is dead at age of 42."

I don't remember Hunter Thompson dying, but my records show that I was somewhere between a talk in College Park, Maryland and a talk in Wrocław, Poland.

10-03-11 *Your Reference* (to J. B. Hartle)

Thanks for the little audience yesterday. I enjoyed it. Also, I'm glad to learn that you're now thinking of probabilities in (kind of) Bayesian ways. As it happens, I'm just starting to slap together a contribution for a conference proceedings, where I've got a footnote which reads, "This is what particularly distinguishes QBism from several other Bayesian approaches to quantum probability. See Refs. `\cite{...}` for details of the other approaches." Footnote 2 in the attached.

If you have further papers than the one I cited [J. B. Hartle, "Quantum Mechanics with Extended Probabilities," Phys. Rev. A **78**, 012108 (2008)], or I didn't cite the most appropriate one and there is something better, please let me know.

13-03-11 *Hurried Remarks* (to M. A. Graydon)

Greetings from Chicago airport. I just had a pleasant time reading your paper (in the Toronto airport and then on the flight). Åsa and I are in the Admiral's Club, and she's off having a bowl of soup (that she paid for), and I of course am having my complimentary beer (because I'm cheap).

Your paper is extremely well written … much like I had expected. Beautiful clarity and organization. (And I'm not making this up.)

My only worry at all is that there is somehow still not enough "oomph" in the first page, abstract, and conclusion. Why is the question you're tackling here important? I feel the reader ought to be left with a memorable sentence in his mind long after the details of your construction have slipped away from him. Indeed, could you find one sentence that would really help draw potential readers in? I don't know, maybe something like: "Ultimately one would like to use the developing technologies of quantum information science to test the validity of complex over quaternionic quantum mechanics. Before that, however, one must have a clear conception of the relations and contrasts between the theories with respect to the full apparatus of quantum information theory — particularly, with respect to generalized quantum measurements and quantum operations, not *merely* projective measurements and unitary operations as has been worked out previously `\cite{Hermie,Joe,Peter}`. This paper fills that gap in the literature." It's not very elegant or finely tuned (or one sentence long either!), but I just wanted to throw something down before Åsa and I have to leave.

13-03-11 *Quaternions for Jesse Jackson* (to M. A. Graydon)

Now I'm writing you from the airplane! First time I've been able to get online on a flight in years. (Several years ago, it was briefly legal, but then the FAA squashed it for quite some time.) Now, for $9.95 I'm in internet bliss.

Funny thing: I was in seat 3E and Åsa was in 6A. I came back to the guy who was sitting beside her and said, "I'll trade you an aisle seat for an aisle seat so that I can sit beside my colleague. If it'll sweeten the pot for you, Jesse Jackson is sitting in the seat beside me." You see, our Åsa is much more important than any politician!

But wouldn't you know, she later said something that made me realize: If I had only been sitting beside him, I'm might have hit him up for help in buying the William James house. Darn, foiled again!

But then again, I'm on the internet! And thus, I can read things like this: `http://query.nytimes.com/gst/fullpage.html?res=9B0DE7DC113CF93AA15752C1A961948260&sec=&spon=&pagewanted=5`. I guess I did the right thing after all.

So let me get back to your notes!

15-03-11 *Itamar's Volume* (to R. Schack)

I guess Meir's "urgent" is now putting me on edge. I hope you've made progress.

I am now up at 3:30 AM working on talk number 2. I'm not sure talk number 1 did much for the general populace, but it did spur a long discussion with Samson Abramsky and Adam Brandenburger. (Samson was the Clifford lecturer three years ago.) Interesting seeing the tensions in Samson. He does take us seriously, but he's got the usual spook, "The Bayesian view is attractive, surely the best notion of probability in many situations [implicitly, he was meaning 'not in physics'], but surely the probabilities in quantum mechanics come about through 'nature's regularities'."

Today, the de Finetti theorem, fidelity, and no-broadcasting will be the main fare.

19-03-11 *Congratulations. Question* (to R. B. Griffiths)

I'm sorry for the delay. I just delivered this year's Clifford lectures at Tulane U in New Orleans, and now I'm having a brief respite with my 82-year-old mom in South Texas on my way to Dallas (for the APS March meeting).

Thanks for the congratulations; it means a lot to me to hear from you.

Griffithsism 2: *I am trying to write up an item where I would like to put a reference to your opinion that quantum information is [only] about the outcomes of future measurements, assuming that I am not mixing you up with someone else. Is there a good accessible reference?*

No, you're probably not mixing me up with anyone else, and *in a sense* that is right. *However*, my students did recently point me to a passage in one of your 2009 papers where you write:

> It seems almost inevitable that if quantum mechanics is incompatible with "local realism" (a term which in many minds is essentially synonymous with Bell inequalities)

> but is still somehow local, then it is realism that must be discarded, and one finds serious arguments to this effect [38]. But if the world of atoms is unreal, what shall we say of the macroscopic objects which most physicists think are composed of such atoms? Are the things we see around us (not to mention we ourselves) unreal?

That does *not* characterize my position now, and never has, though I'm getting better and better at articulating what it is that I am trying to get after. Let me thus send you to this paper: `http://arxiv.org/abs/1003.5209`. It is probably better read as a whole, but if you want to go straight to the metaphysics (i.e., what is real), go to Section's VI an VII on page 19. It is not at all that there is no microscopic (or macroscopic) reality—it never has been—it is that there is too much of it. As one philosopher once put it, it is that "The world is not sentence shaped." Give the reading a chance; at the least I hope you'll find it entertaining. Also, if you back up to Section V, you'll find my own take on the significance of the Bell inequalities.

Finally, let me attach an interview that is not posted yet. [See "Interview with a Quantum Bayesian," `arXiv:1207.2141v1`.] I hope it tackles some of these same issues adequately. In fact these two documents together, I believe, make the clearest and most complete statements yet of what it is that I see as my research program.

I wish I were going to see you at the March meeting, but as far as I can tell you won't be. It'd be nice to discuss these things with you when they might be fresh on your mind. Would you be interested in visiting the Perimeter Institute sometime this year? I could arrange it.

20-03-11 *Notes on Norsen* (to N. Argaman)

Let me start by quoting a passage from William James's essay "The Will to Believe":

> Let us give the name of *hypothesis* to anything that may be proposed to our belief; and just as the electricians speak of live and dead wires, let us speak of any hypothesis as either *live* or *dead*. A live hypothesis is one which appeals as a real possibility to him to whom it is proposed. If I ask you to believe in the Mahdi, the notion makes no electric connection with your nature,—it refuses to scintillate with any credibility at all. As an hypothesis it is completely dead. To an Arab, however (even if he be not one of the Mahdi's followers), the hypothesis is among the mind's possibilities: it is alive. This shows that deadness and liveness in an hypothesis are not intrinsic properties, but relations to the individual thinker. They are measured by his willingness to act. The maximum of liveness in an hypothesis means willingness to act irrevocably. Practically, that means belief; but there is some believing tendency wherever there is willingness to act at all.

The truth is, at the moment, I've just got no energy for the nonlocality debate. Nonlocality is just not a "live hypothesis" for me. And when I've got so many other urgent matters to take care of (like the Clifford lectures I gave last week or the 400 talks I've organized for the APS March meeting this week), it seems a special burden to even think the slightest amount about it.

I'm sorry; I just can't muster the steam. The best I can say is that Section V of `http://arxiv.org/abs/1003.5209` already speaks my piece on the subject. At the moment, I've got nothing else to say.

But, look, good luck in your journey.

21-03-11 *In Place of Regularities* (to S. Abramsky)

I've spent the early morning hours today reviewing a lot of things from last week ... not only my iniquities, but also the discussion we had at the reception where I shunned your phrase "regularities of nature". Anyway, in that regard, I hope you'll sometime have the chance to read my paper `http://arxiv.org/abs/1003.5209` particularly Section VI, starting on page 19. I'm not quite sure how to put what it's striving at in a pithy way, but I do know that it is an attempt to put something else—"things in common"—in place of your "regularities".

27-03-11 *NY Anytime Soon?* (to A. Plotnitsky)

I've been spending the morning re-organizing my bookshelf to make room for 18 new purchases. (Photo of one of the two walls in case, I haven't shown you before.) And I came across my two copies of *Complementarity*! (The signed paperback you gave me and the hard cover in perfect condition that I found sometime later.) It sent me on a trail of thinking about our discussions, but it also made me wonder whether you'll be in New York anytime soon, visiting Paula or your sister. Maybe you're even there now? I ask because there is a $300 set I'd like to purchase from The Strand, but I'm wondering what kind of condition it's really in. And I'd only want to trust a real book lover's opinion.

Oh, if you look in the middle column near the arm of the chair, you'll see the two copies of *Complementarity*.

Will you be in Växjö this year? It'd be nice to see you again and talk more extensively with you than I have the last couple of years. Recently, I've taken a renewed interest in Bohr and his complementarity. It has to do with my SIC work actually. The key is that one can always think of quantum state space as arising from an algebra with *only* two generators (Weyl-Heisenberg group). Appleby particularly has me starting to wonder whether Bohr saw this very fact ... in his own (to me usually inscrutable) way. I'd love to pick your brain on this!

Hope you're doing well. All the best .... Wait, let me attach a new composition that you might enjoy. It's an interview for Max Schlosshauer's new book. David Mermin wrote one too; but maybe you should ask him for it directly if you'd like to read it.

28-03-11 *Stream O'* (to M. Schlosshauer)

Schlosshauerism 36: *I was just reading a long essay about Joyce's* Ulysses*, and I learned that it was William James who coined the term "stream of consciousness." I had no idea! This James is really one hell of a personality. As they'd say in sports, "Go James!"*

- big bang
- multiverse
- stream of consciousness
- turtles all the way down
- block universe

Yep, he's the man. Have I told you how I've become obsessed with purchasing his old farm (beautiful big house and 44 acres of forest) and turning it into an institute for law-without-law studies? All I need to do is gather $895K quickly and then figure out a source of sustaining funds. Yeah right!

29-03-11 *NY Anytime Soon?, 2* (to A. Plotnitsky)

Thanks so much for being willing to look into this. The item is a four volume set titled, *Cambridge School of Pragmatism* edited by John R. Shook and Andre de Tienne. The price is $300 and the only description is "very good," with no further details.

Please tell me what you think of it, as you have a chance. If it sounds like it's roughly of the condition of any anything else on my bookshelf (no pencil markings, rips in the cover, etc.), then I will probably order it from them. I hope this is not too much trouble on you.

Thanks so much for sending me your draft. I absolutely love the title "Dark Materials to Create More Worlds"!! It's just chock full of good stuff. And I so love that Milton quote. I'm drawn to it. "His dark materials to create more worlds." I'm fascinated with that line particularly, even if I ultimately want to misuse it for my purposes: I want to think of "quantum systems" as the "dark materials," rather than the "chance" that spews from them in a quantum measurement setting. In my mind it has a kind of connection to a Pauli quote in the attached excerpt from my new samizdat (the one starting at the end of page 525 about quantum measurement being like a "black mass"). [See 19-06-05 note "Philosopher's Stone" to G. L. Comer.] When things cool down for me a bit, I'd like to continue this discussion on "dark materials".

30-03-11 *A Thought I Would Call Religious* (to the QBies)

> I must say one word about the extraordinarily intimate and important character which the phenomenon of effort assumes in our own eyes as individual men. Of course we measure ourselves by many standards. Our strength and our intelligence, our wealth and even our good luck, are things which warm our heart and make us feel ourselves a match for life. But deeper than all such things, and able to suffice unto itself without them, is the sense of the amount of effort which we can put forth. Those are, after all, but effects, products, and reflections of the outer world within. But the effort seems to belong to an altogether different realm, as if it were the substantive thing which we *are*, and those were but externals which we *carry*. If the 'searching of our heart and reins' be the purpose of this human drama, then what is sought seems to be what effort we can make. He who can make none is but a shadow; he who can make much is a hero. The huge world that girdles us about puts all sorts of questions to us, and tests us in all sorts of ways. Some of the tests we meet by actions that are easy, and some of the questions we answer in articulately formulated words. But the deepest question that is ever asked admits of no reply but the dumb turning of the will and tightening of our heartstrings as we say, *"Yes, I will even have it so!"* When a dreadful object is presented, or when life as a whole turns up its dark abysses to our view, then the worthless ones among us lose their hold on the situation altogether, and either escape from its difficulties by averting their attention, or if they cannot do that, collapse into yielding masses of plaintiveness and fear. The effort required for facing and consenting to such objects is beyond their power to make. But the heroic mind does differently. To it, too, the objects are sinister and dreadful, unwelcome, incompatible with wished-for things. But it can face them if necessary, without for that losing its hold upon the rest of life. The world thus finds in the heroic man its worthy match and mate; and the effort which he is able to put forth to hold himself erect and keep his heart unshaken is the direct measure of his worth and function in the game of human life. He can *stand* this Universe. He can meet it and keep up his faith in it in presence of those same features which lay his weaker brethren

low. He can still find a zest in it, not by 'ostrich-like forgetfulness,' but by pure inward willingness to face it with those deterrent objects there. And hereby he makes himself one of the masters and the lords of life. He must be counted with henceforth; he forms a part of human destiny. ...

Thus not only our morality but our religion, so far as the latter is deliberate, depend on the effort which we can make. *"Will you or won't you have it so?"* is the most probing question we are ever asked; we are asked it every hour of the day, and about the largest as well as the smallest, the most theoretical as well as the most practical, things. We answer by *consents or non-consents* and not by words. What wonder that these dumb responses should seem our deepest organs of communication with the nature of things! What wonder if the effort demanded by them be the measure of our worth as men! What wonder if the amount which we accord of it were the one strictly underived and original contribution which we make to the world!

William James

Psychology, A Briefer Course

31-03-11 *A Good Day's Impressions* (to D. Fraser)

I want to thank you again for yesterday's opportunity; I much enjoyed the experience. And actually one of the strongest impressions I got was in getting to know you better: You had a grasp of things, and my own idiosyncrasies, that impressed me much. Genuinely, if much had been the same, but [Philosophy Professor X, not at U. Waterloo] (for instance) had led the discussion, I don't think I would have encountered such understanding. That is not to say *agreement*, which you may not have had (i.e., I well expect a face of neutrality from a lecturer in a situation such as this), but what sets you apart in my mind is that you did not give the impression of hearing only non sequiturs spewing from me (as indeed so many philosophers portray of me). That built a sense of camaraderie, and that's much better for getting to the heart of these matters. I can learn something from that, and I appreciate it.

Doreen's Preply

I'm teaching an undergrad/grad seminar on philosophy of QM this term and I'm wondering whether you'd be willing to make a guest appearance near the end of term. I've scheduled (most of) two weeks on information-theoretic approaches to QM and it would be great to have you for the second of the two weeks. I will assign the students readings to complete in advance and the class will be devoted to 15 minute presentations by some of the students and discussion. The readings are listed as TBA in the syllabus; I'm thinking that I will assign most of Chris Timpson's survey chapter in the *Ashgate Companion to Contemporary Physics* and then a paper of yours and Chris' paper "QB: A Study." But I'm open to suggestions! [...]

I've attached the schedule of readings for the course. I have 12 undergrads evenly split between honors philosophy majors and (mostly) math/physics majors, 3 philosophy grad students and a handful of auditors. I'm using Albert's textbook—which has the virtue of being accessible to the philosophy audience—and supplementing it with additional readings. Teaching this course to the diverse audience is a bit of a challenge, but we've already had some good exchanges between the philosophers and the physicists.

04-04-11 *Les Papillons* (to H. C. von Baeyer)

It is 10:20 AM in Waterloo, and the review meeting will start at 11:00. I'm sitting at home, hiding, and my stomach is in butterflies, almost to the point of nausea. I thought it might help to write you; so here I am.

This morning, I have been using the coffee mug Emma bought for her mother at the Eiffel tower, when we were there two years ago. Somehow, the mug has gotten transferred to my nearly sole use of it, and it's generally considered one of "dad's mugs" now. It's got two scenes of the tower, and Katie was looking at it pretty thoroughly this morning at breakfast. I started to tell her stories of how she will be so impressed when she walks around a corner and spies it for the first time.

How I wish I were in the city with you today. I could so use a good serious discussion on QBism, Pauli, and alchemy again. And to do it in the right atmosphere would cap it all off. Or this would nice: Sitting in some nice Parisian café reading Boutroux and Renouvier! Ahh, the possibilities you have in your life.

Let me come back to the issue of criticism of QBism. Attached is a file I put together for the review. One faculty member had asked if there were any published criticisms of QBism. So it mostly contains the ones you've already seen, but there are some other ones in there as well:

1. D. Styer, S. Sobottka, W. Holladay, T. A. Brun and R. B. Griffiths, P. Harris, letters to editor in "Quantum Theory—Interpretation, Formulation, Inspiration," Phys. Tod. **53**(9), 11 (2000).

2. A. Hagar, "A Philosopher Looks at Quantum Information Theory," Phil. Sci. **70**, 752 (2003).

3. P. Grangier, "Contextual Objectivity and Quantum Holism," `arXiv:quant-ph/0301001v2` (2003).

4. E. Dennis and T. Norsen, "Quantum Theory: Interpretation Cannot be Avoided," `arXiv:quant-ph/0408178v1` (2004).

5. L. Marchildon, "Why Should We Interpret Quantum Mechanics?," Found. Phys. **34**, 1453 (2004).

6. M. Ferrero, D. Salgado, and J. L. Sánchez-Gómez, "Is the Epistemic View of Quantum Mechanics Incomplete?," Found. Phys. **34**, 1993 (2004).

7. A. Hagar, "Quantum Information—What Price Realism?," Int. J. Quant. Info. **3**, 165 (2005).

8. A. Hagar and M. Hemmo, "Explaining the Unobserved—Why Quantum Mechanics Ain't Only About Information," Found. Phys. **36**, 1295 (2006).

9. U. Mohrhoff, "Objective Probability and Quantum Fuzziness," `arXiv:quant-ph/0703035v1` (2007).

10. D. Wallace, "The Quantum Measurement Problem: State of Play," `arXiv:0712.0149v1 [quant-ph]` (2007).

11. V. Palge and T. Konrad, "A Remark on Fuchs' Bayesian Interpretation of Quantum Mechanics," Stud. Hist. Phil. Sci. Part B **39**, 273 (2008).

12. C. J. Timpson, "Quantum Bayesianism: A Study", Stud. Hist. Phil. Mod. Phys. **39**, 579 (2008).

13. A. Stairs, "A Loose and Separate Certainty: Caves, Fuchs and Schack on Quantum Probability One," to appear in Stud. Hist. Phil. Mod. Phys.

14. M. S. Leifer, "Retrodiction In Quantum Bayesianism, Or Why Wigner's Friend Is Fuchs' Enemy"

15. S. Friederich, "How to spell out the epistemic conception of quantum states," `arXiv:1101.1975v1` (2011).

16. J. Bub, "Quantum probabilities as degrees of belief," Stud. Hist. Phil. Mod. Phys. **38**, 232 (2007).

17. G. Jaeger, *Entanglement, Information, and the Interpretation of Quantum Mechanics*, (Springer, 2009).

Probably the best recommendations in there are Bub's paper and Stairs's paper. Their email addresses are `jbub@umd.edu` and `stairs@umd.edu` in case you want to get the papers directly from them. (I know that Allen's paper was refereed, and so have may have changed somewhat since I last saw it.) I'll attach the latest version of Matt Leifer's paper, though he said a day or two ago that he is expecting to substantially revise it. The key thing that Matt misses is the two-levels of personalism, but I expect that the article might be enlightening otherwise. (I haven't actually read it yet.)

Maybe in the next note, I'll send you the bigger presentation I made up for Lucien. Who knows, maybe some of that will be useful for your own QBism summary. It's not too very braggarty (compared to some of my other documents) ... mostly factual.

Thanks again for the nice note the other evening. There are times when little compliments help a lot.

07-04-11 *The Betterized Mermin* (to R. W. Spekkens & M. S. Leifer)

I dug this up yesterday, but then I forgot to send it to you. It is the article where David Mermin thinks he does a better job than he did on the three-man BFM paper.

I've got to say, I'm much taken with your program ... even though there are several philosophical divides from my own program ... the deepest being that quantum theory is a *generalization* of probability theory. You know that I would now say it is standard personalist probability theory (which includes for me, if I need to say so explicitly, van Fraassen's reflection principle)—not a generalization at all—with some structure about counterfactuals added to it. I.e., it is a more particular structure than abstract probability theory. But that doesn't get in the way of my appreciating this great formalism you're developing and all the things you're able to tackle with it.

07-04-11 *Huangjun Zhu Visiting at the Moment* (to R. W. Spekkens & M. S. Leifer)

Huangjun Zhu gave his talk today, and it was quite good. (Giulio was there, and you may consult him for an independent opinion.) But the talk can be viewed on PIRSA already: `http://pirsa.org/11040105/`.

Only they left out my dramatic introduction for Huangjun, telling the story of how Hermann Weyl became excited after a visit from Max Born in September 1925, where Born revealed that imposing the canonical commutation relations for position and momentum might be the key axiom for a new quantum mechanics. Weyl's excitement led him to discovering the Weyl commutation relations, so that he could reframe the Born-Jordan assumption in terms of bounded operators, but more importantly, so that he could define a quantum theory for finite systems. Weyl's letter announcing the discovery was dated 27 September 1925; the very same day the Born-Jordan paper—the very first to write down the full theory of quantum mechanics—was submitted for publication. After telling the tale, I returned to the subject of Huangjun to say that he would present a result that shows the deep connection between SIC POVMs in prime dimension and that very starting point of quantum theory.

08-04-11 *Thinking of You* (to W. G. Demopoulos)

Demopoulosism 49: *I recently ran across a reference to Santayana's* Character and Opinion*. In general, I find him a bit to literary for my taste, but this is not to say he isn't insightful. The book (based on lectures given in California) contains a chapter on James that I thought hit some nails on their heads pretty well. Have a look—there's a new edition, but I'd have to look up the reference again—which I'm happy to do if you can't find it—here it is, edited by James Seaton.*

That's one Santayana book I don't have; I'll be on the lookout for it.

I read your Poincaré introduction this morning with my coffee. It was nice. I really liked the passage you plucked out:

> . . . . . . more than a dozen processes, entirely independent and that I would not be able to enumerate without tiring you, lead us to the same result. If there were more or less molecules per gram, the brightness of the blue sky would be entirely different; incandescent bodies would radiate more or radiate less, etc.; one has to admit, we see atoms.

That's the style of reasoning that leads us to epistemic states. That's why I've always liked this passage from Spekkens's original toy model paper.

> We shall argue for the superiority of the epistemic view over the ontic view by demonstrating how a great number of quantum phenomena that are mysterious from the ontic viewpoint, appear natural from the epistemic viewpoint. These phenomena include [about a million things]. . . . The greater the number of phenomena that appear mysterious from an ontic perspective but natural from an epistemic perspective, the more convincing the latter viewpoint becomes. . . .
>
> Of course, a proponent of the ontic view might argue that the phenomena in question are not mysterious *if* one abandons certain preconceived notions about physical reality. The challenge we offer to such a person is to present a few simple *physical* principles by the light of which all of these phenomena become conceptually intuitive (and not merely mathematical consequences of the formalism) within a framework wherein the quantum state is an ontic state. Our impression is that this challenge cannot be met. By contrast, a single information-theoretic principle, which imposes a constraint on the amount of knowledge one can have about any system, is sufficient to derive all of these phenomena in the context of a simple toy theory, as we shall demonstrate.

I'll go back to the actual Poincaré paper later.

18-04-11 *If Words Have Meaning* (to N. D. Mermin)

Attached is a copy of the one article out there that cites your nonworld nonview paper. Have you seen it before? It's quite something.

I was just re-reading this passage in your paper:

> This is the quintessential quantum situation: How can you tell whether your experiment is giving you information about the object of study (particle), the apparatus (box), or some combination of the two?
>
> Figure 2 shows a way to tell. Suppose you can test particles before they get to the box, and on the basis of the results of the test you can predict in advance which bin each particle ends up in. Clearly that rules out the possibility that the box disposes randomly of the particle. Indeed, if you can specify in which bin the particle ends up before it even reaches the box, then, if words have any meaning at all, we can say that two kinds of particles enter the box: those that always get put into the left bin, and those that always get put into the right bin. We can call them particles of type L and particles of type R. There are indeed two kinds of particle, and the box is sorting them out.

So, I see our debate on "certainty" started all the way back in 1992.

18-04-11 *If Words Have Meaning, 2* (to N. D. Mermin)

Merminition 230: *Apropos of the content, all I'm doing there is repeating the EPR reality criterion (which is, after all, nothing but common sense.) The debate started in 1935.*

Aha! So you indirectly admit that the trouble with Bell is the assumption of the EPR criterion after all! For, you write in the text:

> Remarkably—amazingly—Bohr was right to do so. But this did not become clear for nearly thirty years. Since the overwhelming majority of physicists believed that Bohr had refuted Einstein in 1935, the remarkable 1964 paper by John Bell showing that Bohr was right to keep his head in the sand, had negligible impact on practicing physicists. Within the last decade, however, there has been a revival of interest in the foundations of quantum mechanics, primarily because experimental techniques are now available that reveal a far greater variety of exotic quantum phenomena than were available to the founders of the theory sixty-five years ago. In 1988 Greenberger, Horne, and Zeilinger came up with a spectacular refinement of the EPR argument and its refutation by Bell, that I shall now describe.

and

> It was thirty years before John Bell pointed out that there were other aspects of the EPR situation (involving the behavior of the particles at additional types of boxes through which they might be sent) which, though not contradicting in any way the data on which EPR based their conclusion, were nevertheless inconsistent with each particle possessing both 1-ness and 2-ness. I shall not pursue Bell's argument, because I believe the argument found a few years ago by GHZ is even more dramatic and compelling.

Shame, shame.

18-04-11 *The One Underived and Original Contribution We Make to the World* **(to N. D. Mermin and C. M. Caves)**

Attached is the promised quote on the will by William James. I felt like copying it in again.

> [I] must say one word about the extraordinarily intimate and important character which the phenomenon of effort assumes in our own eyes as individual men. Of course we measure ourselves by many standards. Our strength and our intelligence, our wealth and even our good luck, are things which warm our heart and make us feel ourselves a match for life. But deeper than all such things, and able to suffice unto itself without them, is the sense of the amount of effort which we can put forth. Those are, after all, but effects, products, and reflections of the outer world within. But the effort seems to belong to an altogether different realm, as if it were the substantive thing which we *are*, and those were but externals which we *carry*. If the "searching of our heart and reins" be the purpose of this human drama, then what is sought seems to be what effort we can make. He who can make none is but a shadow; he who can make much is a hero.
>
> The huge world that girdles us about puts all sorts of questions to us, and tests us in all sorts of ways. Some of the tests we meet by actions that are easy, and some of the questions we answer in articulately formulated words. But the deepest question that is ever asked admits of no reply but the dumb turning of the will and tightening of our heartstrings as we say, *"Yes, I will even have it so!"* When a dreadful object is presented, or when life as a whole turns up its dark abysses to our view, then the worthless ones among us lose their hold on the situation altogether, and either escape from its difficulties by averting their attention, or if they cannot do that, collapse into yielding masses of plaintiveness and fear. The effort required for facing and consenting to such objects is beyond their power to make. But the heroic mind does differently. To it, too, the objects are sinister and dreadful, unwelcome, incompatible with wished-for things. But it can face them if necessary, without for that losing its hold upon the rest of life. The world thus finds in the heroic man its worthy match and mate; and the effort which he is able to put forth to hold himself erect and keep his heart unshaken is the direct measure of his worth and function in the game of human life. He can *stand* this Universe. He can meet it and keep up his faith in it in presence of those same features which lay his weaker brethren low. He can still find a zest in it, not by "ostrich-like forgetfulness," but by pure inward willingness to face the world with those deterrent objects there. And hereby he becomes one of the masters and the lords of life. He must be counted with henceforth; he forms a part of human destiny. . . .
>
> Thus not only our morality but our religion, so far as the latter is deliberate, depend on the effort which we can make. *"Will you or won't you have it so?"* is the most probing question we are ever asked; we are asked it every hour of the day, and about the largest as well as the smallest, the most theoretical as well as the most practical, things. We answer by *consents* or *non-consents* and not by words. What wonder that these dumb responses should seem our deepest organs of communication with the nature of things! What wonder if the effort demanded by them be the measure of our worth as men! What wonder if the amount which we accord of it be the one strictly underived and original contribution which we make to the world!

21-04-11 *Quick Question* (to H. C. von Baeyer)

von Baeyerism 68 : *Reading Timpson has been very useful. I do have a question though. One of his principal complaints is the "explanatory deficit" of QBism – that you cannot match conventional quantum theory in explaining the thermal conductivity of lithium, for example. In particular, he claims: "When we are disallowing the possibility of any descriptive theory below this kind of level of generality it seems that there is little we can say about why macroscopic objects have the properties they do. . . ."*

Are you indeed disallowing this possibility? I thought that the Born rule and the Schr. equation are the twin pillars of conventional q.m., and that you have succeeded in a finding a new role for the former, but have not yet found the replacement for the latter*. (Timpson, in his last sentence, does allow for the possibility that you may resolve this problem.)*

I am not expecting the Schr. equation to be translated literally into the language of Bayesian probabilities. It may look quite different in character – just as your Born rule does now. But is the Schr. equation disallowed*?*

If Timpson is right, and it is *disallowed, where do the actual numbers that go into the Born rule come from?*

Well, they don't come from the Schrödinger equation itself: They come from the largest practical Bayesian web of beliefs. Do a word search on the term "mesh" in `http://arxiv.org/abs/1003.5209` and that will take you to some of the appropriate discussions. And do the same in the attached document. In fact, the discussion there might be better anyway:

> Now, our path back to quantum theory is complete because I want to say this: A quantum state just *is* a probability assignment. The particular character of the quantum world places new, physically-influenced consistency requirements on our mesh of beliefs (like the second equation in my answer to Q2), but in the end, even quantum probabilities must port into probability theory more generally. A quantum state assignment is only one element in a much larger Bayesian mesh of beliefs each agent inevitably uses for his calculations. It is a numerical *commitment* to how he will gamble and make his decisions when he plans to interact with a quantum system.

But back to the meaning of the Schrödinger equation. In the end, I want to say it too is a nothing else than a consistency requirement on various beliefs, just like the urgleichung. In fact, ultimately I want to say it just *is* the urgleichung in a different guise. See footnote 22 on page 13 of the `arXiv` paper. Rob Spekkens and Matt Leifer have some outstanding formal work coming out along these lines; there might be some discussions in there that will help you (forgetting about the new formalism). I will see if they are willing to share the draft at this stage (it may be too rough still).

Also, maybe I haven't sent you this little summary article for the QCMC proceedings, attached. It has a little discussion of unitarity as well. . . . Oh, maybe it doesn't (I just discover). But I'll send it to you anyway.

On this business of "explanatory power," my best recommendation for preparing to answer is to read Louis Menand's book *The Metaphysical Club*. It's the very best book I read in 2003 (and I read a lot of books that year). Here's a passage from it on the subject:

> The world is filled with unique things. In order to deal with the world, though, we have to make generalizations. On what should we base our generalizations? One answer, and it seems the obvious answer, is that we should base them on the characteristics things have in common. No individual horse is completely identical to any other

horse; no poem is identical to any other poem. But all things we call horses, and all things we call poems, share certain properties, and if we make those properties the basis for generalizations, we have one way of "doing things" with horses or poems—of distinguishing a horse from a zebra, for example, or of judging whether a particular poem is a good poem or a bad poem. These common properties can be visible features or they can be invisible qualities; in either case, we create an idea of a "horse" or a "poem," or of "horseness" or "poetry," by retaining the characteristics found in all horses or poems and ignoring characteristics that make one horse or poem different from another. We even out, or bracket, the variations among individuals for the sake of constructing a general type.

Darwin's fundamental insight as a biologist was that among groups of sexually reproducing organisms, the variations are much more important than the similarities. "Natural selection," his name for the mechanism of evolutionary development that he codiscovered with Alfred Russel Wallace, is the process by which individual characteristics that are more favorable to reproductive success are "chosen," because they are passed on from one generation to the next, over characteristics that are less favorable. Darwin regretted that the word "selection" suggested an intention: natural selection is a blind process, because the conditions to which the organism must adapt in order to survive are never the same. In periods of drought, when seeds are hard to find, finches that happen to have long narrow beaks, good for foraging, will be favored over finches with broad powerful beaks: more of their offspring will survive and reproduce. In periods of abundance, when seeds are large and their shells are hard, the broad-beaked finches will hold the adaptive advantage. "Finchness" is a variable, not a constant.

Darwin thought that variations do not arise because organisms need them (which is essentially what Lamarck had argued). He thought that variations occur by chance, and that chance determines their adaptive utility. In all seasons it happens that some finches are born with marginally longer and narrower beaks than others, just as children of the same parents are not all exactly the same height. In certain environmental conditions, a narrower beak may have positive or negative survival value, but in other conditions—for example, when seeds are plentiful and finches are few—it may make no difference. The "selection" of favorable characteristics is therefore neither designed nor progressive. No intelligence, divine or otherwise, determines in advance the relative value of individual variations, and there is no ideal type of "finch," or essence of "finchness," toward which adaptive changes are leading.

Natural selection is a law that explains *why* changes occur in nature—because, as Darwin and Wallace both realized after reading, independently, Thomas Malthus's *Essay on the Principle of Population* (1798), if all members of a group of sexually reproducing organisms were equally well adapted, the population of the group would quickly outgrow the resources available to sustain it. Since some members of the group must die, the individuals whose slight differences give them an adaptive edge are more likely to survive. Evolution is simply the incidental by-product of material struggle, not its goal. Organisms don't struggle because they must evolve; they evolve because they must struggle. Natural selection also explains *how* changes occur in nature—by the relative reproductive success of the marginally better adapted. But natural selection does not dictate *what* those changes shall be. It is a process without mind.

A way of thinking that regards individual differences as inessential departures from a general type is therefore not well suited for dealing with the natural world. A general type is fixed, determinate, and uniform; the world Darwin described is characterized by

> chance, change, and difference—all the attributes general types are designed to leave out. In emphasizing the particularity of individual organisms, Darwin did not conclude that species do not exist. He only concluded that species are what they appear to be: ideas, which are provisionally useful for naming groups of interacting individuals. "I look at the term species," he wrote, "as one arbitrarily given for the sake of convenience to a set of individuals closely resembling each other .... [I]t does not essentially differ from the term variety, which is given to less distinct and more fluctuating forms. The term variety, again, in comparison with mere individual differences, is also applied arbitrarily, and for mere convenience sake." Difference goes all the way down.

And maybe this one is good to see too, though it may not completely reflect to my own beliefs on the subject. In any case there is so much food for thought in the book. And wonderfully written.

> Darwinism was a scandal to many Laplaceans. In the Laplacean worldview, randomness is only appearance; in the Darwinian, it is closer to a fact of nature—in some respects, it is *the* fact of nature. Herschel, the man who had helped introduce Quetelet to British readers, wrote in 1850 that if all the literature of Europe were to perish and only Laplace's *Système du monde* and *Essai sur les probabilités* remained, "they would suffice to convey to the latest posterity an impression of the intellectual greatness of the age which could produce them, surpassing that afforded by all the monuments antiquity has left us." But when *On the Origin of Species* appeared, in 1859, he ridiculed Darwin's theory as "the law of higgledy-pigglety."[228]
>
> What does it mean to say we "know" something in a world in which things happen higgledy-pigglety? Virtually all of Charles Peirce's work—an enormous body of writing on logic, semiotics, mathematics, astronomy, metrology, physics, psychology, and philosophy, large portions of it unpublished or unfinished—was devoted to this question. His answer had many parts, and fitting them all together—in a form consistent with his belief in the existence of a personal God—became the burden of his life. But one part of his answer was that in a universe in which events are uncertain and perception is fallible, knowing cannot be a matter of an individual mind "mirroring" reality. Each mind reflects differently—even the same mind reflects differently at different moments—and in any case reality doesn't stand still long enough to be accurately mirrored. Peirce's conclusion was that knowledge must therefore be social. It was his most important contribution to American thought, and when he recalled, late in life, how he came to formulate it, he described it—fittingly—as the product of a group. This was the conversation society he formed with William James, Oliver Wendell Holmes, Jr., and a few others in Cambridge in 1872, the group known as the Metaphysical Club.

We start our little pilgrimage to Chocorua this afternoon. But I will contemplate more on a better answer to you ... in between contemplating the words I'll use for various job enquiries.

21-04-11 *Quick Question, 2* (to H. C. von Baeyer)

I probably didn't send you the right passage from *The Metaphysical Club*. I know there is something more closely related to your question; it's a question of finding it. I will try my best to give you a proper answer this weekend.

[228]Charles Darwin to Charles Lyell, December 10, 1859: "I have heard by round about channel that Herschel says my Book 'is the law of higgledy-pigglety'".

21-04-11 *Quick Question, 3* (to H. C. von Baeyer)

von Baeyerism 69: *In particular, he claims: "When we are disallowing the possibility of any descriptive theory below this kind of level of generality it seems that there is little we can say about why macroscopic objects have the properties they do...."*

Maybe another way to make a stab at answering you is to suggest you read James's essay "The Sentiment of Rationality". Here's one place to get it online: `http://www.archive.org/details/sentimentration02jamegoog`.

28-04-11 *A Standing Ovation for Reductionism* (to M. A. Graydon)

Graydonism 6: *Here is a transcription of part of the discussion during Christopher Stubbs's colloquium last week. I remember coming home with these words burning in my mind, and I wanted to preserve them as a reminder.*

> **Christopher Stubbs:** I mean, it's funny. I came of age in the 1980s. I went to grad school when the standard model of particle physics was built, right. And running coupling constants, and grand unification, and that had a very definite impact on my outlook as a physicist. Now, whether that was a good or a bad thing, I don't yet know. I crave in my deepest, darkest soul that there is some fundamental theory of everything that is uniquely determined by some symmetry principle that we don't yet understand, and things are the way they are because they had no choice. I want it to be that way in the most fervent [way] you can imagine.
>
> ****ovation for reductionism****
>
> But, just because I want it to be that way doesn't mean it's so. I am personally doing everything I can to continue to push the reductionist paradigm, because that's how I was brought up.
>
> **Neil Turok:** You said that this program [reductionism] has worked for centuries and why do we give it up now for something which doesn't actually give any prediction at all. It's more like: forget about science, let's all go and do art and music ... I mean that's what I see the anthropic tendency, or spiritualism, dare I say it.

So I guess it didn't help my case to write a section titled "Quantum Gravity in the Light of Nonreductionism" in my PI research proposal?

Fires, floods, and bad philosophy—who would have thought the world could carry such destructive tendencies?

29-04-11 *Questions* (to I. Bengtsson)

Bengtssonism 3: *In the not-too-distant future I should give a talk where I make the point that it is not true — as Bogdan Mielnik, who is to be celebrated, used to complain — that all Hilbert spaces are alike. Because the dimension matters a lot. I think you sometimes say things that goes in the direction that it is the dimension that really reflects the underlying reality? If you recognize that sentence, can you direct me to the place where you say it most forcefully?*

With regard to some spirited writing of mine on dimension, perhaps see Sections VI, VII, and VIII of `http://arxiv.org/abs/1003.5209`. Another good place to look is to look at the story titled “The More and the Modest” starting on pdf file page 883 (alternatively text page 874) on `http://www.perimeterinstitute.ca/personal/cfuchs/nSamizdat-2.pdf`. Beyond that, do searches on “capacity” and “alchemy” and “degree of detachedness” and you’ll find any number of crazy things.

30-04-11 *Abstract for Conceptual Foundations Conference* (to G. Chiribella)

OK, I bend. Below is my title and abstract . . . and some evidence that there is no such clean line between science and emotions as the reductionism-lovers might want in a world picture.

> Title: Some Negative Remarks on Operational Approaches to Quantum Theory
>
> Abstract: Over the last 10 years there has been an explosion of “operational reconstructions” of quantum theory. This is great stuff: For, through it, we come to see the myriad ways in which the quantum formalism can be chopped into primitives and, through clever toil, brought back together to form a smooth whole. An image of an IQ-Block puzzle comes to mind, `http://www.prismenferngl as.de/iqblock_e.htm` [“THE IQ-BLOCK, or a game for big and small children you could get addicted to”]. There is no doubt that this is invaluable work, particularly for our understanding of the intricate connections between so many quantum information protocols. But to me, it seems to miss the mark for an ultimate understanding of quantum theory; I am left hungry. I still want to know what strange property of matter forces this formalism upon our information accounting. To play on something Einstein once wrote to Max Born, “The quantum reconstructions are certainly imposing. But an inner voice tells me that they are not yet the real thing. The reconstructions say a lot, but do not really bring us any closer to the secret of the ‘old one’.” In this talk, I hope to expand on these points and convey some sense of why I am fascinated with the problem of the symmetric informationally complete POVMs to an extent greater than axiomatic reconstructions

02-05-11 *A JTF William James Center?* (to H. S. Choi)

I have been informed that you will be visiting Perimeter Institute May 9 and will be scheduled to meet with me for part of that time. I look forward to meeting you and telling you all about what Appleby and I plan to do with our new JTF grant. I wish Appleby could be around to meet you as well—you would be impressed by his breadth of knowledge—but he will be in the UK at that time.

The reason I write you today, however, has to do with something completely independent of Perimeter Institute concerns. My wife and I have been thinking for some years about how we might run a small research center (a place to mingle quantum physics, philosophy and theology and excite a synergy between them). For the first time a clear-cut opportunity has arisen that might put our vision within reach.

This is because I happen to know that William James’s home and property in Chocorua, New Hampshire will soon go on the market. It is a home built in 1842, the very year James was born, and the home in which he died in 1910. It is where he wrote the major part of his *Principles of*

Psychology and had debates with Josiah Royce and Charles Sanders Peirce and any number of other philosophers. When James first discovered the property in 1886, he wrote to his brother Henry, "It is only 4 hours from Boston by rail and 1 hour's drive from the station. Few neighbors, but good ones; hotel a mile off. If this is a dream, let me, at least indulge it a week or so longer!"

Well, I can tell you, the home remains every bit as dreamlike to this day, though now it is only a 2 hour 20 minute drive from Boston Logan airport. My wife and I have made one trip to the property already and have inspected it in detail. (My wife is an expert on old homes; please see the attached article on QBism House.) I will make a second reconnaissance trip this Thursday to gather more information and photos of the surrounding forest and lakes.

The home is 4,400 sq feet in size and immaculate in condition; very well maintained with a brand new roof. The house has an easy, elegant charm and flow to it conducive to all that is needed of a research station: spaces for private work, areas for conversation, solitude for contemplation. Some distance away from the house, in the yard, there is a rather large artist studio that James built for one of his sons—it could easily be converted into a conference room.

The property comes with 44 acres of land, mostly forest, and abuts a NH state forest. Chocorua Lake is a two minute walk away. The town of North Conway is a 15 minute drive (smaller villages in between) and has a variety of restaurants and cafes that puts our downtown Waterloo (where Perimeter Institute is situated) to shame. The region is filled with hiking trails, ski slopes, lakes, opportunities for cycling, fishing, and much more.

The owners already had the home on the market last Fall, but took it off the market for the Winter. They plan to put it back on the market again very soon, for Springtime viewing. When they last listed it, they were asking $895,000.

The vision I presently have for the research center is that it would provide workspace and interaction space for three postgraduate researchers (two year terms each)—one a physicist, one a philosopher, one a theologian—as well as the director (myself, whose own research spans the first two subjects). These four researchers would all live off-site. The bedrooms of the home would be used to house up to three visiting researchers at any one time, with stays ranging from 1 week to 3 months. From time to time, conferences could also be hosted by the center. A key component of the idea is to excite a synergy between the three subjects in a setting nearly perfect for their mixture. What the James home in particular brings to the table is an automatic branding for the product.

As I wrote in the QBism House article, "Ideas, like children, need homes where they can be loved, nurtured, and raised to independence."

Anyway, this is all in the way of introduction. When you visit Waterloo, I wonder whether I might be able to schedule some time with you outside of the Perimeter Institute setting to discuss all this? The late afternoon or early evening May 8 or May 9 would be ideal from my point of view: We could sit on the porch of QBism House if the weather cooperates. It is an atmosphere congenial for discussions of this nature (see attached *Maclean's Magazine* article discussing Perimeter Institute, QBism House, and William James, all in one go).

I could have a reasonably polished presentation prepared for you by then . . . with photos, maps, a discussion of the other institutes that I would like to model this one upon (drawing elements from the Traunkirchen Academy, Schloss Dagstuhl, and the Stellenbosch Institute for Advanced Study, all of which I know intimately), a proposed advisory board, funding models, the deep connection between William James's views and Sir John Templeton's, etc., etc.

I realize that I am not approaching the JTF through the standard funding portal (nor during the standard funding timeline) by sending this note, but there is some urgency in me to try to remove the house from the market on fear of another (inevitable) buyer. If I could get some guidance from you and the John Templeton Foundation, it would be invaluable to me.

To give you a bit more sense of where I'm coming from with the connections I see between William James's philosophy, John Wheeler's post-Everettian cosmology (that "the Big Bang is here, all around us" in moments of constant creation), and my Quantum Bayesian interpretation of quantum mechanics, please see the attached recent interview—particularly my answers to Questions 8, 13, 14, and 17. [See "Interview with a Quantum Bayesian," `arXiv:1207.2141v1`.]

Finally I attach a current CV. It speaks to some of my credentials for seeing a project like this through (for instance detailing my chairmanship of the 1,100-member APS topical group on quantum information, the many conferences I've organized, my recognition in the community through my citation record, etc., etc.). [...]

I apologize for this very long note, so please let me summarize:

1) The old William James house in Chocorua, NH will soon be on market.

2) I have a vision to turn it into a research center for quantum physicists, philosophers, and theologians to live and learn from each other and make great discoveries on its grounds.

3) The key point of the James house is that it comes with a "brand" that will be recognized by philosophers, theologians, psychologists, and many more beyond that the world around.

4) Might we meet and discuss this in more detail outside your Perimeter Institute schedule during your visit to Waterloo? I would appreciate any guidance the John Templeton Foundation could give me.

Thank you much for your time,

11-05-11 *Thinking of You* (to H. J. Bernstein)

I hope everything went well yesterday. You were in my thoughts yesterday, as your "realit*t*y" has been in my thoughts for years. Few understand how malleable the world is as you. Keep making it happen.

Mon travail est purement autobiographique. Il n'y est question que de moi et de ce qui m'est proche. C'est une tentative de mise en mémoire. Je travaille à partir des gens qui m'intéressent, qui m'importent, à qui je pense, dans le décor des pièces que j'habite, que je connais.

— *Lucian Freud*
